SPIE would like to express its deepest appreciation to the symposium chairs, conference chairs, program committees, session chairs, and authors who have so generously given their time and advice to make this symposium possible.

The symposium, like our other conferences and activities, would not be possible without the dedicated contribution of our participants and members. This program is based on commitments received up to the time of publication and is subject to change without notice.

Conference 9904: Space Telescopes and Instrumentation 2016: Optical, Infrared, and Millimeter Wave

SPIE. ASTRONOMICAL TELESCOPES + INSTRUMENTATION

Sunday - Friday 26–1 July 2016

Part of Proceedings of SPIE Vol. 9904 Space Telescopes and Instrumentation 2016: Optical, Infrared, and Millimeter Wave

9904-1, Session 1

The James Webb Space Telescope: observatory status and the path to launch

Michael W. McElwain, Charles W. Bowers, Mark Clampin, Malcolm B. Niedner, NASA Goddard Space Flight Ctr. (United States)

The James Webb Space Telescope (JWST) is a NASA flagship mission that will address multiple science themes including our Universe's first light, the assembly of galaxies, the birth of stars and planetary systems, and planets and the origins of life. The JWST is a large (6.5 m) segmented aperture telescope equipped with near- and mid-infrared instruments (0.6-28 microns), all of which are passively cooled to ~40 K by a 5-layer sunshield while the mid-infrared instrument is actively cooled to 7 K. The JWST will be launched to an L2 orbit aboard a European Space Agency (ESA) supplied Ariane 5 rocket, whose payload volume constraints require that the JWST structure is stowed for launch. JWST is currently in the integration and test phase, with parallel activities on-going across the program such as the integrated science instrument module, optical telescope element, spacecraft, and the sunshield. The JWST deployments to the flight configuration are also undergoing alignment and deployed loads testing. The current estimated JWST performance metrics will be presented, such as the image quality, pointing stability, sensitivity, and stray light backgrounds. The JWST development status and future schedule will be described for the full integration, launch, and commissioning. JWST is an international project with contributions from NASA, ESA, and the Canadian Space Agency (CSA). Northrop Grumman Aerospace Systems is the prime contractor for the JWST, and the Space Telescope Science Institute will serve as the science operations center.

9904-2, Session 1

Status of the JWST optical telescope element

Charles B. Atkinson, Scott C. Texter, Northrop Grumman Aerospace Systems (United States); Lee D. Feinberg, Ritva Keski-Kuha, NASA Goddard Space Flight Ctr. (United States)

Significant progress has been made in the development of the Optical Telescope Element (OTE) for the James Webb Space Telescope (JWST) Observatory. At the time of the conference, the OTE will have been completely assembled, including deployment testing and optics alignment and installation. This paper will discuss those accomplishments.

9904-3, Session 1

JWST telescope integration and test progress

Gary W. Matthews, Tony L. Whitman, Thomas R. Scorse, Harris Corp. (United States); Lee D. Feinberg, Ritva Keski-Kuha, Mark F. Voyton, Juli A. Lander, NASA Goddard Space Flight Ctr. (United States)

The James Webb Space Telescope (JWST) is a 6.5m, segmented, IR telescope that will explore the first light of the universe after the big bang. The JWST Optical Telescope Element (Telescope) integration and test program is well underway. The telescope was completed in the spring of 2016 and the cryogenic test equipment has been through two optical test programs leading up to the final flight verification program. The details of the telescope mirror integration will be provided along with the current status of the flight observatory. In addition, the results of the two optical ground support equipment cryo tests will be shown and how these plans fold into the flight verification program.

9904-4, Session 1

Status of the JWST sunshield and spacecraft bus

Jonathan W. Arenberg, James R. Flynn, Andy Cohen, Northrop Grumman Aerospace Systems (United States); Richard Lynch, James L. Cooper, NASA Goddard Space Flight Ctr. (United States)

This paper reports on the development, manufacture and integration of the James Webb Space Telescope's sunshield and spacecraft bus. Both of these JWST elements have completed design and development testing. This paper will review basic architecture and roles of these systems. Also to be presented is the current state of manufacture, assembly integration and test. This paper will conclude with a look at the road ahead for each subsystem prior to integration with the integrated telescope and instrument elements at Northrop Grumman's Space Park facility in late 2017.

9904-5, Session 2

Status of the James Webb Space Telescope science instrument payload

Matthew A. Greenhouse, NASA Goddard Space Flight Ctr. (United States)

The Integrated Science Instrument Module (ISIM) is the science instrument payload of the JWST and is one of three elements that comprise the JWST space vehicle. It is expected to complete flight qualification testing and delivery for integration with the telescope shortly before this conference. The "as delivered" status of the ISIM system will be presented.

9904-6, Session 2

James Webb Space Telescope optical telescope element: integrated science instrument module (OTIS) status

Lee D. Feinberg, Ritva Keski-Kuha, Mark F. Voyon, Juli A. Lander, NASA Goddard Space Flight Ctr. (United States); Gary W. Matthews, Harris Corp. (United States)

The James Webb Space Telescope Optical Telescope Element (OTE) and

Integrated Science Instrument Module (ISIM) are integrated together to form the OTIS. Once integrated, the OTIS undergoes primary mirror center of curvature optical tests, electrical and operational tests, acoustics and vibration testing at the Goddard Space Flight Center before being shipped to the Johnson Space Center for cryogenic optical testing of the OTIS. In preparation for the cryogenic optical testing, the JWST project has built a Pathfinder telescope and has completed two Optical Ground System Equipment (OGSE) cryogenic optical tests with the Pathfinder. In this paper, we will summarize OTIS optical test results to date and status the final Pathfinder test and the OTIS integration and environmental test preparations.

9904-7, Session 2

Cryo-vacuum testing of the JWST integrated science instrument module (ISIM)

Randy A. Kimble, NASA Goddard Space Flight Ctr. (United States); Maria B. Vila, SGT, Inc. (United States) and NASA Goddard Space Flight Ctr. (United States); Julie M. Van Campen, NASA Goddard Space Flight Ctr. (United States); Stephan M. Birkmann, European Space Research and Technology Ctr. (Netherlands); Brian J. Comber, Comber Thermal Solutions (United States) and NASA Goddard Space Flight Ctr. (United States); Curtis C. Fatig, NASA Goddard Space Flight Ctr. (United States); Alistair C. H. Glasse, UK Astronomy Technology Ctr. (United Kingdom); Stuart D. Glazer, NASA Goddard Space Flight Ctr. (United States); Douglas M. Kelly, The Univ. of Arizona (United States); Steven D. Mann, The Hammers Co. (United States) and NASA Goddard Space Flight Ctr. (United States); Andre' R. Martel, Space Telescope Science Institute (United States) and NRC Herzberg Astronomy and Astrophysics (Canada); Kevin J. Novo-Gradac, SGT, Inc. (United States); Raymond G. Ohl, NASA Goddard Space Flight Ctr. (United States); Konstantin I. Penanen, Jet Propulsion Lab. (United States); Scott O. Rohrbach, NASA Goddard Space Flight Ctr. (United States); Joseph F. Sullivan, Ball Aerospace & Technologies Corp. (United States); Dean Zak, CSRA (United States); Julia Zhou, COM DEV Canada (Canada)

In late 2015/early 2016, a major cryo-vacuum test was carried out for the Integrated Science Instrument Module (ISIM) of the James Webb Space Telescope. This test, executed after the ambient environmental testing program for the ISIM (vibration, acoustics, and electromagnetic interference/compatibility testing) represents the final cryo-certification and calibration test of the ISIM before its delivery for integration with the rest of the JWST observatory.

The ISIM, comprised of the four flight science instruments (the FGS/NIRISS, MIRI, NIRCam, and NIRSpec), a composite support structure, and harness radiator (the preceding all cryogenic), as well as an associated nearby compartment housing warm electronics, was tested in the largest thermal-vacuum chamber of NASA's Goddard Space Flight Center. In this test, the ISIM was exposed to a thermal environment set to match the predicted ISIM environment within the JWST observatory in flight, while being illuminated with a cryo-certified telescope simulator designed to feed the various instruments beams of flight-like wavefront quality, position, chief ray angles, f/#, and pupil location.

Over the roughly 100-day period of the round-the-clock test program (designated CV3, as it was the third in the ISIM cryo-vacuum test series), the fully-integrated flight ISIM system was put through a comprehensive program of thermal, optical, electrical, and operational tests. One particularly important aspect of this final cryo-test was the comparison of optical and thermal performance data taken before the ambient environmental test program (in 2014's CV2 cryo-test program) with the corresponding data taken after, for verification of critical stability requirements. In brief, the goals of CV3 were to verify the ISIM system in its final configuration after environmental exposure and to provide a post-environmental performance baseline, including critical ground calibrations needed for science data processing in flight.

In this paper, we briefly summarize the goals, setup, execution, and key results for this critical JWST milestone.

9904-8, Session 2

Wavefront-sensing demonstration testing of the James Webb Space Telescope (JWST) integrated science instrument module (ISIM)

Randal C. Telfer, Space Telescope Science Institute (United States); D. Scott Acton, J. Scott Knight, Ball Aerospace & Technologies Corp. (United States); Bruce H. Dean, Thomas P. Zielinski, NASA Goddard Space Flight Ctr. (United States); Marshall D. Perrin, Charles-Philippe Lajoie, Space Telescope Science Institute (United States); David L. Aronstein, Jeffrey S. Smith, NASA Goddard Space Flight Ctr. (United States)

This paper describes the analysis of the portion of the James Webb Space Telescope (JWST) Integrated Science Instrument Module (ISIM) cryogenic-vacuum testing dedicated to wavefront sensing (WFS) performance relevant to flight commissioning of the optical telescope element (OTE). These tests provide the most representative wavefront-sensing imagery during ground testing of the ISIM regarding several stages of the commissioning process. Aspects covered include imaging of the JWST pupil with the NIRCam pupil imaging lens (PIL), coarse piston sensing of the primary mirror segments with the NIRCam Dispersed Hartmann Sensors (DHSs), fine piston sensing of the primary mirror segments via focus-diverse phase retrieval using the NIRCam weak lenses, and focus-diverse phase retrieval in all science instruments as part of the field-dependent sensing process known as Multi-Instrument Multi-Field (MIMF). The data are used to demonstrate wavefront-sensing performance with the Wavefront Analysis Software (WAS) designed for JWST commissioning. The test suite also includes final cross-checks, characterization, and calibration of WFS components. Calibrations and cross-checks include distortion of the PIL image, dispersion of the DHS sub-apertures, and power and wavefront error of the weak lenses. In this paper, we discuss the component calibration and cross-check results and the overall wavefront-sensing performance of the WAS on the demonstration data. The results are evaluated by comparison to expected results, analysis with independent algorithms, and consistency checks of the output.

9904-9, Session 3

Stray light field dependence for the James Webb Space Telescope

Paul A. Lightsey, Ball Aerospace & Technologies Corp. (United States)

The James Webb Space Telescope (JWST) is a large space based astronomical telescope that will operate at cryogenic temperatures. The architecture has the telescope exposed to space, with a large sun shield providing thermal isolation and protection from direct illumination from the sun. The instruments will have the capability to observe over a

spectral range from 0.6 um to 29 um wavelengths. Stray light analysis has been performed to characterize the stray light getting to the instrument focal planes from the celestial sky. A Radiance Transfer Function (RTF) is defined for the susceptibility of stray light to sky radiance relative to the observatory frame of reference. The stray light is calculated by overlaying the radiance maps of the celestial sky background (both galactic and zodiacal background) onto the RTF map. The product of the two is summed to obtain the total stray light background at the instrument detectors. The orientation of the observatory for observing a given field location in the sky depends on the direction of the sun, hence the day of the year. The variability of stray light with time of year for observing a given sky locations is determined.

9904-10, Session 3

Preparing for JWST wavefront sensing and control operations

Marshall D. Perrin, Space Telescope Science Institute (United States); D. Scott Acton, Ball Aerospace & Technologies Corp. (United States); Charles-Philippe Lajoie, Space Telescope Science Institute (United States); J. Scott Knight, Ball Aerospace & Technologies Corp. (United States); Matthew D. Lallo, Marsha Allen, Elizabeth Barker, Space Telescope Science Institute (United States); Eric Coppock, Ball Aerospace & Technologies Corp. (United States); Bruce H. Dean, William L. Hayden, Michael W. McElwain, NASA Goddard Space Flight Ctr. (United States); Bernard Kulp III, Space Telescope Science Institute (United States); Luis Meza, Northrop Grumman Aerospace Systems (United States); Edmund P. Nelan, John Stansberry, Space Telescope Science Institute (United States); Andria L. Welsh, Northrop Grumman Aerospace Systems (United States); Thomas P. Zielinski, NASA Goddard Space Flight Ctr. (United States)

The James Webb Space Telescope's segmented primary and deployable secondary will be actively controlled to achieve optical alignment, through a complex series of steps that will extend across several months during the observatory's commissioning. This process will require an intricate interplay between individual wavefront sensing and control tasks, instrument-level checkout and commissioning, and observatory-level calibrations, which involves many subsystems across both the observatory and the ground system. Furthermore, commissioning will often exercise observatory capabilities under atypical circumstances, such as fine guiding with unstacked or defocused images, or planning targeted observations in the presence of substantial time-variable offsets to the telescope line of sight. Coordination for this process across the JWST partnership has been conducted through the Wavefront Sensing & Control Operations Working Group. We will describe at a high level the activities of this group, and the resulting detailed commissioning operations plans, supporting software tools development, and ongoing test and rehearsal activities at the Science & Operations Center. These efforts are leading to a robust and well-tested process and preparing the team for an efficient and successful commissioning of JWST's active telescope.

9904-11, Session 3

Hartmann test for the James Webb Space Telescope

J. Scott Knight, Ball Aerospace & Technologies Corp. (United States); Lee D. Feinberg, NASA Goddard Space Flight Ctr. (United States); D. Scott Acton, Ball Aerospace & Technologies Corp. (United States); Tony L. Whitman, Harris Corp. (United States); Koby Z. Smith, Ball Aerospace & Technologies Corp. (United States)

The James Webb Space Telescope (JWST) requires testing of the full optical system in a cryogenic vacuum environment before launch. During recent JWST Pathfinder checkout testing at the Johnson Space Center's (JSC) Chamber A thermal vacuum facility, the vibration in this environment has proven challenging for the baseline test architecture, which uses phase retrieval over the sparse aperture testing of the entire JWST telescope element. However, a strategy that was conceived and tested during the recent JWST Pathfinder testing to utilize classic Hartmann test principles combined with precise mirror mechanisms to provide a testing approach that is robust to the dynamics environment of the cryogenic vacuum chamber. The implementation and sensitivity of this test to perform certain JWST system level optical assessments is similar to using phase retrieval over the sparse aperture test. Prior to the JWST pathfinder test, this Hartmann test concept was implemented on the JWST Test Bed Telescope, which provided the rationale and empirical evidence indicating that this Hartmann style approach would be valuable in supplementing the baseline test approach.

This paper presents the results of the Hartmann approach implemented during the recent Pathfinder test along with the test approach that is currently being considered for the full optical system test of JWST. Comparisons are made between the baseline phase retrieval approach and the Hartmann approach in addition to demonstrating how the two test methodologies support each other to reduce risk during the JWST full optical system test.

9904-12, Session 3

Getting JWST's NIRSpec back in shape

Maurice Te Plate, Peter Rumler, Peter L. Jensen, European Space Research and Technology Ctr. (Netherlands); Robert Eder, Ralf Ehrenwinkler, Frank Merkle, Peter Mosner, Andreas Rödel, Max Speckmaier, Airbus Defence and Space (Germany); Brent Mott, Stephen Snodgrass, Thomas E. Johnson, NASA Goddard Space Flight Ctr. (United States); Stephan M. Birkmann, European Space Research and Technology Ctr. (Netherlands)

The James Webb Space Telescope (JWST) Observatory is the follow-on mission to the Hubble Space Telescope. JWST will be the biggest space telescope ever built and it will lead to astounding scientific breakthroughs. The mission will be launched in 2018. NIRSpec, one of the four instruments on board of the mission, recently underwent a major upgrade. New infrared detectors were installed and the Micro Shutter System (MSA) was replaced as well. The rework was necessary because both systems were found to be degrading. The techniques and procedures that were applied during this campaign will be elaborated. Some first cold test results of the upgraded instrument will be presented as well.

9904-13, Session 3

Slitless spectroscopy with the JWST NIRCam instrument

Thomas P. Greene, NASA Ames Research Ctr. (United States); Laurie Chu, Klaus W. Hodapp, Univ. of Hawai'i (United States); Eiichi Egami, Douglas M. Kelly, Jarron M. Leisenring, Marcia Rieke, The Univ. of Arizona (United States); Massimo Robberto, John Stansberry, Space

Telescope Science Institute (United States)

The James Webb Space Telescope Near-infrared camera (JWST NIRCam) has two 2.2' x 2.2' fields of view that are capable of either imaging or spectroscopic observations. Either of two R ~ 1700 grisms with orthogonal dispersion directions can be used for slitless spectroscopy over 2.4 - 5.0 microns wavelength in each module, and shorter wavelength observations of the same fields can be obtained simultaneously. We present the latest predicted grism sensitivities, saturation limits, resolving power, and wavelength coverage performance values, based on component measurements, instrument tests, and end-to-end modeling. Operational considerations including subarray sizes, data rate limits, and simultaneous shorter wavelength observations will also be discussed. Simultaneous shorter wavelength imaging observations can be done in several filters either in-focus or defocused via weak lenses internal to NIRCam. We also discuss the possibility of simultaneous 2.4 - 5.0 micron grism and 1.0 - 2.0 micron spectroscopy using dispersed Hartmann sensors (DHSs). Both the weak lenses and DHS elements were included in NIRCam primarily for wavefront sensing purposes but have significant science applications. Finally, we illustrate potential scientific uses of the grisms by presenting simulated observations of deep extragalactic fields, galactic dark clouds, and transiting exoplanets.

9904-14, Session 3

The JWST/NIRSpec instrument: update on status and performances

Stephan M. Birkmann, European Space Agency (United States); Pierre Ferruit, European Space Agency (Netherlands); Catarina Alves de Oliveira, Torsten Böker, European Space Agency (United States); Giovanna Giardino, European Space Agency (Netherlands); Nora Lützgendorf, European Space Agency (United States); Anthony Marston, European Space Agency (Spain); Timothy Rawle, Marco Sirianni, European Space Agency (United States); Martin Stuhlinger, European Space Agency (Spain); Maurice Te Plate, European Space Agency (United States); Peter L. Jensen, Peter Rumler, European Space Agency (Netherlands); Bernhard Dorner, Max-Planck-Institut für Astronomie (Germany); Hermann Karl, Peter Mosner, Airbus Defence and Space (Germany); Ray Wright, Bay Engineering Innovations, Inc. (United States); Robert Rapp, The Hammers Co. (United States)

The Near-Infrared Spectrograph (NIRSpec) is one of the four instruments on the James Webb Space Telescope (JWST) which is scheduled for launch in 2018. NIRSpec is developed by the European Space Agency (ESA) with Airbus Defense & Space Germany as prime contractor. The instrument offers seven dispersers covering the wavelength range from 0.6 to 5.3 micron with resolutions from R~100 to ~2700. NIRSpec will be capable of obtaining spectra for more than 100 objects simultaneously using an array of micro-shutters. It also features an integral field unit with 3" x 3" field of view and a range of slits for high contrast spectroscopy of individual objects and time series observations of e.g. transiting exoplanets.

NIRSpec is in its final flight configuration and underwent cryogenic performance testing at the Goddard Space Flight Center in Winter 2015/16 as part of the Integrated Science Instrument Module (ISIM). We present the current status of the instrument and also provide an update on NIRSpec performances based on results from the ISIM level test campaign.

9904-15, Session 4

Potential large Decadal missions enabled by NASA's space launch system

H. Philip Stahl, Randall C. Hopkins, Andrew R. Schnell, NASA Marshall Space Flight Ctr. (United States); David Alan Smith, NASA Marshall Space Flight Center (United States); Angela Jackman, NASA Marshall Space Flight Ctr. (United States); Keith R. Warfield, Jet Propulsion Lab. (United States)

NASA's "Planning for the 2020 Decadal Survey" white paper calls for consideration of a Habitable Exoplanet Imaging Mission (HabEx) and a Large UV/Optical/IR Surveyor (LUVOIR) as well as Far-IR and an X-Ray Surveyor missions. NASA's Enduring Quests Daring Visions2 called for an 8- to 16-meter Large UV-Optical-IR (LUVOIR) Surveyor mission to "enable ultra-high-contrast spectroscopic studies to directly measure oxygen, water vapor and other molecules in the atmospheres of exoEarths"; and, "decode the galaxy assembly histories through detailed archeology of their present structure." And, AURA's From Cosmic Birth to Living Earths details the potential revolutionary science that could be accomplished with a 12-m class space telescope: from "directly finding habitable planets showing signs of life" to "producing transformational scientific advances in every area of astronomy and astrophysics from black hole physics to galaxy formation, from star and planet formation to the solar system."

There are many potential HabEx and LUVOIR architectures, but they are all challenged by how to affordably get a large telescope into space. JWST was severely constrained by the mass and volume capacities of its launch vehicle. This problem is solved by using the Space Launch System (SLS) with its 8 or 10 meter diameter fairings and ability to deliver 35 to 45 metric tons of payload to Sun-Earth Lagrange-2. This paper details how to the SLS's capacities fundamentally change the design rules for large space telescopes and shows how these rules can be applied to three potential mission concepts: a 4-meter monolithic off-axis telescope, an 8-meter monolithic on-axis telescope and a 12-meter segmented on-axis telescope.

9904-16, Session 4

End-to-end assessment of a large aperture segmented Ultraviolet Optical Infrared (UVOIR) Telescope architecture

Lee D. Feinberg, Norman Rioux, Matthew R. Bolcar, Alice K. C. Liu, NASA Goddard Space Flight Ctr. (United States); Olivier Guyon, The Univ. of Arizona (United States); Christopher C. Stark, Space Telescope Science Institute (United States)

Key challenges of a future large aperture, segmented Ultraviolet Optical Infrared (UVOIR) Telescope capable of performing a spectroscopic survey of hundreds of Exoplanets will be sufficient stability to achieve 10^-10 contrast measurements and sufficient throughput and sensitivity for high yield Exo-Earth spectroscopic detection. Our team has collectively assessed an optimized end to end architecture including a high throughput coronagraph capable of working with a segmented telescope, a cost-effective and heritage based stable segmented telescope, a control architecture that minimizes the amount of new technologies, and an Exo-Earth yield assessment to evaluate potential performance. These efforts are combined through integrated modeling, coronagraph evaluations, and Exo-Earth yield calculations to assess the potential performance of the selected architecture. In addition, we discusses the scalability of this architecture to larger apertures and the technological tall poles to enabling it.

9904-17, Session 4

An evolvable space telescope for future astronomical missions: 2016 update

Ronald S. Polidan, Jonathan W. Arenberg, Northrop Grumman Aerospace Systems (United States); James B. Breckinridge, Breckinridge Associates, LLC (United States); Charles F. Lillie, Lillie Consulting, LLC (United States); Howard A. MacEwen, Reviresco LLC (United States); Martin R. Flannery, Brian K. Baldauf, Northrop Grumman Aerospace Systems (United States)

In 2014 and 2015 we presented a concept for an Evolvable Space Telescope (EST) that is assembled on orbit in 3 stages, growing from a 4x12 meter telescope in Stage 1, to a 12-meter filled aperture in Stage 2, and then to a 20-meter filled aperture in Stage 3. At each "Stage" the telescope is a fully functional observatory and begins gathering science data immediately. At Stages 2, 3, and beyond, if desired, the observatory is augmented in space with additional mirror segments, structures, subsystems, and new instruments to evolve the telescope and improve performance over the years. The Evolvable Space Telescope has significantly matured since mid-2015. This paper discusses recent technical developments and future plans.

9904-18, Session 4

A technology development roadmap for a future large-aperture UV-optical-infrared space telescope

Matthew R. Bolcar, Mark Clampin, Julie A. Crooke, Lee D. Feinberg, Kate Hartman, Norman Rioux, Harley A. Thronson Jr., NASA Goddard Space Flight Ctr. (United States)

The NASA Astrophysics Division's 30-year roadmap, Enduring Quests, Daring Visions, prioritized a future large-aperture space telescope operating in the ultra-violet/optical/infrared (UVOIR) wavelength regime. The Association of Universities for Research in Astronomy (AURA) envisioned a similar observatory, the High Definition Space Telescope (HDST), in their report, From Cosmic Birth to Living Earths. Both documents outline a broad science case that combines general astrophysics with the search for biosignatures via direct-imaging and spectroscopic characterization of habitable exoplanets. We present a technology development roadmap that would enable such an observatory. Key technologies include: starlight suppression systems for high-contrast imaging; ultra-stable optical systems; precision metrology, sensing, and control systems; high-sensitivity broadband large-format detectors; and high-quality, high-throughput mirror coatings. Specific technology performance goals include 10-10 raw contrast at small inner working angles (~2?/D); wavefront error stability on the order of 10s of picometers per wavefront control step; autonomous on-board sensing and control; single-photon detectors spanning the UVOIR band; and low-polarization mirror coatings that enable high-throughput from below 100 nm through the near-infrared. These technologies will enable significant advances over current and planned observatories in terms of sensitivity, angular resolution, stability, and high-contrast imaging. We review the potential science goals of a large UVOIR observatory and outline the top-level telescope and instrument performance requirements. We define the required technology capabilities, current state-of-the-art performance, and current Technology Readiness Level (TRL), thus identifying the current technology gaps. Current, planned, and recommended technology development efforts are also reported.

9904-87, Session PS1

Coatings induced phase shift and impact on Euclid imaging performance

Luis Miguel Gaspar Venancio, European Space Research and Technology Ctr. (Netherlands); Lionel Carminati, Airbus Defence and Space SAS (France); Jose Lorenzo Alvarez, European Space Research and Technology Ctr. (Netherlands); Jérôme Amiaux, Commissariat à l'Énergie Atomique (France); Luciana Bonino, Thales Alenia Space (Italy); Jean-Christophe Salvignol, European Space Research and Technology Ctr. (Netherlands); Roland Vavrek, European Space Astronomy Ctr. (Spain); René J. Laureijs, Alexander D. Short, Tobias Boenke, European Space Research and Technology Ctr. (Netherlands)

Euclid is an European Space Agency mission to map the geometry of the dark Universe. The mission will investigate the distance-redshift relationship and the evolution of cosmic structures. It achieves this by measuring shapes and redshifts of galaxies and clusters of galaxies out to redshifts ~2, or equivalently to a look 10 billion years back in time. Euclid makes use of two cosmological probes, in a wide survey over the full extragalactic sky. One is based on the the Weak Gravitational Lensing (WL) and the other is the Baryonic Acoustic Oscillations (BAOs). Each probe has a dedicated instrument working, each working in a specific spectral range: the visible range (500 nm to 900nm) for the WL probe and the near-infra-red (920 nm to 2000nm) for the BAO probe. The light is spectrall separated by a dichroic reflecting the visible part of the light. The WL is a method to map the dark matter and measure dark energy by measuring the distortions of galaxy images by mass inhomogeneities along the line-of-sight. This probe requires extreme image quality thus constraining the optical system wavefront error.

The challenging constraints imposed on the telescope imaging performances have driven the design, manufacturing and characterisation of the multi-layered coatings of the dichroic. Indeed the coatings inhomoeneities will introduce a wavelength dependent phase-shift resulting in PSF changes. Such changes must be characterized and/or simulated since they could be non-negligible contributors to the scientific performance accuracy. Several papers on this topic can be found in litterature, however the results can not be applied directly to Euclid's dichroic coatings. In particular an applicable model of the phase-shift variation with the wavelength could not be found and needed to be developped. We will present in this paper the outcomes of the work performed for the characterization and modelisation of the dichroic wavefront in reflection for any wavelenght.

9904-88, Session PS1

The Euclid VIS focal plane assembly STM: from the integration to the qualification tests

Jérôme Martignac, Benoît Horeau, François Visticot, Michael Carty, Jean Fontignie, Jean-Yves Roussé, Thierry Tourrette, Thierry Orduna, Damien Bachet, Michel G. Berthé, Jérôme Amiaux, Commissariat à l'Énergie Atomique (France); Philippe R. Ferrando, Luc Dumaye, Duc-Dat Huynh, CEA-Ctr. de SACLAY (France); Diana Renaud, Frédéric Le Berrurier, Vincent Hennion, Pascal Contrepois, Patrice Charon, Christophe Roques, Arnaud Roger, Jean-Michel Joubert, Dominique Gibier, Commissariat à l'Énergie Atomique (France); Sabrina

Pottinger, James Denniston, Mark S. Cropper, Sami M. Niemi, Thomas Hunt, Richard E. Cole, Mullard Space Science Lab. (United Kingdom); Cédric Thizy, Sylvie Liebecq, Valérie Samain, Univ. de Liège (Belgium); Pascale Danto, Ctr. National d'Études Spatiales (France)

In the frame work of the ESA Euclid mission to be launched in 2020, the Euclid Consortium is developing an extremely large and stable focal plane for the VIS instrument. After an extensive phase of definition and study over 4 years made at CEA on the thermo-mechanical architecture of that Focal Plane, the first model (Structural and Thermal Model) has been assembled and qualified.

The VIS Focal Plane Assembly integrates 36 CCDs (operated at 150K) connected to their front end electronics (operated at 280K). This Focal Plane will be the largest focal plane (?0.6 billion pixels) ever built for space application after the GAIA one. The CCDs are CCD273 type specially designed and provided by the e2v company under ESA contract, front end electronics is studied and provided by MSSL.

The Thermal and Structural Model is fully representative of the Flight Model regarding the thermo-mechanical architecture. As the instrument development philosophy follows a Proto Flight approach this choice has been made very early in the development program in order to reduce the risk on the PFM program. So the AIT/AIV plan has been built in order to fully validate since the STM program the overall integration, verification and qualification sequences, taking into account the very stringent cleanliness requirement. The FPA STM integrates 36 CCDs representative of the flight model except for the detection function. Electrical configuration of the front end electronics provides electrical interface in order to power the CCDs and check integrity of all the electrical links to CCDs.

In this paper we first recall the architecture of the VIS-FPA and especially the solutions proposed to cope with the scientific needs of an extremely stable focal plane, both mechanically and thermally leading to a SiC structure. The modular architecture concept, considered as a key driver for such big and complex focal plane is detailed. Parallel to that, the integration workflow including verification steps is fully depicted including specific aspects linked to the use of SiC. Validation and qualification test program is described. A summary of geometrical measurements, thermal balance tests and vibrations tests including the main Ground Support Equipment description are reported.

9904-89, Session PS1

The Euclid/VIS shutter unit

Ludovic Genolet, Univ. de Genève (Switzerland); Enrico Bozzo, ISDC Data Ctr. for Astrophysics (Switzerland); Stéphane Paltani, Univ. de Genève (Switzerland)

The VIS instrument on-board the Euclid mission will feature a shutter unit (RSU), which main function is to prevent direct light from falling onto the instrument CCDs when the latter are flushed between one scientific exposure and the next. The RSU permits at the same time to keep the fine guidance sensors of the instrument to be exposed to light continuously, in order to maintain the required instrument pointing accuracy and stability. The RSU will be operating at cryogenic temperatures (110-160 K) and planned to perform about a milion of opening/closing cycles.

The engineering model of the RSU has been already manufactured and tested, while the structural thermal model is under assembly and will be tested in the early 2016. The RSU flight model will be completed in 2017.

In this contribution we provide an overview of the consolidated RSU design, following the completion of the final detailed design phase, and summarize the remaining development stages.

9904-90, Session PS1

The power and mechanism control unit of the VIS instrument for the Euclid space mission

Christophe Cara, Diana Renaud, Eric Doumayrou, Alain Goetschy, François Nico, Thierry Tourrette, Jean Fontignie, Michel G. Berthé, Jérôme Martignac, Michel Lortholary, Commissariat à l'Énergie Atomique (France); Pascale Danto, Ctr. National d'Études Spatiales (France)

EUCLID is a European Space Agency (ESA) scientific space borne mission designed to map the geometry of the dark universe. The satellite will be equipped with a 1.2m telescope and two instruments on-board: a high quality visible imager (VIS) and a near-infrared spectrometer and photometer (NISP). The VIS instrument is composed of different subsystems: the Focal Plane Assembly (FPA), a 36 CCD focal plane in charge of the detection of visible light for imaging, the Readout Shutter Unit (RSU) to close the optical path during focal plane readout and for dark calibration, the Calibration Unit (CU) to illuminate the FPA with flat field for calibration, all being located in the satellite payload module and other subsystems, located in the service module, the Command and Data Processing Unit (CDPU) to control the whole instrument, perform data processing and interface with the spacecraft for data handling and the Power and Mechanism Control Unit (PMCU) to control the RSU, CU and monitor FPA temperature.

The PMCU is under the responsibility of the French Atomic Energy Commission (CEA), with support of the French space agency CNES. This unit receives high-level commands from the CDPU and processes it by controlling with a high degree of autonomy the CU and the RSU. It performs as well the acquisition of a large number of analogue housekeeping parameters of the three payload located VIS subsystems for both real time monitoring by CDPU software and on-ground monitoring and analysis.

The precision and the repeatability of the motion of the RSU, and consequently of control performed by the PMCU, have a direct impact on the science since they define the detector exact exposure time. Moreover the motion profile is defined to limit parasitic vibrations that may affect the very accurate pointing system of the satellite. In the same manner the CU subsystem requires to the PMCU to drive multiple wavelength LED-based calibration sources with a high stability all along the mission.

In this paper, we will present the design of the PMCU that of been defined to fulfil the requirement specifications and higher-level requirements such as reliability, failure mode and radiation mitigation. We will as well present results of functional and early performance tests performed on the EM model of the unit.

9904-92, Session PS1

Detailed design and first tests of the application software for the instrument control unit of Euclid-NISP

Sebastiano Ligori, Leonardo Corcione, Vito Capobianco, Donata Bonino, INAF - Osservatorio Astrofisico di Torino (Italy); Gabriele Sirri, Federico Fornari, Istituto Nazionale di Fisica Nucleare (Italy); Francesco Giacomini, INFN CNAF (Italy); Laura Patrizii, Istituto Nazionale di Fisica Nucleare (Italy); Luca Valenziano, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy)

In this paper we describe the detailed design of the application software (ASW) of the instrument control unit (ICU) of NISP, the Near-Infrared Spectro-Photometer of the Euclid mission. This software is based on a

real-time operating system (RTEMS) and will interface with all the subunits of NISP, as well as the command and data management unit (CDMU) of the spacecraft for telecommand and housekeeping management. We briefly review the main requirements driving the design and the architecture of the software that is approaching the Critical Design Review level.

The interaction with the data processing unit (DPU), which is the intelligent subunit controlling the detector system, is described in detail, as well as the concept for the implementation of the failure detection, isolation and recovery (FDIR) algorithms.

The first version of the software is under development on a Breadboard model produced by AIRBUS/CRISA. We describe the results of the tests and the main performances and budgets.

9904-93, Session PS1

Modeling effects of common molecular contaminants on the Euclid infrared detectors

Warren A. Holmes, Jet Propulsion Lab. (United States); Christopher M. McKenney, Jet Propulsion Lab. (United States) and California Institute of Technology (United States); Hyung J. Cho, Jet Propulsion Lab. (United States); Analia Cillis, Univ. of Maryland, Balitmore County (United States); Jean Claude Clemens, Ctr. de Physique des Particules de Marseille (France); Olivia R. Dawson, Jet Propulsion Lab. (United States); Gregory S. Delo, NASA Goddard Space Flight Ctr. (United States); Ali R. Feizi, AK Technology Corp. (United States); Ned W. Ferraro, Jet Propulsion Lab. (United States); Roger D. Foltz, NASA Goddard Space Flight Ctr. (United States); Timothy M. Goodsall, Jet Propulsion Lab. (United States); Michael Hickey, NASA Goddard Space Flight Ctr. (United States); Tsuwei Hwang, Arctic Slope Regional Corp. (United States); Ulf E. Israelsson, Jet Propulsion Lab. (United States); Murzy D. Jhabvala, Duncan M. Kahle, Emily Kan, Eric Kan, Gennadiy N. Lotkin, NASA Goddard Space Flight Ctr. (United States); Steven S. McClure, Jet Propulsion Lab. (United States); Laddawan R. Miko, Lantrang N. Nguyen, NASA Goddard Space Flight Ctr. (United States); Timothy J. Powers, Arctic Slope Regional Corp. (United States); Steven H. Pravdo, Michael D. Seiffert, Jet Propulsion Lab. (United States); Paolo Strada, European Space Research and Technology Ctr. (Netherlands); Corey J. Tucker, NASA Goddard Space Flight Ctr. (United States); Kyle Turck, Global Science & Technology, Inc. (United States); Augustyn Waczynski, NASA Goddard Space Flight Ctr. (United States); Frederick Wang, Arctic Slope Regional Corp. (United States); Carissa T. Weber, Jet Propulsion Lab. (United States); James W. Williams, Global Science & Technology, Inc. (United States)

Cleanliness specifications determine the level of particulates and areal density of molecular contaminant on surfaces. The chemical composition of these contaminants is not specified beyond the density. Here we use a toy model antireflection coating fit to the measurements of prototype infrared detector arrays to assess the impact on detector quantum efficiency of contaminant thickness and type. Provided that the contaminant does not react with the detector surface, layers at thickness meeting typical specifications, ~1microgram/cm2, have a negligible effect on the detector quantum efficiency.

9904-94, Session PS1

A comprehensive stray-light analysis of the Euclid NISP instrument

Frank U. Grupp, Univ.-Sternwarte München (Germany); Eberhard Lange, Simuloptics GmbH (Germany); Norbert Geis, Max-Planck-Institut für extraterrestrische Physik (Germany); Eric Prieto, Aix-Marseille Univ. (France); Ralf Bender, Max-Planck-Institut für extraterrestrische Physik (Germany)

An ASAP analysis has been conducted for the CDR of the EUCLID-NISP near infra-red instrument. The results are presented and compared to analytical estimates as well as to a previously published ZEMAX study. In order to have a profound basis for our dust modelling we compare the model parameters to measurements of actual lenses that where pre-contaminated (and cleaned again) in our facilities.

Special attention is drawn on the modelling of structural parts, as well as on the baffling structures. Complex light paths are identified along the mechanics to show the depth of analysis that is possible in such a study.

9904-95, Session PS1

How to test NISP instrument for Euclid mission in laboratory

Anne Costille, Michael Carle, Christophe Fabron, Eric Prieto, Florent Beaumont, Lab. d'Astrophysique de Marseille (France); Niels C. Jessen, DTU Space (Denmark); Peter Jakobsen, Univ. of Copenhagen (Denmark) and Niels Bohr Institute (Denmark); Michael I. Andersen, Anton N. Sørensen, Niels Bohr Institute (Denmark); Frank U. Grupp, Max-Planck-Institut für extraterrestrische Physik (Germany); Thierry Maciaszek, Ctr. National d'Études Spatiales (France); Anne Ealet, William Gillard, Jean-Claude Clemens, Ctr. de Physique des Particules de Marseille (France)

The ESA mission Euclid is designed to explore the dark side of the Universe and to understand the nature of the dark energy responsible of the accelerating expansion of the Universe. Its objective is to map the geometry of the dark Universe by investigating the distance-redshift relationship and the evolution of cosmic structures. The NISP (Near Infrared Spectro-Photometer) is one of the two Euclid instruments operating in the near-IR spectral region (0.9-2?m). NISP will be fully integrated and tested at Laboratory d'Astrophysique de Marseille (LAM). In particular, NISP flight model (FM) has to be tested under vacuum and thermal conditions respectively in order to qualify the instrument in its operating environment and to perform the final acceptance test before delivery to the payload. The test campaign will regroup functional tests of the detectors and wheels, performance tests of the instrument, calibration procedure validation and observations scenario test, all done at LAM. One of the main objectives of the test campaign will be the measurement of the focus position of NISP with respect to the EUCLID object plane. In order to achieve these tests campaign, a global Ground Support Equipment (GSE) called the Verification Ground System (VGS) has to be developed. The VGS will be a complex set of GSE, developed by LAM and its partners, to fulfil all the requirements of the test campaign. All the VGS parts will be integrated into ERIOS chamber. The VGS is made of: a telescope simulator to simulate the EUCLID telescope and to inject light into NISP for optical performance tests, a thermal environment to be used for NISP thermal balance and verification, a sets of mechanical interfaces to align and install all the parts into ERIOS chamber, the NISP Electrical GSE (EGSE) to control the instrument during the test and a metrology system to measure

the positions of the components during the test. We will present the preliminary design and concepts chosen for the NISP test configuration, in particular the trade-off made for the design of the thermal and mechanical GSE and the foreseen configuration for the test into ERIOS. In particular we will show the main difficulties we have to deal with: design of thermal environment at 95K with 4mK stability, the development of a metrology system in vacuum, knowledge of the focus position within 150µm in cold, etc. The main objectives of the NISP test will be explained and how the VGS responds to the test requirement. In addition, we will underline the challenges that represent such an important and long test of NISP FM and how this test campaign is foreseen.

9904-96, Session PS1

Focal plane mechanical design of the NISP/Euclid instrument

Anne Bonnefoi, William Bon, Lab. d'Astrophysique de Marseille (France); Mathieu Niclas, Ctr. de Physique des Particules de Marseille (France); Bjarte G. B. Solheim, Oyvind Torvanger, Robert Schistad, CMR Prototech (Norway); Benjamin Foulon, José Garcia, Lab. d'Astrophysique de Marseille (France); Sébastien Vives, Lab. d'Astrophysique de Marseille (France) and Aix-Marseille Univ. (France)

Currently in phase C, the Euclid mission selected by ESA in the Cosmic Vision program is dedicated to understand dark energy and dark matter. NISP (standing for Near Infrared Spectro-Photometer) is one of the two instruments of the mission. NISP will combine a photometer and a spectrometer working in the near-IR (0.9-2 microns). Its detection subsystem (called NI-DS) is based on a mosaic of 16 IR detectors cooled down to 90K which are supported by a molybdenum plate. The front-end readout electronics (working at 130K) are supported by another structure in Aluminum. The NI-DS is mounted on NISP main structure thanks to a panel in Silicon Carbide (SiC). Finally an optical baffle in Titanium will prevent the rogue light to reach the detectors.

On top of the complexity due to the wide range of temperatures and the various materials imposed at the interfaces; the NI-DS has also to incorporate an internal adjustment capability of the position of the focal plane in tip/tilt and focus.

This article will present the detailled design of the detection system of NISP and its development status. In particular, it will describe the complete breadboard model which has been developed and tested at Laboratoire d'Astrophyique de Marseille (LAM).

9904-97, Session PS1

EGSE customization for the Euclid NISP instrument AIV/AIT activities

Enrico Franceschi, Massimo Trifoglio, Fulvio Gianotti, John B. Stephen, Luca Valenziano, INAF - IASF Bologna (Italy); Jeppe J. Andersen, Niels Bohr Institute (Denmark)

The Near Infrared Spectro-Photometer (NISP) on board the Euclid ESA mission will be developed and tested at various levels of integration using various test equipment. The Electrical Ground Support Equipment (EGSE) shall be required to support the assembly, integration, verification and testing (AIV/AIT) and calibration activities at instrument level before delivery to ESA, and at satellite level, when the NISP instrument is mounted on the spacecraft. In the case of the Euclid mission this EGSE will be provided by ESA to NISP team, in the HW/SW framework called "CCS Lite", with a possible first usage already during the Warm Electronics (WE) AIV/AIT activities. In this paper we discuss how we will customize that "CCS Lite" as required to support both the WE and Instrument test activities. This customization will primarily involve building the NISP Mission Information Base (the CCS MIB tables) by gathering the relevant data from the instrument sub-units and validating these inputs through specific tools. Secondarily, it will imply developing a suitable set of test sequences, using uTOPE (an extension to the TCL scripting language, included in the CCS framework), in order to implement the foreseen test procedures. In addition and in parallel, custom interfaces shall be set up between the CCS and the NI-IWS (the NISP Instrument Workstation, which will be in use at any level starting from the WE activities), and also between the CCS and the TCC (the Telescope Control and command Computer, to be only and specifically used during the instrument level tests).

9904-98, Session PS2

Quantum efficiency measurement of the Transiting Exoplanet Survey Satellite (TESS) CCD detectors

Akshata Krishnamurthy, George R. Ricker, Steven E. Kissel, Sara Seager, Jesus N. S. Villasenor, Carolyn Thayer, Robert A. Lyle, Massachusetts Institute of Technology (United States); Adrien Deline, Univ. de Genève (Switzerland); Edward H. Morgan, Roland Vanderspek, Massachusetts Institute of Technology (United States)

The Transiting Exoplanet Survey Satellite (TESS) will search for planets transiting bright stars with Ic ? 13. TESS has been selected by NASA for launch in 2017 as an Astrophysics Explorer mission and is expected to discover a thousand or more planets that are smaller in size than Neptune, including dozens of Earth-sized planets. TESS will employ four wide-field optical charge-coupled device (CCD) cameras with a band-pass of 600 nm – 1000 nm to detect temporary drops in brightness of stars due to planetary transits. The 1000 nm limit is set by the quantum efficiency of the CCDs. The detector assembly consists of four back-illuminated MIT Lincoln Laboratory CCID-80 devices. Each CCID-80 device consists of 2048x2048 imaging array and 2048x2048 frame store regions, with 15x15 ?m pixels. The 2x2 array of CCDs is contained within 62x62 mm area with a 2 mm gap between the CCDs.

Very precise on-ground calibration and characterization of CCD detectors will significantly assist in the analysis of the science data obtained in space. The characterization of absolute quantum efficiency of the CCD detectors is a crucial part of the characterization process because it will hugely aid in data analysis of the mission. Quantum efficiency affects the performance of the CCD when working at very low light levels. An accurate optical test bench with very high photometric stability has been developed to perform precise measurements of the absolute quantum efficiency. The setup consists of a vacuum dewar with a single CCID-80 device mounted on a cold plate that is maintained at the operating temperature of -75? to reduce the dark current to a negligible level. A calibrated reference photodiode is mounted next to the CCD and maintained at the calibration temperature of 25?. The CCD electronics package consists of two compact printed circuit boards that are located beneath the cold plate. Eleven band-pass filters over the range of 575 nm – 1075 nm with 50 nm bandwidth are used for wavelength selection. A very stable laser-driven light source is integrated with a closed-loop intensity stabilization unit to control variations of the light source down to a few parts-per-million when averaged over 60 s. The stabilization unit is a patented development by the CHaracterising ExOPlanet Satellite (CHEOPS) team at the University of Geneva. Light from the stabilization unit enters a 20 inch integrating sphere. The output light from the sphere produces near-uniform illumination on the cold CCD and on the calibrated reference photodiode inside the dewar. The ratio of the CCD and photodiode signals provides the absolute quantum efficiency measurement. The design, key features, noise and error analysis, and results from the test campaign are presented. Future work involving precision flat-field calibration of single CCDs using the same setup is also discussed.

9904-99, Session PS2

Photometric testing of the TESS engineering camera

Jesus N. S. Villasenor, Roland Vanderspek, Edward H. Morgan, Carolyn Thayer, Gábor Fúrész, Robert A. Lyle, MIT Kavli Institute for Astrophysics and Space Research (United States); Robert MacDonald, MIT Lincoln Lab. (United States); Tam N. T. Nguyen, George R. Ricker, Timothy A. Sauerwein, MIT Kavli Institute for Astrophysics and Space Research (United States); Deborah F. Woods, MIT Lincoln Lab. (United States)

The Transiting Exoplanet Survey Satellite (TESS) is scheduled for launch in 2017 by NASA's Explorers Program. TESS will conduct an all-sky survey during its 2-year mission using four optical cameras to find transiting planets around dwarf stars in the solar neighborhood. In order to demonstrate the photometric precision that is required to detect Earths and Super-Earths, an engineering camera with flight like design and functionality was built. We have constructed a test bed for testing this camera that consists of a thermal vacuum chamber which cools the entire camera to its operating temperature of -75C, and an optical bench containing a highly collimated system which projects point sources (a target star and multiple guide stars) from a fiber head. The camera is held inside the chamber by a cradle that coarsely yaws and rolls the instrument on its axes, allowing projection of the target and guide stars anywhere on the focal plane. The fiber head is mounted on an xy picomotor stage, providing fine motion which translates the star images on the focal plane with sub-pixel resolution. The laser driven light source is wide band and highly stable. The output is split between the target and the guide stars, and is filtered for desired wavelengths and attenuated for appropriate intensity. The guide stars are used to cancel out thermo-mechanical motion caused by the cooling cycles via a closed loop feedback to the xy stage. Jitter motion can be added to determine its effect on the photometric precision. The target star is fixed to the same pixels for more than two weeks mimicking an orbital period, to evaluate the photometric precision. Transits are simulated to depths of <100 ppm, using a controlled shutter.

9904-100, Session PS2

The testing and characterization of TESS CCDs

Carolyn Thayer, Jesus N. S. Villasenor, Steven E. Kissel, Edward H. Morgan, Gregory Y. Prigozhin, MIT Kavli Institute for Astrophysics and Space Research (United States); Ilya Prigozhin, MIT Lincoln Lab. (United States); George R. Ricker, Timothy A. Sauerwein, MIT Kavli Institute for Astrophysics and Space Research (United States); Vyshnavi Suntharalingam, MIT Lincoln Lab. (United States); Roland Vanderspek, MIT Kavli Institute for Astrophysics and Space Research (United States)

The Transiting Exoplanet Survey Satellite (TESS) is an Explorer-class mission dedicated to finding planets around bright, nearby stars so that more detailed follow-up studies can be done. TESS is due to launch is 2017 and careful characterization of the detectors will need to be completed on ground before then to ensure that the cameras will be within their photometric requirement of <60ppm. TESS will fly MIT-Lincoln Laboratories CCID80s as the main scientific detector for its four cameras. They are 100-micron deep depletion devices which have low dark current noise levels, enough so that they can operate at low light levels at room temperature. They also each have a frame store region, which reduces smearing during readout and allows for near continuous integration. This paper describes the methodology and hardware that are being developed for testing individual CCID80s with optical and X-ray illumination. In order to determine accurate linearity, an LED system that generates a programmable series of pulses is used. The same system is employed to establish the gain at high signal levels (up through full well), while 55Fe and 109Cd X-ray sources are used at low signal levels. The gain dependence on thermal variation over the operational range is measured. Finally, the CCID80 has a charge injection register that is used to determine the upper limit of the charge transfer inefficiency.

9904-101, Session PS2

The instrument control unit of the ESA-PLATO 2.0 mission

Mauro Focardi, INAF - Osservatorio Astrofisico di Arcetri (Italy); Stefano Pezzuto, Giovanni Giusi, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Maurizio Pancrazzi, Vladimiro Noce, INAF - Osservatorio Astrofisico di Arcetri (Italy); Roland Ottensamer, Univ. Wien (Austria); Manfred Steller, Space Research Institute (Austria); Anna M. Di Giorgio, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Emanuele Pace, Univ. degli Studi di Firenze (Italy); Rosario Cosentino, Fundación Galileo Galilei - INAF (Spain); Philippe Plasson, Lab. d'Etudes Spatiales et d'Instrumentation en Astrophysique (France); Gisbert Peter, Deutsches Zentrum für Luft- und Raumfahrt e.V. (Germany); Isabella Pagano, INAF - Osservatorio Astrofisico di Catania (Italy)

PLATO 2.0 has been selected by ESA as the third medium-class Mission (M3) of the Cosmic Vision Program, to be launched in 2024. Its Payload is conceived for the study of planetary system formation and evolution and to answer fundamental questions concerning the existence of other planetary systems like our own, including the presence of potentially habitable new worlds.

It is composed of 34 small telescopes whose fields of view will cover more than 2200 square degrees. The telescopes are split into two groups of 32 and 2 units. The latter will provide the capability to observe bright targets and are dubbed fast telescopes. Combined with the 32 (normal) telescopes, the whole set will make it possible to attain a large photometric visible magnitude range, from ~4 to ~16.

Focusing on a subset of brighter targets (mv 4-11), the PLATO Payload will be able to detect and characterise planets down to Earth size by means of photometric transits, with their masses determined through ground-based radial velocity follow-up measurements. Moreover, given the brightness of this subset of samples, PLATO will extensively perform asteroseismology on these targets to obtain highly accurate stellar parameters as masses, radii and ages allowing for a precise characterisation of planetary bulk parameters.

The adoption of an observing program including two long pointing of 2-3 years each, will provide the capability to observe planets down to the habitable zone of solar-like stars with a first basic assessment of the main characteristics of their atmospheres, opening the way to future space missions designed to perform spectroscopy of these targets.

The main scientific requirement to detect and characterise a large number of terrestrial planets around bright stars plays a key role in defining the PLATO observing strategy and its own Payload.

In particular, the 4 CCDs per focal plane, for a total of 136 CCDs, pose strong constraints on the readout and the subsequent processing of a huge set of data, which requires then a customised Data Processing System (DPS).

The DPS is composed of 16 Normal DPUs (Data Processing Units) and 2 Fast DPUs (one per each Fast camera/telescope) designed to pre-process

the downloaded images and to extract the photometric signal from the selected targets as well as to select a reduced sample of imagettes around a subset of stellar targets. The DPUs will also be in charge of the detection and removal of outliers from the photometric signals. All the scientific data and payload housekeepings will be collected by an Instrument Control Unit (ICU) acting as the main interface between the Payload and the spacecraft. The PLATO 2.0 ICU will be in charge of data collection from DPS and pre-processing, data compression, managing of the Payload SpaceWire network and received telecommands, telemetry formatting towards the SC. It is conceived as a full cold-redundant unit implementing a minimal cross-strapping to improve the DPS reliability.

This paper gives an overview of the overall PLATO 2.0 DPS, mainly focusing on the architecture and processing capabilities of the ICU.

9904-102, Session PS2

Manufacturing and alignment tolerance analysis through Montecarlo approach for PLATO

Demetrio Magrin, Roberto Ragazzoni, Jacopo Farinato, Valentina Viotto, Maria Bergomi, Davide Greggio, Simonetta Chinellato, Luca Marafatto, Marco Dima, Federico Biondi, Marco Gullieuszik, INAF - Osservatorio Astronomico di Padova (Italy); Matteo Munari, Isabella Pagano, INAF - Osservatorio Astrofisico di Catania (Italy); Mauro Ghigo, Francesco Borsa, Stefano Basso, Daniele Spiga, INAF - Osservatorio Astronomico di Brera (Italy); Daniele Piazza, Giordano Bruno, Univ. Bern (Switzerland); Valery Mogulsky, Mario Schweitzer, OHB-System AG (Germany); Heike Rauer, Deutsches Zentrum für Luft- und Raumfahrt e.V. (Germany); Alexis Brandeker, Stockholm Univ. (Sweden); Martin Rieder, Timothy Bandy, Mathias Brändli, Univ. Bern (Switzerland)

The project PLAnetary Transits and Oscillations of stars (PLATO) is one of the selected medium class (M class) missions in the framework of the ESA Cosmic Vision 2015-2025 program. The main scientific goal of PLATO is the discovery and study of extrasolar planetary systems by means of planetary transits detection.

According to the current baseline, the scientific payload consists of 34 all refractive telescopes having small aperture (120mm) and wide field of view (diameter greater than 37 degrees) observing over 0.5-1 micron wavelength band. The telescopes are mounted on a common optical bench and are divided in four families of eight telescopes with an overlapping line-of-sight in order to maximize the science return. Remaining two telescopes will be dedicated to support on-board star-tracking system and will be specialized on two different photometric bands for science purposes.

The performance requirement, adopted as merit function during the analysis, is specified as 90% enclosed energy contained in a square having size 2 pixels over the whole field of view with a depth of focus of +/-20 micron. Given the complexity of the system, we have followed a Montecarlo analysis approach for manufacturing and alignment tolerances. We will describe here the tolerance method and the preliminary results, speculating on the assumed risks and expected performances.

9904-103, Session PS2

Radiation, thermal gradient, and weight: a threefold dilemma for PLATO

Demetrio Magrin, Roberto Ragazzoni, Jacopo Farinato, Valentina Viotto, Maria Bergomi, Davide Greggio, Simonetta Chinellato, Luca Marafatto, Marco Dima, Federico Biondi, Marco Gullieuszik, INAF - Osservatorio Astronomico di Padova (Italy); Matteo Munari, Isabella Pagano, INAF - Osservatorio Astrofisico di Catania (Italy); Daniele Piazza, Giordano Bruno, Univ. Bern (Switzerland); Mauro Ghigo, Francesco Borsa, Stefano Basso, Daniele Spiga, INAF - Osservatorio Astronomico di Brera (Italy); Valery Mogulsky, Mario Schweitzer, OHB-System AG (Germany); Heike Rauer, Deutsches Zentrum für Luft- und Raumfahrt e.V. (Germany); Martin Rieder, Timothy Bandy, Mathias Brändli, Univ. Bern (Switzerland); Alexis Brandeker, Stockholm Univ. (Sweden)

The project PLAnetary Transits and Oscillations of stars (PLATO) is one of the selected medium class (M class) missions in the framework of the ESA Cosmic Vision 2015-2025 program. The main scientific goal of PLATO is the discovery and study of extrasolar planetary systems by means of planetary transits detection.

The opto mechanical subsystem of the payload is made of 34 normal telescope optical units (N-TOUs) ad 2 fast telescope optical units (F-TOUs). The optical configuration of each TOUs is an all refractive design based on six properly optimized lenses. In the current baseline, in front of each TOUs a Suprasil window is foreseen. The main purposes of the entrance window is to shield the following lenses from possible damaging high energy radiation and to mitigate the thermal gradient that the first optical element will experience during the launch from ground to space environment. In contrast, the presence of the window increases the overall mass by a non-negligible quantity. We describe here the radiation and thermal analysis and their impact on the quality and risks assessment, summarizing the trade-off process with pro and cons on having or dropping the entrance window in the optical train.

9904-104, Session PS2

Thermal effects on PLATO point spread function

Marco Gullieuszik, Demetrio Magrin, Roberto Ragazzoni, Maria Bergomi, Federico Biondi, INAF - Osservatorio Astronomico di Padova (Italy); Giordano Bruno, Univ. Bern (Switzerland); Simonetta Chinellato, Marco Dima, Jacopo Farinato, Davide Greggio, Luca Marafatto, INAF - Osservatorio Astronomico di Padova (Italy); Valery Mogulsky, OHB-System AG (Germany); Matteo Munari, Isabella Pagano, INAF - Osservatorio Astrofisico di Catania (Italy); Daniele Piazza, Univ. Bern (Switzerland); Mario Schweitzer, OHB-System AG (Germany); Valentina Viotto, INAF - Osservatorio Astronomico di Padova (Italy); Heike Rauer, Deutsches Zentrum für Luft- und Raumfahrt e.V. (Germany)

The PLAnetary Transits and Oscillations of stars (PLATO) space mission primary science goal is to detect and characterise exoplanets around bright solar-type stars. The PLATO instrument consists of 32 telescopes with an aperture of 12 cm and will provide a 48.5o x 48.5o field of view (FoV). To achieve its science goals, PLATO will need to provide measurements of the magnitude of the target stars with an accuracy of a few tens part per million (ppm). To this end, the instrument stability is a major issue in the instrument design.

Here we propose a concept study aiming at analysing thermal effects in PLATO in terms of overall temperature, longitudinal and lateral gradients.

We characterise these effects by evaluating the PSF centroids shift and

the Enclosed Energy variations across the whole FoV. These patterns can then be used to gauge the thermal behaviour of each individual telescope in order to improve the local photometric calibration across the PLATO FoV. This is going to be compared in our study with respect to the most conventional photometry flat fielding taking in both cases advantages of the large number of continuously monitored stars (up to a hundred million).

9904-105, Session PS2

A display model for the TOU of PLATO: just a cool toy or a cluster of opportunities?

Marco Dima, Giancarlo Farisato, Luca Marafatto, Valentina Viotto, INAF - Osservatorio Astronomico di Padova (Italy); Davide Greggio, INAF - Osservatorio Astronomico di Padova (Italy) and Univ. degli Studi di Padova (Italy); Demetrio Magrin, Federico Biondi, INAF - Osservatorio Astronomico di Padova (Italy); Isabella Pagano, INAF - Osservatorio Astrofisico di Catania (Italy); Jacopo Farinato, Maria Bergomi, INAF - Osservatorio Astronomico di Padova (Italy); Matteo Munari, INAF - Osservatorio Astrofisico di Catania (Italy); Roberto Ragazzoni, INAF - Osservatorio Astronomico di Padova (Italy)

We produced a "toy-model" of one Telescope Optical Unit of PLATO, the Medium sized mission selected by ESA to fly in 2024. This is a six lenses dioptric very wide field camera with a window in front to take care of radiation impact on the first lens whose optical glass cannot be replaced with a radiation hardened one. The main aim of this project

is just to produce a "cool" model for display purposes, in which one can

"explore" the details of the inside through some openings in the tube, in order to visually inspect some of the fine details of the opto-mechanics. While its didactic and advertising role is out of doubt, during its construction we realized that some interesting outcome can be of some relevance for the project itself and that some findings could be useful, in order to assess the ability of producing with the same technology some (of course of much more modest quality) optical systems. In this context, we immediately dropped the option of producing the lenses with opaque material painted with a color resembling a refractive material (like blue for instance) and decided

to actually produce them with transparent plastic. Furthermore the surfaces are then finely polished in order to give them basic optical properties. Such an optical system has only very coarsely the converging

properties of the original nominal design for a number of reasons: the refractive indexes are not the nominal ones, the quality of the surfaces and their nominal values are only roughly, within a few percent, the targeted one, and the way the surfaces are built up makes them prone to some diffraction effects. However, the bulk of the lens and the surface roughness will give a large magnification of the scattering effects that will be experienced, at a much lower level, on the actual flight model. We investigated through propagation of a laser beam and by digital camera the main stray light modes that this toy-model offers. In other words, the model amplifies, to a large extent, the negative bulk scattering and spurious reflection just because surfaces and materials are orders of magnitude rougher that the intended one. Even if this did not allow to attempt to make any quantitative measurement, in order to scale down to the actual one, we used it to look out independently for the main sources of stray light and we compared them with the one discussed by the optical design team, obtained using professional ray tracing code.Finally, we point out some of the technicalities used in the design to mimic the finest mechanical elements that cannot be safely incorporate in the final design and to produce pieces of size much larger than the maximum volume allowed by our 3D printer in a single shot.

9904-106, Session PS2

An integrated payload design for the Atmospheric Remote-sensing Infrared Exoplanet Large-survey (ARIEL)

Paul Eccleston, STFC Rutherford Appleton Lab. (United Kingdom); Giovanna Tinetti, Univ. College London (United Kingdom); Jean-Philippe Beaulieu, Institut d'Astrophysique (France); Manuel Guedel, Univ. Wien (Austria); Paul Hartogh, Max-Planck-Institut für Sonnensystemforschung (Germany); Giuseppina Micela, INAF - Osservatorio Astronomico di Palermo Giuseppe S. Vaiana (Italy); Michiel Min, SRON Netherlands Institute for Space Research (Netherlands); Miroslaw Rataj, Space Research Ctr. (Poland); Tom Ray, Dublin Institute for Advanced Studies (Ireland); Ignasi Ribas, Institut de Ciències de l'Espai (Spain); Bart Vandenbussche, KU Leuven (Belgium); Jean-Louis Auguères, Commissariat à l'Énergie Atomique (France); Georgia Bishop, STFC Rutherford Appleton Lab. (United Kingdom); Vania Da Deppo, IFN-CNR LUXOR Lab. (Italy); Mauro Focardi, INAF - Osservatorio Astrofisico di Arcetri (Italy); Thomas Hunt, Mullard Space Science Lab. (United Kingdom); William D. Taylor, UK Astronomy Technology Ctr. (United Kingdom)

ARIEL (the Atmospheric Remote-sensing Infrared Exoplanet Large-survey) is one of the three candidates for the next ESA medium-class science mission (M4) expected to be launched in 2026. This mission will be devoted to observing spectroscopically in the infrared a large population of warm and hot transiting exoplanets (temperatures from ~500 K to ~3000 K) in our nearby Galactic neighbourhood, opening a new discovery space in the field of extrasolar planets and enabling the understanding of the physics and chemistry of these far away worlds. The three candidate missions for M4 are now in a Phase A study which will run until mid-2017 at which point one mission will be selected for implementation.

ARIEL is based on a 1-m class telescope feeding both a moderate resolution spectrometer covering the wavelengths from 1.95 to 7.8 microns, and a four channel photometer (which also acts as a Fine Guidance Sensor) with bands between 0.55 and 1.65 microns. During its 3.5 years of operation from an L2 orbit, ARIEL will continuously observe exoplanets transiting their host star.

This paper presents the overall view of the integrated design of the payload which is proposed for this mission. It tightly integrates the various payload elements in order to allow the exacting photometric stability targets to be met while providing simultaneous spectral and photometric data from the visible to the mid-infrared. We identify and discuss the key requirements and technical challenges for the payload and address the trade-offs that we are undertaking. We will show how we will produce a fully integrated and calibrated payload for ARIEL that can be built within the mission and programmatic constraints and will meet the challenging scientific performance required for transit spectroscopy.

9904-107, Session PS2

Design of an afocal telescope for the ARIEL mission

Vania Da Deppo, IFN-CNR Padova (Italy) and INAF - Osservatorio Astronomico di Padova (Italy); Kevin F. Middleton, STFC Rutherford Appleton Lab. (United Kingdom); Mauro Focardi, INAF - Osservatorio Astrofisico di Arcetri (Italy); Gianluca Morgante, INAF - IASF Bologna (Italy); Emanuele Pace, Univ. degli Studi di Firenze (Italy); Riccardo U. Claudi, INAF - Osservatorio Astronomico di Padova (Italy); Giuseppina Micela, INAF - Osservatorio Astronomico di Palermo Giuseppe S. Vaiana (Italy)

ARIEL (the Atmospheric Remote-sensing Infrared Exoplanet Large-survey) is one of the three candidates for the next ESA medium-class science mission (M4) expected to be launched in 2026. This mission will be devoted to observing spectroscopically in the infrared (IR) a large population of known transiting planets in our Galaxy, opening a new discovery space in the field of extrasolar planets and enabling the understanding of the physics and chemistry of these far away worlds.

ARIEL is based on a 1-m class telescope ahead of two spectrometer channels covering the band 1.95 to 7.8 microns. In addition there are two photometric channels: one in the visible and one in the near-IR, to monitor the stellar activity, measure the albedo and detect clouds. During its 3.5 years operations from L2 orbit, ARIEL will continuously observe exoplanets transiting their host star.

The ARIEL design is conceived as a fore-module common afocal telescope that will feed the spectrometer and photometric channels. The telescope optical design is an off-axis portion of a two-mirror classical telescope coupled to a tertiary off-axis paraboloidal mirror collimating the output beam.

The telescope and optical bench operating temperatures, as well as that of some subsystems, will be monitored and fine tuned/stabilised mainly by means of a thermal control subsystem (TCU- Telescope Control Unit) working in feedback closed-loop and hosted by the main Payload electronics unit, the Instrument Control Unit (ICU). In particular, one of the main functions of the TCU will be to switch on/off the Payload decontamination heaters when operating the instrument in Decontamination Mode, during the Commissioning Phase and cyclically, if required.

The TCU will be also in charge of controlling the Refocusing Mirror (M2) mechanism and the Fine Steering tip/tilt Mirror (M4) mechanism thanks to proper electronic driver sections.

In this paper the telescope requirements will be given together with the foreseen design. The technical solution chosen to passively cool the telescope unit will be detailed discussed.

9904-108, Session PS2

AIRS: the infrared spectrometer of the ARIEL space mission

Jean-Philippe Beaulieu, Institut d'Astrophysique (France)

ARIEL (the Atmospheric Remote-sensing Infrared Exoplanet Large-survey) is one of the three candidates for the next ESA medium-class science mission (M4) scheduled for launching in 2026. The three candidate missions for M4 are now in a Phase A study which will run until mid-2017 at which point one mission will be selected for implementation.

ARIEL is a 3.5 years spectroscopic survey in the infrared of a population of hundredth of warm and hot (temperatures from ~500 K to ~3000 K) transiting gas giants, Neptunes and super-Earths planets around a range of host star in our nearby Galactic neighbourhood. We target planets hotter than 500K to take advantage of their well-mixed atmospheres which should show minimal condensation and sequestration of high-Z materials and thus reveal their bulk and elemental composition (especially C, O, N, S, Si).

ARIEL will explore the nature of exoplanet atmospheres and interiors and, through this, the key factors affecting the formation and evolution of planetary systems.

ARIEL is a 1-m class telescope on L2 orbit carrying a single, highly capable and stable spectrometer (named AIRS) covering 1.95 – 7.80 ?m with a resolving power of 200. It is mounted on a single optical bench with a Fine Guidance Sensor (FGS) that provides closed-loop feedback to the high stability pointing of the spacecraft. The FGS provides simultaneous information on the photometric stability of the target stars in 4 broad bands between 0.55 and 1.65 microns. The instrument design uses only technologies with a high degree of technical maturity.

We will present in details the concept of the AIRS spectrometer. AIRS is a single module that incorporates two channels separated by a dichroic filter covering the 1.95-3.9 ?m and 3.9-7.8 ?m ranges, respectively. The preliminary design of the spectrometer consists mainly of separate optics and grating for each of the wavelength channels integrating the full wavelength range onto a single detector. The optical design is kept simple with the minimal number of components and without any mechanisms, thus providing many advantages in terms of compact and lightweight instrument architecture. The baseline detectors actively cooled to a temperature of 35K are the Teledyne MCT arrays developed for NEOCAM, but we are also studying alternatives with European manufacturers, Seles-eS, AIM and CEA/LETI development programs. We wil discuss the performance of AIRS.

9904-109, Session PS2

The Atmospheric Remote-sensing Infrared Exoplanets Large-survey (ARIEL) payload electronic subsystems

Mauro Focardi, INAF - Osservatorio Astrofisico di Arcetri (Italy); Emanuele Pace, Univ. degli Studi di Firenze (Italy); Josep Colomé, Ignasi Ribas, Institut de Ciències de l'Espai (Spain); Miroslaw Rataj, Space Research Ctr. (Poland); Roland Ottensamer, Univ. Wien (Austria); Maria Farina, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Maurizio Pancrazzi, INAF - Osservatorio Astrofisico di Arcetri (Italy); Stefano Pezzuto, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Gianluca Morgante, INAF - IASF Bologna (Italy); Anna M. Di Giorgio, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Giuseppina Micela, INAF - Osservatorio Astronomico di Palermo Giuseppe S. Vaiana (Italy); Biel Artigues, Carles Sierra-Roig, Institut de Ciències de l'Espai (Spain)

The ARIEL mission has been proposed to ESA by an European Consortium as the first space mission to extensively perform remote-sensing on the atmospheres of a well defined set of warm and hot transiting exoplanets, with temperatures ranging between ~600 K and ~3000 K. ARIEL will observe a large number (~500) of gas giants, Neptunes and super-Earths around a variety of host star types exploiting transit spectroscopy in the ~2-8 ?m spectral range and broad-band optical photometry. It will target planets hotter than 600 K to take advantage of their well-mixed atmospheres, which should show minimal condensation and sequestration of heavy materials, revealing their bulk properties. ARIEL will also address habitable planets, albeit not directly. Instead, this will follow from its capability to detect the presence of atmospheres on many terrestrial planets outside the habitable zone and, in many cases, characterise them.

This will represent a fundamental breakthrough in understanding the physical and chemical processes of a large sample of exo-atmospheres and to probe in-space technology for the next generation of dedicated space-based observatories, able to detect and characterise Earth analogues.

ARIEL has been proposed as a medium-class mission competing for the M4 ESA launch opportunity in the context of the Cosmic Vision program. Thanks to the heritage from previous studies on similar space instrumentation, its overall payload and electronics subsystems are designed to fully comply with the limitations imposed by the constraints of the ESA call. In particular, the payload electronics subsystems will aim at a full integration and simplification, respecting mass, power, volume and thermal budgets and guaranteeing the fulfilment of the science requirements. The ARIEL electronics subsystems shall mainly drive and control the telescope mirrors actuators, the mirrors temperatures when operated in decontamination mode, the IR calibration source as well as interfacing the spectrometer detectors Cold Front End Electronics (CFEEs), collecting and processing the produced data and managing the guidance sensor. A dedicated unit acting as FGS (Fine Guidance Sensor) is foreseen to guarantee the spacecraft attitude and the fine pointing on the selected target along with an Instrument Control Unit as the main payload electrical interface to the detectors CFEEs and the spacecraft. The ICU is designed as a highly integrated subsystem able to host and to perform the main functions required to interface the spectrometer cold-end, to perform data processing and to fully control the overall payload. It shall manage the payload operational modes, the received commands from the spacecraft and format the science telemetry towards the satellite mass memory, once properly compressed. ICU will be a fully cold redundant unit with a minimal internal cross-strapping, improving its own reliability.

This paper will provide an overview on the ARIEL payload electronics subsystems, showing the main choices leading to a compliant design with respect to the ESA foreseen budgets.

9904-111, Session PS2

Dimensional stability testing in thermal vacuum of the CHEOPS optical telescope assembly

Ad L. Verlaan, Wimar A. Klop, TNO (Netherlands)

In October 2012 CHEOPS was selected as the first S-class mission in the ESA Cosmic Vision program 2015-2025. This mission is executed as a partnership between Switzerland and ESA's Science Programme, with important contributions from Austria, Belgium, France, Germany, Hungary, Italy, Portugal, Spain, Sweden, and the United Kingdom. Here the university of Bern is responsible for the optical instrument and the OTA itself is constructed by Almatech. Launch readiness is foreseen for 2017.

The CHEOPS telescope is a 32cm diameter (30cm clear aperture)on-axis Ritchey-Chrétien telescope. Zerodur mirror are positioned in a CFRP structure, in combination with a kinematic mounting the assembly is integrated on the thermally isolated optical bench. Main goal here is to achieve the dimensional stability required for the scientific operation, where a distinction is made between the in-orbit stability case and the settling-stability case. For the settling deformations between the telescope mirrors are allowed of up to ~5µm and ~20µRad whereas the in orbit stability requires deformations to be smaller than 0.75µm and 5µRad. Requirements on the metrology setup are even more stringent than this.

TNO has designed, commissioned and validated a test setup for this experiment making use of the in-house expertise and facilities. The overall thermal vacuum testing was split in thermal vacuum cycling and the stability test, the main difference being that the length metrology system was not included in the thermal cycling. All thermal vacuum tests are performed in TNO's VCF facility inDelft. For the thermal cycling test a simple test interface was used and no thermal insulation was applied to increase the radiative transfer between the test facility and test object. For the stability tests the OTA is accurately aligned using a theodolite and integrated on a metrology frame equipped with three interferometers. The laser source and detectors are placed outside the vacuum facility. An active beam alignment system is implemented to preserve the beam alignment on the test object, compensating for facility deformation during the thermal vacuum test. This approach allows nm-level monitoring of length changes between the dummy mirrors in the OTA over three different paths. These three measurements are converted to deformations between the mirrors. During the latter experiment thermal insulation is added around the OTA to assure the thermal stability and homogeneity of the OTA during testing. In the experiments on the STM2, it is demonstrated that all stability requirements are met. Based on the results of these experiments the STM is upgraded to the FM.

This paper describes operation of the test facilities as well as the validation of its performance during qualification experiment. It describes the implementation of the metrology inserts on the test object and concludes with the achieved overall performance of the CHEOPS OTA itself.

9904-112, Session PS2

The performance of the CHEOPS calibration bench

François Wildi, Bruno Chazelas, Michael Sordet, Adrien Deline, Mirsad Sarajlic, Observatoire de Genève (Switzerland)

The CHaracterising ExOPlanet Satellite (CHEOPS) is a photometric transits mission aimed a characterizing already known exoplanets. By being able to point at nearly any location on the sky, it will provide the unique capability of determining accurate radii for a subset of those planets for which the mass has already been estimated from ground-based spectroscopic surveys. To reach its goals CHEOPS will measure photometric signals with a precision of 20 ppm in 6 hours of integration time for a 9th magnitude star.

Achieving the precision goal requires thorough post-processing of the data acquired by CHEOPS to remove the instrument's signature. To this purpose, a rigorous calibration campaign will be conducted before launch order to measure its behavior under the different environmental conditions.

The main tool of this calibration campaign is a purpose-built calibration system that will inject a stimulus beam in the CHEOPS and measure its response to the variation of electrical and environmental parameters. Ultimately, the CIS photometric performance will be measured on an artificial star, applying the correction model.

The design of this calibration system has been presented previously In this paper we want to address the actual performance of this bench and how we have validated it before mating it with CHEOPS. Light stabilization, field tracking, pupil tracking, beam shifts, all major contributor to the photometric budget have been characterized separately.

9904-113, Session PS2

Aligning the demonstration model of CHEOPS

Maria Bergomi, Federico Biondi, Luca Marafatto, Demetrio Magrin, Marco Dima, Valentina Viotto, Jacopo Farinato, Giancarlo Farisato, Davide Greggio, Marco Gullieuszik, Luigi Lessio, Elisa Portaluri, Roberto Ragazzoni, INAF - Osservatorio Astronomico di Padova (Italy); Matteo Munari, Isabella Pagano, INAF - Osservatorio Astrofisico di Catania (Italy); Massimo Marinai, Andrea Novi, Carlo Pompei, SELEX ES S.p.A. (Italy); Daniele Piazza, Thomas Beck, Virginie Cessa, Willy Benz, Univ. Bern (Switzerland)

CHEOPS (CHaracterizing ExOPlantes Satellite) is an ESA Small Mission, planned to be launched at the end of 2017. It will be sent into a low Earth (650-800 km) sun-synchronous orbit with the main goal to perform, through photometry, precise characterization of radii of exo-planets orbiting bright stars (V<12) bright stars already known to host planets.

It is a Ritchey-Chretien two mirrors centered telescope with an aperture of 320 mm followed by a Back End Optics (BEO) whose main purposes are to re-image the telescope focal plane on the detector, to provide an intermediate pupil to place a mask for the straylight rejection and to reshape a defocused PSF accordingly to specifications. It will provide a FoV with a diameter of 0.32 degrees.

As for every space mission, the development of intermediate models is highly important in order to decrease all possible risks. In particular, being CHEOPS also a fast-track mission, it is of paramount importance to demonstrate the feasibility and the reliability of the AIV procedures, as well as the development of adequate GSEs, ahead of their implementation on the Flight Model.

For this reason, in collaboration with the University of Bern and the Italian Prime Contractor, SELEX ES, a Demonstration Model of CHEOPS telescope was developed. It consists in a non-flying CHEOPS model whose mechanics is fully representative concerning interfaces but not thermally equivalent (it is realized in aluminum), and whose optics exhibits optical quality and handling capabilities almost identical to the flight model, allowing to test procedures for handling, integration, alignment and characterization, with accent on the optical viewpoint.

In this paper we describe the work performed at the laboratories of INAF Padova, where the CHEOPS Demonstration Model was assembled, aligned and tested in ambient temperature, with emphasis on the verification of the uncertainty in the optical quality measurements introduced by the starlight simulator and the way the alignment and optical surfaces are measured.

9904-114, Session PS2

High-spatial-frequency diversity for coronagraphic wavefront sensing with COFFEE

Laurent M. Mugnier, ONERA (France); Jean-François Sauvage, ONERA (France) and Lab. d'Astrophysique de Marseille (France); Olivier Herscovici-Schiller, ONERA (France); Pierre Baudoz, Raphaël Galicher, Lab. d'Etudes Spatiales et d'Instrumentation en Astrophysique (France); Jean-Michel Le Duigou, Ctr. National d'Études Spatiales (France)

The final performance of current and future instruments dedicated to exoplanet detection and characterization is limited by intensity residuals in the scientific image plane, which originate in uncorrected optical aberrations.

After correction of the atmospheric turbulence in the case of ground-based instruments (such as SPHERE on the VLT, GPI on Gemini South or future instruments on the ELTs), the main contribution to these residuals comes from the quasi-static aberrations introduced upstream of the coronagraph, which create long-lived speckles in the detector plane that can easily be mistaken for planets.

In order to reach very high contrast such as the ones required to image earth-like planets, these aberrations needs to be compensated for. We have proposed a dedicated focal-plane wave-font sensor called COFFEE (for COronagraphic Focal-plane wave-Front Estimation for Exoplanet detection), which consists in an extension of conventional phase diversity to a coronagraphic system: aberrations both upstream and downstream of the coronagraph are estimated using two or three coronagraphic focal-plane images, recorded from the scientific camera itself, without any differential aberration. Such a system has been successfully validated on the SPHERE instrument, where the phase reconstructed with COFFEE has been used to compensate for the aberrations upstream of the coronagraph, leading to a contrast optimization in the whole focal plane area controlled by the adaptive optics loop.

For high contrast space missions, the aimed contrast is several orders of magnitude higher than for the current ground-based dedicated high contrast instruments, and this has at least two consequences. Firstly one must estimate not only phase aberrations but also amplitude aberrations. Secondly, these aberrations must be measured and compensated for all the more frequently as the contrast requirement is more drastic, so the measurement of these aberrations should ideally be made during the scientific observation and not in-between observations.

In this communication, we study the extension of COFFEE to the joint estimation of the phase and the amplitude in the context of space-based coronagraphic instruments. In particular, we show that it is possible to perform estimation of the complex field (phase and amplitude) using a high-spatial-frequency diversity phase such as waffle instead of the defocus (or defocus plus astigmatism) that has been used so far with COFFEE. This way, the impact of the diversity phase is mostly located far away from the star, at the border of the correction region, and the same focal-plane images can be used for scientific exploitation and for wavefront sensing.

Additionally, we optimize the diversity phase in a compromise that minimizes the wavefront estimation while limiting the brightness of the few speckles created by the diversity. Lastly, we assess the wavefront estimation performance of this technique by means of simulations.

9904-116, Session PS2

Demonstration of broadband wavefront control with a shaped pupil Lyot coronagraph for the WFIRST-AFTA Observatory

Eric J. Cady, Kunjithapatham Balasubramanian, Jet Propulsion Lab. (United States); N. Jeremy Kasdin, Princeton Univ. (United States); Brian D. Kern, Andreas C. Kuhnert, Camilo Mejia Prada, Ilya Y. Poberezhskiy, Jet Propulsion Lab. (United States); A. J. E. Riggs, Princeton Univ. (United States); Hong Tang, Hanying Zhou, Jet Propulsion Lab. (United States); Neil T. Zimmerman, Princeton Univ. (United States) and Space Telescope Science Institute (United States)

A shaped pupil Lyot coronagraph uses an optimized binary pupil-plane mask to suppress light in a localized region of a focal plane 2.8-9 lambda/D from the PSF center, even in the presence of a telescope obscuration and spiders. A focal plane mask sized to that region and a subsequent Lyot stop suppress the starlight further, permitting high contrast imaging at small inner working angles with good tolerances to low-order aberrations. Demonstrations of the performance of this coronagraph have been ongoing as part of the technology development program for WFIRST-AFTA, and we present the results of the WFIRST-AFTA coronagraph milestone 5: demonstration of <9e-9 contrast in a 10% band centered at 550nm with the shaped pupil Lyot coronagraph.

9904-117, Session PS2

High-contrast imaging for complex aperture telescopes (HiCAT): hybrid-shaped pupil: apodized pupil Lyot coronagraph designs for arbitrary apertures

Mamadou N'Diaye, Laurent Pueyo, Space Telescope Science Institute (United States); Alexis Carlotti, Institut de Planétologie et d'Astrophysique de Grenoble (France); Neil T. Zimmerman, Johan Mazoyer, Lucie Leboulleux, Sylvain Egron, Space Telescope Science Institute (United States); Stuart B. Shaklan, Jet Propulsion Lab. (United States); Marshall D. Perrin, Christopher C. Stark, Rémi Soummer, Space Telescope Science Institute (United States)

We present two coronagraph designs adopted for HiCAT. The testbed goals are to study high-contrast imaging strategies for future large segmented telescopes, using starlight suppression with coronagraphy and wavefront control. For the HiCAT coronagraph we developed a hybrid concept by combining an Apodized Pupil Lyot Coronagraph (APLC) with a shaped pupil (SP) apodization, which can be manufactured using black silicon technologies developed for the WFIRST mission. This has the advantage of providing a fully reflective design more favorable for broadband coronagraphic observations. We present the methodology used to optimize these APLC/SP hybrid designs and show an example of a design that could produce a 1e-10 raw contrast dark zone over a 10% bandpass for a large segmented telescope aperture. We apply these results to the case of HiCAT, with a reduced contrast goal for this testbed operating in air, and for two configurations: (i) a design optimized to address all the diffraction features with an on-axis segmented aperture (central obstruction, spiders, segment gaps), (ii) a design optimized for a centrally obstructed circular aperture, for which the effects of the support structures are addressed by the Active Control of Aperture Discontinuities (ACAD) technique, which uses two-Deformable mirrors to remap the beam geometry. We report on the expected performance results of the HiCAT coronagraphs in terms of bandpass, inner working angle, throughput and sensitivity to pointing errors using end-to-end modeling.

9904-118, Session PS2

High-contrast imaging for complex aperture telescopes (HiCAT): first wavefront control results

Lucie Leboulleux, Space Telescope Science Institute (United States) and Univ. Aix-Marseille (France); Mamadou N'Diaye, Space Telescope Science Institute (United States); A. J. E. Riggs, Princeton Univ. (United States); Sylvain Egron, Space Telescope Science Institute (United States) and Univ. Aix-Marseille (France); Johan Mazoyer, Laurent Pueyo, Élodie Choquet, Marshall D. Perrin, Space Telescope Science Institute (United States); Jean-François Sauvage, Thierry Fusco, ONERA (France) and Lab. d'Astrophysique de Marseille (France); Rémi Soummer, Space Telescope Science Institute (United States)

Segmented telescopes are a possible approach to enable large-aperture space telescopes for the direct imaging and spectroscopy of habitable worlds. However, the increased complexity of their aperture geometry, due to their central obstruction, support structures and segment gaps, makes high-contrast imaging very challenging. The HiCAT testbed was designed to study and develop solutions for such telescope pupils using wavefront control and starlight suppression. The testbed design has the flexibility to enable studies with increasing complexity for telescope aperture geometries starting with off-axis telescopes, then on-axis telescopes with central obstruction and support structures (e.g. WFIRST), up to on-axis segmented telescopes e.g. including various concepts for a Large UV, Optical, IR telescope (LUVOIR), such as the High Definition Space Telescope (HDST). We completed optical alignment in the summer of 2014 and a first deformable mirror was successfully integrated in the testbed, with a total wavefront error of 13nm RMS over a 18mm diameter circular pupil in open loop. HiCAT will also be provided with a segmented mirror conjugated with a shaped pupil representing the HDST configuration, to directly study wavefront control in the presence of segment gaps, central obstruction and spider. In this communication, we report on the first wavefront control results on HiCAT using a classical Lyot coronagraph, obtained with different methods of wavefront control implemented on the testbed, including Speckle Nulling, Dark Hole and Stroke Minimization, and present a comparison of the resulting contrast level performance.

9904-119, Session PS2

PISCES: The WFIRST coronagraph integral field spectrograph technology demonstrator

Michael W. McElwain, Bradford Greeley, Qian Gong, Avi Mandell, NASA Goddard Space Flight Ctr. (United States); Jorge Domingo Llop Sayson, The Catholic Univ. of America (United States); Timothy D. Brandt, Institute for Advanced Study (United States); Bryan Grammer, Design Interface, Inc. (United States); George M. Hilton, Universities Space Research Association (United States); Nargess Memarsadeghi, Karl R. Stapelfeldt, NASA Goddard Space Flight Ctr. (United States); Marshall D. Perrin, Space Telescope Science Institute (United States); Richard T. Demers, Hong Tang, Brian D. Kern, Janan Ferdosi, Jet Propulsion Lab. (United States)

We present the integration and test of the Prototype Imaging Spectrograph for Coronagraphic Exoplanet Studies (PISCES) integral field spectrograph (IFS). The PISCES design meets the science requirements for the Wide-Field InfraRed Survey Telescope (WFIRST) Coronagraph Instrument (CGI) and its performance will be assessed at the High Contrast Imaging Testbed (HCIT) as part of the CGI technology development program. The PISCES instrument was built at NASA Goddard and recently received first light with the Shaped Pupil Coronagraph (SPC) HCIT testbed. The HCIT SPC/PISCES configuration represents the first laboratory demonstration that achieves 10^-9 contrast with an IFS. This is done by incorporating a lenslet array with a pinhole mask in a non-telecentric beam to limit the cross-talk from diffraction between imaging elements. We discuss the alignment and calibration of the spectrograph at Goddard and preliminary results of the HCIT testing at JPL.

9904-121, Session PS2

Recent achievements on ASPIICS: an externally occulted coronagraph for PROBA-3

Etienne Renotte, Cédric Thizy, Jean-Sébastien Servaye, Univ. de Liège (Belgium)

This paper presents the current status of ASPIICS, a solar coronagraph that is the primary payload of ESA's formation flying in-orbit demonstration mission PROBA-3.

The "sonic region" of the Sun corona remains extremely difficult to observe with spatial resolution and sensitivity sufficient to understand the fine scale phenomena that govern the quiescent solar corona, as well as phenomena that lead to coronal mass ejections (CMEs), which influence space weather. Improvement on this front requires eclipse-like conditions over long observation times. The space-borne coronagraphs flown so far provided a continuous coverage of the external parts of the corona but their over-occulting system did not permit to analyse the part of the white-light corona where the main coronal mass is concentrated.

The PROBA-3 Coronagraph System, also known as ASPIICS (Association of Spacecraft for Polarimetric and Imaging Investigation of the Corona of the Sun) is designed as a classical externally occulted Lyot coronagraph but it takes advantage of the opportunity to place the external occulter on a companion spacecraft, about 150m apart, to perform high resolution imaging of the inner corona of the Sun as close as ~1.1 solar radii. The images will be tiled and compressed on board in an FPGA before being down-linked to ground for scientific analyses.

ASPIICS is built by a large European consortium including about 20 partners from 7 countries under the auspices of the European Space Agency. This paper is reviewing the recent development status of the ASPIICS instrument as it is approaching CDR.

9904-122, Session PS2

Contrast improvement with imperfect pre-coronagraph and dark-hole

Jun Nishikawa, National Astronomical Observatory of Japan (Japan) and The Graduate Univ. for Advanced Studies (Japan) and National Institutes of Natural Sciences (Japan); Masahito Oya, Nihon Univ. (Japan); Naoshi Murakami, Hokkaido Univ. (Japan); Motohide Tamura, The Univ. of Tokyo (Japan) and National Institutes of Natural Sciences (Japan); Takashi Kurokawa, National Astronomical Observatory of Japan (Japan) and Tokyo Univ. of Agriculture and Technology (Japan); Yosuke Tanaka, Tokyo Univ. of Agriculture and Technology (Japan); Shiomi Kumagai, Nihon Univ. (Japan); Takayuki Kotani, National Astronomical Observatory of Japan (Japan) and National Institutes of Natural Sciences (Japan)

We have studied a coronagraph system with an unbalanced nulling interferometer (UNI) which considered to be an imperfect (low-contrast) pre-coronagraph. The system consists of an upstream deformable mirror, the pre-coronagraph, a deformable mirror, and a main coronagraph, in sequence. A pre-reduction of the star light to 1/100 at the pre-coronagraph stage enables to enhance the final contrast by 100. It was not operated by the dark-hole control before but a wavefront sensor. We found that the dark-hole control was possible when the pre-coronagraph status could be exchanged between perfect and imperfect nulling. In the style of the nulling interferometer, it could be obtained by phase shift operations. In the case of a focal-plane mask coronagraph it could be obtained by exchanging the masks with a small difference of transmittance pattern. Although we do not make the dark-hole control for the pre-coronagraph, yet, but only for the main coronagraph, it would be promising to implement the dark-hole control for the pre-coronagraph.

We are planning to construct an experimental optics with two vortex mask coronagraphs and two deformable mirrors to validate the techniques. We obtained a contrast of 8E-8 with a vortex mask coronagraph without the pre-coronagraph method where a 12x12 deformable mirror was used. We expect a better contrast if we can use a deformable mirror with more actuators as well as the pre-coronagraph.

9904-123, Session PS2

Low-signal, coronagraphic wavefront estimation with Kalman filtering in the high-contrast imaging testbed

A . J. E. Riggs, Princeton Univ. (United States); Eric J. Cady, Camilo M. Prada, Brian D. Kern, Hanying Zhou, Jet Propulsion Lab. (United States); N. Jeremy Kasdin, Tyler D. Groff, Princeton Univ. (United States)

For direct imaging and spectral characterization of several cold exoplanets in reflected light, the proposed Wide-Field Infrared Survey Telescope-Astrophysics Focused Telescope Assets (WFIRST-AFTA) Coronagraph Instrument (CGI) will carry two types of coronagraphs. The High Contrast Imaging Testbed (HCIT) at the Jet Propulsion Laboratory has been testing both coronagraph types and demonstrated their abilities to achieve high contrast. Focal plane wavefront correction is used to estimate and mitigate aberrations. As the most time-consuming part of correction during a space mission, the acquisition of probed images for electric field estimation needs to be as short as possible. We present results from the HCIT of monochromatic, low-signal wavefront estimation tests using a Shaped Pupil Lyot Coronagraph (SPLC) designed for WFIRST-AFTA. We show that wavefront correction is possible using the minimum theoretical stellar signal in each estimation image. In the low-flux regime, we find that the Kalman filter and iterative extended Kalman filter provide faster correction, better achievable contrast, and more accurate estimates than batch process estimation.

9904-125, Session PS2

Performance results of a starshade at flight Fresnel numbers in the laboratory

Yunjong Kim, Princeton Univ. (United States); Dan Sirbu, NASA Ames Research Ctr. (United States); Michael Galvin, N. Jeremy Kasdin, Robert J. Vanderbei, Princeton Univ. (United States)

A major science goal of exoplanet exploration is the direct detection and spectral characterization of Earth-like planets. The main challenge with the direct observation of Earth-like extra planets is that these planets are ten billion times fainter than the parent stars and the angular separation between the parent stars and the planets are less than a hundred milliarcseconds.

Many approaches have been suggested over the last couple of decades for imaging these planets. One of the main candidates for creating high-contrast for future Earth-like planets detection is a sharshade. The starshade is a spacecraft flown along the line-of-sight of a space telescope to suppress starlight and enable high-contrast direct imaging of exoplanets. The starshade is typically tens of meters in diameter and the separation from the telescope is of the order of tens of thousands of kilometers. Optical testing of a full-scale starshade on the ground is impossible because of the long separations. Therefore, laboratory verification of starshade designs is necessary to validate the optical models used to design and predict starshade performance.

At Princeton, we have designed and built a testbed that allows verification of scaled starshade at flight-like Fresnel numbers whose suppressed shadow is mathematically identical to that of a space starshade. The goal of this experiment is to demonstrate a pupil plane suppression of better than 1e-9 with a corresponding image plane contrast of better than 1e-11. The starshade testbed uses a 76.4 m optical propagation distance to realize the flight Fresnel number of 14.5. The starshade mask will be placed 38.2 m from the artificial source and the camera is located 38.2 m from the starshade mask. We will use an etched silicon mask as the starshade. The starshade is illuminated by a diverging laser beam to reduce the

aberrations from the collimating optics before the starshade.

We calculate the performance of the laboratory mask under scaled conditions corresponding to a diverging input beam. We generate a two-dimensional mask model with n x n samples and allow the pixels to take on “gray” values (less than 1 but greater than 0) at the petal edges. These gray values are computed via a g x g anti-aliasing subgrid at each edge pixel. A mask model with (n, g) and with radius R will therefore be representative of the resulting feature size given by ?R = 2R/n/g. This feature size of points along the edges represents the accuracy of the polygons used in the CAD model supplied to the Jet Propulsion Laboratory’s Microdevices Lab (MDL) for manufacture. Based on conversations with MDL, we expect that 0.5 ?m feature size is achievable resolution in the mask manufacturing process and is therefore likely the indicator of the best possible performance. We also perform two-dimensional optical propagations with different errors. We find that we can still expect a predicted suppression of better than 1e-9 and the corresponding contrast.

Here, we present first light result of a sample design operating at a flight Fresnel number. We compare the experimental results with simulations that predict the ultimate contrast performance.

9904-126, Session PS2

Results of edge scatter testing for a starshade mission

Suzanne Casement, Steven Warwick, Daniel K. Smith, Northrop Grumman Aerospace Systems (United States); Scott Ellis, Photon Engineering LLC (United States); John C. Stover, The Scatter Works Inc. (United States)

In the field of ExoPlanet detection and characterization, the use of a Starshade, an external occulter in front of a telescope at large separations, has been identified as one of the highly promising methods to achieve the goals. Control of scattered sunlight from the edges of the starshade into the telescope was identified as one of the key technology development areas in order to make the starshade feasible (Lawson, JPL D-72279, 2013). Modeling of the scattered light has resulted in very different results (Casement et al., SPIE Vol. 8442, 4H, 2012, Martin et al., SPIE Vol. 8864, 88641A, 2013) so a campaign of experimentation with edge samples was undertaken to attempt to resolve the discrepancies.

Here, we present our results from the measurement of samples of materials which would be suitable for manufacturing the starshade edge and related models. We have focused on coating metallic samples for ease of fabrication: Titanium, Aluminum, and a BerylliumCopper alloy. Using standard machine shop methods, we fabricated samples which had edges with radius of curvature between 10 and 20 microns. We then had these samples coated by two suppliers to evaluate how well these coating types would conform to the edge and provide scatter suppression. The results of scatter measurements of these coated edge samples are presented. In addition, we have subjected these samples to a limited set of environments to evaluate their durability. We will present these results with their impact on the overall starshade mission architecture and error budgets.

9904-127, Session PS2

Ground-based testing and demonstrations of starshades

Anthony Harness, Univ. of Colorado at Boulder (United States); Dayne Kemp, NASA Ames Research Ctr. (United States); Ann Shipley, Univ. of Colorado at Boulder (United States); Matthew Sorgenfrei, NASA Ames Research Ctr. (United States); Webster Cash, Univ. of Colorado at Boulder (United States); Steven Warwick, Northrop Grumman Aerospace Systems (United States)

The direct detection and characterization of an Earth-like exoplanet is of the highest scientific priority and a leading technology that will enable such discovery is the starshade external occulter. We report on the latest results in ground-based efforts for demonstrating and advancing the technology of starshades.

We report on a recent flight campaign investigating Vertical Takeoff Vertical Landing (VTVL) rockets as a stable platform for a suborbital starshade demonstration. In this campaign supported by the NASA Flight Opportunities Program, we flew a 60 cm starshade on a VTVL rocket and used a suite of sensors to quantify the flight stability of the rocket and its potential as a starshade platform. We also tested a vision-based formation flying sensor that can be used for relative attitude determination and can provide feedback to position the rocket in the line of sight between ground telescope and astronomical target.

Using the McMath-Pierce Solar Telescope at Kitt Peak National Observatory, we are able to keep a stable beam of light from a celestial object behind a starshade to allow for astronomical observations with a starshade. We report on the latest results in which we used a 30 cm starshade to achieve high-contrast images at an inner working angle of 10 arcseconds and at a flight-like Fresnel number.

Finally, we report on the latest results from a NASA Technology Development for Exoplanet Missions (TDEM) study investigating formation flying sensors to enable long range position sensing at the precision needed for a full-scale starshade mission.

9904-128, Session PS2

Diffraction-based analysis of tunnel size for a scaled external occulter testbed

Dan Sirbu, NASA Ames Research Ctr. (United States); N. Jeremy Kasdin, Robert J. Vanderbei, Princeton Univ. (United States)

To test the performance of an external occulter mask (also called a starshade), scaled testbeds have been developed to determine the suppression of the occulter shadow in the pupil plane and measure contrast in the image plane. For occulter experiments the scaling is typically performed by maintaining an equivalent Fresnel number. The original Princeton occulter testbed was oversized with respect to both input beam and shadow propagation to limit any diffraction effects due to laboratory edges; however, to operate at realistic space-mission equivalent Fresnel numbers an extended testbed is currently under construction. With the longer propagation distances involved, diffraction effects due to the edge of the tunnel must now be considered in the experiment design. Here, we present a diffraction-based model of two separate tunnel effects. First, we consider the effect of tunnel-edge induced diffraction ringing upstream from the occulter mask. Second, we consider the diffraction effect due to clipping of the output shadow by the tunnel downstream from the occulter mask. These calculations are performed for the propagation size of the new Princeton occulter experiment, but we also present non-dimensionalized relations that can be used for other propagation distances.

9904-129, Session PS2

Measurements of high-contrast starshade performance in the field

Daniel Smith, Steven Warwick, Tiffany M. Glassman, Megan C. Novicki, Michael C. Richards, Northrop Grumman Aerospace Systems (United States); Anthony Harness, Univ. of Colorado at Boulder (United States);

Keith D. Patterson, Jet Propulsion Lab. (United States)

The external Starshade is a method for the direct detection and spectral characterization of terrestrial planets around other stars, a key goal identified in ASTRO2010. In an effort to validate the starlight-suppression performance of the Starshade, we have measured contrast better than 1X10-9 using 60 cm Starshades at points just beyond the Starshade tips. These measurements were made over a 50% spectral bandpass, using an incoherent light source (a white LED), and in challenging outdoor test environments. Our experimental setup is designed to provide Starshade to telescope separation and telescope aperture size that are scaled as closely as possible to the flight system. The measurements confirm not only the overall starlight-suppression capability of the Starshade concept but also the robustness of the setup to optical disturbances such as atmospheric effects at the test site. The spectral coverage is limited only by the optics and detectors in our test setup, not by the Starshade itself. Here we describe our latest results as well as detailed comparisons of the measured results to model predictions. Plans and status of the next phase of ground testing are also discussed.

9904-130, Session PS2

Engineering considerations applied to starshade repointing

Norman Rioux, Aki Roberge, Avi Mandell, Shawn Domagal-Goldman, Lee D. Feinberg, Matthew R. Bolcar, Eric T. Stoneking, NASA Goddard Space Flight Ctr. (United States)

Using a starshade free-flying in formation with a space telescope provides a method of suppressing starlight to enable spectroscopy and imaging of an exoplanet orbiting its host star. In order to move to observe a different star, the starshade must perform a delta V maneuver to a new orbit location to line up with the telescope's next pointing location. This paper examines some practical engineering aspects of transferring a starshade to a new orbit location that can be used to increase the detail and fidelity of exoplanet yield calculations for a telescope-starshade system. This paper considers a starshade flying in formation with a telescope in Sun-Earth L2 orbit. Orbit dynamics and environmental effects are considered, and a relationship between starshade target slew time and associated propellant expenditure is calculated. The analysis also considers the number of targets that can be observed with respect to propellant consumption.

9904-131, Session PS2

Lenslet array to further suppress star light for direct exoplanet detection

Qian Gong, Michael W. McElwain, Ron Shiri, NASA Goddard Space Flight Ctr. (United States)

The direct imaging plays a key role in the detection and characterization of exoplanets orbiting within its host star's habitable zone. Many innovative ideas for starlight suppression and wavefront control have been proposed and developed in the past decade. However, several technological challenges still lie ahead to achieve the required contrast including controlling the observatory jitter performance, tight optical tolerances on starlight masks, the development of wavefront control algorithms, stray light controls, photon counting detectors, and other issues. This paper explores how a lenslet array and pinhole mask may be implemented to further suppress the residual star light. The star shade is used as an example to demonstrate the principal, even though this approach can be implemented for any of the proposed direct exoplanet detection methods. We also discuss how to use a simple relay optics to control the inner working field of view and the level of the suppression is also addressed. Furthermore, if a spectrometer is added after the lenslet array to make it an Integral Field Spectrometer (IFS), the spectral information of the planets can be obtained to determine if the observed planet is inhabited.

9904-133, Session PS2

Orbital differential imaging: a post-processing method enabling the direct detection of an Earth-like planet with a small telescope

Jared R. Males, The Univ. of Arizona (United States); Ruslan Belikov, Eduardo A. Bendek, NASA Ames Research Ctr. (United States)

We present the post-processing method that will enable characterization of Earth-like planets with a coronagraphic space telescope dedicated to observing the alpha Centauri system . Orbital differential imaging (ODI) exploits the motion of a planet with respect to the point spread function (PSF). Given repeated high-cadence observations of an exoplanet with a sufficiently short orbital period, orbital motion allows us to discriminate the planet from the PSF. In addition to using powerful PSF subtraction algorithms, time domain analyses can further increase the signal-to-noise ratio. We have developed techniques to model and simulate PSF evolution and speckle dynamics over the years-long timescales under consideration for a dedicated mission. Our simulations suggest that ODI can leverage the large number of images from a small dedicated mission to gain a deeper contrast than would be possible with conventional post-processing techniques or on a mission with many targets. This performance gain potentially enables the direct detection of Earth-like planets in the habitable zone with a space telescope as small as 30-45cm.

9904-134, Session PS2

Synergies of Galaxy Evolution Spectroscopic Explorer (GESE) and Subaru: prime focus spectrograph (PFS)

Massimo Robberto, Space Telescope Science Institute (United States); Luciana Bianchi, Johns Hopkins Univ. (United States); James E. Gunn, Princeton Univ. (United States); Sara R. Heap, NASA Goddard Space Flight Ctr. (United States); Timothy M. Heckman, Johns Hopkins Univ. (United States); Olivier C. Le Fèvre, Lab. d'Astrophysique de Marseille (France); Michael A. Strauss, Jenny Greene, Princeton Univ. (United States)

The Galaxy Evolution Spectroscopic Explorer (GESE) will obtain UV spectra (0.2-0.4 microns) of redshift, z-1-2 galaxies already observed by Subaru's Hyper Suprime Camera (HSC) and Prime Focus Spectrograph (PFS). The combined spectra of over 50,000 galaxies will cover the spectral range, 0.2-1.3 microns, (e.g. spectra covering 0.1-0.65 microns as emitted by redshift, z=1 galaxies). Knowledge gained from Subaru's HSC and PFS observations (spectroscopic redshifts, colors, coordinates) will enable GESE to identify and acquire its targets efficiently, while GESE will provide a deep g-band image of the field. GESE will obtain unique information on star-formation and stellar feedback and Lyman-? emitting galaxies, while Subaru/PFS will obtain unique information on the growth of stellar mass and stellar feedback, and growth of black holes and AGN feedback. The combined results should lead to a better understanding of the evolution of stars and galaxies over the course of history of the universe.

9904-135, Session PS2

The JWST/NIRSpec exoplanet exposure time calculator

Louise Nielsen, Pierre Ferruit, Giovanna Giardino, European Space Research and Technology Ctr. (Netherlands); Stephan M. Birkmann, Space Telescope Science Institute (United States) and European Space Agency (United States); Antonio García Muñoz, Technische Univ. Berlin (Germany); Jeff A. Valenti, Space Telescope Science Institute (United States); Kate Isaak, European Space Research and Technology Ctr. (Netherlands); Catarina Alves de Oliveira, European Space Agency (United States) and Space Telescope Science Institute (United States); Torsten Böker, Space Telescope Science Institute (United States); Nora Lützgendorf, European Space Agency (United States) and Space Telescope Science Institute (United States); Timothy Rawle, Space Telescope Science Institute (United States) and European Space Agency (United States); Marco Sirianni, European Space Agency (United States) and Space Telescope Science Institute (United States)

The James Webb Space Telescope (JWST), with its unprecedented sensitivity, will provide a unique set of tools for the study of transiting exoplanets and their atmospheres. One of these tools is the high-contrast aperture-spectroscopy mode of the near-infrared spectrograph NIRSpec, one of four instruments on JWST.

In this context, we are developing the NIRSpec Exoplanet Exposure Time Calculator (NEETC), which is optimised to deal with observations of transiting exoplanets. It will allow future users to fully investigate NIRSpec's observation modes and capabilities while testing the feasibility of specific observations.

The NEETC differ from a classical ETC in a number of ways. For example, the user can input both stellar and planetary components of the spectrum along with the observation type (transit, eclipse or full phase curve). Simulated spectra will give the user a realistic idea of the quality that can be achieved of a given observation.

The NEETC will also aid the user in the choice of optimal instrument configuration by calculating signal-to-noise ratios for different readout setups. The exposure parameters giving the best duty cycle without saturating the detector will also be an output.

We give examples of how the NEETC can be used to prepare observations, and present examples of outputs and results obtained with the NEETC, higligting the capabilities and limitations of NIRSpec.

9904-136, Session PS2

Exoplanet atmospheres with JWST: degeneracy, systematics, and how to avoid them

Joanna K. Barstow, Patrick G. J. Irwin, Sarah Kendrew, Suzanne Aigrain, Univ. of Oxford (United Kingdom)

The high sensitivity and broad wavelength coverage of the James Webb Space Telescope will transform the field of exoplanet transit spectroscopy. Transit spectra are inferred from minute, wavelength-dependent variations in the depth of a transit or eclipse as the planet passes in front of or is obscured by its star, and the spectra contain information about the composition, structure and cloudiness of exoplanet atmospheres. Atmospheric retrieval (e.g. Barstow et al. 2013b) is the preferred technique for extracting information from these spectra, but the process can be confused by astrophysical and instrumental systematic noise (Barstow et al. 2013a, Barstow et al. 2015).

We present results of retrieval tests based on synthetic, noisy JWST spectra, for clear and cloudy planets and active and inactive stars. We find that the ability to correct for stellar activity is likely to be a limiting factor for planets orbiting nearby cool stars, as the presence of molecular features in star spots may introduce spurious detections of these gases in a planet's atmosphere.

We discuss the pros and cons of the available JWST instrument combinations for transit spectroscopy, and consider the effect of clouds and aerosols on the spectra. Aerosol high in a planet's atmosphere obscures molecular absorption features in transmission, reducing the information content of spectra in wavelength regions where the cloud is optically thick. We discuss the usefulness of particular wavelength regions for identifying the presence of cloud, and suggest strategies for solving the highly-degenerate retrieval problem for these objects.

Archival legacy investigation of circumstellar environments: overview of the debris disk detections

Élodie Choquet, Marshall D. Perrin, Rémi Soummer, Laurent Pueyo, Christine H. Chen, James B. Hagan, Space Telescope Science Institute (United States); Elena Gofas-Salas, Institut d'Optique Graduate School (France); Abhijith Rajan, Arizona State Univ. (United States); David A. Golimowski, Dean C. Hines, Space Telescope Science Institute (United States); Glenn H. Schneider, The Univ. of Arizona (United States); Jean-Charles Augereau, Institut de Planétologie et d'Astrophysique de Grenoble (France); John H. Debes, Johan Mazoyer, Christopher C. Stark, Space Telescope Science Institute (United States); Schuyler G. Wolff, Johns Hopkins Univ. (United States); Mamadou N'Diaye, Space Telescope Science Institute (United States); Kevin Hsiao, Johns Hopkins Univ. (United States)

Over the past three years, we have conducted a comprehensive and consistent re-processing of the HST-NICMOS coronagraphic archive using advanced PSF subtraction methods, entitled the Archival Legacy Investigations of Circumstellar Environments program (ALICE). This virtual campaign of about 400 targets has produced numerous detections of previously unidentified point sources and circumstellar structures. In this publication, we present a summary of our debris disk detections. Debris disks are second-generation dust belts orbiting main sequence stars and are the remnants of the star's planet formation period. In this program, we obtained improved images of 7 debris disks already resolved with NICMOS, and we obtained new images of 10 other debris disks that were either never previously detected with NICMOS or never before imaged in scattered light at all. These images enable a newly comprehensive comparative analysis of a large fraction of all debris disks imaged in scattered light, all imaged by the same instrument in the main infrared filters, reduced in a consistent fashion with a single analysis pipeline, and characterized using the same metrics. We will present the methods used for this study, which includes careful attention to obtaining unbiased measurements by calibration of PSF subtraction algorithm throughputs, and the results of this comparative analysis regarding the morphology and dust properties of these debris disks.

9904-138, Session PS2

An end-to-end simulator of exoplanet transit spectroscopy

Subhajit Sarkar, Enzo Pascale, Andreas Papageorgiou, Cardiff Univ. (United Kingdom)

Exoplanet transit spectroscopy has in recent years yielded a number of planetary spectra in both primary and secondary transit, giving us the first insights into the atmospheric composition and characteristics of these distant worlds. A number of dedicated space-borne instruments are being planned to fully realise the potential of this pioneering technique. Instrument simulators have become an integral part of the design process for major astronomical projects. We have designed the first generically applicable, open-access, end-to-end simulator for exoplanet transit spectroscopy ('ExoSim'), which can be modified easily for a number of different telescope designs, and used to simulate observations for these projects.

ExoSim is written in Python and C and utilizes a number of standard Python packages. It has been optimized for speed, efficiency and modularity. A single input XML file is used, that can be modified for different instruments, telescopes, detectors, astronomical objects, and observational modes. ExoSim uses a number of modules and classes to model the various components of the observation in an end-to-end time-domain simulation. These elements include the astrophysical scene, telescope, instrument channels (including all transmissions and emissions), detector, and the observational timeline. ExoSim can draw information directly from the online Open Exoplanet Catalogue and selects stellar Phoenix spectra automatically, allowing it to perform large planet 'surveys' to obtain bulk performance metrics for the instruments concerned. Foregrounds such as zodiacal light (or for ground-based simulations, Earth atmospheric emission and transmission) can be added. Intra- and inter-pixel variations are included, and non-standard point-spread functions can be used as well. The planet input spectrum is used to generate light curves at different wavelengths, which then modulate the stellar spectrum in time. Correlated and uncorrelated noise sources are simulated and include pointing jitter, photon shot and wave noise, read noise and intrinsic detector noise (which includes pixel-to-pixel and time correlations).

Non-destructive reads can be simulated to allow for 'up-the-ramp' or correlated double sampling methods, and a realistic detector 'duty cycle' is used. The output of ExoSim are FITS files containing 'exposures' akin to image files from a real observation, which can then undergo data reduction to extract signal and noise and reconstruct the planetary spectrum.

ExoSim is currently the end-to-end simulator for the Ariel mission, and is being utilized to explore and optimize the instrument design It is also being used to help formulate optimal observational strategies to achieve science goals. We have also developed a version that simulates the Hubble Wide Field Camera 3 infra-red instrument in scanning mode, to investigate the noise characteristics of this instrument which has been used for several exoplanet studies. We are in the process of adding a stellar variability module as a 'plug in' to ExoSim to investigate the effects of stellar astrophysical noise on observations and to study how to decorrelate the effect using multi-wavelength component separation analyses.

ExoSim will also be open access software made available to the astronomical community.

9904-305, Session PS2

Results of ground-based starshade tests

Benjamin R. Zeiger, Anthony Harness, Ann Shipley, Univ. of Colorado Boulder (United States); Steven Warwick, Northrop Grumman Aerospace Systems (United States)

Starshades are the most promising technology for studying exoplanets. Over the past decade, we have demonstrated the ability of starshades to suppress light from broad-spectrum natural and artificial light sources in test configurations spanning a wide range of Fresnel numbers. The range of test environments includes vacuum chambers, enclosed laboratory environments, and open-air tests. We present a summary of the tests and their results.

9904-139, Session PS3

Far IR surveyor: what lessons can be learned from the JWST experience?

Jonathan W. Arenberg, Northrop Grumman Aerospace Systems (United States)

The Far IR Surveyor (FIS) now under study will be a large cryogenic observatory. The James Webb Space Telescope (JWST) is also a large, cryogenic observatory. Despite the differences in size and temperature, there are definitely lessons spanning the entire life cycle that have been learned on JWST that are applicable to the FAR-IR Surveyor. This paper will introduce a number of these lessons and the rationale for their use by the FIS team. These lessons range from architectural choices to verification.

9904-141, Session PS3

SAFARI optical system architecture and design concept

Carmen Pastor, INTA Instituto Nacional de Técnica Aeroespacial (Spain); Willem Jellema, SRON Netherlands Institute for Space Research (Netherlands); David L. Arrazola, Marianela Fernández-Rodriguez, Pablo Zuluaga, INTA Instituto Nacional de Técnica Aeroespacial (Spain); Michael Damian Audley, SRON Netherlands Institute for Space Research (Netherlands); Tomás Belenguer-Dávila, Luis Miguel González Fernández, Josefina Torres Redondo, INTA Instituto Nacional de Técnica Aeroespacial (Spain); Jaap Evers, Martin J. Eggens, Peter R. Roelfsema, SRON Netherlands Institute for Space Research (Netherlands); Francisco Najarro de la Parra, Ctr. de Astrobiología (Spain)

SAFARI (SpicA FAR-infrared Instrument) is one of the instruments planned for the SPICA mission. The SPICA mission is the next great leap forward in space-based far-infrared astronomy and will study the evolution of galaxies, stars and planetary systems. SPICA will utilize a deeply cooled 2.5m-class telescope, provided by European industry, to realize zodiacal background limited performance, and high spatial resolution. The instrument SAFARI is a cryogenic grating-based point source spectrometer working in the wavelength domain 34 to 210 ?m, providing spectral resolving power from 300 to at least 3000.

The instrument shall provide low and high resolution spectroscopy in three spectral bands. Low Resolution mode is the native instrument mode, while the high Resolution mode is achieved by means of a Martin-Pupplet interferometer.

The optical system is all-reflective and consists of three main modules; an input optics module, followed by the Band & Mode Distributing Optics and the grating Modules. The instrument utilizes Nyquist sampled filled linear arrays of very sensitive TES detectors.

The work presented in this paper describes the optical design architecture and design concept compatible with the current instrument performance and volume design drivers.

9904-142, Session PS3

Sensitivity estimates for the SPICA mid-infrared instrument (SMI)

Itsuki Sakon, The Univ. of Tokyo (Japan); Shinki Oyabu, Daisuke Ishihara, Nagoya Univ. (Japan); Takehiko Wada, Japan Aerospace Exploration Agency (Japan); Naofumi Fujishiro, Kyoto Sangyo Univ. (Japan); Hidehiro Kaneda, Nagoya Univ. (Japan)

We present the latest results of the sensitivity estimate for SPICA Mid-Infrared Instrument (SMI). SMI has three spectroscopic channels; low resolution spectrometer (LRS), medium resolution spectrometer (MRS) and high resolution spectrometer (HRS). LRS is a multi-slits prism spectrometer covering the wavelength range from 17 micron to 37 micron with a spectral resolution of R=50—120. The spectra along the four long slits, each of which has a size of 3".7 width by 10' length, are obtained on the Si:Sb detector array. MRS is a crossed Echelle grating spectrometer covering the wavelength range from 18 micron to 36 micron with R~1000. The spectra over six different orders from m=6th to 11th along a long slit, which has a size of 3".7 width by 120" length, are obtained on the Si:Sb detector array. HRS is a crossed Echelle immersion grating spectrometer covering the wavelength range from 12 micron to 18.7 micron with R~27,000. The spectra over 34 different orders from 85th to 118th, which successively covers the wavelengths from 12.14 micron to 17.03 micron, and those over 8 different orders from 77th to 84th, which partly covers the wavelengths from 17.03 micron to 18.75 micron, are obtained on the Si:As detector array. Taking account of the results of optical design of each spectrometer and the latest information of the expected performance of detector arrays, the continuum sensitivity for a point source, the continuum sensitivity for an extended source, the line sensitivity for a point source, the line sensitivity for an extended source, and the saturation limit are calculated for LRS, MRS and HRS; e.g., the 1 hour 5-sigma continuum sensitivity for a point source achieved by LRS is ~20 uJy at 20 micron and ~55 uJy at 30 micron, the 1 hour 5-sigma line sensitivity for a point source achieved by MRS is ~3?10^{-20} W/m^{2} at 20 micron and ~5?10^{-20} W/m^{2} at 30 micron, and the 1 hour 5-sigma line sensitivity for a point source achieved by HRS is ~1.5?10^{-20} W/m2^{2} at 15 micron. All the results of our calculations are provided in this presentation.

9904-143, Session PS3

Mechanical cooler system for the next-generation infrared space telescope SPICA

Keisuke Shinozaki, Hiroyuki Ogawa, Takao Nakagawa, Yoichi Sato, Hiroyuki Sugita, Toshihiko Yamawaki, Tadahito Mizutani, Hideo Matsuhara, Mitsunobu Kawada, Japan Aerospace Exploration Agency (Japan); Akinobu Okabayashi, Shoji Tsunematsu, Katsuhiro Narasaki, Sumitomo Heavy Industries, Ltd. (Japan)

The Space Infrared Telescope for Cosmology and Astrophysics (SPICA) is a pre-project of JAXA in collaboration with ESA to be launched in the 2020s. The SPICA mission is to be launched into a halo orbit around the second Lagrangian point in the Sun-Earth system, which allows us to use effective radiant cooling in combination with a mechanical cooling system in order to cool a 2.5m-class large IR telescope below 8K. Recently, a new system design in particular thermal structure of the payload module has been studied by considering the technical feasibility of a cryogenic cooled telescope within current constraints of the mission in the CDF (Concurrent Design Facility) study of ESA/ESTEC. Then, the thermal design of the mechanical cooler system, for which Japanese side is responsible, have been examined based on the CDF study and the feasible solution giving a proper margin has been obtained. As a baseline, 4K / 1K-class Joule-Thomson coolers are used to cool the telescope and thermal interface for Focal Plane Instruments (FPIs). Additionally, two sets of double stirling coolers (2STs) are used to cool the Telescope shield. In this design, nominal operation of FPIs can be keeped when one mechanical cooler is in failure.

9904-144, Session PS3

Final photometric calibration of warm IRAC data

Sean J. Carey, James G. Ingalls, Patrick J. Lowrance, Jessica E. Krick, William J. Glaccum, Spitzer Science Ctr. (United States)

The Spitzer Space Telescope has been conducting a wide range of science investigations including measurement of atmospheric properties of exoplanets and masses of the most distant galaxies during the post-cryogenic operations phase which started in 2009. These investigations using the Infrared Array Camera (IRAC) at 3.6 and 4.5 microns will likely continue through 2018 when the James Webb Space Telescope will succeed Spitzer. In preparation for the eventual end of the mission and exploiting the excellent stability of the instrument and spacecraft, we have finalized the calibrations for the IRAC instrument in advance of the mission end to minimize the cost of the closeout process. The calibrations for the warm mission phase have been substantially revised with the absolute photometric calibration performed with the same methodology as the final cryogenic calibration. We present the revised form of the intra-pixel gain variation and array-location dependent photometric corrections. The absolute photometric calibration is compared with independent ground truth using stellar templates from StScI. The stability of the calibration of IRAC over the duration of the entire mission is examined on both short (days) and long (years) time scales. We discuss the limiting factors to absolute calibration and identify future directions that can be explored in the calibration of JWST, Euclid and WFIRST.

9904-145, Session PS3

Hysteresis in dark patterns in the IRAC InSb arrays in the Spitzer Warm mission

William J. Glaccum, Spitzer Science Ctr. (United States); Peter L. Capak, California Institute of Technology (United States); Jessica E. Krick, Patrick J. Lowrance, Sean J. Carey, James G. Ingalls, Seppo J. Laine, Spitzer Science Ctr. (United States)

Images taken with the Infrared Array Camera (IRAC) on the Spitzer Space Telescope have underlying patterns that depend on how the InSb arrays were clocked in the minutes to hours preceding the images. We investigated this dependence by comparing 120000 images of a dark field of the sky at 3.6 and 4.5 microns that were taken in weekly and other calibrations during the first 5 years of the Spitzer Warm Mission. We made a dark image from each raw calibration image by removing the background and masking stars and stray light. IRAC data are taken with Fowler sampling, so the relaxation of the ROIC unit cells and output amplifiers between pedestal and signal samples generates jail bars and a pattern in the dark images that is related to pixel capacitance. For each of the 19 combinations of integration time and clocking speed (fast, sub-array; slow, full-array) in each array, we made a mean weekly dark image and a median image over the weekly darks, then we studied how individual dark images differed from the means. The principal short-term effect on an image is due to the amount of time an array idles between the image and the previous image. There are strong effects that depend on the integration time of the previous frame. The effects of idle times and integration times of preceding images decrease with time. Fast clocking

for a long time adds a different pattern to the darks for minutes to hours. These effects are strong in the 3.6 micron array, and weak at 4.5 microns. In addition to the short-term variations, there was a slow change of the dark pattern at 3.6 microns over the span of 5 years. Latent images appear in nearly every image. In making basic calibrated data (BCDs), the average sky dark from a weekly calibration is subtracted and jail bars are removed. This is a good correction for much of the IRAC data, but it leaves significant residual patterns in BCDs where data were taken either in staring mode or in dithers with more than one frame per pointing. We are developing a multi-parameter dark image model that we expect will provide better dark corrections. We have a model based on one parameter, the idle time preceding a frame, for all kinds of integrations. It was tested on long integrations at 3.6 microns on dithered observations made with more than one frame per pointing. Mosaics made with our corrections had better appearance and lower noise than those made with uncorrected BCDs.

9904-146, Session PS4

Use of living technical budgets to manage risk on the James Webb Space Telescope optical element

Daniel A. Porpora, Allison A. Barto, Paul A. Lightsey, J. Scott Knight, Ball Aerospace & Technologies Corp. (United States)

The optical telescope element of the James Webb Space Telescope (JWST) is a three mirror anastigmat design. The Primary Mirror (PM) and Secondary Mirror (SM) are deployable relative to the rest of the optics. The PM consists of 18 segment assemblies which are aligned on-orbit using hexapod actuators. The aligned segments function as a single monolithic optic. The SM also has hexapod actuators for alignment. The complexity of the construction, size, deployments, and active alignments introduces risk that a combination of manufacturing errors and integration misalignments of individual components could result in a system with an unexpected optical train. The result could compromise performance, even with the active control. In order to monitor risk exposure throughout the life of the project, a series of interrelated technical budgets have been created and are continually updated with as-built data to provide confidence in the state of the system as well as the path to completion. Additionally, independent cross-checks of each of the key optical performance characteristics are taken to ensure that no single measurement error could result in a mischaracterized optical system. Measurements taken to-date are presented, indicating the health of the system and setting expected bounds on future measurements planned for later in the program lifecycle.

9904-147, Session PS4

Alignment of the James Webb Space Telescope optical telescope element

Tiffany M. Glassman, Northrop Grumman Aerospace Systems (United States)

The optical telescope element (OTE) of the James Webb Space Telescope has now been integrated and aligned. The OTE comprises the flight mirrors and the structure that supports them – there are 18 primary mirror segments, the secondary mirror, and the tertiary and fine steering mirrors (both housed in the aft optics subsystem). The primary mirror segments and the secondary mirror have actuators to actively control their positions during operations. This allows the requirements for aligning the OTE subsystems to be in the range of microns rather than nanometers. During OTE integration, the alignment of the major subsystems of the OTE structure and optics are controlled to ensure that, when the telescope is on orbit, the active mirrors are within the adjustment range of the actuators. This paper describes the complex and intricate alignment process and talks about lessons learned in making the alignment process go smoothly. The implications of these lessons for future space observatories are also considered.

9904-150, Session PS4

Characterization of the JWST center of curvature optical assembly (CoCOA) during cryogenic testing of the JWST Pathfinder telescope

Conrad Wells, Harris Geospatial Systems (United States); James B. Hadaway, The Univ. of Alabama in Huntsville (United States); Gene A. Olczak, Tony L. Whitman, Joseph A. Cosentino, Mark T. Connolly, Harris Corp. (United States); David M. Chaney, Ball Aerospace & Technologies Corp. (United States); Randal C. Telfer, Space Telescope Science Institute (United States)

The JWST Optical Telescope Element (OTE) consists of a 6.6 m clear aperture, 18 segment primary mirror, all-reflective, three-mirror anastigmat operating at cryogenic temperatures. To verify performance of the primary mirror, a full aperture center of curvature optical null test is performed under cryogenic conditions in Chamber A at NASA Johnson Space Center. This alignment utilizes a series of optical systems to successfully align the primary mirror. A photogrammetry system and absolute distance meter globally align the mirror and set the RoC. The interferometer within the CoCOA provides feedback to fine align and measure the mirror surface. A software package takes the collected interferometric data and processes it to produce mirror pose corrections to coarse and then fine align the mirror segments. To prepare for the flight test, three cryogenic tests on the JWST Pathfinder are being performed in 2015. As the first opportunity to exercise the system as a whole, a series of tests to characterize the systems capabilities were performed. This paper will discuss the results of the characterizations of the alignment systems, interferometer and the operational aspects of the software to properly globally align and fine phase the primary mirror.

Testing that will be discussed in this paper.

• Ability to globally align the PM to the aft optics subsystem via photogrammetry. Fore optics to aft optics alignment.

• Secondary mirror alignment via photogrammetry.

• Sensitivity testing for coarse and fine alignment of the primary mirror to the null lens/interferometer.

• Reduction of segment level astigmatism vs. global alignment of the CoCOA. Photogrammetry and interferometer measurements will be compared.

• Characterization of the RoC measurement system.

9904-151, Session PS4

MIRI/JWST detector characterization

Stacey Bright, Space Telescope Science Institute (United States); Michael E. Ressler, Jet Propulsion Lab. (United States); Alberto Noriega-Crespo, Space Telescope Science Institute (United States); Stacey Alberts, The Univ. of Arizona (United States); Jane Morrison, The Univ. of Arizona (United States) and Space Telescope Science Institute (United States); Ori D. Fox, Space Telescope Science Institute (United States)

We report on tests of the Mid-Infrared Instrument (MIRI) focal plane electronics and detectors conducted at Jet Propulsion Laboratory. Goals of these tests are to: characterize readout mode performance; establish subarray operations; characterize performance changes when switching between subarrays and/or readout modes; fine-tune detector settings to mitigate residual artifacts; optimize anneal effectiveness; and characterize persistence. Testing is part of a continuing effort to support MIRI pipeline development through better understanding of detector behavior. An extensive analysis to determine the readout mode performance was completed. We report specifically on the comparison between fast and slow readout modes and subarray recovery tests.

9904-152, Session PS4

Calibration results using highly aberrated images for aligning the JWST instruments to the telescope

Koby Z. Smith, D. Scott Acton, Benjamin B. Gallagher, J. Scott Knight, Ball Aerospace & Technologies Corp. (United States); Bruce H. Dean, Alden S. Jurling, Thomas P. Zielinski, NASA Goddard Space Flight Ctr. (United States)

The James Webb Space Telescope (JWST) project is an international collaboration led by NASA's Goddard Space Flight Center (GSFC) in Greenbelt, MD. JWST is NASA's flagship observatory that will operate nearly a million miles away from Earth at the L2 Lagrange point. JWST's optical design is a three-mirror anastigmat with four main optical components; 1) the eighteen Primary Mirror Segment Assemblies (PMSA), 2) a single Secondary Mirror Assembly (SMA), 3) an Aft-Optics Subsystem (AOS) consisting of a Tertiary Mirror and Fine Steering Mirror, and 4) an Integrated Science Instrument Module consisting of the various instruments for JWST. JWST's optical system has been designed to accommodate a significant amount of alignment capability and risk with the PMSAs and SMA having rigid body motion available on-orbit just for alignment purposes. However, the Aft-Optics Subsystem and Integrated Science Instrument Module (ISIM) are essentially fixed optical subsystems within JWST, and therefore the cryogenic alignment of the Aft-Optics Subsystem (AOS) to the Integrated Science Instrument Module (ISIM) is critical to the optical performance and mission success of JWST.

In support of this cryogenic alignment of the AOS to ISIM, an array of fiber optic sources, known as the AOS Source Plate Assembly (ASPA), are placed near the intermediate image location of JWST (between the secondary and tertiary mirrors) during thermal vacuum ground-test operations. The AOS produces images of the ASPA fiber optic sources at the JWST focal plane location, where they are captured by the various science instruments. In this manner, the AOS provides an optical yardstick by which the instruments within ISIM can evaluate their relative positions to and the alignment of the AOS to ISIM can be quantified. However, since the ASPA is located at the intermediate image location of the JWST three-mirror anastigmat design, the images of these fiber optic sources produced by the AOS are highly aberrated with approximately 2-3μm RMS wavefront error consisting mostly of 3rd-order astigmatism and coma. This is because the elliptical tertiary mirror of the AOS is used off of its ideal foci locations without the compensating wavefront effects of the JWST primary and secondary mirrors. Therefore, the PSFs created are highly asymmetric with relatively complex structure and the centroid and encircled energy analyses traditionally used to locate images are not sufficient for ensuring the AOS to ISIM alignment.

A novel approach combining phase retrieval and spatial metrology was developed to both locate the images with respect to the AOS and provide calibration information for eventual AOS to ISIM alignment verification. During final JWST OTE and ISIM (OTIS) testing, only a single thru-focus image will be collected by the instruments. Therefore, tools and processes were developed to perform single-image phase retrieval on these highly aberrated images such that any single image of the ASPA source can provide calibrated knowledge of the instruments' position relative to the AOS. This paper discusses the results of the methodology, hardware, and calibration performed to ensure that the AOS and ISIM are aligned within their respective tolerances at JWST OTIS testing.

9904-153, Session PS4

The mid-infrared instrument for the James Webb Space Telescope: performance and operation of the low-resolution spectrometer

Sarah Kendrew, Univ. of Oxford (United Kingdom) and European Space Agency (France); Silvia Scheithauer, Max-Planck-Institut für Astronomie (Germany); Patrice Bouchet, Jerome Amiaux, Commissariat à l'Énergie Atomique (France); Ruyman Azzollini, Dublin Institute for Advanced Studies (Ireland) and Univ. College London (United Kingdom); Jeroen Bouwman, Max-Planck-Institut für Astronomie (Germany); Christine H. Chen, Space Telescope Science Institute (United States); Didier Dubreuil, Commissariat à l'Énergie Atomique (France); Sebastian Fischer, Deutsches Zentrum für Luft- und Raumfahrt e.V. (Germany); Alistair C. H. Glasse, UK Astronomy Technology Ctr. (United Kingdom); Thomas P. Greene, NASA Ames Research Ctr. (United States); Pierre-Olivier Lagage, Commissariat à l'Énergie Atomique (France); Fred Lahuis, SRON Netherlands Institute for Space Research (Netherlands); Samuel Ronayette, Commissariat à l'Énergie Atomique (France); David Wright, SGT, Inc. (United States); Gillian S. Wright, UK Astronomy Technology Ctr. (United Kingdom)

We describe here the performance and operational concept for the Low Resolution Spectrometer (LRS) of the mid-infrared instrument (MIRI) for the James Webb Space Telescope. The LRS will provide R~100 long-slit and slitless spectroscopy from 5 to 12 micron, and its design is optimised for observations of compact sources, such as exoplanet host stars. We provide here an overview of the design of the LRS, and its performance as measured during extensive test campaigns, examining in particular the delivered image quality, dispersion, and resolving power, as well as spectrophotometric performance. The instrument also includes a slitless spectroscopy mode, which is optimally suited for transit spectroscopy of exoplanet atmospheres. We provide an overview of the calibration and pipeline procedures currently under development ahead of the JWST launch in 2018.

9904-154, Session PS4

In-orbit commissioning plan for the NIRSpec instrument on the James Webb Space Telescope

Torsten Böker, European Space Agency (United States); James Muzerolle, John Bacinski, Space Telescope Science Institute (United States); Catarina Alves de Oliveira, Stephan M. Birkmann, European Space Agency (United States); Pierre Ferruit, European Space Agency (Netherlands); Hermann Karl, Robert Lemke, Airbus Defence and Space (Germany); Nora Lützgendorf, European Space Agency (United States); Anthony Marston, European Space Agency (Spain); Peter Mosner, Airbus Defence and Space (Germany); Timothy Rawle, Marco Sirianni, European Space Agency (United States); Martin Stuhlinger, SERCO (Spain)

The James Webb Space Telescope (JWST) is a large-aperture, infrared-optimized space telescope, to be launched in late 2018. Following launch, JWST will begin a ~6 month long commissioning campaign, during which all observatory elements will be activated, and their functionality verified. In particular, JWST's segmented primary mirror must be aligned and phased, and all science instruments must demonstrate their expected performance. One of these is the Near-Infrared Spectrograph (NIRSpec) which was designed and built by Airbus GmbH in Ottobrunn (Germany) for the European Space Agency (ESA). NIRSpec is a multi-object spectrograph that will be able to observe up to 100 astronomical objects simultaneously. It has a large field of view (≈3'?3') and is highly sensitive over the wavelength range 0.6?5?m. The main purpose of NIRSpec is to enable low, medium-, and high-resolution NIR spectroscopy in support of all JWST science themes.

Some of the NIRSpec commissioning activities are "functional" in nature, e.g. the power-on of electronics boxes, the verification of mechanism movements, or the active control of contamination heaters during the cooldown phase. Other activities require the collection of detector exposures, either without light (mostly for detector characterization) or with illumination from internal lamps or celestial objects. We describe the currently foreseen implementation for both types of activities, and highlight those that are essential for enabling NIRSpec science as soon as possible after the launch of JWST. In addition, this paper (i) summarizes the objectives of the NIRSpec commissioning campaign, (ii) outlines the sequence of activities needed to achieve these objectives, and (iii) demonstrates that the list of activities is sufficient to enable the full range of NIRSpec observing modes with the specified performance.

9904-156, Session PS4

The spectral calibration of JWST/NIRSpec: results from the recent cryo-vacuum campaign (ISIM-CV3)

Giovanna Giardino, European Space Research and Technology Ctr. (Netherlands); Nora Luetzgendorf, Space Telescope Science Institute (United States); Bernhard Dorner, Max-Planck-Institut für Astronomie (Germany); Pierre Ferruit, European Space Research and Technology Ctr. (Netherlands); Catarina Alves de Oliveira, Stephan M. Birkmann, Torsten Böker, Anthony Marston, Marco Sirianni, Space Telescope Science Institute (United States)

The NIRSpec instrument for the James Webb Space Telescope (JWST) can be operated in multi-object (MOS), long-slit, and integral field modes with spectral resolutions from 100 to 2700. Its MOS mode uses about a quarter of a million individually addressable mini-slits for object selection, covering a field of view of ~ 9 square-arcminute.

We have developed a procedure that uses the calibration data acquired for a limited subset of the NIRSpec modes - and in particular only 1.5% of NIRSpec's a quarter of a million slits - to derive a highly realistic model of the instrument's optical geometry. This allows the light paths within the spectrograph to be accurately computed and, as such, provides the basis for the extraction of wavelength calibrated spectra from NIRSpec data, from any of the apertures, for all modes.

This model-based approach greatly improves the efficiency with which the instrument can be operated. In particular, the conventional approach of carrying separate empirical calibrations for each individual NIRSpec slitlet and each disperser is clearly not practical, and with the model-based approach the need to take matching calibration exposures during each observation is no longer required.

In early 2015, NIRSpec was fitted with new and improved detector arrays and an upgraded Micro Shutter Assembly and in this final flight configuration the instrument has recently undergone a long test campaign, in the large thermal vacuum chamber at NASA's Goddard Space Flight Center, together with the other three scientific instruments installed in the Integrated Science Instrument Module (ISIM) of JWST.

In this contribution, we summarize the procedure that we have undertaken to optimize the values of the model parameters using these recently-acquired data and present the results in terms of the expected spatial and spectral calibration accuracy of NIRSpec.

9904-157, Session PS4

Flat-fielding strategy for JWST/NIRSpec multi-object spectrograph

Timothy Rawle, European Space Agency (United States); Guido de Marchi, Giovanna Giardino, European Space Research and Technology Ctr. (Netherlands); Catarina Alves de Oliveira, Stephan M. Birkmann, Torsten Böker, European Space Agency (United States); Pierre Ferruit, European Space Research and Technology Ctr. (Netherlands); Nora Luetzgendorf, Marco Sirianni, European Space Agency (United States)

The James Webb Space Telescope (JWST) will launch in 2018 with the first ever space-borne Multi-Object Spectrograph (MOS), part of the NIRSpec instrument. NIRSpec contains a suite of 7 dispersive elements and 8 filters to cover the wavelength range 0.6–5?m at 3 spectral resolutions. The MOS comprises a quarter of a million shutters which can be individually addressed to select up to 100 target objects within a ~3.2x3.4 arcmin field of view.

In this paper we present the strategy for flat-fielding MOS observations from NIRSpec. The flat-field is used to correct for the combined effects of the full telescope throughput (observatory and instrument) and detector response, and is therefore a function of wavelength, field angle and incident pixel.

For NIRSpec MOS observations, the correspondence between wavelength and pixel depends on which micro-shutters are configured open. Concerns for observatory efficiency and persistence effects dictate that a dedicated flat-field observation per configuration is unsupportable, and there are too many possibilities for all shutters to be covered by a complete set of calibration exposures. Consequently, a well-designed calibration campaign, employing a sub-set of available shutters, must provide a universal flat-field reference cube to be used for all MOS observations.

We describe the two-step strategy envisaged. 1) The observations and processing required to create the flat-field reference cube, which includes an algorithm to remove the intrinsic grid-like shadowing pattern caused by the micro-shutter frame. 2) The on-the-fly generation of a 2D flat-field frame for any specific MOS configuration, including estimates of uncertainty from interpolation. After launch the flat-field cube will encapsulate the full throughput, with absolute calibration via spectro-photometric standard star observations across the field. The flat-field cubes presented here originate from internal calibration lamp exposures in late 2015, which do not include the telescope and instrument fore-optics. Finally, we briefly discuss plans for the implementation of this strategy within the automatic data processing pipeline.

9904-158, Session PS4

The James Webb Space Telescope NIRISS optical simulator

Jonathan St-Antoine, René Doyon, Loïc Albert, Univ. de Montréal (Canada)

The Near Infrared Imager and Slitless Spectrograph (NIRISS) Optical Simulator (NOS) is a laboratory simulation of the single-object slitless spectrograph and aperture masking interferometry modes of the NIRISS instrument onboard the James Webb Space Telescope (JWST). A transiting exoplanet will be simulated by periodically eclipsing a small portion (1% - 10ppm) of a super continuum laser source (.7?m-2.9?m) with a methyl chloride filled container. Methyl chloride exhibits multiple absorption features in the infrared domain hence the net effect is analogous to the atmospheric absorption features of an exoplanet transiting in front of its host star. The NOS uses an HAWAII-2RG and an ASIC controller cooled to liquid nitrogen temperatures. A separate photometric beacon provides a flux reference to monitor laser variations. The telescope jitter will be simulated using a high-resolution motorized pinhole placed along the optical path. White light curves and transiting spectroscopy data will be produced from this simulation to refine the analysis methods, characterise the noise due to the jitter, to characterize the noise floor and to develop better observation strategies.

9904-159, Session PS4

In-focus phase retrieval using JWST-NIRISS's non-redundant mask

Alexandra Z. Greenbaum, Johns Hopkins Univ. (United States); Anand Sivaramakrishnan, Space Telescope Science Institute (United States)

The James Webb Space Telescope's Near InfraRed Imager and Slitless Spectrograph (NIRISS) contains a 7-hole non-redundant mask (NRM) in its pupil. NIRISS's Aperture Masking Interferometry (AMI) mode is useful both for science as well as wavefront sensing. In-focus science detector NRM and full pupil images of unresolved stars can be used to measure the wavefront without any dedicated wavefront sensing hardware or moving mirrors. Using routine science operational sequences, these images can be taken prior to any science visit. We demonstrate that consecutive masked and unmasked exposures provide enough information to reconstruct a wavefront with up to ~1-2 radians of error. NRM fringe phases constrain Gerchberg-Saxton phase retrieval to disambiguate the sign of the phase error. We present results using this approach for both simulation and laboratory experiments, in the context of contingency for JWST segment phasing.

We discuss extending our method to ground-based AO systems and future space telescopes.

9904-160, Session PS4

Aperture masking interferometry with JWST NIRISS: performance predictions from ground testing

Anand Sivaramakrishnan, Space Telescope Science Institute (United States)

The Aperture Masking Interferometry (AMI) mode of the James Webb Space Telescope's Near Infrared Imager and Slitless Spectrograph (JWST NIRISS) has undergone three cryovac tests at Goddard Space Flight Center. The third test utilized the flight detector. We report on performance predictions of in-flight science observations, and advances in data reduction methods applicable to this mode. This informs the types of early science NIRISS AMI can do during commissioning and early science observations. The stability enabled by space-based imaging with the non-redundant mask (NRM) that the AMI mode uses should support improved astrometry compared to similar ground-based NRM imaging. We use image-plane-based data analysis methods to recover interferometric fringe amplitudes and visibilities of cryovac data, and demonstrate refined measures of the position of a point source. This analysis yields the pixel scale(s) and the overall NRM pupil geometry. We also assess the stability of fringe amplitude measurements with the flight detector, as these quantities measure centro-symmetric extended structure around a point source. In order to perform these measurements we refined the analytical model of the NRM PSF to incorporate linear distortions and pupil rotation using the Lacour-Greenbaum NRM-specific data analysis algorithm that is used in the science data reduction pipeline for JWST NIRISS AMI data.

9904-161, Session PS4

Alignment test results of the JWST Pathfinder Telescope mirrors in the cryogenic environment

Tony L. Whitman, Conrad Wells, Harris Corp. (United States); James B. Hadaway, The Univ. of Alabama in Huntsville (United States); J. Scott Knight, Ball Aerospace & Technologies Corp. (United States); Sharon Lunt, Harris Corp. (United States)

After integration of the Optical Telescope Element (OTE) to the Integrated Science Instrument Module (ISIM) to become the OTIS, the James Webb Space Telescope OTIS is tested at NASA's Johnson Space Center (JSC) in the cryogenic vacuum Chamber A for alignment and optical performance.

Is space, the mirrors are aligned using the images from a known star onto the Science Instrument detectors. On earth in the chamber at cryogenic temperatures, the mirrors are aligned using photogrammetry cameras with reflective targets attached to the sides of the mirrors. Then a multi-wavelength interferometer is aligned to the 18-segment primary mirror using cameras at the center of curvature to align reflected light from the segments and using fiducials at the edge of the primary mirror. Once the interferometer is aligned, the 18 primary mirror segments are then adjusted to optimize wavefront error of the aggregate mirror. This process phases the piston and tilt positions of all the mirror segments. Then an optical fiber placed at the Cassegrain focus of the telescope emits light towards the secondary mirror to create a collimated beam emitting from the primary mirror. Portions of the collimated beam are retro-reflected from flat mirrors at the top of the chamber to pass through the telescope to the S detector. The image on the detector is used for fine alignment of the secondary mirror and a check of the primary mirror alignment using many of the same analysis techniques used in the on-orbit alignment.

The entire process was practiced and evaluated in 2015 at cryogenic temperature with the Pathfinder telescope, the Aft Optics Subsystem from the OTIS, and with a Beam Image Analyzer (BIA) placed at the telescope image. The process included the exercise of the operation, the data flow, and the in-situ analysis. The Pathfinder telescope includes 2 primary mirror segments and a secondary mirror. The entire process will be reviewed with images from the cameras and detectors. The resulting alignment results will be discussed with the alignment uncertainties and other related learning. Although the telescope is on the order of 10 meters in size, the mirrors are aligned to a small fraction of a millimeter, and the segments are phased to a fraction of a visible wavelength. The results show excellent preparedness for the alignment of the OTIS in the chamber at cryogenic temperatures.

9904-162, Session PS4

James Webb Space Telescope optical simulation testbed III first experimental results with linear-control alignment

Sylvain Egron, Space Telescope Science Institute (United States) and Univ. Aix-Marseille (France); Rémi Soummer, Marshall D. Perrin, Élodie Choquet, Mamadou N'Diaye, Charles-Philippe Lajoie, Marie Ygouf, Space Telescope Science Institute (United States); Lucie Leboulleux, Space Telescope Science Institute (United States) and Aix-Marseille Univ. (France); Laurent Pueyo, Space Telescope Science Institute (United States); Vincent Michau, ONERA (France); Clement Escolle, Lab. d'Astrophysique de Marseille (France); Thierry Fusco, Lab. d'Astrophysique de Marseille (France) and ONERA (France); Marc Ferrari, Emmanuel Hugot, Lab. d'Astrophysique de Marseille (France)

The James Webb Space Telescope (JWST) Optical Simulation Testbed (JOST) is a tabletop experiment designed to study wavefront sensing and control for a segmented space telescope, including both commissioning and maintenance activities. JOST is complementary to existing testbeds for JWST (e.g. the Ball Aerospace Testbed Telescope TBT) given its compact scale and flexibility, ease of use, and colocation at the JWST Science & Operations Center. The design of JOST reproduces the physics of JWST's three-mirror anastigmat (TMA) using three custom aspheric lenses. It provides similar quality image as JWST (80% Strehl ratio) over a field equivalent to a NIRCam module, but at 633 nm. An Iris AO segmented mirror stands for the segmented primary mirror of JWST. Actuators allow us to control (1) the 18 segments of the segmented mirror in piston, tip, tilt and (2) the second lens, which stands for the secondary mirror, in tip, tilt and x, y, z positions. We present the experimental optical quality of the testbed evaluated using phase retrieval sensing, and study the linearity of the main aberration modes (focus, astigmatism, coma) both as a function of the field point and level of misalignment of the secondary mirror. We present the linear control alignment strategy developed for the testbed, and illustrate its performance by reproducing some of the main phases of the JWST commissioning from an initial misaligned state.

9904-163, Session PS4

A new method of superbias construction for NIRCam

Bryan Hilbert, Armin Rest, Massimo Robberto, Space Telescope Science Institute (United States); Karl Misselt, Jarron M. Leisenring, The Univ. of Arizona (United States)

The subtraction of a superbias image from NIRCam data is an essential step in the calibration process. Only by removing the bias signal is it possible to observe more subtle electronic noise effects in the data (e.g. 1/f noise).

We have developed a new technique to construct superbias images from NIRCam data. We measure and subtract the 1/f noise from a series of dark current observations, leaving behind only bias signal.

Averaging multiple integrations together, we construct a superbias image with significantly lower noise than can be achieved using the traditional line-fitting technique.

We find that with only 15-20 shortwave channel dark current integrations, one can create a superbias image in which the readnoise and residual 1/f noise contributions have been reduced to negligible levels for the purposes of data calibration. Tests show that using this superbias as part of the standard data reduction scheme results in calibrated frames with noise levels approaching the kTc noise floor, implying that other noise sources have been successfully made irrelevant.

9904-164, Session PS4

Wavefront-error performance characterization for the James Webb Space Telescope (JWST) integrated science instrument module (ISIM) science instruments

David L. Aronstein, Jeffrey S. Smith, Thomas P. Zielinski, NASA Goddard Space Flight Ctr. (United States); Randal C. Telfer, Space Telescope Science Institute (United States); Severine C. Tournois, Sigma Space Corp. (United States); Dustin B. Moore, James R. Fienup, The Institute of Optics (United States)

The science instruments (SIs) comprising the James Webb Space Telescope (JWST) Integrated Science Instrument Module (ISIM) were tested in three cryogenic-vacuum test campaigns in the NASA Goddard Space Flight Center (GSFC)'s Space Environment Simulator (SES).

In this paper, we describe the results of optical wavefront-error performance characterization of the SIs. The wavefront error is determined using image-based wavefront sensing (also known as phase retrieval), and the primary data used by this process are focus sweeps, a series of images recorded by the instrument under test in its as-used configuration, in which the focal plane is systematically changed from one image to the next. High-precision determination of the wavefront error also requires several sources of secondary data, including 1) spectrum, apodization, and wavefront-error characterization of the optical ground-support equipment (OGSE) illumination module, called the OTE Simulator (OSIM), 2) plate scale measurements made using a Pseudo-Nonredundant Mask (PNRM), and 3) pupil geometry predictions as a function of SI and field point, which are complicated because of a tricontagon-shaped outer perimeter and small holes that appear in the exit pupil due to the way that different light sources are injected into the optical path by the OGSE. One set of wavefront-error tests, for the coronagraphic channel of the Near-Infrared Camera (NIRCam) Longwave instruments, was performed using data from transverse translation diversity sweeps instead of focus sweeps, in which a sub-aperture is translated and/or rotated across the exit pupil of the system.

Several optical-performance requirements that were verified during this ISIM-level testing are levied on the uncertainties of various wavefront-error-related quantities rather than on the wavefront errors themselves. This paper also describes the methodology, based on Monte Carlo simulations of the wavefront-sensing analysis of focus-sweep data, used to establish the uncertainties of the wavefront error maps.

9904-166, Session PS4

Model predictions and observed performance of JWST cryogenic position metrology system

Sharon Lunt, David Rhodes, Andrew DiAntonio, John Boland, Harris Corp. (United States); Trevis Gigliotti, Principal Point Geospatial Solutions (Canada); Gary J. Johanning, Geodetic Systems, Inc. (United States)

The James Webb Space Telescope cryogenic testing has begun at the Johnson Spaceflight Center's Chamber A and requires measurement systems that both obtain a very high degree of accuracy and can function in a high vacuum, low temperature environment. Close-range photogrammetry was identified as meeting those criteria.

Testing the capability of a close-range photogrammetric system prior to its existence is a challenging problem. Computer simulation was chosen over building a scaled mock-up, because of the size and complexity of the experiment. Before any of the hardware was in the chamber the entire photogrammetry system as well as all the hardware was simulated to generate synthetic images representative of what the actual camera systems would see. The simulated images were generated using the Digital Image and Remote Sensing Image Generation, DIRSIG, tool. DIRSIG is a physics-based first principles radiometric image generation software that is extensively used in the remote sensing community.

The created model included CAD-based representation of all of the key objects inside the chamber, including the chamber itself, the flash level expected from the camera system as the sole source of illumination, and the experimentally derived properties of the reflective materials to be used for photogrammetry targets. The most challenging material to measure and model was the retroreflective target material.

Models for each phase of chamber testing were created and used to test proposed camera pointing sequences and target configurations. By using this approach, best case solutions and optimum trade-offs were achieved for when the actual system was used inside the chamber.

Extensive validation work was done to ensure that the actual as-built system meet accuracy and repeatability requirements and the results were also compared to the model predictions. The simulated image data when passed through the photogrammetry software predicted the uncertainty in measurement to be within specification and this prediction proved to be borne out by the initial tests accomplished in Chamber A.

9904-167, Session PS4

Updated cryogenic performance test results for the flight model JWST fine guidance sensor

Neil Rowlands, Gerry Warner, Julia Zhou, COM DEV Canada (Canada)

The Integrated Science Instrument Module (ISIM) for the James Webb Space Telescope (JWST) has successfully completed its final cryogenic performance verification tests. The performance of the newly upgraded Fine Guidance Sensor (FGS) / Near Infrared Imager and Slitless Spectrometer (NIRISS) was evaluated in these tests. We describe some of the key guider performance results which have been obtained and compare them to previous results with an older generation of H2RG infrared detector arrays. The identification mode sensitivity improvement is described along with noise equivalent angle (NEA) performance improvements in tracking and fine guiding modes. Tracking mode allows the Observatory line of sight to settle in advance of the fine guidance mode and also facilitates moving target observing. The NEA of the FGS-Guiders will in part determine the ultimate image quality of the JWST Observatory.

9904-251, Session PS4

Performance of the primary mirror center-of-curvature optical metrology system during cryogenic testing of the JWST Pathfinder Telescope

James B. Hadaway, The Univ. of Alabama in Huntsville (United States); Conrad Wells, Gene A. Olczak, Mark Waldman, Tony L. Whitman, Joseph A. Cosentino, Mark T. Connolly, Exelis Geospatial Systems (United States); David M. Chaney, Ball Aerospace & Technologies Corp. (United States); Randal C. Telfer, Space Telescope Science Institute (United States)

The James Webb Space Telescope (JWST) primary mirror (PM) is 6.6 m in diameter and consists of 18 hexagonal segments, each 1.5 m point-to-point. Each segment has a six degree-of-freedom hexapod actuation system and a radius-of-curvature (RoC) actuation system. The full telescope will be tested at its cryogenic operating temperature at Johnson Space Center. This testing will include center-of-curvature measurements of the PM, using the Center-of-Curvature Optical Assembly (COCOA) and the Absolute Distance Meter Assembly (ADMA). The COCOA includes an interferometer, a reflective null, an interferometer-null calibration system, coarse & fine alignment systems, and two displacement measuring interferometer systems. A multiple-wavelength interferometer (MWIF) is used to enable alignment & phasing of the PM segments. By combining measurements at two laser wavelengths, synthetic wavelengths up to 15 mm can be achieved, allowing mirror segments with millimeter-level piston errors to be phased to the nanometer level. The ADMA is used to measure, and set, the spacing between the PM and the focus of the COCOA null (i.e. the PM center-of-curvature) for determination of the RoC. The performance of these metrology systems, along with that of all the other ground support equipment to be used during the flight telescope testing, was assessed during two recent cryogenic tests at JSC. This testing was performed using the JWST Pathfinder telescope, consisting mostly of engineering development & spare hardware. The Pathfinder PM consists of two spare segments. These tests provided the opportunity to assess how well the center-of-curvature optical metrology hardware, along with the software & procedures, performed using real JWST telescope hardware. This paper will describe the test setup, the testing performed, and the resulting metrology system performance. The knowledge gained and the lessons learned during this testing will be of great benefit to the accurate & efficient cryogenic testing of the JWST flight telescope.

9904-168, Session PS5

On the performance of the Gaia auto-collimating flat mirror assembly: could it be even better?

Arjo Bos, Technische Univ. Eindhoven (Netherlands) and TNO (Netherlands); Gert Witvoet, Hajo P. Pereboom, TNO (Netherlands); Maarten Steinbuch, Technische Univ. Eindhoven (Netherlands)

The Auto-collimating Flat Mirror Assembly (AFMA) simulated the spinning of the Gaia satellite around its vertical axis. As such, it was one of the most important ground support equipment tools to test the payload performance of the Gaia mission. A laser point source, positioned at a CCD-array, is retro reflected onto the CCD-array via a scanning auto-collimating mirror positioned opposite to Gaia's telescope mirror.

The scanning performance around the vertical axis (azimuth), with a 20 mrad range and nrad stability requirement, was most critical.

TNO already delivered two compliant AFMA's a couple of years ago, but meeting the required nrad stability has been a big challenge in the project. In particular, providing accurate predictions of the system dynamics and positioning performance in the design phase of the project, and correlating them to later measurements was not a trivial task. This was partly caused by ground vibrations and the dynamic interaction with the back structure, mostly low-frequent in nature, which were contributing most to the steady-state position error. To suppress these low-frequent contributions, sufficient disturbance suppression at these frequencies is required. This results in requirements for the controller sensitivity at these frequencies and thus the controller bandwidth; the controller sensitivity (below the controller bandwidth) automatically decreases when the controller bandwidth of the system is increased However, achieving the

required bandwidth was challenging, mainly because of some interesting discrepancies between the predicted and measured open loop transfer functions.

Although AFMA eventually performed within spec, using improved ground vibration suppression, an advanced controller, and minor tweaks in the mechanical design, some of the dynamical behaviour could not be fully explained. Therefore, the dynamic behaviour of Gaia AFMA has recently again been analysed and back-engineered.

First, the mechanical design has been analysed; AFMA is a box-in-a-box design, with a rotating (inner) box connected to a fixed (outer) box. A virtual axis of rotation for the scanning motion is positioned at the front surface of a SiC mirror, which is created by an elastic cross-hinge. This cross-hinge is assembled with two stiffened flexure hinges. The mirror is connected to the rotating (inner) box, and the cross-hinge connects this rotating box to the fixed (outer) box. The scanning motion is actuated by two modules connected to the outer box. Design improvements on these scanning modules have been developed.

Furthermore, dynamic analyses have been performed, starting with a comparison of a 1D dynamical model comprising of a mass-spring-damper model, with actual measurements..

Next, a simplified 3D CAD model is implemented in FEM and a modal analysis has been performed. With the information of the modal analysis, and by defining the in- and outputs, a modal state space description is obtained, being able to simulate an FRF to compare with the measurements. Also, an experimental modal analysis (EMA) has been performed and compared to the finite element analysis (FEA). The main dynamical problems are pointed out, and possible design improvements have been derived.

9904-169, Session PS5

How mission requirements affect the observations: case of the PICARD mission

Abdanour Irbah, Mustapha Meftah, Alain Hauchecorne, LATMOS (France)

The scientific objectives of a space mission translate into instrumental developments and satellites operations to observe the astronomical objects of interest. The payload in its space environment is however subject to important thermal variations that affect the observations. This is well observed when images of the Sun are recorded with the constraint of having the solar rotational axis in a constant direction relatively to the camera reference system. Consequences are then clearly observed on the image positions that follow the thermal variations on the satellite orbit. This is particularly the case for the PICARD space mission. This phenomenon is similar to the defocus and motions of the images recorded with ground-based telescopes. We will present in this work some simulations showing this effect in space. We will then compare our results with real data obtained from the PICARD solar mission.

9904-170, Session PS5

Optical designing of LiteBIRD

Hajime Sugai, Kavli Institute for the Physics and Mathematics of the Universe (Japan); Shingo Kashima, National Astronomical Observatory of Japan (Japan); Kimihiro Kimura, Osaka Prefecture Univ. (Japan); Tomotake Matsumura, Japan Aerospace Exploration Agency (Japan); Masanori Inoue, Makoto Ito, Osaka Prefecture Univ. (Japan); Toshiyuki Nishibori, Japan Aerospace Exploration Agency (Japan); Yutaro Sekimoto, National Astronomical Observatory of Japan (Japan); Hirokazu Ishino, Okayama Univ. (Japan)

The scientific purpose of LiteBIRD (Lite (Light) satellite for the studies of B-mode polarization and Inflation from cosmic background Radiation Detection) is to reveal the era before the big bang. In this inflation era immediately after the beginning of the universe, the universe is believed to have exponentially expanded and to have produced the primordial gravitational wave. LiteBIRD aims to detect the footprint of this wave on the Cosmic Microwave Background (CMB) in a form of special polarization pattern called B mode. For this we will reach the tensor/scalar ratio of $r<0.001$, by carrying out three-year measurements of linear polarization of the CMB in the whole sky.

The CMB has its emission peak at millimeter wavelength. In order to separate it from the Galactic emission including the synchrotron and the dust emission, our measurements cover the wide frequency range of 35GHz to 450GHz.

The LiteBIRD optics consists of crossed Dragone type, which provides a compact configuration with a wide field of view. Both of the primary and secondary reflectors have anamorphic non-spherical surfaces. A continuously rotating half-wave plate modulator is placed at the aperture position, facing directly to the sky, and separates the sky linear polarization from the artificially produced one. The whole optical system is cooled down to around 4K to minimize the thermal emission. We are now developing the design, including the selection of mirror material.

We use two kinds of approaches: searching proper design candidates with the ray tracing, and obtaining the strict design solution around such candidates by using the physical optics (GRASP). We have carried out tradeoff studies including the optical system size and the stray light avoidance. Furthermore, in order to confirm the accuracy of the GRASP calculation, particularly in terms of detailed baffle/hood designs, we have produced a 1/3 scale model aluminum mirror and are pursuing radio property measurements at 200GHz. This corresponds to 60GHz in a full model.

The candidate materials for mirrors are CFRP, C/SiC, SiC, and aluminum. We are measuring mechanical and thermal properties of these candidate materials. If we select honeycomb structure of CFRP, which has advantages in weight and in coefficient of thermal expansion, it is concerned that it might have dimpling caused by this structure. The dimpling might give additional errors on polarization measurements disturbing the beam shapes. We have developed the method to treat this effect quantitatively in designing, which enables us to select the mirror material in an appropriate way.

9904-171, Session PS5

Polarization modulator for LiteBIRD

Tomotake Matsumura, Institute of Space and Astronautical Science (Japan); Takuro Fugino, Yokohama National Univ. (Japan); Masaya Hasegawa, Masashi Hazumi, High Energy Accelerator Research Organization, KEK (Japan); Fumiya Irie, Yokohama National Univ. (Japan); Hirokazu Ishino, Okayama Univ. (Japan); Nobuhiko Katayama, Kavli Institute for the Physics and Mathematics of the Universe (Japan); Atsuko Kibayashi, Y. Kida, Okayama Univ. (Japan); Kimihiro Kimura, Osaka Prefecture Univ. (Japan); K. Komatsu, Okayama Univ. (Japan); Ryo Nagata, High Energy Accelerator Research Organization, KEK (Japan); Kunitoshi Nishijo, Japan Aerospace Exploration Agency (Japan); Shingo Kashima, National Astronomical Observatory of Japan (Japan); Akito Kusaka, Lawrence Berkeley National Lab. (United States); Giampaolo Pisano, Cardiff Univ. (United Kingdom); Yutaro Sekimoto, National Astronomical

Observatory of Japan (Japan); Hajime Sugai, Kavli Institute for the Physics and Mathematics of the Universe (Japan); Y. Yamada, Okayama Univ. (Japan); Shin Utsunomiya, Japan Aerospace Exploration Agency (Japan)

LiteBIRD is a next generation cosmic microwave background polarization satellite to measure the primordial B-mode, fingerprints of the cosmic inflation. The science goal of LiteBIRD is to measure the tensor-to-scalar ratio with the sensitivity of sigma(r) < 0.001. LiteBIRD observes the fully sky by spinning the satellite at the seond Lagrange point for three years. The baseline design of a mission instrument covers the observational frequency of 40-400 GHz. A telescope consists of a cryogenically cooled optical system and about 2,000 superconducting detector arrays at 100 mK cooled by a sub-kelvin cooler. LiteBIRD is currently under the transition toward Phase-A. The targeted launch year is in early 2020s.

The sensitivity of LiteBIRD requires the stringent control of stability in the detector chain and the systematic errors. One possibility to suppress those effects is to introduce a polarization modulator in the mission system in addition to the optimal scan strategy. The required functionalities are to up-convert the signal and also to treat each linearly polarized sensitive detector independently. A continuously rotating cryogenically cooled achromatic half-wave plate can supply the required functionality. We introduce the pros and cons of introducing the polarization modulator, and discuss the feasibility of its implementation to a satellite platform. We also discuss the current status of the two major developments, a cryogenically cooled rotation system and an achromatic half-wave plate.

9904-172, Session PS5

The cosmic infrared background experiment-2 (CIBER-2) for studying the near-infrared extragalactic background light

Mai Shirahata, Institute of Space and Astronautical Science (Japan); Toshiaki Arai, Tohoku Univ. (Japan); John O. Battle, California Institute of Technology (United States); Asantha R. Cooray, Univ. of California, Irvine (United States); Akito Enokuchi, Genesia Corp. (Japan); Viktor V. Hristov, California Institute of Technology (United States); Min-Gyu Kim, Seoul National Univ. (Korea, Republic of); Phillip Korngut, California Institute of Technology (United States) and Jet Propulsion Lab. (United States); Alicia Lanz, California Institute of Technology (United States); Dae-Hee Lee, KAIST (Korea, Republic of); Peter V. Mason, California Institute of Technology (United States); Toshio Matsumoto, Institute of Astronomy and Astrophysics - Academia Sinica (Taiwan); Shuji Matsuura, Kwansei Gakuin Univ. (Japan); Tracy A. Morford, California Institute of Technology (United States); Yosuke Onishi, Tokyo Institute of Technology (Japan); Won-Kee Park, Korea Astronomy and Space Science Institute (Korea, Republic of); Kei Sano, The Univ. of Tokyo (Japan); Norihide Takeyama, Genesia Corp. (Japan); Kohji Tsumura, Tohoku Univ. (Japan); Takehiko Wada, Japan Aerospace Exploration Agency (Japan); Shiang-Yu Wang, Institute of Astronomy and Astrophysics - Academia Sinica (Taiwan); Michael Zemcov, Rochester Institute of Technology (United States); Yoshikazu Kanai, Genesia Corp. (Japan)

We present the current status of the Cosmic Infrared Background ExpeRiment-2 (CIBER-2) project, whose goal is to make a rocket-borne measurement of the near-infrared Extragalactic Background Light (EBL), under collaborate with U.S.A., South Korea, and Taiwan.

The Extragalactic Background Light is the integrated light of all extragalactic sources of emission back to the early Universe. At near-infrared wavelengths, measurement of the EBL is a promising way to detect the diffuse light from the first collapsed structures at redshift z~10, which are impossible to detect as individual sources. However, recently, the intra-halo light (IHL) model is advocated as the main contribution to the EBL, and our new result of the EBL fluctuation from CIBER experiment is also supporting this model. In this model, EBL is contributed by accumulated light from stars in the dark halo regions of low-redshift (z<2) galaxies, those were tidally stripped by the interaction of satellite dwarf galaxies. Thus, in order to understand the origin of the EBL, both the spatial fluctuation observations with multiple wavelength bands and the absolute spectroscopic observations for the EBL are highly required.

After the successful initial CIBER experiment, we are now developing a new instrument CIBER-2, which is comprised of a 28.5-cm aluminum telescope and three broad-band, wide-field imaging cameras. The three wide-field (2.3x2.3 degrees) imaging cameras use the 2Kx2K HgCdTe HAWAII-2RG arrays, and cover the near-infrared wavelength range of 0.5--0.9 um, 0.9--1.4 um and 1.4--2.0 um, respectively. Combining a large area telescope with the high sensitivity detectors, CIBER-2 will be able to measure the spatial fluctuations in the EBL at much fainter levels than those detected in previous CIBER experiment. Additionally, we will use a linear variable filter installed just above the detectors so that a measurement of the absolute spectrum of the EBL is also possible.

In this paper, the scientific motivation and the expected performance for CIBER-2 will be presented. The detailed designs of the telescope and imaging cameras will also be discussed, including the designs of the mechanical, cryogenic, and electrical systems.

9904-173, Session PS5

Prime focus architectures for large space telescopes

James B. Breckinridge, Breckinridge Associates, LLC (United States)

Conceptual architectures are now being developed to identify future mission & technology directions for post JWST large space telescope systems. With few exceptions, current space telescope architectures are founded on systems optimized for ground-based astronomy. Both HST and JWST are classical Cassegrain space telescopes derived from the ground-based requirement to co-locate the massive primary mirror and the instruments at the same end of the metrology structure. This requirement derives from the dual need to 1. Minimize observatory dome size & cost in the presence of the Earth's 1-g gravitational field and 2. Let the astronomer view through a convenient eyepiece while near the observing floor. Space telescopes, however function in the zero gravity of space, without an observatory dome and the 1-g constraint is relieved to the advantage of astronomers. Prime focus telescope systems in space potentially have higher transmittance, better pointing, improved thermal and structural control, less internal polarization and broader wavelength coverage than Cassegrain telescopes. This architecture is particularly suited to the evolvable space telescope (EST). This paper discusses several prime focus space telescope architectures within the framework of the astronomical science measurement objectives as presented and prioritized by NASA science advisory committees.

9904-174, Session PS5

Reaching sub-milimag photometric precision on Beta Pic with a nanosat: the PicSat mission payload

Mathias Nowak, Sylvestre Lacour, Vincent Lapeyrere, Lester David, Observatoire de Paris à Meudon (France); Philippe Trebuchet, Agence nationale de la sécurité des systèmes d'information (France); Thierry Lemoult, Chelles Observatory (France)

Beta Pictoris (HD 39060) is an A6V star of magnitude 3.86 (V band) which, due to its proximity (~20 pc from Earth), youth (~12 Myr), and the presence of a circumstellar disk (discovered in 1984), has always been a most promising target for the study of circumstellar environment and planetary systems.

In 2003, beta Pictoris b, a young giant exoplanet, was directly imaged around this star. Its orbit was latter characterized using multiple astrometric position measurements acquired from 2009 to 2013, and it is now strongly suspected that this is a transiting exoplanet, with a next transit event expected for mid 2017 or late 2018. This represents a unique window of opportunity to finely characterize a young giant exoplanet and its close environment (Hill sphere).

To take advantage of this possibility, a nanosatellite is currently being developed to observe the transit. The PicSat mission is based on a 3U Cubesat architecture, with a small but ambitious ~1 kg opto-mechanical payload specifically designed for high precision photometry. The satellite is planned to be launched in early 2017, on a 600 km Sun synchronous orbit. The main objective of the mission is the constant monitoring of the brightness of beta Pic at an unprecedented combination of reliability and precision (200 ppm per hour, with interruptions of at most 30 minutes) to finely characterize the transiting exoplanet and detect exocomets in the beta Pictoris system.

To achieve this difficult objective, the payload is designed with a 3.5 cm effective aperture telescope which injects the light in a single-mode optical fiber linked to an avalanche photodiode. A two-axis piezoelectric actuation system, driven by a tailor-made feedback loop control algorithm, is used to lock the fiber on the center of the star in the focal plane. These actuators complement the attitude determination and control system of the satellite to maintain the sub-arcsecond pointing accuracy required to reach the excellent level of photometric precision. Overall, the mission raises multiple very difficult challenges: high temperature stability of the avalanche detector (achieved with a thermoelectric cooler module), high pointing accuracy and stability, and short timeframe for the development.

We will present the science objectives of the PicSat mission, discuss the design of its high precision photometric payload, and detail the tracking algorithm used to lock the fiber on the star in the focal plane.

9904-175, Session PS5

Twinkle: a low earth orbit visible and infrared exoplanet spectroscopy observatory

Giorgio Savini, Univ. College London (United Kingdom)

Twinkle is a space mission dedicated to the spectroscopic observation of the atmospheres of extrasolar planets. With the recent discovery of almost 2000 exoplanets, there is a need to move from the single detection of molecular species in given exoplanets to statistical observation of molecular species in such bodies to understand the likeliness of given planetary systems.

Twinkle is a small dedicated satellite with a payload designed to optimize the spectroscopy observations while adapting to the design of an existing Low Earth Orbit commercial satellite platform. The SSTL-300 bus to be launched into a low-Earth sun-synchronous polar orbit by 2019 would carry a half-metre class telescope with two instruments (visible and near-IR spectrographs -between 0.5 and 4.5μm - with resolving power R~300 at the lower end of the wavelength scale) using mostly flight proven spacecraft systems designed by Surrey Satellite Technology Ltd and a combination of high TRL instrumentation and a few lower TRL elements built by a consortium of UK institutes. During its 5 years of operation, Twinkle will observe in excess of a hundred known exoplanets with the potential of discovering the presence of a large number of molecular species.

9904-176, Session PS5

The infrared spectrometer for Twinkle

Martyn Wells, UK Astronomy Technology Ctr. (United Kingdom)

Twinkle is a small satellite mission to observe the atmospheres of exoplanets in the visible to near infrared. This paper describes the design of the infrared (1.3 to 4.5 micron) spectrometer which works at the diffraction limit of the 450mm diameter telescope and at a resolving power of 300 (1.3-2.4 microns) and, in order to achieve the required SNR, R=30 for 2.4-4.5 microns. The planetary spectrum is obtained by taking differences between the spectra of star + planet at different phases of the planet's orbit so there is an emphasis of spectral and radiometric stability. The design incorporates a number of features to enhance this stability

- compact all aluminium structure and mirror substrates to reduce alignment offsets when cooled to the operating temperature of ~100K

- pupil imaging in the across dispersion direction to minimise changes due to sub-pixel variations in sensitivity and reduce the number of illuminated pixels for background measurements

9904-177, Session PS5

ACCESS: integration, pre-flight performance, and calibration

Mary E. Kaiser, Matthew J. Morris, Johns Hopkins Univ. (United States); Jeffrey W. Kruk, Bernard J. Rauscher, Randy A. Kimble, NASA Goddard Space Flight Ctr. (United States); Edward L. Wright, Univ. of California, Los Angeles (United States); Robert Kurucz, Harvard-Smithsonian Ctr. for Astrophysics (United States); Stephan R. McCandliss, Russell Pelton, Lauren N. Aldoroty, Paul D. Feldman, Henry W. Moos, Johns Hopkins Univ. (United States); Adam G. Riess, Johns Hopkins Univ. (United States) and Space Telescope Science Institute (United States); Dominic J. Benford, Jonathan P. Gardner, NASA Goddard Space Flight Ctr. (United States); Ralph C. Bohlin, Susana E. Deustua, William V. Dixon, David J. Sahnow, Space Telescope Science Institute (United States); Michael Lampton, Space Sciences Lab. (United States); Saul Perlmutter, Lawrence Berkeley National Lab. (United States) and Univ. of California, Berkeley (United States)

Using SNeIa to distinguish dark energy models from one another levies a requirement for 1% precision in the cross-color calibration of the SNe Ia flux across a bandpass extending from 0.35 ? 1.7 ?m. The systematic errors in the flux calibration network spanning the visible through the NIR currently exceed 1%. ACCESS, Absolute Color Calibration Experiment for Standard

Stars, is a series of rocket-borne sub-orbital missions and ground-based experiments that will leverage the significant technological advances in detectors, instruments, and the precision of the fundamental laboratory standards used to calibrate these instruments to enable improvements in the precision of the astrophysical flux scale through the transfer of absolute laboratory detector standards from the National Institute of Standards and Technology (NIST) to a network of stellar standards with a calibration accuracy of 1% and a spectral resolving power of 500 across the 0.35 to 1.7 micron bandpass. The ACCESS Cassegrain telescope feeds a compact (Rowland circle design) spectrograph with a cross dispersing Fery prism.

The detector, a HST/WFC3 heritage 1024x1024 HgCdTe array, is sensitive across the full 0.35 to 1.7 micron bandpass. Vibration and thermal vacuum testing of the detector have been successful. Ground-based detector characterization is on-going. The thermal vacuum system is being assembled and tested. The ACCESS telescope and spectrograph are currently in stages of assembly, test, and integration. Integration and alignment of the spectrograph optics will be described. Calibration strategy and status, ground-based integration, vibration testing and instrument performance results will be presented. Launch is expected within the year. NASA sounding rocket grant NNX14AH48G supports this work.

9904-178, Session PS5

CALISTO: a single-aperture far-IR surveyor concept

Charles M. Bradford, Paul F. Goldsmith, David C. Redding, Jet Propulsion Lab. (United States) and California Institute of Technology (United States); Lee Armus, California Institute of Technology (United States) and Jet Propulsion Lab. (United States)

We present a study of the scientific requirements and implementation options for a wide-field cryogenic telescope architecture for the Far-Infrared Surveyor. The starting point is the actively-cooled 4x6-meter CALISTO concept, but we are including advanced imaging and spectroscopic instrumentation covering 30-600 microns, operating at the photon background limit, with a total detector count of a few hundred thousand, a 100-fold increase at these wavelengths.

A sensitive far-IR space capability is a long-term astrophysics imperative for NASA. Integrated over cosmic time, most of the energy released by star formation and black hole growth in galaxies emerges in the far-IR, yet this band is inaccessible from the ground. The rest-frame mid- to far-IR both measures the total bolometric energy release, and provides direct access to the inner workings of galaxies and Galactic star-forming regions. Particularly compelling are the suite of powerful spectroscopic diagnostics that measure redshifts as well as the properties of gas at the interaction between energy sources and their surrounding interstellar material. In aggregate, sensitive far-IR measurements will: measure the onset of heavy elements and organic molecules, chart the total history of star formation (including that in galaxies below the individual detection threshold), probe the cycling of matter and energy in the Milky Way, and conduct a census of gas mass and conditions in protoplanetary disks throughout their evolutionary sequence.

The scientific investigations require excellent spectroscopic and surface-brightness sensitivity only possible with an actively-cooled telescope. A large 4-K system is new, but all individual technologies have been demonstrated. Scaling from experience with Planck indicates that the combination of V-groove radiators and an active heat lift of ~2 W at T~20 K and 150 mW at 4 K should overcome the telescope parasitics as well as the heat rejected by the sub-K instrument coolers. These heat lifts can be provided with 4He closed-cycle coolers, with a total observatory power below 1500 W. We study the impact of on-axis vs off-axis telescope design, and consider the possibility of active mirror technologies that may reduce the need for costly cryogenic testing.

CALISTO will include both broad-band cameras and wide-band direct-detection spectrometers. For broad-band imaging, the sensitivity of the cold telescope provides very fast mapping speeds, and with the shallow source counts, the 5-meter telescope goes much deeper than Herschel. At 100 microns, a 4000-beam camera can conduct an all-sky survey to the confusion limit, some 450 micro-Jy, corresponding to 3e10 Lsun at z=2. Much deeper imaging is possible at shorter wavelengths.

The bulk of the detector resources will be deployed in a suite of wide-band imaging spectrometer modules, which combine to cover the 30 to 600 micron range. Background-limited spectroscopy with a cold telescope offers potential for million-fold improvements in survey speed, and technical progress in this area is particularly compelling. Each spectrometer will have resolving power~500-1000 across the full sub-band, and ~100-200 spatial resolution elements. We present spectrometer concepts as well as sensitivities and mapping speeds, and dependencies of these scientific performance metrics on aperture size, configuration, and temperature.

9904-179, Session PS5

The FLARE mission: deep and wide-field 1-5um imaging and spectroscopy for the early universe

Denis Burgarella, Patrick Levacher, Kjetil Dohlen, Sébastien Vives, Sandrine Pascal, Lab. d'Astrophysique de Marseille (France)

FLARE (First Light And Reionization Explorer) is a space mission that will be submitted to ESA (M5 call). Its primary goal (~80% of lifetime) is to identify and study the universe before the end of the reionization at z>6. A secondary objective (~20% of lifetime) is to survey star formation in the Milky Way. FLARE's strategy optimizes the science return: imaging and spectroscopic integral-field observations will be carried out simultaneously on two parallel focal planes and over very wide instantaneous fields of view.

FLARE will help addressing two of ESA's Cosmic Vision themes: a) « How did the universe originate and what is it made of? » and b) « What are the conditions for planet formation and the emergence of life? » and more specifically, « From gas and dust to stars and planets ».

The main goals of FLARE are:

- detect and identify a sample of ~100 candidates primordial galaxies at z > 10.

- The first stars produced and dispersed heavy elements, paving the way for the formation of stellar systems like ours. FLARE's spectrograph will be able to follow the evolution of metallicity at 3< z<10.

- detect and study the emission (including lines) of the first quasars at z>6 to better understand the formation of super-massive black holes.

- FLARE's angular resolution at lambda>2 micrometer, where the extinction is negligible, will observe the formation of stars in the Milky Way from a very wide survey.

To meet FLARE's objectives, the following requirements have been defined: high sensitivity (M1 diameter: 1.8–2.0 m) in the Near-Infrared (1-5 micrometer), relatively high angular resolution (~0.4 arcsec) and above all, wide field of view (~0.2 sq. deg in imaging and 1 sq. arcmin integral-field spectroscopy with 500< R<1000).

The strategy is optimized to build a deep imaging survey over 100–200 sq. deg. down to m_AB = 28 (5 sigma) and an integral-field spectroscopic survey over 1–2 sq. deg, down to a flux 10^-18 erg/cm2/s (5 sigma).

Why do we need a FLARE-like project when JWST, EUCLID, WFIRST and the ELTs will scrutinize the sky? Because only FLARE will combine the following mandatory requirements:

To identify galaxies at z > 10 means:

- we need to search for emissions at lambda > 2-3 micrometers, which

corresponds to the rest-frame 200nm UV emission at 10< z<15.

- We need to be able to confirm their redshift, spectroscopically, which translates into m_AB < 28, even for the E-ELT spectrographs

- These objects are likely to be rare (expected 1 per sq. deg), so, we need at least 100 sq. deg to build a statistically useful sample.

- To reach m_AB = 28 over > 100 sq. deg, we need a 2.0m-class telescope and a dedicated 5-year mission (an observatory shares its time over different projects).

Finally, after JWST, FLARE will work in synergy with SKA, for the re-ionization, ATHENA for the formation and early evolution of quasars and the ELTs for the first galaxies.

9904-180, Session PS5

Optical design of the wide-field, multi-band photometer and integral field spectrograph for the FLARE mission

Sébastien Vives, Kjetil Dohlen, Sandrine Pascal, Patrick Levacher, Denis Burgarella, Lab. d'Astrophysique de Marseille (France)

FLARE (First Light And Reionization Explorer) is a space mission that will be submitted to ESA (M5 call). Its primary goal is to identify and study the universe before the end of the reionization at z>6.

FLARE will perform imaging and spectroscopic integral-field observations simultaneously on two parallel focal planes and over very wide instantaneous fields of view.

The 2.0m-class telescope has a Korch configuration (3-mirror and a folding) allowing to observe a wide FoV (about 0.4x0.8deg). A focal plane composed of 18 2kx2k IR detectors will be dedicated to the imaging survey in 6 spectral bands (3 detectors per band).

FLARE will also have spectroscopic capability with an integral field spectrograph (IFS) working in the same spectral regions than the imager with an instantaneous field of view of about 1 arcmin2. It is composed of 6 identical integral field units which slices the entrance 2D field in a long 1D-slit. Finally, each slit feeds two spectrographs covering the 2 octaves of the spectral band.

The FoV is arranged in such a way as to allow mapping of >200 square degrees in imagery and >2 square degrees in spectroscopy, covering simultaneously all spectral bands with no moving parts.

In this article we will describe the overall optical design of the FLARE mission.

9904-181, Session PS5

2020 astrophysics decadal large mission concept Ultraviolet/Optical/Infrared (UVOIR) surveyor status and path forward

Julie A. Crooke, Aki Roberge, Shawn Domagal-Goldman, Avi Mandell, Matthew R. Bolcar, Norman Rioux, Lee D. Feinberg, NASA Goddard Space Flight Ctr. (United States)

In preparation for the 2020 Astrophysics Decadal Survey, an Ultraviolet/Optical Infrared (UVOIR) Surveyor is one of four large mission concepts NASA is studying. Several UVOIR Surveyor variants have been either identified and/or minimally studied to date, including, but not limited to, the 2010 Astrophysics Decadal Survey, "New Worlds New Horizons" which identified the highest priority medium-scale space program priority, a "New Worlds Technology Development Program - to study nearby habitable exoplanets"; the 2013 NASA Visionary Astrophysics 30-Year Roadmap, "Enduring Quests Daring Visions" identified a large UVOIR (LUVOIR) Surveyor; the Associated Universities for Research in Astronomy (AURA) Report, "From Cosmic Births to Living Earths" identified the High Definition Space Telescope (HDST); and several other variants have been studied to varying degrees by industry, NASA field centers, and academia. This broad interest exemplifies the enthusiasm by the community to explore and answer a myriad of compelling science questions in the 2030s, one of the most fundamental humanitarian questions now with our grasp, 'Are We Alone in the Universe?' Assuming current projected funding levels, the mission prioritized by the 2020 Decadal Survey will not receive a programmatic start until nearing the launch of WFIRST-AFTA (~2024-2025), thus, not launching well into the 2030's. In this era, the Hubble Space Telescope (HST), the James Webb Space Telescope (JWST), ESA's Euclid and M4 missions and WFIRST-AFTA will have achieved their exciting science goals and will no longer be in operation. Additionally, ESA's L2 mission, Athena, will have launched in ~2028, and ground-based observatories will have been in operation such as ALMA, ELT, GMT, LBT, LSST, and TMT, to name a few. Mission concepts currently being studied must take into account this scientific and technological context and landscape. Specifically, with the next Decadal Survey identifying the highest priority science (and/or type of mission) in 2019-2020, the identified mission will not get a programmatic start until well into the mid-2020s at the earliest. NASA's Goddard Space Flight Center is providing institutional leadership for the (L)UVOIR Surveyor with a growing multi-institutional team consisting of NASA field centers, academia, industry and potential international partners where the NASA Headquarters appointed Science and Technology Definition Team (STDT) will provide a national community-led fresh and more in-depth consideration of the science objectives, goals, and their relative priorities taking into consideration new and ever-evolving scientific and technology information. Ultimately, the STDT will decide which and how many architectures to study. The (L)UVOIR Surveyor Study Team intends to provide the Decadal Survey and the broad science community with a mission concept with a range of architectural/scaling options associated with different levels of science capability dictated by different starting technology maturities, implementation feasibility, and cost/schedule risks. In the post-HST, post-JWST era, the (L)UVOIR Surveyor is poised to deliver transformative science, as HST has done, across all of astrophysics including Cosmic Origins (COR), Exoplanet Exploration (ExEP), Physics of the Cosmos (PCOS) as well as Solar System planetary science. This paper presents the UVOIR Surveyor mission concept study status, context, and path forward to maximize community involvement.

9904-183, Session PS5

Architecture trades for a habitable-zone exoplanet direct imaging mission

Keith R. Warfield, Jeffrey T. Booth, Jet Propulsion Lab. (United States); H. Philip Stahl, NASA Marshall Space Flight Ctr. (United States); Bertrand P. Mennesson, Karl R. Stapelfeldt, Jet Propulsion Lab. (United States)

The recently formed NASA Science and Technology Definition Team for the Habitable-Exoplanet Imaging Mission (HabEx) study has been tasked by NASA with developing a compelling and feasible exoplanet direct imaging concept as part of the 2020 Decadal Survey. Exoplanet and other science capabilities must be traded against cost and risk for a variety of mission architectures to find a concept that meets the standard of both compelling and feasible. Trade areas will include, but are not limited to: direct imaging method, coronagraph type, starshade size and type, telescope size and design, and potential secondary payloads. This paper discusses the architecture trades explored to date, as well as the plan moving forward in the HabEx study.

The Euclid mission design

Giuseppe D. Racca, European Space Research and Technology Ctr. (Netherlands)

Euclid is a space-based optical/near-infrared survey mission of the European Space Agency (ESA) designed to investigate the nature of dark energy, dark matter and gravity by observing their signatures on the geometry of the Universe and on the formation of large structures over cosmological timescales. Euclid will use two main techniques in the detection of the signature of dark matter and energy: Weak gravitational Lensing, which requires the measurement of the shape and photometric redshifts of distant galaxies, and Galaxy Clustering, based on the measurement of the 3-dimensional distribution of galaxies through their spectroscopic redshifts. The mission is scheduled for a launch date in the first half of 2020 and is designed for 6 years of nominal survey operations. The Euclid Spacecraft is composed of a Service Module and a Payload Module. The Service Module comprises all the conventional spacecraft subsystems, the instruments warm electronics units, the sun shield and the solar arrays. In particular the Service Module provides the extremely challenging pointing accuracy required by the scientific objectives. The Payload Module consists of a 1.2 m three-mirror Korsch type telescope and of two instruments, the visible imager and the near-infrared spectro-photometer, both covering a large common field-of-view enabling to survey more than 35% of the entire sky.

Starting from the overall mission requirements, we will describe the spacecraft architectural design and expected performance and will provide a view on the current project status.

9904-20, Session 6

VIS: the visible imager for Euclid

Mark S. Cropper, Sabrina Pottinger, Sami M. Niemi, James Denniston, Magdalena B. Szafraniec, Mullard Space Science Lab. (United Kingdom); Yannick Mellier, Institut d'Astrophysique de Paris (France); Michel G. Berthé, Jérôme Martignac, Christophe Cara, Commissariat à l'Énergie Atomique (France); Anna M. Di Giorgio, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Andrea Sciortino, CGS S.p.A. Compagnia Generale per lo Spazio (Italy); Stéphane Paltani, Ludovic Genolet, ISDC Data Ctr. for Astrophysics (Switzerland); Richard E. Cole, Mullard Space Science Lab. (United Kingdom); Jean-Jacques Fourmond, Maryse Charra, Institut d'Astrophysique Spatiale (France); Phillip R. Guttridge, Berend Winter, Mullard Space Science Lab. (United Kingdom); James Endicott, e2v technologies plc (United Kingdom); Andrew D. Holland, e2v Ctr. for Electronic Imaging (United Kingdom); Jason P. D. Gow, Neil J. Murray, The Open Univ. (United Kingdom); David J. Hall, e2v Ctr. for Electronic Imaging (United Kingdom); Jérôme Amiaux, Commissariat à l'Énergie Atomique (France); René J. Laureijs, Giuseppe D. Racca, Jean-Christophe Salvignol, Alexander D. Short, Jose Lorenzo Alvarez, European Space Research and Technology Ctr. (Netherlands); Thomas Kitching, Mullard Space Science Lab. (United Kingdom) and The Royal Observatory, Edinburgh (United Kingdom); Henk Hoekstra, Leiden Observatory (Netherlands); Richard J. Massey, The Royal Observatory, Edinburgh (United Kingdom) and Durham Univ. (United Kingdom)

Euclid-VIS is the large format visible imager for the ESA Euclid space mission in their Cosmic Vision program, scheduled for launch in 2020. Together with the near infrared imaging within the NISP instrument, it forms the basis of the weak lensing measurements of Euclid. VIS will image in a single r+i+z band from 550-900 nm over a field of view of ~0.5 deg2. By combining 4 exposures with a total of 2260 sec, VIS will reach to deeper than V=24.5 (10sigma) for sources with extent ~0.3 arcsec. The image sampling is 0.1 arcsec. VIS will provide deep imaging with a tightly controlled and stable point spread function (PSF) over a wide survey area of 15000 deg2 to measure the cosmic shear from nearly 1.5 billion galaxies to high levels of accuracy, from which the cosmological parameters will be measured. In addition, VIS will also provide a legacy dataset with an unprecedented combination of spatial resolution, depth and area covering most of the extra-Galactic sky. Here we will present the results of the study carried out by the Euclid Consortium during the period up to the Critical Design Review.

9904-21, Session 6

Euclid end-to-end straylight performance assessment

Luis Miguel Gaspar Venancio, Charlotte Pachot, Jose Lorenzo Alvarez, European Space Research and Technology Ctr. (Netherlands); Jérôme Amiaux, Commissariat à l'Énergie Atomique (France); Lionel Carminati, Airbus Defence and Space SAS (France); Eric Prieto, Lab. d'Astrophysique de Marseille (France); Luciana Bonino, Thales Alenia Space (Italy); Jean-Christophe Salvignol, René J. Laureijs, Alexander D. Short, Tobias Boenke, European Space Research and Technology Ctr. (Netherlands)

Euclid is an European Space Agency mission dedicated to the mapping of the geometry of the dark Universe. The mission will investigate the distance-redshift relationship and the evolution of cosmic structures. This is achieved by measuring shapes and redshifts of galaxies and clusters of galaxies out to redshifts ~2, or equivalently to a look 10 billion years back in time. Euclid makes use of two cosmological probes, in a wide survey over the full extragalactic sky : the Weak Gravitational Lensing (WL) and the Baryonic Acoustic Oscillations (BAOs). The WL is a method to map the dark matter and measure dark energy by measuring the apparent distortion of galaxy images by mass inhomogeneities along the line-of-sight. This probe requires extreme image quality thus constraining the optical system imaging quality. The BAOs are wiggle patterns, imprinted in the clustering of galaxies, which provide a standard ruler to measure dark energy and the expansion in the Universe. This experiment involves the determination of the redshifts of galaxies with an accuracy better than 0.1%.

Each probe has a dedicated instrument in the Euclid Payload Module (PLM). The WL experiment involves an instrument (VIS) operating in the visible (500 nm to 900nm) spectral range. The BAO experiment is implemented with the Near Infrared Spectrometer-Photometer (NISP) instrument operating in the near infrared (920 nm to 2000nm) spectral range. Both instruments are fed light by a 1.2 meter-class Korsch type telescope

The extreme constraints imposed on the telescope performances by the probes specifications have driven the definition of stringent straylight requirements for the telescope and both instruments. The straylight induced degradation of the signal-to-noise ratio and light-pollution of spectrum between two close objects in the sky has a direct impact on the number of valid observed objects in the survey. We will present in this paper a brief introduction to the Euclid PLM system. The approach chosen to assess the end-to-end straylight performance and its impact on the scientific outcomes is reported as well. Furthermore we will show the latest assessed performances at system level for both instruments.

9904-22, Session 6

Euclid near infrared spectro photometer (NISP) instrument concept and first test results obtained for different breadbords models at the end of phase C

Thierry Maciaszek, Ctr. National d'Études Spatiales (France); Anne Ealet, Ctr. de Physique des Particules de Marseille (France); Knud Jahnke, Max-Planck-Institut für Astronomie (Germany); Rémi Barbier, Institut de Physique Nucléaire de Lyon (France); Eric Prieto, Lab. d'Astrophysique de Marseille (France); Yannick Mellier, Institut d'Astrophysique de Paris (France) and Commissariat à l'Énergie Atomique (France); Anne Costille, Anne Bonnefoi, Lab. d'Astrophysique de Marseille (France); Franck Ducret, Lab. d'Astrophysique de Marseille (France); Christophe Fabron, Lab. d'Astrophysique de Marseille (France); Jean-Luc Gimenez, Laurent Martin, Lab. d'Astrophysique de Marseille (France); Christelle Rossin, Tony Pamplona, Sébastien Vives, Lab. d'Astrophysique de Marseille (France); Jean Claude Clémens, Ctr. de Physique des Particules de Marseille (France); Gérard Smadja, Institut de Physique Nucléaire de Lyon (France); Jérôme Amiaux, Jean Christophe Barrière, Michel Berthe, Commissariat à l'Énergie Atomique (France); Adriano De Rosa, Enrico Franceschi, INAF - IASF Bologna (Italy); Gian Paolo Guizzo, INAF - IASF (Italy); Gianluca Morgante, Massimo Trifoglio, Luca Valenziano, INAF - IASF Bologna (Italy); Carlotta Bonoli, Favio Bortoletto, INAF - Osservatorio Astronomico di Padova (Italy); Andrea Balestra, INAF - Osservatorio Astronimico di Padova (Italy); Maurizio D'Alessandro, INAF - Osservatorio Astronomico di Padova (Italy); Leonardo Corcione, Sebastiano Ligori, INAF - Osservatorio Astronomico di Torino (Italy); Frank U. Grupp, Carolin Wimmer, Max-Planck-Institut für extraterrestrische Physik (Germany); Felix Hormuth, Gregor Seidel, Stefanie Wachter, Max-Planck-Institut für Astronomie (Germany); Jose Javier Diaz, Instituto de Astrofisica de Canarias (Spain); Cristóbal Padilla, Institut de Física d'Altes Energies (Spain); Mikel Mamensans, Institut de Física d'Altes Energies (Spain); Ricard Casas, Institut de Física d'Altes Energies (Spain); Rafael Toledo, Universidad Politécnica de Cartagena (Spain); Per B. Lilje, Univ. I Oslo (Norway); Corinne Toulouse-Aastrup, SSC (Denmark); Allan Hornstrup, DTU Space (Denmark); Michael I. Andersen, Technical Univ. of Denmark (Denmark); Warren A. Holmes, Ulf E. Israelsson, Michael D. Seiffert, Jet Propulsion Lab. (United States); Augustyn Waczynski, NASA Goddard Space Flight Ctr. (United States); René J. Laureijs, Giuseppe D. Racca, Jean-Christophe Salvignol, Tobias Boenke, Paolo Strada, European Space Agency (Netherlands)

The Euclid mission objective is to understand why the expansion of the Universe is accelerating by mapping the geometry of the dark Universe by investigating the distance-redshift relationship and tracing the evolution of cosmic structures. The Euclid project is part of ESA's Cosmic Vision program with its launch planned for 2020.

The NISP (Near Infrared Spectro-Photometer) is one of the two Euclid instruments and is operating in the near-IR spectral region (0.9-2?m) as a photometer and spectrometer. The instrument is composed of:

- a cold (135K) optomechanical subsystem consisting of a SiC structure, an optical assembly (corrector and camera lens), a filter wheel mechanism, a grism wheel mechanism, a calibration unit and a thermal control system

- a detection subsystem based on a mosaic of 16 HAWAII2RG cooled to 95K with their front-end readout electronic cooled to 140K, integrated on a mechanical focal plane structure made with Molybdenum and Aluminum. The detection subsystem is mounted on the optomechanical subsystem structure

- a warm electronic subsystem (280K) composed of a data processing / detector control unit and of an instrument control unit that interfaces with the spacecraft via a 1553 bus for command and control and via Spacewire links for science data

This presentation describes the architecture of the instrument at the end of the phase C (Detailed Design Review), the expected performance, the technological key challenges and preliminary test results obtained for different NISP subsystem breadboards and for the NISP Structural and Thermal model (STM).

9904-23, Session 6

Final tolerancing approach and results for the Euclid NISP instrument

Frank U. Grupp, Max-Planck-Institut für extraterrestrische Physik (Germany); Eric Prieto, Anne Costille, Aix-Marseille Univ. (France) and Ctr National de la Recherche Scientifique (France); Ralf Bender, Max-Planck-Institut für extraterrestrische Physik (Germany)

For the EUCLID-NISP near infra-red instrument's CDR, a refined tolerance analysis has been performed. This takes into account the manufacturing, assembly, spacecraft integration and operational stability of the instrument. The influence of thermal gradients across each of the NISP lenses has been studied to show that this is not causing performance problems. In addition simulations have been done to evaluate the influence of alignment insecurities due to imperfect knowledge of the location of the pupil interface towards the telescope.

These analysis are shown in this paper together with an approach to derive wave-front requirements for optical instrument testing from the encircled energy requirements at NISP system level.

An important part in the analysis is the close relation between tolerance analysis and alignment technology. As the latter is based on multi-zone computer generated holograms (CGH) the properties and accuracies of these elements is also addressed in the paper.

9904-24, Session 6

Optical verification tests of the NISP/ Euclid GRISM qualification model

Amandine Caillat, Lab. d'Astrophysique de Marseille (France) and Aix-Marseille Univ. (France); Anne Costille, Lab. d'Astrophysique de Marseille (France); Sandrine Pascal, Sébastien Vives, Lab. d'Astrophysique de Marseille (France) and Aix-Marseille Univ. (France); Christelle Rossin, Lab. d'Astrophysique de Marseille (France); Patrice Sanchez, Joël Le Merrer, Lab. d'Astrophysique de Marseille (France) and Aix-Marseille Univ. (France) and Ctr National de la Recherche Scientifique (France); Benjamin Foulon, Lab. d'Astrophysique de Marseille (France)

Dark matter and dark energy mysteries will be explored by the Euclid ESA M-class space mission which will be launched in 2020. Millions of galaxies will be surveyed through visible imagery and NIR imagery and spectroscopy in order to map the Universe at different evolution stages over the past 10 billion years.

In particular, the massive NIR spectroscopic survey will be done efficiently by the NISP (Near Infrared Spectro-Photometer) instrument thanks to the use of GRISMs (for "Grating pRISMs"). These dispersive optical components allow acquiring the spectra of all galaxies in the imagery field of view at the same time contrary to slit spectroscopy. Four GRISMs mounted on a rotating wheel are used in NISP in order to cover two spectral bands from 0.9 to 1.85μm and to avoid spectra overlapping by rotating the dispersion direction. In addition, the NISP GRISMs integrate three other optical functions: spectral filtering, focus adjustment and spectral wavefront correction. Indeed, a multilayer filter selecting the spectral band passes (0.9-1.3μm and 1.25-1.85μm) is deposited on the curved first face of the prism (kind of lens) and the grooves of the grating made on the other prism face are not straight and parallel allowing spectral aberrations corrections. Therefore, these optical elements are very challenging to manufacture (3 industrial partners work on a single optical component) and to test before integration into NISP.

In this paper, we present the optical verification tests done on the GRISM Engineering Qualification Model at each step of the manufacturing process: (1) grating on a parallel plate, (2) prism with curved face and (3) filter deposition. First, we verify the groove profile and transmitted efficiency specified to be more than 65% on a wide spectral band (1.25-1.85μm) in order one. Second, we measure the grating and the filter surfaces error specified to be respectively less than 30nm RMS without focus. Finally, the total transmitted efficiency, the out of band rejection and the wavefront error including focus are measured after the filter manufacturing.

9904-25, Session 6

Latency model of Euclid H2RG IR detectors for the NISP instrument of the Euclid mission

Benoît Serra, Anne Ealet, Ctr. de Physique des Particules de Marseille (France) and Institut National de Physique Nucléaire et de Physique des Particules (France); Rémi Barbier, Institut de Physique Nucléaire de Lyon (France) and Institut National de Physique Nucléaire et de Physique des Particules (France); Aurélia Secroun, Jean Claude Clémens, Ctr. de Physique des Particules de Marseille (France) and Institut National de Physique Nucléaire et de Physique des Particules (France); Bogna Kubik, Institut de Physique Nucléaire de Lyon (France) and Institut National de Physique Nucléaire et de Physique des Particules (France); Thierry Maciaszek, Eric Prieto, Lab. d'Astrophysique de Marseille (France) and Observatoire Astronomique de Marseille-Provence (France); Gérard Smadja, Eric Chabanat, Sylvain Ferriol, Institut de Physique Nucléaire de Lyon (France) and Institut National de Physique Nucléaire et de Physique des Particules (France); Ralf Kohley, European Space Astronomy Ctr. (Spain); Pierre-Elie Crouzet, European Space Research and Technology Ctr. (Netherlands); Philippe Lagier, Mathieu Niclas, Laurence Caillat, Ctr. de Physique des Particules de Marseille (France) and Institut National de Physique Nucléaire et de Physique des Particules (France)

Euclid is an ESA mission to map the geometry of the dark Universe with a planned launch date in 2020. The Near-Infrared photo-spectrometer instrument (NISP) contains a large focal plane assembly of 16 Teledyne H2RG detectors. CPPM is in charge of the final characterization of the flight H2RG infrared detectors . The knowledge of detectors performances is crucial to the instrument calibration and requires a thorough characterization effort. Engineering grade Euclid-like detectors are currently being tested at CPPM to validate associated characterization test plan. One major goal for this activity is to prepare future analyses and corrections needed for precise calibration and performance control after flight. One main issue is to define a test plan to control and correct if needed the persistence effects of these detectors throughout the mission. A characterization plan is under study to measure and establish a reliable model of the in-flight H2RG detector persistence signal that

can be used to predict and correct the flight data. An initial study of the persistence behavior of those detectors will be presented and a model will be proposed and data analysis described, based on representative engineering data. In the next phase, flight detectors, selected and tested by NASA, will be received and fully characterized for persistence effect at CPPM before their integration.

9904-26, Session 7

The Primordial Inflation Explorer (PIXIE)

Alan J. Kogut, NASA Goddard Space Flight Ctr. (United States); Jens Chluba, Univ. of Cambridge (United Kingdom); Dale J. Fixsen, NASA Goddard Space Flight Ctr. (United States); Stephan S. Meyer, The Univ. of Chicago (United States); David N. Spergel, Princeton Univ. (United States)

The Primordial Inflation Explorer is an Explorer-class mission to measure the gravity-wave signature of primordial inflation through its distinctive imprint on the linear polarization of the cosmic microwave background. PIXIE uses an innovative optical design to achieve background-limited sensitivity in 400 spectral channels spanning 2.5 decades in frequency from 30 GHz to 6 THz (1 cm to 50 micron wavelength). Multi-moded non-imaging optics feed a polarizing Fourier Transform Spectrometer to produce a set of interference fringes, proportional to the difference spectrum between orthogonal linear polarizations from the two input beams. Multiple levels of symmetry and signal modulation combine to reduce systematic errors to negligible levels. PIXIE will map the full sky in Stokes I, Q, and U parameters with angular resolution 2.6 deg and sensitivity 0.2 μK per 1 deg square pixel. The principal science goal is the detection and characterization of linear polarization from an inflationary epoch in the early universe, with tensor-to-scalar ratio r < 10-3 at 5 standard deviations. The PIXIE mission complements anticipated ground-based polarization measurements such as CMB-S4, providing a cosmic-variance-limited determination of the E-mode signal to measure the optical depth, constrain models of reionization, and improve limits on the neutrino mass. In addition, PIXIE will measure the absolute frequency spectrum to characterize deviations from a blackbody spectrum with sensitivity 3 orders of magnitude beyond the seminal COBE/FIRAS limits. The sky cannot be black at this level; the expected results will constrain physical processes ranging from inflation to the nature of the first stars and the physical conditions within the interstellar medium of the Galaxy. We describe the PIXIE instrument and mission architecture required to measure the CMB to the limits imposed by astrophysical foregrounds.

9904-27, Session 7

LiteBIRD: lite satellite for the study of B-mode polarization and inflation from cosmic microwave background radiation detection

Hirokazu Ishino, Okayama Univ. (Japan)

LiteBIRD is a next generation satellite for the detection of the B-mode polarization of the Cosmic Microwave Background (CMB) to measure the tensor-to-scaler ratio with the sensitivity of 0.002 at the 95% confidence level, offering us the test of the major large-single-field slow-roll inflation models.

LiteBIRD is planned to conduct an all sky survey at the sun-earth 2nd Lagrange point (L2) with an angular resolution of about 0.5 degrees to measure the B-mode power spectrum in the range of ell=2 to 200 in its three years of operation.

The measurement system contains an optical system, focal plane detector arrays and polarization modulators. The optical system contains two telescopes: one makes use of the modified crossed-Dragone telescope that offers the telecentric field of view of 10 x 20 degrees in the frequency range of 40 to 235 GHz, called the Low Frequency Telescope (LFT), and another is a refractor telescope operating from 280 to 402 GHz, called the High Frequency Telescope (HFT). The two focal planes of the LFT and the HFT are kept at 100 mK with an adiabatic demagnetization refrigerator (ADR). On each focal plane, an array of superconducting detectors is located. The 2276 superconducting detectors in total provide a sensitivity of 1.7 uKarcmin which includes the degradations due to the production yield, ADR duty cycle and cosmic ray glitch removal. The superconducting detector candidates are Transition Edge Sensors (TES) and Microwave Kinetic Inductance Detector (MKID). Each telescope has a continuous rotating Half Wave Plate (HWP) that modulates the polarization of the incoming photons. The separation of the two telescopes relaxes the requirements imposed on the HWP specification in terms of the bandwidth and anti-reflection.

The LiteBIRD mission is being designed with respect to the specification of the satellite, the data transfer to the ground and the mission operation concept. One of the items critical to determine the satellite design is the scan strategy. The baseline scan is a combination of the precession and the spin rotation. The precession angle with respect to the sun-earth axis is 65 degrees with the rate of about 90 minutes per revolution, and the boresight rotates around the spinning axis with an angle of 30 degrees. The revolution rate of the spin is 0.1rpm. In case of the mulfunction of the HWP, the spin rate can be increased to 0.3 rpm. The estimated data rate is about 400 kbps with the HWP. The data are transferred to the ground stations using the X-band telemetry.

The LiteBIRD mission has been down-selected as a candidate of the JAXA strategic large missions and is in the transition to the Phase-A1 study. During Phase-A1, the satellite specification will be fixed and reviewed to proceed to Phase-A2. The LiteBIRD US team's proposal for the NASA Missions of Opportunity has also been down-selected for the Phase-A study to design the focal plane detectors and the ADR as well as the data analyses. The target launch year is in early 2020s.

9904-28, Session 7

Scientific overview of the Galaxy Evolution Spectroscopic Explorer (GESE)

Sara R. Heap, NASA Goddard Space Flight Ctr. (United States); Massimo Robberto, Space Telescope Science Institute (United States); Zoran Ninkov, Rochester Institute of Technology (United States)

GESE is a multi-object slit spectrograph designed to help understand galaxy evolution in a critical era in the history of the universe: the period when star formation peaked and started its decline which continues to the present day. To isolate the various processes driving the evolution of these galaxies, GESE will obtain rest-frame far-UV spectra of >50,000 galaxies at redshifts, z~1-2. To obtain such a large number of spectra, multiplexing over a wide field is an absolute necessity. A digital micro-mirror device (DMD) offers an innovative solution to this challenge. By forming small "slits" around target galaxies in the field, a DMD enables spectroscopy of hundreds of sources in a single exposure while eliminating overlapping spectra of other sources and blocking unwanted background like zodiacal light. The actual multiplexing factor in the GESP case is a function of the field of view and the limiting sensitivity of the spectrograph. We find that a 1m-class space telescope combined with a custom orbit enabling a high fraction of time on target and uninterrupted long exposures (~10 hr) are optimal for this spectroscopic survey program.

9904-29, Session 8

Main results of the PICARD mission

Mustapha Meftah, Abdanour Irbah, Alain Hauchecorne, LATMOS (France)

PICARD is a mission devoted to solar variability observation, through imagery and radiometric measurements, with the goal to provide data for scientific investigation first in the area of solar physics, and second in the assessment of the influence of the solar variability on the Earth climate variability. PICARD contains a double program with in-space and on-ground measurements. The PICARD spacecraft was launched on June 15, 2010, commissioned in-flight in October of the same year, and was retired in April 2014. PICARD ground-based is functional since May 2011, and is still operational today. We shall give an overview of the PICARD instrumentation. New estimates of the absolute values of the total solar irradiance, of the solar spectral irradiance at typical wavelengths, and of the solar oblateness will be given. We will also report about helioseismic studies. Finally, we will present our current results about solar radius variations after six years of solar observations.

9904-30, Session 8

Geometrical distortion calibration of the stereo camera for the BepiColombo mission to mercury

Emanuele T. Simioni, Vania Da Deppo, IFN-CNR LUXOR Lab. (Italy); Giampiero Naletto, Univ. degli Studi di Padova (Italy); Elena Martellato, INAF- Osservatorio Astronomico di Padova (Italy); Cristina Re, INAF - Osservatorio Astronomico di Padova (Italy); Donato Borrelli, Michele Dami, Iacopo Ficai Veltroni, Gianluca Aroldi, SELEX ES S.p.A. (Italy); Gabriele Cremonese, INAF - Osservatorio Astronomico di Padova (Italy)

The ESA-JAXA mission BepiColombo, to be launched in 2017, is dedicated to the observation of Mercury, the innermost planet of the Solar System. Simbiosys is its remote sensing suite, which consists of three instruments: the High Resolution Imaging Channel (HRIC), the Visual and Infrared Hyperspectral Imager (VIHI), and the Stereo Camera (STC). The latter will provide the global three dimensional reconstruction of the Mercury surface, and it represents the first push-frame stereo camera on board of an astronomical satellite.

Based on a new design telescope, STC combines the advantages of a compact single detector to the convenience of a double direction acquisition system that permits to minimize mass and volume and allows push-frame imaging. The camera common sensor is divided in six portions: four are covered with suitable filters, the others, one looking forward and one backwards with respect to nadir direction, are covered with a panchromatic filter and supply stereo image pairs of the planet surface. The basic STC scientific requirements are to reconstruct the Mercury surface with a vertical accuracy better than 80 m and an imaging grid size of 65 m at periherm.

Scope of this work is to present the on-ground geometric calibration pipeline for a so unique instrument. Classical push-broom camera present a simpler distortion definition. STC offers on the other side all the advantages of a push-frame instrument but a delicate configuration considering the photogrammetric purposes of STC and the harsh environment where it will work.

The selected STC off-axis configuration obliges to change the classical definition of the distortion map, this is a delicate argument in the photogrammetric field where the stereo matching process needs pinhole undistorted or orthorectified images as first input of the DTM processor pipeline.

Additional considerations are connected to the detector, a Si-Pin hybrid CMOS, which is characterized by a high fixed pattern noise. This had a great impact in pre-calibration phases compelling to use a not common approach to the definition of the spot centroids in the distortion calibration process.

Thermic variability is another issue worth to be analysed, as also shown by other missions (as NASA MESSENGER) on Mercury; thus, different temperature effects on the distortion model for both the panchromatic channels of the instrument have been taken in account.

A specific set-up has been realized for the geometrical distortion calibration in cleanroom It is composed by a lens collimator, and a flat steering mirror mounted on a double axis rotational stage to redirect the collimated light beam with the desired inclination toward STC input aperture. A second rotational stage is able to handle the thermal-vacuum camera, containing the STC instrument, in order to select one STC sub-channel or the other.

This work presents the results obtained by the distortion calibration of STC, for three different temperatures. These results are then used to define the corresponding distortion models of the camera.

9904-31, Session 8

Development of compact metal-mirror image slicer unit for optical telescope of the SOLAR-C mission

Yoshinori Suematsu, National Astronomical Observatory of Japan (Japan); Kosuke Saito, Masatsugu Koyama, Yukiya Enokida, Yukinobu Okura, Tomonao Nakayasu, Takashi Sukegawa, Canon Inc. (Japan)

The SOLAR-C is a Japan-led international solar mission designed to investigate the magnetic activities of the Sun, focusing on the study in heating and dynamical phenomena of the chromosphere and corona. For these purposes, SOLAR-C will carry three dedicated instruments; the Solar UV-Vis-IR Telescope (SUVIT), the EUV Spectroscopic Telescope and the High Resolution Coronal Imager, to jointly observe the entire visible solar atmosphere with essentially the same high spatial resolution (0.1-0.3 arcsec), performing high resolution spectroscopic measurements over all atmospheric regions and spectro-polarimetric measurements from the photosphere through the upper chromosphere. The SUVIT is a meter-class telescope in order to grasp sufficient spatial resolution and S/N ratios. The SUVIT spectro-polarimeter for spectral lines such as Fe I 525 nm, Ca II 854 nm, and He I 1083 nm should be equipped with a powerful integral field unit to grasp the rapidly changing chromospheric phenomena with about 10 arcsec x 10 arcsec field-of-view. Integral field spectroscopy is a two dimensional spectroscopy, providing spectra simultaneously for each spatial direction of an extended two-dimensional field. From the view point of a high efficiency spectroscopy, a wide wavelength coverage and a precision spectro-polarimetry, the mirror image slicer is the best option. The role of the image slicer unit (IFU) is to couple between the telescope and the spectrograph by reformatting optically a rectangular field into a quasi-continuous pseudo-slit located at the entrance focal plane of the spectrograph. The mirror image slicers are presently limited either by their risk in the case of glass polishing techniques or by their performances when constituted by metallic mirrors. We present an innovative optical design for IFU and manufacturing method to attain high performances of micro image slicer; accurate roughness, sharp edges, surface form, etc., using a novel technique developed by Canon. The IFU consists of image slicer of 45 arrayed 30-micron-thick metal mirrors and a pseudo pupil mirror array for three pseudo-slits, providing possible optical configuration for a coexistence with a conventional single-slit spectrograph. We confirmed that the surface roughness, the surface accuracy and the tilt errors of all surfaces of a prototype pupil mirror are less than 1.3 nm rms, 59 nm PV and 4.6 arcsec, respectively.?The IFU mirrors were deposited by a protected silver coating for high reflectivity. The IFU need to be equipped with a field lens at the slit plane to feed telecentric beam into

the spectrograph. We describe the optical design, performance of IFU and space qualification of the silver coating for SOLAR-C SUVIT.

9904-32, Session 9

Wide-Field InfraRed Survey Telescope (WFIRST) slitless spectrometer: design, prototype, and status

Qian Gong, David A. Content, Margaret Dominguez, NASA Goddard Space Flight Ctr. (United States); Ulf Griesmann, National Institute of Standards and Technology (United States); John G. Hagopian, Sigma Space Corp. (United States); Alden S. Jurling, Jeffrey W. Kruk, Catherine T. Marx, Thomas E. Wallace, NASA Goddard Space Flight Ctr. (United States); Arthur L. Whipple, SGT, Inc. (United States)

The slitless spectrometer plays an important role in the WFIRST/AFTA mission for the survey of emission-line galaxies. This will be an unprecedented very wide field, HST quality 3D survey of emission line galaxies. The concept of the compound grism has been presented previously. This presentation briefly discusses the challenges and solutions of the optical design, and recent specification updates, as well as a brief comparison between the prototype and the latest design. However, the emphasis of this presentation is the progress of the grism prototype: the fabrication and test of the complicated diffractive optical elements and powered prism, as well as grism assembly design and alignment. Especially how to use different tools and methods, such as phase shift interferometry and Point Diffraction Interferometry (PDI), and phase retrieval, to complete the element and assembly tests. The paper also discusses the cryogenic test plan, to be performed after the ambient test on the prototype grism assembly. Finally we briefly touch how the test results will be used to improve the flight spectrometer design during phase A.

9904-33, Session 9

Canadian contributions study for the WFIRST coronagraph instrument

Jean-Francois Lavigne, ABB Analytical Measurement (Canada); Frédéric J. Grandmont, ABB Inc. (Canada); David Lafrenière, Univ. de Montréal (Canada); Christian Marois, NRC - Herzberg Astronomy & Astrophysics (Canada); Olivier Daigle, Nüvü Caméras Inc. (Canada); Simon Thibault, Univ. Laval (Canada); Neil Rowlands, COM DEV Canada (Canada); David Schade, NRC - Herzberg Astronomy & Astrophysics (Canada); Étienne Artigau, Univ. de Montréal (Canada) and Univ. McGill (Canada); Denis Brousseau, Univ. Laval (Canada); Jérôme Maire, Univ. of Toronto (Canada); Gabrielle Cretot-Richert, Marie-Ève Ducharme, Nüvü Caméras Inc. (Canada); Luc E. Levesque, ABB Inc. (Canada); Denis Laurin, Jean Dupuis, Canadian Space Agency (Canada)

WFIRST-AFTA is the top American mission that was identified in the New World, New Horizon survey. This mission will provide insights in key modern astrophysical questions through a high-latitude survey to study dark energy, a galactic bulge survey to detect microlensing events for large orbit and free-floating companion detection, coronagraphic observations of cold planets and of proto-planetary discs and a Guest Observer Program. This will be done with two main instruments, a wide field imager and a coronagraphic instrument. There is a great interest in having an international collaboration in this mission that addresses some of the deep questions identified in the Canadian LRP2010. In this context, the Canadian Space Agency has awarded two contracts to study a Canadian participation in the mission, one related to each instrument. This paper reports the results of the study for the coronagraphic instrument, its potential impact on the Canadian science and on the Canadian industry.

9904-34, Session 9

The WFIRST coronagraph instrument: from technology advancement to flight design

Richard T. Demers, Jet Propulsion Lab. (United States)

The Wide Field InfraRed Survey Telescope (WFIRST) is a NASA space observatory that has been designed to probe dark energy, to carry out wide-field near infrared (NIR) surveys, and to discover and characterize extrasolar planets (hereafter exoplanets) in the visible spectrum. WFIRST observatory will make use of an existing 2.4-m aperture Astrophysics Focused Telescope Asset (AFTA) and will advance what is currently possible in exoplanet spectral characterization and imaging. The AFTA coronagraph also matures direct imaging technologies to high TRL for an Exo-Earth Imager in the next decade. The coronagraph will carry out direct imaging and detailed visible spectroscopy of a sample of exoplanets. The coronagraph will be able to detect and characterize cold Jupiters, mini-Neptunes, and possibly super-Earths and for the first time directly image planets analogous to those in our solar system. This spectroscopic characterization will reveal the atmospheric composition of these planets and will be used to search for spectral signatures of life. In addition, the coronagraph will be used to characterize debris disks in and around planetary orbits—an important tool that can be used to improve our understanding of planet formation.

The coronagraph Design Reference Mission (DRM) optical design is based on the highly successful High Contrast Imaging Testbed (HCIT), with modifications to accommodate the AFTA telescope design, service-ability, volume constraints, and the addition of an Integral Field Spectrograph (IFS). In order to optimally satisfy the three science objectives of planet imaging, planet spectral characterization and dust debris imaging, the coronagraph is designed to operate in two different modes: Hybrid Lyot Coronagraph or Shaped Pupil Coronagraph. Active mechanisms change pupil masks, focal plane masks, Lyot masks, and bandpass filters to shift between modes. A single optical beam train can thus operate alternatively as two different coronagraph architectures.

In order to adequately form images and collect spectra of exoplanets, it is necessary to suppress the starlight to a contrast of order 10?9 for cold Jupiters, mini-Neptunes, and super-Earths. The coronagraph accomplishes this by using (1) a series of masks to reject starlight, to block diffracted light, and to reduce starlight speckles, and (2) an adaptive optics system, employing a pair of deformable mirrors (DMs) in order to eliminate residual speckles due to optical imperfections in the entire optical beamtrain. When carrying out planet discovery, photometry, and disk imaging, the coronagraph relays an image of the high-contrast “dark hole” onto the imaging camera. A stationary polarizing beam splitter in front of the imaging camera separates the dark hole image into two orthogonal polarizations, whose two resulting images fill a small rectangular area of the detector. When taking planetary spectra, by contrast, the Integral Field Spectrograph (IFS) images a regular grid of spectrally dispersed PSFs onto the detector. The very low expected photon count requires sub-electron read noise, dark current, and clock-induced charge (CIC) to carry out planet spectroscopy.

9904-35, Session 9

WFIRST-AFTA coronagraph starlight suppression technology progress

Ilya Y. Poberezhskiy, Feng Zhao, Kunjithapatham Balasubramanian, Jet Propulsion Lab. (United States); Ruslan Belikov, NASA Ames Research Ctr. (United States); Eric J. Cady, Brian L. Gordon, Frank Greer, Jet Propulsion Lab. (United States); Olivier Guyon, The Univ. of Arizona (United States); N. Jeremy Kasdin, Princeton Univ. (United States); Brian D. Kern, John E. Krist, Duncan Liu, David S. Marx, Camilo M. Prada, Dwight C. Moody, Keith D. Patterson, Jet Propulsion Lab. (United States); A. J. E. Riggs, Princeton Univ. (United States); Daniel J. Ryan, Byoung-Joon Seo, Fang Shi, Erkin Sidick, Hong Tang, John T. Trauger, James K. Wallace, Daniel W. Wilson, Victor E. White, Karl Y. Yee, Hanying Zhou, Jet Propulsion Lab. (United States); Neil T. Zimmerman, Space Telescope Science Institute (United States)

NASA's WFIRST-AFTA mission will use an existing 2.4 meter diameter telescope and include an active, high-contrast stellar coronagraph instrument that will be capable of directly imaging and spectrally characterizing exoplanets and circumstellar disks in reflected starlight. NASA has selected the Occulting Mask Coronagraph (OMC) that combines two well-known starlight suppression approaches, Shaped Pupil and Hybrid Lyot, as the primary design for WFIRST, and the Phase-Induced Amplitude Apodization Complex Mask Coronagraph (PIAACMC) as the backup design.

Since early 2014, both the primary and backup coronagraph technologies have been aggressively matured to demonstrate (1) the performance and space flight readiness of the key starlight suppression components designed for WFIRST and (2) the ability of the coronagraph to achieve the required level of starlight suppression with the WFIRST-AFTA telescope "as is," including its obscured pupil, expected thermal drifts, and the observatory pointing jitter. NASA's timeline calls for bringing the system level coronagraph to Technology Readiness Level (TRL) 5 in 2016, with 9 independently reviewed milestones to track the technology progress along the way. The first 6 of these 9 WFIRST coronagraph milestones were met on schedule in 2014 and 2015. These milestones have demonstrated that:

1. The novel occulting and pupil apodization masks for starlight suppression with WFIRST-AFTA telescope can be successfully fabricated for all primary and backup starlight suppression approaches

2. The coronagraph has demonstrated repeatable convergence to a high level of starlight suppression in a vacuum testbed with WFIRST telescope pupil. The testbed results show consistent convergence to better than 10-8 average contrast in 10% broadband light between 3 and 9 ?/D for both Hybrid Lyot and Shaped Pupil OMC modes.

3. Operation of the low order wavefront sensing and control subsystem that uses the starlight rejected by the coronagraph to measure and correct observatory pointing jitter and thermal drifts to the level needed to observe the exoplanet targets.

During the course of 2016, the fidelity of the testbed demonstrations will increase further, with the new testbed design closely following the flight instrument, and a sophisticated optical telescope assembly simulator to inject the wavefront disturbances expected on orbit into the coronagraph. All these accomplishments and up-to-date WFIRST coronagraph technology progress will be summarized.

9904-36, Session 9

Exoplanet and disk detection with the WFIRST coronagraph

Wesley A. Traub, Jet Propulsion Lab. (United States)

The Coronagraph Instrument (CGI) on the planned WFIRST mission will detect and characterize reflected-light images and spectra from exoplanets and dust disks around nearby stars. The CGI will operate in several visible wavelength bands, and will be able to take polarized-light images of exoplanets and disks, as well as obtaining spectra. Recent advances in the science and technology of the CGI are improving our ability to forecast the sensitivity and limits of this instrument. This paper presents the current status of our expectation for science results, including recent advances in our understanding of targets, backgrounds, and instrument and detector performance.

9904-37, Session 10

Managing the optical wavefront for high contrast exoplanet imaging with the WFIRST-AFTA coronagraph

John T. Trauger, Dwight C. Moody, John E. Krist, Jet Propulsion Lab. (United States)

The prospect of extreme high contrast astronomical imaging from space has inspired developments of new coronagraph methods for exoplanet imaging and spectroscopy. However, the requisite contrast, at levels of a billion to one or better for the direct imaging of cool mature exoplanets in reflected visible starlight, leads to challenging new requirements on the stability and control of the optical wavefront at levels currently beyond the reach of ground based telescopes. We review the designs, laboratory validations, and science prospects for direct imaging and spectroscopic characterization of exoplanet systems with an actively corrected Lyot coronagraph. We review exoplanet science performance predicted for NASA's WFIRST-AFTA coronagraph. Together with a pair of deformable mirrors for optical wavefront control, the Lyot coronagraph creates high contrast dark fields of view extending to angular separations within 0.1 arcsec from the central star at visible wavelengths. Performance metrics are presented, including image contrast and spectral bandwidth, and laboratory validation experience.

9904-38, Session 10

Low-order wavefront sensing and control for WFIRST coronagraph

Fang Shi, Kunjithapatham Balasubramanian, Randall C. Hein, Raymond K. Lam, Milan Mandic, Douglas M. Moore, James Moore, Keith D. Patterson, Ilya Y. Poberezhskiy, Joel F. Shields, Erkin Sidick, Hong Tang, Tuan Truong, James K. Wallace, Xu Wang, Daniel W. Wilson, Jet Propulsion Lab. (United States)

NASA's WFIRST Coronagraph will be capable of directly imaging and spectrally characterizing giant exoplanets similar to Neptune and Jupiter, and possibly even super-Earths, around nearby stars. To maintain the required performance of WFIRST Coronagraph in a realistic space environment, a Low Order Wavefront Sensing and Control (LOWFS/C) subsystem is necessary. The LOWFS/C will use the rejected stellar light from coronagraph to sense and suppress the telescope line-of-sight (LoS) pointing drift and jitter as well as low order wavefront drifts due to the changes in thermal loading of the telescope and the rest of the observatory. The LOWFS/C uses a Zernike wavefront sensor (ZWFS)

with the phase shifting disk combined with the stellar light rejecting occulting mask, a key concept to minimize the non-common path error. For wavefront corrections, WFIRST LOWFS/C uses a dedicated fast steering mirror (FSM) for line-of-sight correction, a focusing mirror for focus drift correction, and one the two deformable mirrors (DM) for other low order wavefront modes correction. Detailed diffraction modeling and analysis have been done to evaluate the performance of LOWFS/C for WFIRST Coronagraph. Developed as a part of the Dynamic High Contrast Imaging Testbed (DHCIT) for the WFIRST technology development, the LOWFS/C subsystem also consists of an Optical Telescope Assembly (OTA) Simulator to generate the realistic wavefront error and LoS drift and jitter from WFIRST telescope's vibration and thermal changes. The entire LOWFS/C subsystem has been integrated, calibrated, and tested in a dedicated LOWFS/C testbed. The testbed results have shown that the Zernike WFS have line-of-sight tilt sensitivity better than 0.2 milli-arcsec and closed-loop post correction residual better than 0.4 milli-arcsec with the presence of the WFIRST-AFTA like LoS drift and jitter (14 milli-arcsec). After the stand alone test on the LOWFS/C testbed the LOWFS/C subsystem including OTA Simulator has been integrated into the DHCIT. In this paper we will describe the LOWFS/C subsystem and present the LOWFS/C performance testbed results as well as the preliminary results of LOWFS/C subsystem working together with the coronagraph on the DHCIT.

9904-39, Session 10

Closing the contrast gap between testbed and model prediction with WFIRST-AFTA shaped pupil coronagraph

Hanying Zhou, Bijan Nemati, John E. Krist, Eric J. Cady, Camilo M. Prada, Brian D. Kern, Ilya Y. Poberezhskiy, Jet Propulsion Lab. (United States)

JPL has recently passed an important milestone in its technology development for a proposed NASA WFIRST-AFTA mission: demonstration of a better than 1e^-8 contrast over broad bandwidth (10%) on both shaped pupil coronagraph and hybrid Lyot coronagraph testbeds with AFTA telescope optics. Challenges remain, however, in the technology readiness for the proposed mission. One such is the discrepancy between the achieved contrast on testbed and that from model prediction. To close the contrast gap between model prediction and actual testbed performance, a series of testbed diagnosis and modeling activity were planned and some have been carried out. A very effective approach we find is to compare and analyze the measured testbed Jacobian matrix and a model-based control Jacobian that is used to control image plane speckle (in a high contrast coronagraph that uses electric field conjugation algorithm for wavefront sensing and control, Jacobian is the image plane complex electric field sensitivity to a pupil plane DM actuator poke). The difference between these two is the error in the control Jacobian (including both amplitude and phase). We show that the level and nature of this error closely explains the contrast performance discrepancy observed in terms of contrast floor and contrast convergence speed, when the error is inserted into a simulation model for coronagraph contrast prediction. This offers a new perspective and represents a big step forward in the model validation for better prediction and understanding of testbed contrast performance limit. It also provides clues to the possible sources for mismatch and points direction for potential testbed improvement. Further simulation on Jacobian error source offers more specific sources for the apparent mismatch. Modifications to both testbed control model as well as prediction model are being implemented.

9904-40, Session 10

Hybrid Lyot coronagraph for WFIRST-AFTA: occulter fabrication and high contrast broadband testbed demonstration

Byoung-Joon Seo, Brian L. Gordon, Brian D. Kern, Andreas C. Kuhnert, David S. Marx, Dwight C. Moody, Richard E. Muller, Ilya Y. Poberezhskiy, John T. Trauger, Daniel W. Wilson, Jet Propulsion Lab. (United States) and California Institute of Technology (United States)

Hybrid Lyot Coronagraph (HLC) is one of the two operating modes of the WFIRST-AFTA coronagraph instrument. It produces starlight suppression over full 360 degrees annular region and thus is particularly suitable for discovery of unknown exoplanets. Since being selected by National Aeronautics and Space Administration (NASA) in December 2013, the coronagraph technology is being matured to Technology Readiness Level (TRL) 5 by September 2016. We present the up-to-date progress of HLC key component fabrication and testbed demonstrations with the WFIRST-AFTA pupil. Circular HLC occulter masks consisting of metal and dielectric layers have been fabricated and characterized. Wavefront control using two deformable mirrors is successfully demonstrated in a vacuum testbed with 10% broadband light centered at 550 nm. As a result, we obtain repeatable convergence below 1E-8 mean contrast in the 360 degrees dark hole with working angle between 3 ?/D and 9 ?/D. We present the hardware and software used in the testbed, the results and the associated analysis, including preliminary estimates of exoplanet yield consistent with the results obtained in the testbed.

9904-41, Session 11

The LATT way towards large active primaries for space telescopes

Runa Briguglio, Marco Xompero, INAF - Osservatorio Astrofisico di Arcetri (Italy); Carmelo Arcidiacono, INAF - Osservatorio Astronomico di Bologna (Italy); Franco Lisi, Armando Riccardi, INAF - Osservatorio Astrofisico di Arcetri (Italy); Roberto Biasi, Christian Patauner, Microgate S.r.l. (Italy); Daniele Gallieni, Paolo Lazzarini, Matteo Tintori, A.D.S. International S.r.l. (Italy); Francesco d'Amato, Istituto Nazionale di Ottica (Italy) and Consiglio Nazionale delle Ricerche (Italy); Mauro Pucci, Istituto Nazionale di Ottica (Italy); Fabrizio Duò, Christian Vettore, CGS S.p.A. Compagnia Generale per lo Spazio (Italy); Alessandro Zuccaro Marchi, European Space Research and Technology Ctr. (Netherlands) and European Space Agency (France)

The Large Aperture Telescope Technology (LATT) goes beyond the current paradigm of future space telescopes, based on a deformable mirror in the pupil relay.

Through the LATT project we demonstrated the concept of a low-weight active primary mirror, whose working principle and control strategy benefit from two decades of advances in adaptive optics for ground-based telescopes. We developed a forty centimeter spherical mirror prototype, with an areal density lower than 22kg/m2, controlled through contactless voice coil actuators with co-located capacitive position sensors. The prototype was subjected to thermo-vacuum, vibration and optical tests, pushing its technical readiness toward level 5.

In this paper we present the background and the outcomes of the LATT

activities under ESA contract, exploring the concept of a lightweight active primary mirror for space telescopes. Active primaries will open the way to very large segmented apertures, actively shaped, which can be lightweight, deployable and accurately phased once in flight.

9904-42, Session 11

Telescope polarization and image quality: uncompensated polarization aberrations

James B. Breckinridge, College of Optical Sciences, The Univ. of Arizona (United States) and California Institute of Technology (United States); W. T. Lam, Russell A. Chipman, College of Optical Sciences, The Univ. of Arizona (United States)

Uncompensated polarization aberrations limit radiometric precision, reduce coronagraph contrast, modify recorded spectra and limit precision astrometry. Optical systems for astronomy are designed, optimized and built using scalar diffraction and geometric aberration theory and hardware. However current astronomical science measurement objectives require high quality imaging only possible using the analysis tools of vector diffraction, partial coherence, non-linear image processing and polarization aberration analysis along with their associated hardware devices and software image processing methods.

This paper presents results of modeling a “typical” telescope for vector diffraction, monochromatic & polychromatic polarization-aberrations and discusses their effects on coronagraph contrast and allowable filter bandwidth, field-dependent PSF asymmetry, transmittance, field of view and calibration. If we are to achieve system performance at these levels: 1. <100nm wavelength, 2. <1% exit pupil spatial uniformity, 3. <0.02% residual polarizance and 4. Maximum phase and amplitude transmittance, over scientifically interesting FOV’s, then polarization aberrations must to be considered in the design and fabrication of modern astronomical telescopes and instruments.

We show that the performance of the WFIRST-coronagraph system will be limited by uncorrected polarization aberrations and discuss several polarization aberration mitigation approaches.

9904-43, Session 11

Innovative focal plane design for large space telescopes

Wilfried Jahn, Emmanuel Hugot, Marc Ferrari, Lab. d’Astrophysique de Marseille (France)

In the frame of a CNES R&T project, LAM and CNES are studying the reorganization of focal plane on scan-drift telescopes for VIS/IR applications. Indeed, physical dimensions of future large scan drift space telescopes are increased leading more complex, massive and bulky systems. In order to reach higher image quality and sensitivity keeping a large field of view, the use of homothetic imaging systems is prohibitive. We present an innovative approach based on the Integral Field Units already used on ground based instrumentation. The idea is to reimage a linear field of view on a 2D detector array, by use of a set of segmenting mirrors. For infrared instruments used in space applications, the volume of the cryostat used to cool down the detectors array is a dimensioning parameter for the lifetime of the mission. This new technology would allow a significant reduction of the size of such space systems. We present studies done so far on optical system design and the first technological demonstrator we developed.

9904-44, Session 11

The CaSSIS imager and FPA: integration and optical performance overview

Lisa Gambicorti, Daniele Piazza, Antoine Pommerol, Victoria Ann Roloff, Michael Gerber, Ruth Ziethe, Mohamed Ramy El-Maarry, Univ. Bern (Switzerland); Thomas Weigel, Michael Johnson, Dervis Vernani, Elena Pelo, RUAG Space AG (Switzerland); Vania Da Deppo, IFN-CNR LUXOR Lab. (Italy); Iacopo Ficai Veltroni, SELEX ES S.p.A. (Italy); Gabriele Cremonese, INAF - Osservatorio Astronomico di Padova (Italy); Nicolas Thomas, Univ. Bern (Switzerland)

The CaSSIS camera (Colour and Stereo Surface Imaging System) is the high-resolution color and stereoscopic imager of the instrument payload on board of the ESA space mission EXOMARS 2016 TGO (Trace Gas Orbiter).

CaSSIS will provide detailed observations to investigate dynamic processes (e.g. sublimation, erosional processes, volcanism) on the Mars surface with a spatial scale of 4.6 m per pixel from an altitude of 400 km (horizontal scale). The CaSSIS stereo capability is based on rotation mechanism that allows the camera to look 10 degrees ahead and 10 degrees behind the spacecraft track acquiring a stereo pair of images of the same area during the same orbit. The stereoscopic reconstruction enables a vertical resolution of about six meters (vertical scale).

The CaSSIS optical system is based on a TMA telescope (Three Mirrors Anastigmatic configuration) with a 4th powered folding mirror compacting the CFRP (Carbon Fiber Reinforced Polymer) structure. The camera EPD (Entrance Pupil Diameter) is 135 mm, and the focal length is 880 mm, giving an F# 6.5; the wavelength range covered by the instrument is 400-1100 nm. The optical system is designed with distortion less than 2% and a worst case MTF (Modulation Transfer Function) of 0.3 at the detector Nyquist spatial frequency (i.e. 50 lp/mm).

The Focal Plane Assembly (FPA) detector is a spare component of the Simbio Sys instrument of the Italian Space Agency (ASI). Simbio Sys will fly on ESA’s Bepi Colombo mission to Mercury. The detector developed by Raytheon Vision Systems is a 2kx2k hybrid Si-PIN array with a 10 ?m pixel allows snapshot operation at a read-out rate of 5 MPixel/s with 14 bit resolution. CaSSIS will operate in push-frame mode with a filter strip assembly (FSA) selecting 4 color bands, integrated by Selex ES (under TAS-I responsibility) directly above the detector sensitive area.

The University of Bern was in charge of the full instrument integration as well as the characterization of the focal plane. The paper will present an overview of CaSSIS and the optical performance of the telescope and FPA. The preliminary results of the on-ground calibration campaign will be described in detail.

9904-184, Session PS6

Correcting for the effects of pupil discontinuities with the ACAD method

Johan Mazoyer, Laurent Pueyo, Space Telescope Science Institute (United States); Colin A. Norman, Johns Hopkins Univ. (United States); Mamadou N’Diaye, Space Telescope Science Institute (United States); Dimitri Mawet, California Institute of Technology (United States)

The current generation of ground-based coronagraphic instruments uses deformable mirrors to correct for phase errors and to improve contrast levels at small angular separations. However, as wavefront control techniques improve, more complex telescope pupil geometries (support structures, segmentation) will be a limiting factor for the next generation

of coronagraphic instruments. The Active Compensation of Aperture Discontinuities (ACAD) method is based on the resolution of the non-linear Monge-Ampere two-mirror propagation equations to calculate the deformable mirror shape solutions that cancel the effects of discontinuities in the pupil for any pupil geometry and any coronagraph used. Taking advantage of the fact that most future coronagraphic instruments will include two deformable mirrors, this technique will allow the use of any coronagraph designed for continuous apertures with complex segmented apertures and secondary mirror support structures, with high throughput, and flexibility to adapt to changing pupil geometry, e.g. in case of segment failure or maintenance of the segments. We here present a study on several pupil geometries (segmented Large UV optical IR –LUVOIR– telescope, off-axis segmented telescope, WFIRST, ELTs) for which we obtained high contrast levels with several deformable mirror setups (size, number of actuators, separation between them), coronagraphs (Vortex, APLC) and spectral bandwidths. However, because contrast level and separation are not the only metrics to maximize the scientific return of an instrument, we also included in this study the influence of these deformable mirror shapes on the throughput of the instrument, sensitivity to pointing jitters and outer and inner working angles.

9904-185, Session PS6

A four mirror anastigmat collimator design for optical payload calibration

Stephen Rolt, Ariadna Z. Calcines, Bart A. Lomanowski, David G. Bramall, Durham Univ. (United Kingdom)

We present here a four mirror anastigmatic optical collimator design intended for the calibration of an earth observation satellite instrument. Specifically the collimator is to be applied to the ground based calibration of the Sentinel-4/UVN instrument. This imaging spectrometer instrument is expected to be deployed in 2019 in a geostationary orbit and will make spatially resolved spectroscopic measurements of atmospheric contaminants.

The purpose of the collimator is to provide collimated light within the two instrument passbands in the UV-VIS (305 – 500 nm) and the NIR (750 – 775 nm). Moreover, that collimated light will be derived from a variety of slit like objects located at the input focal (object) plane of the collimator which is uniformly illuminated by a number of light sources. The collimator must relay these objects with exceptionally high fidelity. To this end, the wavefront error of the collimator should be less than 20 nm rms across the collimator field of view. This field is determined by the largest object which is a large rectangular slit, 4.4° x 0.25°. Other important considerations affecting the optical design are the requirements for input telecentricity and the size (85 mm) and location (2500 mm 'back focal distance') of the exit pupil.

The requirement for diffraction limited performance across a very wide spectral range suggests the use of a mirror design. Since defocus forms part of the wavefront error requirement, the design must be substantially achromatic. Correction of the five primary Gauss-Seidel aberrations would, at first sight, require the use of three mirrors. This forms the basis of the well-known Three Mirror Anastigmat (TMA) design. However, in this case an additional constraint is imposed – that of telecentricity. Therefore, in this design an additional mirror is introduced to provide an extra degree of freedom. As with the TMA, this four mirror anastigmat design uses off axis conics.

Extensive tolerancing analysis of the design has been carried out and is reported here. For the majority of the mirrors, the form error must be less than 10 nm rms. Whilst this is within manufacturing tolerances, it does pose a significant challenge. The tolerancing and sensitivity analysis described also impacts the system alignment strategy which is also outlined here. Great attention has also been paid to the mechanical design and, in particular, the mounting of the individual mirrors. Significant mounting distortions must be avoided in any event and the design of suitable mirror mounts is described in some detail. The impact of thermal distortions is also described.

As a calibration source for a spectroscopic instrument, an important part of the calibration exercise is the characterisation of stray light. Therefore, the straylight produced by this collimator design must be characterised in detail and minimised as far as possible. Results of a non-sequential straylight model are presented in detail and strategies for minimising scattered light are discussed.

9904-186, Session PS6

Xenon arc lamp spectral radiance modelling for satellite instrument calibration

Stephen Rolt, Paul Clark, Jurgen Schmoll, Benjamin J. Shaw, Durham Univ. (United Kingdom)

Precise radiometric measurements play a central role in many areas of astronomical and terrestrial observation. We focus on the use of continuum light sources in the absolute radiometric calibration of detectors in an imaging spectrometer for space applications. The application, in this instance, revolves around the ground based calibration of the Sentinel-4/UVN instrument. This imaging spectrometer instrument is expected to be deployed in 2019 and will make spatially resolved spectroscopic measurements of atmospheric chemistry.

Of key importance to the fidelity of these measurements is the ground based calibration campaign. When deployed, the instrument will compare the spectral radiance of the of the Earth's atmosphere with the (variable) solar irradiance. These measurements will be made using two separate paths, the 'Earth Port' and the 'Sun Port'. Knowledge of the relative sensitivities of these two optical paths is essential to the function of the instrument. A major part of this calibration process will involve a comparison of the ratio of these two sensitivities using a highly stable continuum light source. This light source will cover the two spectral ranges of the instrument, namely the UV-VIS (305-500 nm) and the NIR (750-775 nm). A short arc xenon lamp is to be the primary source in this calibration process.

Xenon short arc lamps provide highly intense and efficient continuum illumination in a range extending from the ultra-violet to the infra-red and their spectrum is well matched to this specific application. Despite their widespread commercial use, certain aspects of their performance are not well documented in the literature. One of the important requirements in this calibration application is the delivery of highly uniform, collimated illumination at high radiance. In the design of optical modules to deliver this uniform illumination, it cannot be assumed that the xenon arc is a point source; the spatial distribution of the radiance must be characterised to assist with optical design process. We present here careful measurements that thoroughly characterise the spatial distribution of the spectral radiance of a 1000W xenon lamp. These results are analysed in order to describe the spatial distribution with a simple mathematical model.

Temporal stability is another exceptionally important requirement in the calibration process. As such, the paper also describes strategies to re-inforce the temporal stability of the lamp output by means of a closed loop attenuation scheme and current control. Although the use of current control and output stability is extensively covered in the literature, there is one specific aspect that has received little attention. The xenon arc spectrum, whilst, for the most part a continuum, does contain a number of highly broadened atomic line features, mostly from Xe I and Xe II. The variation in output of these lines with lamp current is different when compared to that of the continuum emission. Some of the lines display a degree of saturation in output with respect to current. Variation of the relative strength of these lines with respect to the continuum could be of significance in the spectral calibration process. This is discussed in detail.

9904-187, Session PS6

Application of Peterson's stray light model to complex optical instruments

Sebastian Fray, OHB System AG (Germany); Michael Göpel, OHB-System AG (Germany); Monika Kroneberger, OHB System AG (Germany)

Gary L. Peterson (Breault Research Organization) presented a simple analytical model for in-field stray light evaluation. It assumes axial optical systems with rotational symmetry. Modelling the scatter distribution on each surface by Harvey-Shack parameters Peterson's approach describes the scattered ray cone at each optical surface in terms of marginal and chief rays and makes use of the optical invariant to trace them through the optical system. Assuming field points close to optical axis the model is able to give an analytical expression for the spatial distribution of the in-field stray light on the focal plane.

Since this approach allows a flexible and fast response within an engineering development cycle, we applied Peterson's idea to the more complex optical instruments of the Meteosat Third Generation (MTG) mission. For the Flexible Combined Imager (FCI) we evaluated the in-field stray light contribution of the front telescope assembly. It is a three-mirror-anastigmat (TMA) with an off-axis angle of 1.4°. For the infrared sounder (IRS) we performed an end-to-end analysis including the front telescope (TMA), interferometric and back telescope assembly and the cold optics. The analytical expressions are adapted to match the way the requirements are formulated. Results are compared with corresponding ASAP (stray light analysis software) simulations for both instruments. Applications for further optical and requirement engineering will be presented.

The MTG Program is being realised through the well-established cooperation between EUMETSAT and ESA. The industrial prime contractor for the space segment is Thales Alenia Space (France) with a core team consortium including OHB-Bremen (Germany) and OHB-Munich (Germany).

The authors acknowledge that this work is supported by an ESA funding through the MTG satellites development.

9904-189, Session PS6

Status of the ISS: image stabilisation system of the high-resolution telescope PHI on board of Solar Orbiter

Reiner Volkmer, Jörg Baumgartner, Thomas Berkefeld, Kiepenheuer-Institut für Sonnenphysik (Germany); José Bosch, Manuel Carmona, Albert Casas, José María Gómez, Atilà Herms, Univ. de Barcelona (Spain); Frank Heidecke, Kiepenheuer-Institut für Sonnenphysik (Germany); Manel López, Univ. de Barcelona (Spain); Christoph Kiess, Thorsten Maue, Eiji Nakai, Kiepenheuer-Institut für Sonnenphysik (Germany); David Roma, Univ. de Barcelona (Spain); Wolfgang Schmidt, Dirk Soltau, Kiepenheuer-Institut für Sonnenphysik (Germany)

The polarimetric accuracy of the high-resolution telescope (HRT) PHI on board of Solar Orbiter requires very high precise pointing stability. To achieve the specifications, the jitter of the satellite pointing needs to be compensated by the image stabilisation system (ISS). The ISS will work as a correlation tracker with a piezo-driven Tip-Tilt mirror (M2 of the telescope) and a fast acquisition camera with more than 420 fps.

The presentation shows the performance of the ISS from simulations and laboratory tests in open and closed loop. Reports of the qualification of the already delivered Tip-Tilt drive and camera will be shown.

9904-190, Session PS6

Visible and near-IR detector technology for biosignature characterization

Bernard J. Rauscher, Edgar R. Canavan, Samuel H. Moseley Jr., Carl M. Stahle, Thomas R. Stevenson, NASA Goddard Space Flight Ctr. (United States)

The search for life on other worlds looms large in NASA's 30-year strategic plan. Already, two concepts exist for a flagship Large UV-Optical-IR (LUVOIR) Surveyor coronagraphic space telescope to search for spectroscopic biosignatures: ATLAST and HDST. Other teams are exploring smaller, more focused "probe class" missions to search for potentially habitable worlds. Taken collectively, these missions require technological advances in precision large-scale optics, ultra-stable structures, starlight suppression, mirror coatings, and detectors. Our focus is on visible and IR (VISIR) detectors for spectroscopic biosignature characterization.

NASA has a long and distinguished history building and operating VISIR space telescopes including IRAS, Hubble, Spitzer, JWST, and most recently WFIRST which is in the beginning stages of its mission lifecycle. These missions generally use semiconductor detectors (CCDs, EMCCDs, and IR arrays) for the VISIR. The lowest risk path forward is for LUVOIR to build on this heritage. However, even with a very large LUVOIR, biosignature characterization is still extremely low background astronomy. We discuss the "technology gaps" that exist between what today's semiconductor detectors deliver and the single photon detectors (SPD) that would be optimal for LUVOIR. In addition to high QE (and going beyond "photon counting"), an SPD has effectively no read noise and no dark count rate. With targeted investment, we believe that incremental improvements in the radiation hardness and sensitivity of today's semiconductor detectors are possible. We provide specific recommendations for how these improvement might be realized.

True SPDs (cryogenic detectors including STJ, TES arrays, and more recently MKID arrays), were first used for ground based astronomy about 20 years ago. These superconducting detectors have neither read noise nor dark current in the conventional sense. Moreover, they provide built-in energy resolution that eliminates the need for conventional spectrograph optics. These advantages are at least partly offset by the need for cooling to ~100 mK in the context of a space coronagraph that requires 10s of picometer wavefront error stability. Moreover, current LUVOIR concepts call for an essentially room temperature observatory. We discuss preliminary concepts for providing the required zero vibration cooling that leverage NASA's flight experience. We identify the "technology gaps" that exist between today's TES and MKID arrays and what is required for biosignature characterization. We recommend specific investments to mature both the cryogenic detectors themselves, and zero vibration cooling technology, so that both the detectors and cooling technology will be sufficiently mature in time for a LUVOIR by the mid to late 2020s.

Our recommended investment plan includes both low risk but incremental improvements in semiconductor detectors, and high risk but high payoff development of superconducting technology and zero vibration cooling. A balanced plan that offers both low risk but also the potential for breakthroughs offers the best chance of detecting potentially habitable worlds using space coronagraphs and biosignatures in the next 20 years.

The shadow position sensors (SPS) formation flying metrology subsystem for the ESA-PROBA3 mission: present status and future developments

Mauro Focardi, INAF - Osservatorio Astrofisico di Arcetri (Italy); Steve Buckley, Kevin O'Neill, SensL (Ireland); Alessandro Bemporad, Silvano Fineschi, INAF -

Osservatorio Astrofisico di Torino (Italy); Vladimiro Noce, Maurizio Pancrazzi, Federico Landini, INAF - Osservatorio Astrofisico di Arcetri (Italy); Cristian Baccani, Univ. degli Studi di Firenze (Italy); Gerardo Capobianco, INAF - Osservatorio Astrofisico di Torino (Italy); Davide Loreggia, INAF - Osservatorio Astronomico di Torino (Italy); Marta Casti, INAF - Osservatorio Astrofisico di Torino (Italy) and ALTEC - Advanced Logistics Technology Engineering Ctr. (Italy); Marco Romoli, Univ. degli Studi di Firenze (Italy); Giuseppe Massone, Gianalfredo Nicolini, INAF - Osservatorio Astrofisico di Torino (Italy); Luciano Accatino, AC Consulting (Italy); Cédric Thizy, Jean-Sébastien Servaye, Etienne Renotte, Univ. de Liège (Belgium)

The ESA PROBA3 Mission is the world's first precision formation flying (FF) mission. Two satellites, the OSC (Occulter Spacecraft) and the CSC (Coronagraph Spacecraft) will fly together in a fixed configuration, when observing at the Sun, as a large rigid structure in space to prove formation flying technologies and to observe the Sun corona at the same time.

The paired satellites will together form a 150 m long solar coronagraph whose aim is to study the faint corona closer to the solar limb than has ever before been achieved. Beside its scientific interest, the experiment will probe the instrument capability to measure the relative attitude and the positioning of the two spacecraft with respect to the Sun. To achieve the required performances (50 ?m transversal and 1 mm longitudinal accuracies are required) and to maintain the relative (i.e. between the two satellites) and absolute (i.e. with respect to the Sun) FF attitude, the Shadow Position Sensor (SPS) subsystem has been foreseen and designed along with some different spacecraft and payload devices dedicated to this function.

This subsystem is based on two independent sets (nominal and redundant) of four silicon photomultipliers able to sense the faint Sun coronal light with the required sensitivity and dynamic range as well. In order to determine the fine pointing of the two spacecraft to the Sun all the measurements coming from a set of devices will be combined thanks to a special algorithm based on a fitting procedure on the in-flight expected illumination profile. The latter shall be in-flight checked and re-calibrated with respect to the achieved profile thanks to the laboratory FF scaled model taking also into account the effects of the light diffracted by the edge of the external occulter hosted by the OSC.

The SPS subsystem error budget has been derived considering the error due to the algorithms fitting procedure as well as other sources of noise limiting the measurement accuracy, as the OSC tilt with respect to the CSC. Tilt, being one of the most important error terms, once properly assessed, could lead to a revised algorithm able to account also for the potential increasing of the number of degrees of freedom bonded to the tilt amplitude and requiring more SPS independent measurements. At the same time, the SPS flange is going to be designed taking into account several requirements concerning the measurements procedure, on-ground and in-flight calibrations and subsystem cleanliness as well.

This paper presents the recent advancements concerning the SPS subsystem design, its developed breadboard and Development Model (DM) as well as some preliminary tests performed on them, before going to realize the Structural and Thermal Model (STM), as required by the subsystem model philosophy.

9904-192, Session PS6

Preliminary evaluation of the diffraction behind the PROBA-3/ASPIICS optimized occulter

Cristian Baccani, Univ. degli Studi di Firenze (Italy); Federico Landini, INAF - Osservatorio Astrofisico di Arcetri (Italy); Marco Romoli, Univ. degli Studi di Firenze (Italy); Matteo Taccola, European Space Research and Technology Ctr. (Netherlands); Hagen Schweitzer, LightTrans International UG (Germany); Silvano Fineschi, Alessandro Bemporad, Davide Loreggia, INAF - Osservatorio Astronomico di Torino (Italy); Gerardo Capobianco, INAF - Osservatorio Astrofisico di Torino (Italy); Maurizio Pancrazzi, Mauro Focardi, Vladimiro Noce, INAF - Osservatorio Astrofisico di Arcetri (Italy); Cédric Thizy, Jean-Sébastien Servaye, Etienne Renotte, Univ. de Liège (Belgium)

PROBA-3 is a technological mission of the European Space Agency (ESA), devoted to the in-orbit demonstration of formation flying techniques and technologies. ASPIICS is an externally occulted coronagraph approved by ESA as payload in the framework of the PROBA-3 mission and is currently in its C/D phase. Classical space-borne externally-occulted coronagraphs are well suited to observe the extended corona but are limited in their performance by vignetting under 2 solar radii. The vignetting effect can be reduced by moving the external occulter farther from the rest of the telescope. Formation flying offers a solution to investigate the solar corona close the solar limb using a two-component space system: the external occulter on one spacecraft and the optical instrument on the other, separated by a large distance and kept in strict alignment. ASPIICS is characterized by an inter-satellite distance of ~144 m and an external occulter diameter of 1.42 m.

The stray light due to the diffraction by the external occulter edge is always the most critical offender to a coronagraph performance: the designer work is focused on reducing the stray light and carefully evaluating the residuals. In order to match this goal, external occulters are usually characterized by an optimized shape along the optical axis. The most effective optimization is based on a diffraction occultation principle that translates in a multiple disks system or in a solid shape along the optical axis, such as, for instance, a truncated cone. The baseline for the ASPIICS coronagraph in phase B has been a truncated cone, now changed to a toroid due to alignment stability and in-flight thermo-elastic deformation issues. Part of the stray light evaluation process is based on the diffraction calculation with the optimized occulter and with the whole solar disk as a source. The evaluation process is even more critical in the ASPIICS case, due to the impossibility of replicating the flight geometry in a laboratory clean environment. We used the field tracing software VirtualLabTM Fusion by Wyrowski Photonics to simulate the diffraction behind both a simple knife-edge and an optimized external occulter. We considered the whole solar disk as a source, and we applied a limb darkening model as well.

The sampling of the impinging electromagnetic wave is one of the key parameters to a successful diffraction evaluation. The definition of the correct sampling required a long preliminary activity and resulted in a great numerical effort that only a very powerful computer was able to bear.

This paper is dedicated to the description of the activity to define the correct set of parameters to be used in VirtualLabTM Fusion and to the results of the diffraction simulation. A comparison is shown among the performance of the simple knife-edge occulter, the toroid and the truncated cone in terms of stray light suppression.

9904-193, Session PS6

Trade-off between TMA and RC configurations for JANUS camera

Davide Greggio, INAF - Osservatorio Astronomico di Padova (Italy) and Univ. degli Studi di Padova (Italy); Demetrio Magrin, INAF - Osservatorio Astronomico di Padova (Italy); Matteo Munari, INAF - Osservatorio

Astronomico di Catania (Italy); Riccardo Paolinetti, SELEX ES S.p.A. (Germany)

JANUS (Jovis Amorum Ac Natorum Undique Scrutator) is a high resolution visible camera designed for the ESA space mission JUICE (Jupiter Icy moons Explorer). The main scientific goal of JANUS, and the main drivers for the design, is to observe the surface of the Jupiter satellites Ganymede and Europa, and the atmosphere of Jupiter and other satellites during the orbit around the planet. In the case of Ganymede, in particular, it is foreseen a complete mapping of the surface with resolution higher than 400 m/px.

During the design phases, we have proposed two possible optical configurations: a Three Mirror Anastigmat (TMA) and a Ritchey-Chrétien (RC) both matching the performance requirements.

The first optical design adopted to meet the scientific requirements is an off-axis TMA with an entrance pupil diameter of 100 mm and two (out of three) mirrors with aspherical shape. The advantages of such a design are a diffraction limited optical quality and a good rejection of stray light due to the small number of optical surfaces and the absence of spiders. The high level of thermal stability required for JANUS, and the limits in terms of mass posed by the spacecraft, require the use of lightweight materials with low CTE like silicon carbide or carbon fiber.

The second optical design is a RC with two hyperbolic mirrors and a field corrector having an equivalent entrance pupil equal to the TMA solution. The advantages of such a solution are the lightness and compactness, the manufacturability and, in general, is more robust in terms of alignment process.

Here we describe the two optical solutions and compare their performance both in terms of achieved optical quality, sensitivity to misalignment and stray light performances.

9904-194, Session PS6

Alignment procedure for detector integration and characterization of the CaSSIS instrument onboard the TGO mission

Antonio De Sio, Univ. degli Studi di Firenze (Italy); Vania Da Deppo, IFN-CNR LUXOR Lab. (Italy); Lisa Gambicorti, Michael Gerber, Ruth Ziethe, Univ. Bern (Switzerland); Gabriele Cremonese, INAF - Osservatorio Astronomico di Padova (Italy); Nicolas Thomas, Univ. Bern (Switzerland)

The Colour and Stereo Surface Imaging System (CaSSIS) is a stereo camera for the ExoMars Trace Gas Orbiter to be launched in 2016. CaSSIS is a high-resolution camera system capable of acquiring colour stereo images of surface features, possibly associated with trace gas sources and sinks, in order to better understand the range of processes that might be related to trace gas emission on Mars. The 4.5 m resolution on the surface of Mars will allow study of the evolution of possible liquid flows and to identify future landing sites.

The optical configuration of CaSSIS is based on a three-mirror anastigmatic off axis imager with a relay mirror. In order to attain telecentric features and to maintain compact the design, the relay mirror has power.

The University of Bern had the task of the detector integration as well as the characterization of the focal plane of CaSSIS. An OGSE (Optical Ground Support Equipment) characterization facility was set-up for this purpose. A pinhole, placed in the focus position of an off-axis paraboloidal mirror, was used to produce a collimated beam. This beam simulates a point like (star) object source placed at infinity which is conjugate with the CaSSIS focus plane. The pinhole could be illuminated either with monochromatic or white light.

In this work, the procedures to align the system and to link together the positions of each optical element will be presented. In particular a Reference System, that can be easily characterized, has been used to understand the mutual alignment of the optical components. The main steps to characterize the position of the object to that of the CaSSIS focal plane have been repeated to guide and to verify the operation performed during the alignment procedures.

In order to have a reliable Reference System, an optical cube has been placed on the optical bench (OBRS) and linked to gravity through its X component (GOBRS).

A calculation system has been designed in order to allow us to work on the optical setup and on the detector simultaneously, and to compute online the new position of the focus plane with respect to the detector.

Such a feedback system has been iterated to find the best position for the detector. All possible movements due to temperature and pressure changes between the lab and the on Mars operating condition have been taken into account. Final results will be shown and discussed.

9904-195, Session PS6

Design and development of a star sensor cum asteroid tracker

Mayuresh N. Sarpotdar, Joice Mathew, Sreejith Aickara Gopinathan, Jayant Murthy, Margarita Safonova, Indian Institute of Astrophysics (India)

We have developed a Star Sensor cum Asteroid Tracker to use in mini-satellites and Cubesats, whose main function is to estimate satellite's attitude / orientation. The sensor is essentially an imaging camera, which extracts information from the star patterns it records in the images. The field of view and limiting magnitude of the camera are decided to be 100 and 6.5m respectively from a sky simulation using the Hipparcos Bright Star Catalog to detect atleast 3 stars in a field pointed anywhere in the sky. A Tessar lens eliminating distortion and coma aberrations is designed and manufactured. The focal length and PSF of the optics is decided from the detector parameters like: pixel size, detector size etc. A radiation hardened detector Star 1000 is used in the system because of its suitability for applications in satellites. The detector is readout using a MIL grade Spartan-6 FPGA, the PCB for which is developed in-house. For online processing of the image data we implement a microcontroller called LEON SPARC v8. The VHDL source code for this core is available open source for educational and academic purposes from Aeroflex Gaisler. The main output of the star sensor is a quaternion which is estimated by processing data from the images acquired. In the process various algorithms are implemented viz. Centroiding algorithm, Geometric Voting algorithm, QUEST algorithm. An all sky simulation and various performance estimation tests of these algorithms is carried out to estimate the sky coverage where the algorithms work accurately, memory required

to implement the algorithms, time to calculate etc.

Having developed a real-time image processing platform on the FPGA board, its utility in other calculation intensive processes is being considered. Synthetic Tracking which essentially is stacking of images after shifting them slightly to compensate for object motion between images, is another such calculation intensive application where a large amount of RAM and processing power is required. We are currently working on implementing synthetic tracking on this hardware for a satellite based payload. This is achieved by making stacks of images for different velocities and then fitting a PSF to find objects in the stacked images which move with corresponding velocities. A suitable combination of such stacked images would help roughly estimate the orbital parameters of the asteroids and thus help in asteroid tracking.

9904-196, Session PS6

Achromatic interfero-coronagraph with variable rotational shear in laboratory experiments

Pavel Frolov, Alexander Kiselev, Alexander Tavrov, Space Research Institute (Russian Federation)

With the first definitive detection of an extrasolar planet in 1995 observational astronomy proved (by radial velocity method) the existence of planets around other stars in the galaxy. So far, indirect methods (i.e. non-imaging methods: radial velocity, transit photometry, astrometry, timing, microlensing) are the most successful in the exoplanet detection and characterization but they have substantial limitations and dependence on the model used to interpret observed data.

Despite all the efforts spent on the detection of exoplanets, both the direct imaging and spectral study of extrasolar planets and especially Earth-like planets remains very challenging research field. The reason is the critical combination of huge brightness contrast between the star and the planet (10^7 in the mid-IR and 10^10 in the visible and near-IR) and the small angular separation between sources (typically 0.1...0.5 arcsec and less).

To observe exoplanets directly and to perform further spectroscopic analysis we propose to use an achromatic interferometric coronagraph (AIC). AIC is in a particular place among the other designs because of the following notable features: starlight suppression is fully achromatic and inner working angle (IWA) of AIC 0.38?/D is the smallest of all coronagraphs. The latter one brings us to the significant drawbacks, high sensitivity to pointing errors and high sensitivity to angular star size which is known as star leakage effect.

Appreciable advance has been made since original AIC design had been published. The common path achromatic interferometric coronagraph (CP-AIC) was devised in 2005 as further development of AIC. CP-AIC uses the same starlight suppression principle as AIC with all its advantages and drawbacks mentioned in a mechanically stable and more robust way since it is a variation of a common path interferometer. In 2008 in order to decrease star leakage effect it was suggested to combine two common path interferometers in tandem to make a nuller which in theory provides an achromatic way to achieve 10^10 contrast with 0.01 ?/D effective angular star size at the expense of a throughput. In 2010 for the same purpose (to get over star leakage effect) the achromatic rotation-shearing coronagraph (ARC) was proposed.

An advantage of ARC over AIC is appreciable with telescope sizes more than 1 meter. The gain in contrast is up to 3 orders of magnitude higher relative to AIC with 2.4-meter telescope with achieved contrast about 10^9 that makes ARC appropriate for direct imaging of exo-Jupiter around nearest stars. There is also a significant gain in detection of exo-Earth around nearest stars since achieved contrast is about 10^5 with 2.4-meter telescope. In addition, ARC allows us to perform spectral analysis of planet light since it is an implementation of rotational shearing interferometer.

We detail achromatic interferometric coronagraph with variable rotational shear – common-path achromatic rotation-shearing coronagraph (CP-ARC), demonstrate laser light nulling and white light nulling with laboratory prototype and discuss possibilities of CP-ARC to carry out spectral analysis.

The reported study is funded by RFBR (grant No. 16-32-00440 ???_a).

9904-197, Session PS6

Thermal study of payload module for Millimetron Space Observatory

Evgeny Golubev, Astro Space Ctr. (Russian Federation); Anatoly Kolesnikov, Alexey P. Popov, JSC “Academician M.F. Reshetnev” Information Satellite Systems” (Russian Federation); Andrey Smirnov, Igor S. Vinogradov, Stanislav Novikov, Astro Space Ctr. (Russian Federation)

Millimetron Space Observatory is a mission optimized for the submillimeter and far-infrared astronomy with a 10-m telescope which is cryogenically cooled down to 4,5K. Due to strict requirements on thermal performance, Millimetron mission will be launched into a halo orbit around the second Lagrange Point (L2) in the Sun-Earth system to obtain a stable thermal environment, which allows us to use effective radiative cooling in combination with a mechanical cooling system. Therefore, the telescope is equipped with large deployable thermal shields to block light and heat from the Sun, Earth, and Moon and cool the telescope passively to the temperature of 40 - 60K. The thermal shields are made from multiple layers of thin two-sided aluminium-plated films, supported by 12 deployable booms and a suit of pre-tensioned flexible cords from aramid fiber. Besides, there is the nearest to primary mirror cryogenic shield, which should be actively cooled to 20K. The thermal shield subsystem and the payload module basic structure with low thermal conductance separate the observatory into a warm sun-side part and a cold part.

This paper introduces details of the thermal design study for the payload module, in which the activity is focused on mitigating heat fluxes to the low temperature regions. First, the design of large deployable thermal shields will be discussed. Next, several development efforts to minimize parasitic heat loads to the cold and pre-cooling stages of mechanical coolers will be described. Finally, analytical results of the thermal design from recent studies will be presented. As the result of this study, the margins of the heat loads budget have been successfully satisfied, while the payload module structural design has been made to be more feasible and reliable.

9904-198, Session PS6

The front-end electronics of LSPE-SWIPE experiment

Flavio Fontanelli, Michele Biasotti, Flavio Gatti, Univ. degli Studi di Genova (Italy)

The SWIPE detector of the Ballon Borne Mission LSPE (see e.g. the contribution of P. de Bernardis et al. in this conference) intends to measure the cosmic microwave background (CMB) intensity and polarization with very good precision. Detector is built around transition edge sensors and bolometers with a squid as a first stage very low noise preamplifier .

This contribution will concentrate on the design, description and first tests on the front-end electronics which processes the squid output (and controls it).

The squid output is first amplified by a very low noise preamplifier based on a discrete JFET input differential architecture followed by a low noise CMOS operational amplifier. The choice of the circuit topology and components value will be discussed together with preliminary results obtained so far at room temperature. Equivalent input noise density is 0.6 nV/√Hz and bandwidth extends up to at least 2 MHz. Both devices (JFET

and CMOS amplifier) have been tested at liquid nitrogen and the possibility to build a simple and cheap cryogenic preamplifier able to work even in liquid nitrogen will be discussed.

The second part of the contribution will discuss design and results of the control electronics, both the flux locked loop for the squid and the "slow control" chain to monitor and set up the system will be reviewed.

The circuit is composed by standard commercial components to simplify and quicken the design and production phase. Control electronics will operate in a reasonably warm environment and no special components are needed. Nevertheless much care is needed to monitor and correct the working conditions to improve stability and detect possible faults without introducing any noise.

The digital interface to the control computer will be discussed.

Finally future plans will be presented.

9904-199, Session PS6

The fabrication and DC performance qualification of the TES bolometers of LSPE

Michele Biasotti, Dario Corsini, Univ. degli Studi di Genova (Italy); Matteo De Gerone, Univ. of Genova (Italy) and Istituto Nazionale di Fisica Nucleare (Italy); Flavio Fontanelli, Flavio Gatti, Daniele Grosso, Univ. degli Studi di Genova (Italy)

The first upgraded release of the bolometers for the CMB Telescope SWIPE of the Balloon Borne Mission LSPE (see contribution of P. de Bernardis et al. in this conference) has been fabricated. This is based on a monolithic silicon excavated square chip where a large circular low stress silicon nitride membrane is suspended at the center. The chip rim act as mechanical, thermal and electrical interface to place and operate the bolometer inside the microwave optical cavity of SWIPE. The suspended spider web membrane covers an area as large as 50 mm2 and the TES sensor is placed in its center. In order to fulfil the performance requirements, the design of such upgraded detector has overcome a trade-off process among: (1) the large area need and (2)fabrication complexity and yield, (3) membrane stress relief and flatness, (4) internal thermal relaxation time among gold absorber and TES, (5) mechanical compatibility for the balloon flight operation. Similarly a second trade-off process among the necessary relative large production (about 300 chips) and the highly equalized operating characteristics and properly-tuned operating temperatures and dynamic range.

Concerning the first trade-off issues, we have successfully achieved good results by making a new design of the spiderweb geometry. It has been obtained numerically with mechanical and thermal models within the COMSOL software toolkit. The new design foresees the increase in number of the membrane suspending rods structure to reduce the strain that causes bending and consequently flatness loss. This is accompanied with a more robust membrane rim that distributes the tension and compression forces along the spiderweb perimeter. We have performed several simulations with COMSOL in order to set the design and fabrication processes to reach this requirements.

Further, the full set of thermal, mechanical and EM requirements have been included in a new design before the fabrication phase. Then we have produced two versions of bolometers with two TES type: TiAu bylayer to operate in the 350-400 mK range and MoAu bilayer for the alternative 500-550 mK range. After the production run, both types have been fully qualified in the corresponding operating temperatures in a dilution fridge, making IV-DC measurement and total noise spectra in a fully shielded isothermal cavity. This work has demonstrated that the new updated release has improved the flatness and shows a greater toughness in the fabrication process. Thermal conductance have been evaluated using usual models from bolometer IV-DC data laying in 3x10-11 W/K. Noise contributions are fully explained with Johnson and SQUID amplifier noise, with negligible excess noise. The recovery time constant has been tested with short diode laser pulses injected in the cavity via an optical fiber.

9904-200, Session PS6

PILOT optical alignment

Yu-Ying Longval, Institut d'Astrophysique Spatiale (France); Baptiste Mot, Institut de Recherche en Astrophysique et Planétologie (France)

PILOT (Polarized Instrument for Long wavelength Observations of the Tenuous interstellar medium) is a balloon-borne astronomy experiment designed to study the polarization of dust emission in the diffuse interstellar medium in our Galaxy. The PILOT instrument allows observations at wavelengths 240 ?m (1.2THz) with an angular resolution about two arcminutes. The observations performed during the first flight in September 2015 at Timmins, Ontario Canada, have demonstrated the good performances of the instrument.

Pilot optics is composed an off axis Gregorian type telescope and a refractive re-imager system. All optical elements are in a cryostat cooled to 3K except the primary mirror, which is at ambient temperature (the room temperature during the end-to-end ground test or the temperature at ceiling altitude ~ 40 km in flight).

All optics system is aligned at room temperature and we have developed a dedicated procedure in order to keep the tight requirements on the focus position and ensure the instrument performances in the different environments.

We combined the optical, 3D dimensional measurement methods and thermoeslastic modeling to perform the optical alignment.

The talk describes the system analysis, the alignment procedure, and finally the performances obtained during the first flight.

9904-201, Session PS6

Near-infrared imaging spectrometer (NISS) onboard NEXTSat-1

Woong-Seob Jeong, Korea Astronomy and Space Science Institute (Korea, Republic of)

After the Science and Technology Satellite (STSAT) series, the next generation of small satellite program (NEXTSat) have been started from 2012, and it is the only space program for the space science in Korea. The NISS (Near-infrared Imaging Spectrometer for Star formation history) onboard the first small satellite of NEXTSat program is one of the scientific mission payloads and have being developed by KASI. To study the distant and local star formation, the NISS has a unique capability of both imaging and low spectral resolution spectroscopy in the wide near-infrared range. For those purposes, the main targets will be nearby galaxies, galaxy clusters, star-forming regions and low background regions.

Due to the limited mass and volume of NEXTSat-1, the NISS have adopted an off-axis optical design with a 15cm aperture. The NISS was optimized to achieve a wide field of view (FoV) of 2 deg. ? 2 deg. with a spatial resolution of 15 arcsec as well as a wide spectral coverage from 0.9 to 3.8?m. The imaging spectroscopy in the near-infrared range with no moving part was realized by using a special spectral filter combined of two linear variable filters. Most of mechanical structure including primary and secondary mirror was designed of the same material, aluminum to minimize thermal variations in the space. The opto-mechanical structure was designed to be safe enough to endure in both the launching and space environment. The telescope and infrared detector will be cooled down to 200K and 80K respectively through a passive and an active cooling with a small mechanical cooler. The electronics composed of a focal plane board and an electronics box have functions of operation of detector, electric interfaces with the spacecraft and a control of the NISS. The engineering model was delivered in 2015 and was tested in space environment. The flight model of NISS will be launched in 2017 and explore the large areal near-infrared sky up to 200 square degree in order to get both spatial and spectral information for astronomical objects.

9904-202, Session PS6

Testing and characterization of a prototype telescope for the enhanced laser interferometer space antenna (eLISA)

Shannon R. Sankar, Jeffrey C. Livas, NASA Goddard Space Flight Ctr. (United States)

The enhanced Laser Interferometer Space Antenna (eLISA) will enable study of gravitational waves in the 0.1 mHz to 1 Hz band inaccessible from ground-based observatories. A plethora of gravitational wave sources is expected in this frequency range, including supermassive black hole binaries and extreme mass ratio binary systems. The eLISA observatory consists of 3 spacecraft in a triangular formation separated by roughly 1 million kilometers a side, with each spacecraft housing free-floating inertial proof masses. Precision laser interferometry at 1064 nm is used to measure the proper displacement of these proof masses with high signal-to-noise as a passing gravitational wave stretches and shrinks spacetime between them. However, in order to perform laser interferometry over such vast baselines, telescopes are needed to provide more efficient exchange of laser beams between spacecraft. This function means that the telescope is in the interferometric beam path, and so its design is directly driven by the requirements of the gravitational wave observatory. Some of these specifications are very different from the usual imaging requirements of conventional telescopes.

As an example of differences from conventional telescopes, the overall noise budget of the gravitational wave observatory allocates less than 1 pm/√Hz displacement noise to the telescope in a band from 0.1 mHz to 1 Hz. This specification constrains the allowable optical path length change of the laser light passing through the telescope. A second, but related, constraint is due to the fact that the telescopes are used to both send and receive laser beams. While transmitting 1 W, the telescope also collects approximately 100 pW from the far spacecraft. Since both beams traverse the same optical elements, scattering has the effect of re-directing some of the outgoing light into the incoming mode. This cross-coupling, in tandem with unwanted displacement noise of the optical elements, can add phase noise to the interferometric measurement - effectively reducing the signal-to-noise with which we can study gravitational waves and their sources. The level of permissible scatter therefore depends on the dimensional stability of the telescope.

Here we describe our efforts to fabricate, test and characterize a prototype telescope for the eLISA mission. Much of our work has centered on the modeling and measurement of scattered light performance. This work also builds on a previous demonstration of a high dimensional stability metering structure using particular choices of materials and interfaces. We will discuss ongoing plans to merge these two separate demonstrations into a single telescope design demonstrating both stray light and dimensional stability requirements simultaneously.

9904-203, Session PS6

SINBAD electronic models of the interface and control system for the NOMAD spectrometer on board ESA ExoMars Trace Gas Orbiter mission

José M. Jerónimo Zafra, Rosario Sanz Mesa, Beatriz Aparicio del Moral, Gian Paolo Candini, Julio F. Rodríguez Gómez, Nicolás Robles Muñoz, Juan M. Gómez López, Maria del Carmen Pastor Morales, Rafael Morales Muñoz, José Juan López-Moreno, Instituto de Astrofísica de Andalucía - CSIC (Spain); Eddy Neefs II, Ann Carine Vandaele, Sophie Berkenbosch, Roland Clairquin, Bojan Ristic, Sabrina Bonnewijn, Jeroen Maes, Rachel Drummond, Sofie Delanoye, Belgian Institute for Space Aeronomy (Belgium); Manish R. Patel, Mark Leese, The Open Univ. (United Kingdom)

NOMAD(Nadir and Occultation for Mars Discovery) is an instrument leaded by BIRA, IAA and OU. NOMAD is composed by three spectrometers, two infrared channels and one ultraviolet and visible channel. NOMAD will be part of the payload on board ESA ExoMars Trace Gas Orbiter Mission.

SINBAD is a NOMAD subsystem in charge of the communication and the management of the power and control between the spacecraft and the instrument channels. Two boards have been designed for these tasks, one board for the power distribution and housekeeping (POW board) and the other one (COM board) for the communication and control of the whole instrument with the spacecraft and the channels: telecommands and telemetry.

SINBAD System implements a microprocessor embedded in a FPGA. The telecommands are received via a 1MHz MIL-STD-1553B bus and the telemetry is sent through a 20MHz SpaceWire redundant bus. UVIS interface is a 1MHz RS-422 bus, while SO and LNO channels communicate through a 100MHz LVDS serial bus. The SINBAD system also controls the peripherals: sensors, actuators (flip mirror and pin-puller), heaters, ADC system.

First, a development board has been made to check the design and configurations, this board is customized with a LEON3FT microprocessor. It was designed in base to a set of stackable boards over a base one. The base board contains an ALDEC adapter with a programmable FPGA. It can be connected to memory and other boards through stackable connectors.

The next board developed (Prototype board) contains two interconnected FPGAs and has been used to check all the functionalities and also to test and develop the NOMAD EGSE.

The delivered models to the ESA were: NOMAD EIM, NOMAD STM, SINBAD PFM and SINBAD FS.

NOMAD EIM is an engineering model fully representative of the flight configuration with the spacecraft interface of the flight model. This model has resistive loads instead of scientific channels and the data and telemetry output is internally generated by software.

SINBAD EM is similar to the EIM, it has all the functionality and is devoted to SW development after the launch. This model has been tested with the last changes made to the system before the implementation into the flight models.

SINBAD PFM is the first model assembled with flight components for the functional testing. It was made in a clean room ISO 5. SINBAD PFM was tested with prototype version of UVIS, resistive loads and simulator for SO/LNO channels and a QM version of flip mirror with stepper motor and sensors. SINBAD PFM has been integrated with the channels and tested in NOMAD PFM. After the electrical and functional tests, this model has been tested for shock, vibration, vacuum and thermal environment.

SINBAD FS is the spare model and fully equal to SINBAD PFM. Both models have been validated to fly.

The NOMAD instrument will be launched from Baikonour in March 2016.

9904-204, Session PS6

Concept study for a compact planetary homodyne interferometer (PHI) for temporal global observation of methane on Mars in IR

Sona Hosseini, Christopher R. Webster, Geoffrey C. Toon, Wesley A. Traub, John T. Trauger, Jet Propulsion Lab. (United States)

We propose to design, develop and demonstrate a new compact, high-performance, high spectral resolution Infrared (IR) spectrometer for Planetary Science of wide applicability to NASA sounding rockets, International Space Station (ISS) and Mars missions, Discovery and New Frontiers including those of planetary atmospheres and cometary science employing deep space missions, orbiting spacecraft, and on-surface landers or rovers.

Here, we will demonstrate capability by targeting Mars atmospheric methane measurement from space-based, Mars orbiter or surface platforms. Methane has been detected in the atmosphere of Mars using different approaches from in situ measurement by Curiosity, ground-based telescopic observations, and remote-sensing measurements from Mars-orbiting spacecraft MEX, MGS, and MRO. Although each approach has reported various results, these results are not necessarily contradictory, due to the possibility of spatial and temporal variability. Thus, more measurements and improved instrument measurement capabilities are required to gain clarity.

We present a concept study to build a new instrument to sequentially and over a long time measure methane abundance on Mars and find out its global seasonal variations, if any. The Planetary Homodyne Interferometer (PHI) offers integrated spectra over a wide field-of-view (FOV) in high spectral resolution (R~105) in a compact design using no (or a small < 1m) primary mirror. The architecture of PHI combines the high étendue of a Fourier Transform Spectrometer with higher optomechanical tolerance and simpler optomechanical design associated with grating spectrometers. PHI is best suited to studies of sources where temporally tracing specific spectral features sensitivity, and spectral resolution is of higher significance than spatial fidelity. We are targeting to measure the mid-infrared absorption of Mars atmospheric CH_4, H_2O, and CO_2 absorption lines by observing the full disk of Mars from Mars's orbit. By coupling the instrument to a small telescope, we will demonstrate measurement capability through laboratory measurements of trace methane in calibration gas mixtures and ground-based measurements of sodium around the Moon. The goal of developing PHI is to conduct planetary science instrument feasibility study, concept formation, proof of concept, and advanced component technology development of a miniature, high R, wide FOV spectrometer targeting spectral features of methane gas on Mars.

Various configurations of instruments similar to CHASE have been developed as proof-of-concept laboratory prototype, ground-based instrumentation, and sounding rocket experiments in the Optical, NUV and FUV wavelengths. These studies have demonstrated high R and high sensitivity UV spectrometers can be built in ultra-compact configurations similar to CHASE with no or small aperture telescope for a variety of space science applications.

9904-205, Session PS6

HST/WFC3: understanding and mitigating radiation damage effects in the CCD detectors

Sylvia M. Baggett, Jay Anderson, Megan L. Sosey, Matthew Bourque, Varun Bajaj, Catherine Gosmeyer, Harish Khandrika, Catherine Martlin, Space Telescope Science Institute (United States)

At the heart of the Hubble Space Telescope Wide Field Camera 3 (HST/WFC3) UVIS channel is a 4096x4096 pixel e2v CCD array. While these detectors are performing extremely well after 7 years in low-earth orbit, the cumulative effects of radiation damage are becoming increasingly evident. The result is a continual increase of the hot pixel population and the progressive loss in charge transfer efficiency (CTE) over time. The decline in CTE has two effects: (1) it reduces the detected source flux as the defects trap charge during readout and (2) it systematically shifts source centroids as the trapped charge is later released. The flux losses can be significant, particularly for faint sources in low background images. In this report, we summarize the radiation damage effects seen in WFC3/UVIS and the evolution of the CTE losses as a function of time, source brightness, and image background level.

In addition, we discuss the available mitigation options, including target placement within the field of view, empirical stellar photometric corrections, post-flash mode and an empirical pixel-based CTE correction. The application of a post-flash has been remarkably effective in WFC3 at reducing CTE losses in low background images for a relatively small noise penalty. Currently, all WFC3 observers are encouraged to consider post-flash for images with low backgrounds. The pixel-based CTE correction software has been released as a standalone routine, to be applied to images after they are acquired. Analagous to the software currently in use in the HST Advanced Camera for Surveys (ACS) pipeline, the algorithm employs an observationally-defined model of how much charge is captured and released in order to reconstruct the image. The CTE correction software is planned for incorporation into the automated WFC3 calibration pipeline in early 2016.

9904-206, Session PS6

Performance of a cryogenic test facility for 4K interferometer delay line investigations

Ian T. Veenendaal, David A. Naylor, Brad G. Gom, Univ. of Lethbridge (Canada); Sudhakar Gunuganti, Blue Sky Spectroscopy Inc. (Canada); Calvin Winter, Quantum Technology Corp. (Canada); Martyn L. Jones, David D. Walker, Glyndwr Univ. (United Kingdom)

Astronomical observations at far-infrared wavelengths provide a unique window to study both star formation in our own galaxy and highly redshifted emission from galaxies in the distant universe. The low energy of far-infrared photons necessitates the use of extremely sensitive detectors operating at sub-Kelvin temperatures. The optical noise equivalent power of state-of-the-art detectors is ~10^(-19) W/√Hz. To ensure that photon noise remains below this level, any spectroscopic instrument employing such detectors must be cooled to ~4 K. Ground-based, cryogenic facilities are required to evaluate the performance of materials, components and subsystems, prior to their implementation in space instrumentation. The University of Lethbridge Test Facility Cryostat (TFC) is such a facility, offering a high volume (70 L), low temperature (4 K) environment with a wide selection of metrology options. The first use of the TFC will be to test key components of the translation mechanism and metrology system of the high resolution spectrometer component of the SAFARI instrument being developed for the SPICA mission.

The TFC incorporates a complex wiring scheme for thermometry and metrology, as well as optical feedthroughs for laser metrology and infrared signal inputs. Cooling of the TFC is provided by dual Cryomech PT415 pulse tube cryocoolers with a total cooling power of 3 W at 4.2 K. In an effort to isolate pulse tube vibrations, a system of flexible copper braids is used to thermally couple the pulse tube and cold components. Multiple layers of radiative shielding, and cryogenic, zero-aperture irises are utilized to minimize radiative heat transfer. Parasitic heat conduction

from mechanical supports is minimized through the use of carbon-fibre-reinforced polymer (CFRP) struts with low thermal conductivity and high stiffness. Additionally, a liquid nitrogen precool system is included in order to decrease the system cooling time.

In order to test complete interferometer systems inside the cryostat, a composite, cryogenic blackbody source has been installed in the in the 4 K volume along with a Chase Research Cryogenics He-10 adsorption refrigerator to cool sensitive detectors to 0.3 K. Apertures have been designed into the TFC to allow for the use of multiple external instruments, including a Renishaw Differential Interferometer and a PLX Electronic Autocollimator. These instruments measure small displacements and rotations, respectively, providing accurate metrology for the characterization of material properties as well as metrology for cryogenic systems. The sensitive metrology provided by these instruments, and accurate internal thermometry, allow one to measure the thermal and mechanical properties of composite materials (e.g. CFRP) at low temperatures. A collaboration with Glyndwr University has been established to investigate the challenges associated with using CFRP in lightweight mirror structures at cryogenic temperatures. This paper discusses the design and performance specifications of the TFC, as well as the techniques used for measuring thermal conductivity, thermal expansion, and elastic modulus of composite materials.

9904-207, Session PS6

Current status of HAWAII-1RG characterization for NISS

Won-Kee Park, Korea Astronomy and Space Science Institute (Korea, Republic of); Dae-Hee Lee, Korea Astronomy and Space Science Institute (Korea, Republic of) and Univ. of Science and Technology (Korea, Republic of); Youngsik Park, Korea Astronomy and Space Science Institute (Korea, Republic of); Woong-Seob Jeong, Korea Astronomy and Space Science Institute (Korea, Republic of) and Univ. of Science and Technology (Korea, Republic of); Sung-Joon Park, Bongkon Moon, Korea Astronomy and Space Science Institute (Korea, Republic of); Dukhang Lee, Kyeong Yeon Ko, Korea Astronomy and Space Science Institute (Korea, Republic of) and Univ. of Science and Technology (Korea, Republic of); Jeonghyun Pyo, Il-Joong Kim, Uk-Won Nam, Korea Astronomy and Space Science Institute (Korea, Republic of); Goo-Hwan Shin, Jang-Soo Chae, Korea Advanced Institute of Science and Technology (Korea, Republic of)

We present the current status of NISS electronics sensor characterization and optimization process. The Near-infrared Imaging Spectrometer for Star formation history (NISS) is a 15cm diameter off-axis reflector developed by Korea Astronomy and Space science Institute (KASI). It is one of two scientific mission payloads for the Next Generation Small Satellite 1 (NEXTSat-1) developed by Korea Advanced Institute of Science and Technology (KAIST). NISS will perform imaging spectroscopy for nearby galaxies, low-background regions and star-forming regions in NIR wavelength band ranging from 0.9~3.8um during the first two years. The NISS uses a HAWAII-1RG sensor as its detector, and two linear variable filters as dispersers with R=20. NISS electronics consists of three boards: DSP board is to generate housekeeping information and make command and status communication with the satellite system. A FPGA on the same board will perform 2 by 2 median pixel binning onboard the satellite to reduce the data amount, and serialize it for data communication. The amp board is for generation of sensor driving clock signal, and amplification of the output signal from the sensor. Lastly, Power board generates all electrical powers for NISS operation. All board designs have heritages either from MIRIS (Han et al., 2014) or CIBER-2 (Lee et al., 2015) HAWAII-1RG was successfully operated in the laboratory under 80K cryogenic condition with NISS EQM electronics boards. Several dark images were obtained along with reference channel images. Although the dark current turned out to be small, the standard deviation of pixel values in the resultant images were larger than expected. Revisions are being made to make HAWAII-1RG performance better. In addition, reference pixels around the imaging area of HAWAII-1RG will be utilized with scheme of Rauscher et al. (2011), to further reduce the noise. After the revisions, we will repeat the procedures again to confirm that the noise gets smaller down to the NISS specification. We will also measure our chip characteristics such as dark current level, pixel well depth, linearity range, and conversion gain, to determine the optimum sensor operation strategy for NISS science. The NEXTSat-1 is scheduled to be launched by a Falcon 9 rocket in the third quarter of 2017.

9904-208, Session PS6

Terahertz intensity interferometry for milli-arcsecond resolution

Hiroshi Matsuo, Hajime Ezawa, Hitoshi Kiuchi, Mareki Honma, National Astronomical Observatory of Japan (Japan); Yasuhiro Murata, Institute of Space and Astronautical Science (Japan)

High angular resolution imaging at far-infrared or terahertz frequencies are foreseen either using large single dish telescopes or interferometers. In this presentation we will focus on realization of a relatively long baseline intensity interferometer at terahertz frequencies which enables milli-arcsecond angular resolution.

Intensity interferometers were first demonstrated by Hanbury-Brown and Twiss.

However, low correlation efficiency and absence of phase information restricted their application to aperture synthesis imaging.

At terahertz frequencies, large number of bunched photons enables delay time measurements and high efficiency aperture synthesis imaging can be realized.

The principle of delay time measurement was recently demonstrated by an intensity interferometer experiment at microwave frequency; the delay time accuracy can be better than that corresponds to one wavelength using a large number of bunched photons.

The experiment showed that the intensity interferometer can be used for aperture synthesis imaging.

Application of intensity interferometry to space terahertz interferometer will be discussed in detail.

With the low background condition of cryogenic space telescopes, photon counting detector is advantageous for high dynamic range intensity measurements.

Intensity interferometry with terahertz photon counting detector can be named as the photon counting terahertz interferometry (PCTI).

Relatively low photon rate of 100 M photon/s from typical bright terahertz sources would realize delay time accuracy better than 0.1 ps within 100 s integration time.

Required NEP for photon counting is only less than 10(-17) W/rtHz when time resolution is 1 ns.

This sensitivity and time response can be realized by using low leakage current (1pA) superconducting tunnel junction detectors.

Combination of PCTI and double Fourier interferometer is proposed to achieve good uv coverage for aperture synthesis imaging in terahertz frequencies.

Shorter baseline is covered by the double Fourier interferometer and longer baseline by PCTI.

With baseline length of 20 km at 3 THz, angular resolution of 1 milli-arcsecond can be achieved.

In terahertz frequency region there are more than 100,000 cataloged point sources brighter than 1 Jy, which will be targets for the space terahertz interferometer.

PCTI can be applied to very long baseline intensity interferometer (VLBII).

Telescope systems on satellite platforms will be similar to space VLBI which use heterodyne receivers, but photon counting detectors will realize much higher sensitivity and wider bandwidth to imag thermal emission sources, such as stars and exo-planets.

9904-209, Session PS6

The latest results from DICE (Detector Interferometric Calibration Experiment)

Antoine Crouzier, Institut de Planétologie et d'Astrophysique de Grenoble (France); Alain R. Leger, Thales Avionics S.A. (France); Fabien Malbet, François B. Hénault, Eric Stadler, Sylvain Rochat, Institut de Planétologie et d'Astrophysique de Grenoble (France); Christophe Cara, Christian C. K. Ketchazo, Commissariat à l'Énergie Atomique (France)

NEAT and Theia were proposed astrometric missions to ESA with the objectives of detecting Earth-like exoplanets in the habitable zone of nearby solar-type stars. Theia requires the capability to measure stellar centroids at an accuracy of 1e-5 pixel. Formerly called NEAT-demo, DICE aims to demonstrate that an interferometric calibration of the CCD can improve accuracy, up to the of previous specification. In this paper we present the latest results obtained after a series of major hardware upgrades. The analysis of the new set of data yielded an astrometric (centroid) accuracy of 6e-5 pixel.

9904-210, Session PS6

A cryogenic testbed for the characterisation of large detector arrays for astronomical and Earth-observing applications in the near to very-long-wavelength infrared

Tom Brien, Peter A. R. Ade, Cardiff Univ. (United Kingdom); Markus Haiml, AIM INFRAROT-MODULE GmbH (Germany); Peter C. Hargrave, Enzo Pascale, Rashmi V. Sudiwala, Cardiff Univ. (United Kingdom); Dirk Van Aken, Caeleste CVBA (Belgium)

We present the preliminary design of a cryogenic testbed for the complete characterisation of large arrays (> 1MP) of infrared detectors (including MCT), operating in the mid-infrared region (8–12 ?m), but also capable to operate in a region of the electromagnetic spectrum from the near-IR to the VLWIR. The testbed can be used to characterise the performance and scientific capabilities of focal planes for space missions such as Ariel, a candidate for the ESA M4 programme currently being studied by ESA, or other IR missions for astronomy and Earth Observing.

The testbed is capable of measuring the performance of the array, both dark and when optically loaded, from a base temperature of 4 K to in excess of 100 K, with high thermal stability (better than 1 mK over long time constants). It contains a filter wheel, driven by a cryogenic stepper motor. This allows the photometric band observed by the array to be switched between three narrow bands or a straight-through (unfiltered) mode. The image lag, also called the persistence effect, can be measured by moving the filter wheel to (or from) a blanked position to rapidly cut (or reinstate) the illumination on the array. The spectral response of the detector array is measured by moving the filter wheel to the unfiltered position and using a Fourier-transform spectrometer to measure the array response as a function of frequency. Finally, the modulation transfer function (MTF) and optical fill factor of the array can be measured by one of two techniques developed for this system. The first of these is an internal (to the cryostat) spot-projector system, which uses a thermal source and reflecting optics to project a focused, sub-pixel sized spot on to the array. This spot is then translated across the array using a three-axis cryogenic translation stage. As a second method for MTF characterisation, we have developed a novel system (at these wavelengths) to measure the average modulation transfer function of the entire array without the need for moving components. This technique uses the properties of so-called continually self-imaging gratings to generate an interference field that does not vary with propagation. To measure the MTF of single pixels using this technique, one need only move the input source of the collimator unit, which is external to the cryostat.

9904-211, Session PS6

Nanostructured optical devices for broadband applications including high contrast imaging and spectroscopy

Kunjithapatham Balasubramanian, Victor E. White, Karl Y. Yee, Eric J. Cady, Jet Propulsion Lab. (United States)

High contrast imaging of exoplanets requires masks to control or block the light from their parent stars from reaching the image plane where faint planet images may appear. A number of techniques have been explored to achieve better than 10-9 contrast between the star and the planet with partially obscured apertures such as WFIRST-AFTA. The shaped pupil coronagraph, a reflective mask with black silicon absorptive islands, is one of the architectures that has been produced and shown to meet milestone criteria. The same criteria could be met with nanostructured glass for transmissive geometry as the nanostructures reduce ghost reflections by modifying the optical admittance of the surfaces which would otherwise cause ghost images due to unwanted reflections. Similarly spectrometers involving prisms and/or gratings and slits require novel techniques to reduce scattered light and ghost reflections. Silts with nanostructures at the edges have enabled high performance spectrometers. Thirdly, silicon devices with increased transmission in the IR have become feasible with nanostructures; such devices while being extremely black in the visible show very high transmission in the IR, a property that could be exploited for many different applications. In this paper, we discuss the fundamental aspects of such nanostructures on surfaces that modify the surface properties in unique ways. We present illustrative examples of fabricated masks and other devices.

9904-212, Session PS6

Development of a near-infrared detector and a fiber-optic integral field unit for a space solar observatory SOLAR-C

Yukio Katsukawa, Yukiko Kamata, National Astronomical Observatory of Japan (Japan); Tetsu Anan, Kyoto Univ. (Japan); Hirohisa Hara, Yoshinori Suematsu, Takamasa Bando, National Astronomical Observatory of Japan (Japan); Kiyoshi Ichimoto, Kyoto Univ. (Japan); Toshifumi Shimizu, Japan Aerospace Exploration Agency (Japan)

It's scientifically critical to make specto-polarimetric observations within a short time-scale to temporally resolve dynamic phenomena in observations of the solar chromosphere. For doing it in the next space-based solar mission, SOLAR-C, we are developing a high sensitivity and

fast readout near-infrared (NIR) detector and an integral field unit (IFU) for making a spectro-polarimetric observations of chromospheric lines, such as He I 1083 nm and Ca II 854 nm. The candidate NIR detector is 1.7 um cutoff HgCdTe H2RG sensor with SIDECAR readout ASIC. Because the detector is cooled only by a radiator in SOLAR-C, it's important to verify the performance in temperature condition around -100 deg C, which is hotter than the typical temperature used for a NIR detector. We built a system for testing the detector between -70 deg and -140 deg C. We verified linearity, read-out noise, and dark current etc. in both the slow and fast readout modes. We found the detector has to be cooled down lower than -100 deg C because of significant increase of number of hot pixels. The read-out noise was around 100 e in the fast readout mode, which is acceptable in the solar observation though we need further improvement and optimization. The IFU consists of fiber-optic bundles of rectangular cores, and we made test fabrication of the IFU and measured its properties of polarization maintenance. An issue was to find a way to fix the fiber bundles in a metal housing to make the fragile fiber-optics tolerant in mechanical environment for space application. Candidate materials for fixation were studied in terms of lower stresses to the fibers, lower viscosity to fill gaps between the fibers, and lower outgas. A silicone adhesive DC-SE9187L was selected and used to make a test piece of IFU. We made measurements of optical and polarization properties of the test IFU and confirmed its polarization maintenance property though polarization calibration and temperature control are necessary to meet polarization accuracy required.

9904-91, Session PS7

Low-noise flux estimate and data quality monitoring in Euclid NISP cosmological survey: how to fit a straight line in the precision cosmology era

Bogna Kubik, Univ. Claude Bernard Lyon 1 (France) and Institut National de Physique Nucléaire et de Physique des Particules (France); Rémi Barbier, Institut de Physique Nucléaire de Lyon (France) and Univ. Claude Bernard Lyon 1 (France); Peter Calabria, Institut National de Physique Nucléaire et de Physique des Particules (France) and Univ. Claude Bernard Lyon 1 (France); Florence Charlieu, Institut National de Physique Nucléaire et de Physique des Particules (France) and Univ. Claude Bernard Lyon 1 (France); Jean-Claude Clemens, Institut National de Physique Nucléaire et de Physique des Particules (France) and Aix-Marseille Univ. (France); Anne Ealet, Ctr. de Physique des Particules de Marseille (France) and Aix-Marseille Univ. (France); Sylvain Ferriol, Institut de Physique Nucléaire de Lyon (France) and Univ. Claude Bernard Lyon 1 (France); William Gillard, Ctr. de Physique des Particules de Marseille (France) and Aix-Marseille Univ. (France); Florent Schirra, Institut National de Physique Nucléaire et de Physique des Particules (France) and Univ. Claude Bernard Lyon 1 (France); Aurélia Secroun, Benoit Serra, Ctr. de Physique des Particules de Marseille (France) and Aix-Marseille Univ. (France); Gérard Smadja, Institut de Physique Nucléaire de Lyon (France) and Univ. Claude Bernard Lyon 1 (France); André Tilquin, Institut National de Physique Nucléaire et de Physique des Particules (France) and Aix-Marseille Univ. (France); Julien Zoubian, Ctr. de Physique des Particules de Marseille (France) and Aix-Marseille Univ. (France)

Euclid, a medium class cosmological survey from space, is designed to understand the origin of the universe's accelerating expansion. The survey will map the large-scale structure spanning over 70% of the age of the universe and provide constraints on the nature of dark energy and dark matter with unprecedented precision.

Precise spectroscopic and photometric redshifts, needed for the analysis of the galaxy clustering and 3 dimensional tomography of the universe, will be provided by the Near-Infrared Spectrometer and Photometer (NISP) equipped with 16 H2RG detectors.

A common technique used in the astronomical and cosmological applications is to read out near-infrared (NIR) arrays in the multiple accumulated sampling (MACC) - the accumulating signal is sampled up the ramp as a function of time. Multiple reads are averaged within groups to reduce the readout noise of the pixels and an equally weighted least square fit is applied to estimate the flux. This procedure completely neglects the fact that the data points are correlated and treats the samples as Gaussian distributed with constant variance.

As a pace mission, Euclid suffers from limitations of CPU and telemetry. The flux of the observed objects must be fitted in flight with an algorithm, which is not too demanding computationally. As the data points used to fit the fluence are not sent on ground, a reliable quality factor of the fit is required. A high precision and accuracy of the flux estimation and a rigorous control of the fit quality are fundamental to assure the strict goals of the mission. Optimal calculation of the flux in terms of signal to noise ratio should use all the information including correlated and uncorrelated errors in the covariance matrix. In that case flux must be computed using numerical methods, which is impossible in flight. For this purpose we propose a method of fitting the flux with Poisson distributed and correlated data, which is unbiased, has an analytic solution and provides a reliable quality factor of the fit. We compare our method to other common techniques of NIR signal estimation and illustrate the anomaly detection, such as nonlinearity or cosmic ray hits, using the quality factor on the flight-like engineering detectors.

Although our discussion is focused on Euclid NISP instrument, we anticipate that much of what is discussed will be of interest to any cosmological mission using similar near-infrared sensors.

9904-165, Session PS7

Small-grid dithers for the JWST coronagraphs

Charles-Philippe Lajoie, Rémi Soummer, Laurent Pueyo, Dean C. Hines, John C. Isaacs III, Edmund P. Nelan, Space Telescope Science Institute (United States); Mark Clampin, NASA Goddard Space Flight Ctr. (United States); Marshall D. Perrin, Space Telescope Science Institute (United States)

The James Webb Space Telescope (JWST) will be equipped with a suite of coronagraphs allowing observers to detect faint sources near or around bright stars and galaxies. Coronagraphic observations typically rely on subtracting a reference star point spread function (PSF) from the science target in order to remove the bright stellar speckles and improve the detectability of faint surrounding objects such as planets and disks. The accuracy of the target acquisition operation on the reference star is very important in order to match the science target and achieve optimal contrast. This is particularly true with phase masks on JWST, which are very sensitive to pointing accuracy. Here, we discuss the results of simulations of a new JWST mode that utilizes many sub-pixel dithered reference images, called Small-Grid Dithers, to optimize coronagraphic PSF subtraction. These sub-pixel dithers are executed with the Fine Steering Mirror under closed-loop fine guidance and are accurate to 2-3

milliarcseconds (mas; 1-sigma/axis). Sub-pixel dithers are limited to ~60 mas, but provide ample speckle diversity to reconstruct an optimized synthetic reference PSF with the use of a variety of algorithms (e.g; LOCI or KLIP). Using realistic noise sources and jitter in simulated images, we discuss and evaluate the performance gains of Small-Grid Dithers compared to the standard target acquisition scenario for both the NIRCam and MIRI coronagraphs. In particular, we find that Small-Grid Dithers can improve contrast by a factor ranging from 2 to more than 10 for the NIRCam and MIRI coronagraphs respectively.

9904-214, Session PS7

The mehod of searching F/G/K type hyper-velocity star candidates from data release one of LAMOST survey

Yinbi Li, Gang Zhao, Ali Luo, National Astronomical Observatories (China)

Hyper-velocity stars (HVSs) are believed to be ejected out from the Galactic center through dynamical interactions between stars and the central massive black hole(s), and they are the decisive evidence of Galactic center super-massive black hole. Therefore, searching for HVSs (or candidates) is a extremely important work, especially how to discover them from massive spectra, which are obtained by the large scale spectroscopic survey, with carefullydesigned criteria. In this work, we develop five steps to select HVS candidates from the LAMOST massive spectra based on the features of LAMOST data products, and we report 19 low mass F/G/K type hyper-velocity star candidates from over one million stellar spectra of the first data release of the LAMOST general survey.

9904-215, Session PS7

Data processing and algorithm development for the WFIRST-AFTA coronagraph

Marie Ygouf, Neil T. Zimmerman, Laurent Pueyo, Rémi Soummer, Marshall D. Perrin, Space Telescope Science Institute (United States); Bertrand P. Mennesson, John E. Krist, Gautam Vasisht, Bijan Nemati, Jet Propulsion Lab. (United States); Bruce A. Macintosh, Stanford Univ. (United States)

Direct detection and characterization of mature giant or sub-Neptune exoplanets in the visible will require space-based instruments optimized for high-contrast imaging with contrasts of 10ˆ-9. In this context, the Wide-Field Infrared Survey Telescope (WFIRST) coronagraph will reach raw contrasts of about 10ˆ-8 or better using state-of-the-art starlight suppression and wavefront control techniques. A ten-fold contrast improvement is therefore required using post-processing techniques in order to detect 10ˆ-9 planets from speckles. Post-processing techniques that are successful on both ground-based and space-based instruments need to be validated at such high contrast levels. In particular, the temporal and chromatic evolutions of residual speckles raise new challenges for these methods. We investigate PSF subtraction techniques for different observation strategies on WFIRST-like images in the presence of deformable mirrors and a coronagraph. In this communication, we present results applied to both simulated datasets and experimental data from the High Contrast Imaging Testbed at JPL, in particular for the WFIRST coronagraph integral field spectrograph (IFS). We demonstrate that PCA-based PSF subtraction using reference images obtained shortly before a science sequence can improve contrast by a factors of 5-30x and 2-4x respectively for simulated and experimental data.

9904-216, Session PS7

Sensitivity analysis of a direct broadband sensing algorithm

Dan Sirbu, Ruslan Belikov, NASA Ames Research Ctr. (United States)

Most coronagraphic instruments use a slow adaptive optics control loop for nulling midspatial frequencies to create a region of high contrast in the focal plane and enable high-contrast imaging of exoplanets. To enable accurate estimation of the wavefront, typically narrowband filters are used in conjunction with deformable mirror probing the science camera focal plane. Recently, we have presented a concept to enable estimation in direct broadband light by using probes that introduce spatially-localized chromatic diversity. Here, we determine the sensitivity of the algorithm in terms of the estimation accuracy of the chromatic spectral component as a function of the input broadband bandwidth. Additionally, we investigate the chromatic estimation error induced by the proximity of probes in the focal plane in order to enable maximal focal plane coverage. Finally, we compare the performance of the direct broadband estimation scheme with a typical narrowband estimation scheme.

9904-217, Session PS7

Centroiding procedure for the PROBA-3 OPSE metrology sub-system's PSF

Davide Loreggia, Silvano Fineschi, INAF - Osservatorio Astronomico di Torino (Italy); Gerardo Capobianco, INAF - Osservatorio Astrofisico di Torino (Italy); Mauro Focardi, Federico Landini, INAF - Osservatorio Astrofisico di Arcetri (Italy); Alessandro Bemporad, INAF - Osservatorio Astronomico di Torino (Italy); Ileana Cernica, Munizer Purica, Mihai Nisulescu, National Institute for Research and Development in Microtechnologies (Romania); Cédric Thizy, Jean-Sebastien Servaye, Univ. de Liège (Belgium); Giuseppe Massone, INAF - Osservatorio Astronomico di Torino (Italy); Gianalfredo Nicolini, Marta Casti, INAF - Osservatorio Astrofisico di Torino (Italy); Maurizio Pancrazi, INAF - Osservatorio Astrofisico di Arcetri (Italy); Marco Romoli, Univ. degli Studi di Firenze (Italy); Vladimiro Noce, Cristian Baccani, INAF - Osservatorio Astrofisico di Arcetri (Italy); Etienne Renotte, Univ. de Liège (Belgium)

Metrology in distributed systems for space applications is one of the most important technology research fields that in recent years have raised increasing interest. Many applications of astronomical observation techniques, as coronography and interferometry get great benefit when moved in space and the employment of distributed systems represents a milestone to step-over in astronomical research. In this work, we present the Optical Position Sensors Emitter – OPSE metrology sub-system on-board of the PROBA3. PROBA3 is an ESA technology mission that will test in-orbit many metrology techniques for the maintenance of a Formation Flying with two satellites, in this case an occulter and a main satellite housing a coronagraph named ASPIICS, kept at an average inter-distance of 144m. The scientific task is the observation of the Sun's Corona at high spatial and temporal resolution (target is the get close to the Sun limb down to 1.08R?). The OPSE will monitor the relative position of the two satellites and consists of three emitters positioned on the rear surface of the occulter that will be observed by the coronagraph itself. A Centre of Gravity algorithm is used to monitor the emitter's PSF at the focal plane of the Coronagraph retrieving the Occulter position with respect to the main spacecraft with a target measurement accuracy of 300microns for

lateral movements and of 20cm for longitudinal movements. A preliminary assessment of the centroiding performances is given.

9904-218, Session PS7

Probability density function approaches to completeness

Daniel Garrett, Dmitry Savransky, Cornell Univ. (United States)

Completeness is a useful metric for exoplanet direct imaging mission analysis and design. It is the probability of a planet falling outside the telescope's obscuration and being bright enough to be detected. Assuming probability density functions for orbital elements (semimajor axis, eccentricity, and orbital orientation) and planetary properties (geometric albedo, radius, and phase function) of planets of interest, a joint probability density function of planet-star separation and difference in brightness between star and planet is found. Completeness is straightforward for a single observation but can also account for multiple observations of the same star at different epochs. Benefits of completeness studies of exoplanet observations include realistic expectations of mission outcomes based on objective terms for search power and a scientific metric to inform and optimize designs.

Single-visit completeness is determined by the assumption that an exoplanet is observable if its angular separation from its star is greater than the observatory's inner working angle (IWA) and less than the observatory's outer working angle (OWA) while also being illuminated such that the difference in brightness between the star and planet is below a limiting value where confusion between the planet signal and noise occur. Dynamic completeness is the completeness of the nth observation of a target star. It is dependent on the elapsed time after the first observation and subsequent observations. Each successive observation reduces the maximum possible value of dynamic completeness. It rebounds from zero just after observation to a time dependent value as planet positions propagate.

Most completeness calculations have relied on Monte Carlo trials because of the complexity of the assumed distributions. A large, equal number of samples are generated from each of the distributions and star-planet separation and difference in brightness are calculated for each set. A two-dimensional histogram of these values generates the completeness joint probability density function. Integrating with respect to separation and difference in brightness over this joint probability density function yields the completeness. The completeness distribution must be sampled fully to find any one point of the joint probability distribution accurately. Because of the number of parameters involved and the wide range of values each of these parameters may take, full sampling requires a large number of Monte Carlo trials. Increasing numbers of Monte Carlo trials increases the computational time of accurately determining completeness.

For exoplanet mission simulators performing such calculations on the fly, it is desirable to produce such calculations quickly. Faster methods of accurately calculating completeness are desirable.

We present probability density function approaches to compute single-visit and dynamic completeness which are computationally faster and avoid the undersampling problem inherent in Monte Carlo approaches. The single-visit completeness joint probability density function is derived from the probability density functions necessary for determining planet-star separation and difference in brightness. Dynamic completeness is computed by incorporating the elapsed time between observations into the single-visit completeness joint probability distribution function. These approaches are computationally faster than performing large Monte Carlo simulations at each successive simulated observation.

9904-219, Session PS7

Performance analysis of the GR712RC dual-core LEON3FT SPARC V8 processor in an asymmetric multi-processing environment

Giovanni Giusi, Anna M. Di Giorgio, Scige J. Liu, Emanuele Galli, Gianluca Li Causi, Stefano Pezzuto, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Andrea M. Di Lellis, AMDL Srl (Italy)

In recent years, data rates and volumes produced by scientific space missions have increased exponentially with consequent new highly demanding requirements on onboard data processing and storage. The high costs in terms of memory and bandwidth increased the need of onboard analysis and compression of the collected data before they are sent to ground.

One possible solution is to have HW systems, e.g. ASICs, dedicated to these onboard activities, but the effort made in the past for producing powerful general purpose radiation tolerant European processors like the Aeroflex Gaisler UT699 LEON3FT SPARC V8, provided an indication of the possibility to implement an alternative and more flexible pure software solution.

In particular, past comparative studies showed the potentialities of the single core LEON3FT, which resulted to be one of the eligible onboard processors for implementing both instrument control and data acquisition and pre-processing functionalities in some of the future medium size missions proposed within the ESA Cosmic Vision program, e.g. Plato, ECho, Ariel.

However, the processor performances have shown to be less appealing when dealing with the very high demanding compression needs of survey missions like Euclid, where huge focal plane arrays (>600Mpix) coupled with stringent compression time requirements made the single-core LEON3FT unusable, forcing either the adoption of dedicated compression HW in the design, or the switching to the use of a more powerful non European processor, e.g. PowerPC based processors like the RAD750 of BAE Systems Information and Electronic Systems Integration Inc.

With the aim of finding a solution to these kind of needs based on the use of a European processor, the possibility to use a multi-core approach has been investigated. More specifically, we decided to start our investigation by carrying out a series of performance tests using a prototype board mounting the Cobham Gaisler GR712RC Dual-Core LEON3FT processor.

The application benchmark is based on the use of the same lossless compression algorithms used in the past for characterizing the performances of the LEON3FT single core. This choice allows a direct comparison with both the previously presented Leon3 results and the measured performances on architectures based on the use of PowerPC. The algorithm is based on a University of New Mexico open source implementation of the CCSDS 121.0-B-1 lossless compressor.

The hardware environment of the test consists of a homogeneous multi-core system architecture with a single bus and shared memory. The software environment is based on the use of RTEMS as operating systems, used in Asymmetric Multi Programming mode. The idea is not to develop a parallel implementation of the algorithm, but to split the overall compression activity into autonomous sub-tasks, acting on independent data sets covering separate portions of the overall focal plane array. The tasks run asynchronously on the individual cores, configured to have separate memory addressable areas and hardware resources. The task communication is implemented by means of standard IPC mechanisms.

To measure the performance we propose here a parametric approach which tests the effect of a variable workload to optimize the shared resources.

9904-220, Session PS7

On-board data processing for the near infrared spectrograph and photometer instrument (NISP) of the Euclid mission

Carlotta Bonoli, Andrea Balestra, Favio Bortoletto, Maurizio D'Alessandro, INAF - Osservatorio Astronomico di Padova (Italy); Stefano Dusini, Chiara Sirignano, Enrico Borsato, Fulvio Laudisio, Istituto Nazionale di Fisica Nucleare (Italy); John B. Stephen, INAF - IASF Bologna (Italy)

The Near Infrared Spectrograph and Photometer (NISP) is one of the two instruments on board the EUCLID mission now under implementation phase. The focal plane detector mosaic consists of 16, 2048x2048 pixels^2 HAWAII-II HgCdTe detectors, now in advanced delivery phase, from Teledyne Imaging Scientific (TIS), and will provide NIR imaging in three bands (Y, J, H) plus slitless spectroscopy in the range 1.1-2.0 micron.

All the observational modes will be supported by different parametrization of the classic Multi-Accumulation IR detector readout mode.

Due to the large number of deployed detectors and to the limited satellite telemetry available to ground, a consistent part of the data processing, conventionally performed off-line, must be accomplished on board, in parallel with the flow of data acquisitions.

This has led to the development of a specific on-board HW/SW data processing pipeline, and to the design of performing control electronics, suited to cope with the time and data flow constraints of the NISP acquisition sequences.

In this paper we present the architecture of the NISP on-board processing system, which interfaces directly to the SIDECAR ASICs managing the detector focal plane, as well as the implementation of the computational aspects of the data-processing i.e. frame co-adding, final frame computation and data compression before transmission to ground.

9904-221, Session PS7

The Precision Projector Laboratory: a facility for emulating high precision astronomical observations

Charles A. Shapiro, Jet Propulsion Lab. (United States); Roger M. Smith, California Institute of Technology (United States); Jason D. Rhodes, Timothy M. Goodsall, Jet Propulsion Lab. (United States); Jason R. Fucik, California Institute of Technology (United States); Barnaby T. P. Rowe, Univ. College London (United Kingdom); Christopher M. Hirata, The Ohio State Univ. (United States); Richard J. Massey, Durham Univ. (United Kingdom)

As astronomical observations from space benefit from improved sensitivity and calibration accuracy, poorly understood image sensor behavior threatens to limit the science reach of missions that demand increasingly strict control of systematic errors. Conventional detector characterization provides a bottom-up path to understanding the underlying detector physics and aids the development of ever more faithful numerical simulations; however, this approach is vulnerable to preconceptions and simplifications. An alternative top-down approach is laboratory emulation, which enables observation, calibration, and analysis scenarios to be tested without relying on a complete understanding of the underlying detector physics. Emulation complements conventional characterization and simulation efforts by testing their validity, and it reduces mission risk by revealing anomalous detector behavior only apparent in science-like images.

This paper describes the Precision Projector Laboratory (PPL), an emulation facility run by Jet Propulsion Laboratory and Caltech Optical Observatories. The primary experimental apparatus is an Offner Relay that projects "scenes" (stars, galaxies, spectra, etc.) with low optical aberration over the full area of a typical optical or near infrared image sensor. The scenes are etched onto high-resolution chrome-on-glass masks and reimaged at unity magnification. Focal ratios of f/8 and slower may be selected, spanning those of most proposed space missions. High Strehl point-spread functions are achieved over a wide field of view and wavelength range to deliver highly predictable image patterns with sub-pixel resolution, stable intensity, and fine motion control.

PPL supports various instruments requiring validation or rapid characterization using science-like data, in particular, the emulation of weak gravitational lensing measurements by the Wide Field Infrared Survey Telescope and high precision spectrophotometry of transiting exoplanets by James Webb Space Telescope.

9904-222, Session PS7

Design-oriented analytic model of phase and frequency modulated optical links

Rosario F. Cimmino, Consorzio Nazionale Interuniversitario per i Transporti e la Logistica (Italy); Pietro Monsurro, Sapienza Univ. di Roma (Italy); Antonio Saitto, Consorzio Nazionale Interuniversitario per i Transporti e la Logistica (Italy); Pasquale Tommasino, Alessandro Trifiletti, A. Vannucci, Sapienza Univ. di Roma (Italy); Francesco Romano, EExSKA (Italy)

High-dynamic range optical links, in which the microwave signal is modulated on an optical carrier, are emerging as an enabling sub-system in different applications such as antenna remoting, beamforming, and optical pre-processor for Photonic Analog to Digital Converters. Amplitude modulation was firstly investigated, and either direct modulation of the laser source or external modulation by means of Mach-Zehnder interferometers in consolidated LiNbO3 technology have been considered, according to system requirements in terms of cost, size, and performance.

In recent years, also phase and frequency modulation of the optical carrier are emerging as alternatives to amplitude modulated links, due to their modulation efficiency and spectral purity. A quadrature biased Mach-Zehnder interferometer was first considered as frequency discriminator at the receiver side. However, its linearity is not sufficient to achieve requirements in terms of Spurious-free dynamic range in most of the applications. Digital filter design techniques have been investigated for the design of optical filters working as frequency discriminator: these components show superior performance in terms of linearity, on the other one designed optical filters can be implemented as a photonic ASIC so reducing cost and size.

A key point for the design of both directly and externally-modulated links is the availability of models for the optical and electrical components, in order to estimate achievable performance during the design phase. In this paper, an analytic design-oriented model of phase and frequency modulated microwave optical links has been developed, that allows link design and performance simulation. A key part of the model is the non-linear and noise model of a Mach-Zehnder interferometer, which allows external phase modulation of the RF input signal. It has to be noted that the frequency roll-off of the optical response is considered. Also the model of the receiver has been developed, consisting of the frequency-dependent transfer function of the discriminator, evaluated in terms of coefficient of the designed digital filter. If needed such coefficients can be expressed as a function of coupling ratios and phase shifts of the related FIR lattice filter that is suitable for implementation as a photonic ASIC. Finally, also the frequency- dependent response of the receiver photodiode has been considered.

In order to demonstrate the feasibility and usefulness of the developed model, it has been used to design and compare links with different discriminators in terms of linearity, gain and dynamic range. Effects of the residual intensity modulation on receiver linearity have been taken into account in the model. All designed discriminators are suitable for implementation as planar lightwave circuits.

9904-223, Session PS7

The quick-look software of the Euclid NISP instrument workstation

John B. Stephen, Massimo Trifoglio, Enrico Franceschi, Fulvio Gianotti, Luca Valenziano, INAF - IASF Bologna (Italy)

The Near Infrared Spectro-Photometer (NISP) on board the Euclid ESA mission will be developed and tested at various levels of integration using various test equipment which shall be designed and procured through a collaborative and coordinated effort. The Electrical Ground Support Equipment (EGSE) shall be required to support the assembly, integration, verification and testing (AIV/AIT) and calibration activities at instrument level before delivery to ESA, and at satellite level, when the NISP instrument is mounted on the spacecraft. An important part of the EGSE is the Instrument Workstation (IWS). The main aim of the this workstation is to archive the instrument data in raw and in FITS format and to perform in near real-time or in retrieval mode the quick look analysis and some offline analysis required to monitor and verify the instrument functionalities and performances throughout the various phases of the NISP lifetime. Herein we describe the data flow and processing which will need to be performed by the IWS at the various stages of integration. In particular we explain in detail the requirements on the quick-look software which will allow the monitoring of the many stages in the instrument assembly, integration and verification. This software, written in the IDL language, allows access in near real time and in retrieval mode all the instrument data and provides the 1-D, 2-D and 3-D display and analysis tools required to verify the instrument functionalities and performance using both the HK and the Science data.

9904-224, Session PS7

Gain determination of non-linear IR detectors with the differential photon transfer curve (dPTC) method

Armin Rest, Bryan Hilbert, Massimo Robberto, Space Telescope Science Institute (United States); Karl Misselt, Jarron M. Leisenring, Marcia Rieke, The Univ. of Arizona (United States)

Conversion gain is a basic detector property which relates the raw counts in a pixel in data numbers (DN) to the number of electrons detected. The standard method for determining the gain is called the Photon Transfer Curve (PTC) method and involves the measurement the change in variance as a function of signal level. For non-linear IR detectors, this method depends strongly on the non-linearity correction and is therefore susceptible to systematic biases due to calibration inaccuracies. We have developed a new, robust, and fast method, the Differential Photon Transfer Curve (dPTC) method, which is independent of non-linearity corrections, but still delivers gain values similar in accuracy and precision.

9904-225, Session PS7

High-fidelity multi-scale local processing for visually optimized FIR/sub-mm Hershel images

Gianluca Li Causi, INAF - Osservatorio Astronomico di Roma (Italy) and INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Eugenio Schisano, Scige John Liu, Sergio Molinari, Anna M. Di Giorgio, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy)

In the context of the Hi-Gal full-plane multi-band mapping of the galactic plane, acquired with the Herschel far-infrared/sub-mm satellite, we have developed a powerful pipeline which produces high definition and high quality color maps, optimized for visual perception of image features. The tool projects the tiles of three selected band maps onto a 3-channel stripe, spanning 360° of galactic longitude by 2.8° galactic latitude, at the resolution of 3.2"/pixel, which is then processed by a custom multi-scale local stretching algorithm, endowed of local color balance and contrast tuning. A further edge-preserving contrast enhancement algorithm is finally applied, in order to perform artifact-free details sharpening. With this tool we have thus produced a giga-pixel color image of the whole galactic plane which join the 70?m, 160?m and 250?m maps and can be navigated in the ViaLactea web site.

9904-226, Session PS7

The boot software of the control unit of the near infrared spectrograph of the Euclid space mission: technical specification

Jaime Gómez-Sáenz-de-Tejada, Rafael Toledo-Moreo, Carlos Colodro-Conde, David Pérez-Lizán, Univ. Politécnica de Cartagena (Spain); Jesús Fernández-Conde, Sebastián Sánchez-Prieto, Univ. de Alcalá (Spain)

The Near Infrared Spectrograph and Photometer (NISP) is one of the instruments on board the ESA EUCLID mission. The Universidad Politécnica de Cartagena and Instituto de Astrofísica de Canarias are responsible of the Instrument Control Unit of the NISP (NI-ICU) in the Euclid Consortium. The NI-ICU main functions are:

- communication with the S/C and the Data Processing Unit via 1553 IFs
- control of the Filter and Grism Wheels
- control of the Calibration Unit
- thermal control of the instrument

The Boot Software (BSW) in a space program is a non-patchable, autonomous software that runs on the CPU and performs a small number of tasks: initialization, self tests of vital HW, memory management (dump, load, check), loading a patchable Application Software (ASW), and giving control to the loaded ASW.

The main features of a BSW design are the following:

• It must be flawless. The BSW is non-patchable, therefore a BSW bug cannot be fixed. A systematic failure can put in jeopardy a complete space program, losing many years of dedicated work and hundreds of millions of euros.

However, there is no such a thing as a flawless SW by design. A complete development process is put in place in order to minimize the probability of flying with buggy SW. The process includes several testing campaigns (with different means and objectives), thorough analysis and continuous reviews.

• It must be robust. Robustness is the ability to cope with errors during

execution. During the 6.5-years mission in space, many events will occur. Some of them can be foreseen, some other will be unexpected. The main external environment events are SEUs (Single Event Upsets, when a charged particle, e.g. a proton, collides with the Spacecraft and changes the value of a bit in memory), and HW degradation (due to continuous radiation). The Spacecraft interfaces could also be degraded, but in any case, no single failure shall lead to a system loss. Before critical decisions are taken, a design mechanism is put in place in order to avoid a single error to trigger a fatal scenario.

Software design techniques deal with expected and unexpected events in order to reach the robustness goal. Features like defensive programming, last-survivor policy, and data reporting approach are key to a successful BSW.

This paper presents the NI-ICU BSW Technical Specification definition and the analysis that optimizes the fulfillment of the design objectives.

9904-227, Session PS7

Simulating observations with the JWST NIRSpec integral field unit and a comparison with the E-ELT/HARMONI

Simon D. Zieleniewski, Sarah Kendrew, Niranjan A. Thatte, Ryan C. W. Houghton, Andrew Bunker, Univ. of Oxford (United Kingdom); Pierre Ferruit, European Space Research and Technology Ctr. (Netherlands)

With the James Webb Space Telescope (JWST) due to launch in 2018 it is becoming ever more critical to prepare for observations by quantitatively analysing its science capabilities, and thus maximising operating efficiency. To this end we have extended the HARMONI simulation package HSIM of Zieleniewski et al. to develop a Python software package capable of simulating observations using the NIRSpec integral field unit (IFU) on the JWST. The software handles input datacubes and creates mock observed datacubes, folding in background, throughput and noise models for the telescope and instrument. It also utilises the WebbPSF package to incorporate detailed point spread functions into simulations. The software allows astronomers to quantitatively assess the feasibility of observations in much greater detail than offered by simple exposure time calculators. We perform an extensive set of simulations of high redshift emission-line galaxies, covering a range of morphologies, redshifts and star formation rates and derive simple limits for the detection and kinematic analysis of these objects. We further compare the performance of NIRSpec to the ground-based HARMONI instrument on the European ELT, and demonstrate the synergies between these two future IFUs.

9904-228, Session PS7

A rigorous approach to the production of reference files for JWST/NIRCam

Massimo Robberto, Bryan Hilbert, Space Telescope Science Institute (United States); Jarron M. Leisenring, Karl Misselt, The Univ. of Arizona (United States); Armin Rest, Space Telescope Science Institute (United States); Marcia Rieke, The Univ. of Arizona (United States)

One of the main outcomes of the final cryo-vacuum tests of a space instrument like JWST/NIRCam is the production of reference files suitable for science calibration in the early phases of the mission. Reference files are required by nearly every step of the pipeline, from raw data to final mosaic images astrometrically and photometrically corrected. Their construction, largely based on extensive sets of darks and illuminated images, must not only take into account the flow of the pipeline, but also prevent the injection of spurious systematics and correlations, while providing a robust estimate of the added uncertainty added at each step, needed for correct noise propagation. In this contribution we describe the approach followed for JWST/NIRCam using the data collected in the final cycle of cryo-vacuum tests (CV3) at NASA Goddard.

9904-229, Session PS7

Is there a best method for removing correlated noise from Spitzer exoplanet photometry?

James G. Ingalls, Jessica E. Krick, Sean J. Carey, John R. Stauffer, Carl J. Grillmair, Patrick J. Lowrance, Spitzer Science Ctr. (United States)

At infrared wavelengths secondary eclipses and phase curves are powerful tools for studying a planet's atmosphere. Extracting information about atmospheres, however, is extremely challenging due to the small differential signals, which are often at the level of 100 parts per million (ppm) or smaller, and require the removal of significant instrumental systematics. For the IRAC 3.6 and 4.5 ?m InSb detectors that remain active on post-cryogenic Spitzer, the interplay of residual telescope pointing fluctuations with intrapixel gain variations in the moderately under sampled camera is the largest source of time-correlated noise. Over the past decade, a suite of techniques for removing this noise from IRAC data has been developed independently by various investigators. In summer 2015, the Spitzer Science Center hosted a Data Challenge in which 7 exoplanet experts, each using a different noise-removal method, were invited to analyze 10 eclipse measurements of the hot Jupiter XO-3 b, as well as a complementary set of 10 simulated measurements. In this contribution we review the results of the Challenge. We describe statistical tools to assess the repeatability, reliability, and validity of data reduction techniques, and to compare and (perhaps) choose between techniques.

9904-230, Session PS7

Spitzer IRAC pipeline: final modifications and lessons learned over a mission

Patrick J. Lowrance, Sean J. Carey, Jason A. Surace, James G. Ingalls, William J. Glaccum, Jessica E. Krick, Spitzer Science Ctr. (United States)

In more than ten years of operations, the Spitzer Space Telescope has conducted a wide range of investigations from observing nearby asteroids to probing atmospheric properties of exoplanets to measuring masses of the most distance galaxies. Observations using the Infrared Array Camera (IRAC) at 3.6 and 4.5um are likely to continue through 2018 when the James Webb Space Telescope will succeed Spitzer. In anticipation of the eventual end of the mission, the basic calibrated data reduction pipeline designed to produce flux-calibrated images has been finalized and used to reprocess all the data taken during the Spitzer warm mission. We discuss final modifications made to the pipeline.

9904-231, Session PS7

The instrument workstation for EGSE of the near infrared spectro-photometer instrument (NISP) of the Euclid mission

Massimo Trifoglio, Fulvio Gianotti, Enrico Franceschi, John B. Stephen, Luca Valenziano, INAF - IASF Bologna (Italy)

The NISP instrument on board the Euclid ESA mission will be developed and tested at different levels of integration using various test equipment which shall be designed and procured through a collaborative and coordinated effort. The NISP Instrument Workstation (NI-IWS) will be part of the EGSE configuration that will support the NISP AIV/AIT activities from the NISP Warm Electronics level up to the launch of Euclid. One workstation is required for the NISP EQM/AVM, and a second for the NISP FM. Each workstation will follow the respective NISP model after delivery to ESA for Payload and Satellite AIV/AIT and launch. At these levels the NI-IWS shall be configured as part of the Payload EGSE, the System EGSE, and the Launch EGSE, respectively. After launch, the NI-IWS will be also re-used in the Euclid Ground Segment in order to support the Commissioning and Performance Verification (CPV) phase, and for troubleshooting purposes during the operational phase.

The NI-IWS is mainly aimed at the local storage in a suitable format of the NISP instrument data and metadata, at local retrieval, processing and display of the stored data for on-line instrument assessment, and at the remote retrieval of the stored data for off-line analysis on other computers.

We describe the design of the IWS software that will create a suitable interface to the external systems in each of the various configurations envisaged at the different levels, and provide the capabilities required to monitor and verify the instrument functionalities and performances throughout all phases of the NISP lifetime.

9904-232, Session PS7

Cross validation of a yield tool based on the EXOSIMS framework

Rhonda M. Morgan, Jet Propulsion Lab. (United States); Patrick J. Lowrance, California Institute of Technology (United States); Dmitry Savransky, Daniel Garrett, Cornell Univ. (United States); Wesley A. Traub, Jet Propulsion Lab. (United States)

The new large mission study concepts for the direct imaging of exo-earths present an exciting opportunity for exoplanet discovery and characterization. While these telescope concepts would also be capable of conducting a broad range of astrophysical investigations, the most difficult technology challenges are driven by the requirements for imaging exo-earths. The exoplanet science yield for these mission concepts will drive design trades and mission concept comparisons.

To assist in these trade studies, the Exoplanet Exploration Program Office (ExEP) is developing a yield estimation tool that emphasizes transparency and consistent comparison of various design concepts. The tool will provide a parametric estimate of science yield of various mission concepts using contrast curves from physics-based model codes and Monte Carlo simulations of design reference missions using realistic constraints, such as solar avoidance angles, the observatory orbit, propulsion limitations of star shades, the accessibility of candidate targets, local and background zodiacal light levels, and background confusion by stars and galaxies. The Python tool utilizes Dmitry Savransky's EXOSIMS (Exoplanet Open-Source Imaging Mission Simulator) design reference mission simulator that is being developed under the WFIRST Preparatory Science program. ExEP is extending and validating the tool for future mission concepts under consideration for the upcoming 2020 decadal review.

The validation of the tool utilizes two approaches. The first approach uses a synthetic star list and Brown completeness to calculate point comparison and evaluate known parametric trends. The comparison is used for both unit testing and end-to-end validation. The second approach is an end-to-end cross-validation against an independently generated consistent comparison of Exo-S, Exo-C, WFIRST/AFTA, and WFIRST/AFTA with Starshade (Traub, in preparation). We present the validation results for both validation approaches.

9904-254, Session PS7

The control unit of the near infrared spectrograph of the Euclid space mission: detailed design

Rafael Toledo-Moreo, Carlos Colodro-Conde, Jaime Gómez-Sáenz-de-Tejada, Univ. Politécnica de Cartagena (Spain); José Javier Díaz-García, Óscar Tubío Araújo, Instituto de Astrofísica de Canarias (Spain); Cayetano Raichs, Jordi Catalán, Crisa, an Airbus Defence and Space Co. (Spain); Isidro Villó, Univ. Politécnica de Cartagena (Spain); Rafael Rebolo-López, Instituto de Astrofísica de Canarias (Spain)

The Near Infrared Spectrograph and Photometer (NISP) is one of the instruments on board the ESA EUCLID mission. The Universidad Politécnica de Cartagena and Instituto de Astrofísica de Canarias are responsible of the Instrument Control Unit of the NISP (NI-ICU) in the Euclid Consortium. The NI-ICU main functions are:

- communication with the S/C and the Data Processing Unit via 1553 IFs
- control of the Filter and Grism Wheels
- control of the Calibration Unit
- thermal control of the instrument

The NI-ICU follows a cold-redundancy scheme with two identical sections that control only their corresponding nominal and redundant elements. The only exception to this is the dual-redundancy of the 1553 IF with the S/C and the DPU.

Internally, each section of the NI-ICU is organized in three boards.

- The LVPS (Low Voltage Power Supply) board features all the DC/DC converters necessary for the secondary power supplies internal to the NI-ICU. It also allocates the EMC filters so as to meet the electromagnetic compatibility requirements. Input voltage for this module comes directly from the primary 28V provided by the S/C. The LVPS shall not provide secondary power to any electronic unit external to the NI-ICU. This module also allocates one 1553 connector and transceiver.

- The CDPU (Central Data Processing Unit) board is based on the GPM (General Purpose Module) developed by Crisa, featuring a MDPA ASIC with a LEON2-FT processor, Memory banks, an RTAX-2000 FPGA, 1553 IF with the S/C and the DPU, Spacewire for inter-board communication and buffering and SPI master.

- The DAS (Driver and Acquisition Support) includes the electronic drivers for the mechanism, calibration lamps and heaters. It features a Secoia ASIC developed by Crisa, for PWM generation and analog acquisition.

In particular this board shall drive:

- 2 motor coils of the stepper motor of the cryo-mechanism that spins the filter and grism wheels
- 1 reference position sensor
- 2 heater lines, one for the opto-mechanical assembly, where the filters and grisms are allocated, the other for the focal plane array of the detectors. The heaters set point will be commanded from ground: no PID will be implemented on board the instrument.
- 5 LEDs of the calibration unit, controlled by PWM

This board must read next sensors:

- 12 temperature sensors PT-100: 6 in the opto-mechanical assembly, 4 in the detector system, and 2 in the cryo-mechanism

All boards will be connected through a backplane motherboard and will be custom-made for the NI-ICU.

This paper presents the NI-ICU status of definition and design at the end of the detailed design phase.

9904-233, Session PS8

Use of updated material properties in parametric optimization of spaceborne mirrors

Tony B. Hull, The Univ. of New Mexico (United States); Thomas Westerhoff, Guenter Weidmann, Rule Kirchhoff, SCHOTT AG (Germany)

Spaceborne sensor mirrors need to be both structurally efficient and to maintain figure through thermal transients. Both properties can be represented in a plot showing structural efficiency (Young's Modulus divided by density) on one axis and thermal transient resilience (Thermal Diffusivity divided by Coefficient of Thermal Expansion) on the other. Such charts have been effectively used by optomechanical engineers for decades for preliminary material selection. However for several materials, the thermal attributes have improved considerably from those used in handbook charts. When contemporary values are used, this comparison chart looks differently. We will express this chart both at room temperature and at cooled temperatures, and look at the formulation of lines of equal merit. We will discuss how these lines of equal merit may be formulated differently depending on the orbit of the mission.

9904-234, Session PS8

Laboratory demonstration of a primary active mirror for space with the LATT: large aperture telescope technology

Roberto Biasi, Microgate S.r.l. (Italy); Marco Xompero, Franco Lisi, INAF - Osservatorio Astrofisico di Arcetri (Italy); Christian Patauner, Microgate S.r.l. (Italy); Daniele Gallieni, Paolo Lazzarini, Matteo Tintori, A.D.S. International S.r.l. (Italy); Francesco d'Amato, Istituto Nazionale di Ottica (Italy) and Consiglio Nazionale delle Ricerche (Italy); Mauro Pucci, Istituto Nazionale di Ottica (Italy) and Consiglio Nazionale delle Ricerche (Italy); Runa Briguglio, INAF - Osservatorio Astrofisico di Arcetri (Italy); Carmelo Arcidiacono, INAF - Osservatorio Astronomico di Bologna (Italy); Armando Riccardi, INAF - Osservatorio Astrofisico di Arcetri (Italy); Fabrizio Duò, Christian Vettore, CGS S.p.A. Compagnia Generale per lo Spazio (Italy); Alessandro Zuccaro Marchi, Joao Pereira do Carmo, Luca Maresi, European Space Research and Technology Ctr. (Netherlands) and European Space Agency (France)

The LATT project is an ESA contract to demonstrate the scalability of the technology from ground-based adaptive mirrors to space active primaries. A prototype spherical mirror based on a 40cm diameter thin glass shell with 19 contactless, voice-coil actuators and co-located position sensors has been manufactured and integrated, into a final unit with an areal density lower than 22kg/m2. Laboratory tests demonstrated the controllability with very low power budget and the survival of the fragile glass shell exposed to launch accelerations, thanks to an electrostatic locking procedure; such achievements pushes the technology readiness toward level 5.

Through such a prototype, the LATT project explored the feasibility of an active and lightweight primary for space telescopes. The concept is attractive for large segmented apertures, fitted with a surface active control to shape and co-phase them once in flight.

In this paper we will describe the findings of the technological advances and the results of the environmental and optical tests carried out on the prototype.

9904-235, Session PS8

Co-phasing primary mirror segments of an optical space telescope using a long stroke Zernike WFS: simulation and laboratory experiments

Kathryn Jackson, California Institute of Technology (United States); James K. Wallace, Victor E. White, Harish M. Manohara, Jet Propulsion Lab. (United States); Sergio Pellegrino, California Institute of Technology (United States); David C. Redding, Jet Propulsion Lab. (United States)

Static Zernike phase-contrast plates have been used extensively in microscopy for half a century and, more recently, in optical telescopes for wavefront sensing. A dynamic Zernike wavefront sensor (WFS) with four phase shifts, for reducing error due to spurious light and eliminating other asynchronous noise, has been proposed for use in adaptive optics. Here, we propose adapting this method for co-phasing the primary mirror of a segmented space telescope. In order to extend the dynamic range of the WFS, which has a maximum range of +/- ? /2, a phase-contrast plate with multiple steps, both positive and negative, has been developed such that errors as large as +/-10? can be sensed. The manufacturing tolerances have been incorporated into simulations, which demonstrate that performance impacts are minimal. We show that the addition of this small optical plate along with a high precision linear translation stage at the prime focus of a telescope and pupil viewing capability can provide extremely accurate segment phasing with a simple white-light fringe fitting algorithm and a closed-loop controller. The original focal-plane geometry of a centro-symmetric phase shifting element is replaced with a much less constrained shape, such as a slot. Also, a dedicated pupil imager is not strictly required; an existing pupil sampler such as a Shack-Hartmann (SH) WFS can be used just as effectively, allowing simultaneous detection of wavefront errors using both intensity and spot positions on the SH-WFS. This could lead to an efficient synergy between Zernike and SH-WFS, enabling segment phasing in conjunction with high-dynamic range sensing.

9904-236, Session PS8

The satellite formation flying in lab: PROBA-3/ASPIICS metrology subsystems test-bed

Gerardo Capobianco, INAF - Osservatorio Astrofisico di Torino (Italy); Davide Loreggia, Silvano Fineschi, INAF - Osservatorio Astronomico di Torino (Italy); Mauro Focardi, INAF - Osservatorio Astrofisico di Arcetri (Italy); Alessandro Bemporad, INAF - Osservatorio Astronomico di Torino (Italy); Marta Casti, INAF - Osservatorio Astrofisico di Torino (Italy); Vladimiro Noce, Federico Landini, INAF - Osservatorio Astrofisico di Arcetri (Italy); Cristian Baccani, Univ. degli Studi di Firenze (Italy); Maurizio Pancrazzi, Marco Romoli, INAF - Osservatorio Astrofisico di Arcetri (Italy); Giuseppe Massone, Gianalfredo Nicolini, INAF - Osservatorio Astrofisico di Torino (Italy); Steve Buckley, Kevin O'Neill, SensL (Ireland); Ileana Cernica, Munizer Purica, National Institute for Research and Development in Microtechnologies

(Romania); Cédric Thizy, Jean-Sébastien Servaye, Etienne Renotte, Univ. de Liège (Belgium)

Formation flying is one of the most promising techniques for the future of astronomy and astrophysics from the space. The capabilities of the rockets strongly impact the dimensions and the weights of telescopes and instrumentation to be launched. Telescopes composed by several smallest satellites in formation flying, could be the key for build big space telescopes. With this aim, the ESA PROBA-3 mission will demonstrate the capabilities of this technology, maintaining two satellites aligned within 1 mm (longitudinal) when the nominal distance between the two is of around 144m. The scientific objective of the mission is the observation of the solar corona from 1.08 solar radii. The Coronagraph Spacecraft (CSC) will observe the Sun, when the second spacecraft, the Occulter Spacecraft (OSC) will work as an external occulter, eclipsing to the CSC the sun disk. The finest metrology sub-systems, the Shadow Position Sensors (SPS) and the Occulter Position Sensor Emitters (OPSE) identifying respectively the CSC-Sun axis and the formation flying (i.e., CSC-OSC) axis will be considered here. In particular this paper is dedicated to the test-bed for the characterization, the performance analysis and the algorithms capabilities analysis of the two metrology subsystems. The test-bed is able to simulate the different flight conditions of the two spacecrafts and will give the opportunity to check the response of the subsystems in the conditions as close as possible to the flight. The first data set relative to the ASPIICS SPS and OPSE demonstration models will be also discussed.

9904-237, Session PS8

CFRP mirror technology for cryogenic space interferometry: review and progress to date

Martyn L. Jones, David D. Walker, Glyndwr Univ. (United Kingdom); David A. Naylor, Ian T. Veenendaal, Brad G. Gom, Univ. of Lethbridge (Canada)

For optical designers to keep pace with the ambitions of the astronomy community, lighter, stiffer and more tailorable materials must be found and developed for telescope primary apertures. A telescope that is designed for far infrared observations requires stable optical performance over extreme temperature ranges. An interferometer with a pair of 2m diameter primary apertures is envisaged which will operate at 4K to eliminate back ground self-emission. The mass of the telescope must be kept to a minimum to enable payload mass for instrumentation and to limit cost of launching such a mission to an L2 orbit.

In partnership with the National Facility for Ultra Precision surfaces at OpTIC St Asaph and the Advanced Composites Training and Development centre in Broughton North Wales, Glyndwr University are developing the capability to create lightweight optical surfaces for a range of applications.

This paper focus' on the research and development of a Carbon Fibre Reinforced Plastic (CFRP) 2m primary for this for an FP7 project, FISICA (Far Infrared Space Interferometer Critical Assessment). In particular, we focus on the history of CFRP mirror technologies and the challenges the optical designers face when using anisotropic material for precision surfaces. We highlight the difficulty in the creation of a primary mirror that will operate in such a low temperature environment. One key aspect of this project was the lack of data for CFRP material properties at cryogenic temperatures. In collaboration with a FISICA partner at the University of Lethbridge, Alberta Canada, a test procedure was developed and the resulting coefficient of expansion properties, dominated by the fibre orientation was fed into an Abaqus Finite Element Analysis (FEA) model in order to ascertain the temporal rigidity of the mirror. A further complication during thermal cycling of samples was observed during the test in that the CTE of the material increased after each cycle. To quantify the effect and determine the cause of the issue an FEA was developed.

We conclude with a discussion of the research and development of this technology in order to raise the technology readiness level of CFRP mirrors for lightweight primary mirror space telescopes.

9904-238, Session PS8

Radiance from an ice-contaminated surface

Jonathan W. Arenberg, Joshua Adamson, George M. Harpole, Northrop Grumman Aerospace Systems (United States); Malcolm B. Niedner, Charles W. Bowers, Kimberly I. Mehalick, NASA Goddard Space Flight Ctr. (United States); Paul A. Lightsey, Ball Aerospace & Technologies Corp. (United States)

The formation of water ice on key thermal and optical surfaces is a consideration in the design and performance of the James Webb Space Telescope. Many of these concerns are related to the mid-infrared stray light and thermal performance of the system. In this paper, an expression for the radiance of a contaminated surface is formulated, including directional, film thickness and cooling effects. The resulting formula is then evaluated to show how radiance emanating from the surface changes for various thicknesses of the ice layer as a function wavelength and the local thermal environment. This paper concludes with an analysis and discussion of this complex behavior.

9904-239, Session PS8

A novel design of dual-channel optical system of star tracker based on non-blind area PAL system

Yujie Luo, Jian Bai, Zhejiang Univ. (China) and State Key Lab. of Modern Optical Instrumentation (China)

Star tracker plays an important role in satellite navigation, which is an optical device to control the attitude and orbit of satellite through capturing real-time images of stars, measuring the positions, and recalculating the motion orbit itself. Considering the satellites on near-Earth orbit, the star trackers usually have two optical systems: one for observing the profile of Earth and the other for capturing the positions of stars. However, the relatively heavy weight of two optical systems will result in an overmuch energy consumption for astronomical satellites. With the purpose of reducing the weight, we demonstrate a novel kind of dual-band optical structure of star tracker based on non-blind area PAL imaging system, which can combine both optical systems into an integrated one and realize the miniaturized design. Panoramic annular lens (PAL) consists of two refractive and two reflective surfaces, and is a kind of special optical system used for imaging the objects around the optical axis, that means the field of view (FOV) is large and centered at a plane orthogonal to optical axis. According to the imaging principle, PAL system can transform a 360° cylindrical FOV onto a two-dimensional annular plane. An inevitable problem of PAL is that the central part of its image plane cannot capture any ray and form a round blind area. In this paper, we try to make use of this round blind area and propose to design an additional correcting lens group in front of PAL system for making up the blind area and imaging the objects before this system. Dichroic filter is a kind of wavelength-based film, which can let some band refract and make some other band reflect. We substitute the conventional reflective film on reflective surfaces of PAL block by the dichroic filter of ultraviolet band reflected and visible band transmitted. Since the feature of this filter, we set the ultraviolet band as the PAL channel to observe the Earth with the FOV ranging from 40°-60°, and set the visible band as the front imaging channel with the FOV ranging from 0°-20° to capture the stars far away from this star tracker. Consequently, the rays of both channels are converged on the same image plane, improving the efficiency of pixels of detector. Obviously, because the UV channel is used to observe the Earth, the FOV of front imaging channel is obstructed, and there must be a mirror in front of the whole system to deflect the beam. As a result, the problem of blind area of PAL is solved and two optical systems are combined into an integrated one.

9904-240, Session PS8

Distortion of the pixel grid in WFC3/UVIS and ACS/WFC CCD detectors and its astrometric correction

Vera Kozhurina-Platais, John Mackenty, Space Telescope Science Institute (United States); David A. Golimovski, Space Telescope Science Institute (United States); Norman Grogin, Space Telescope Science Institute (United States); Marco Sirianni, Space Telescope Science Institute (United States); Jay Anderson, Space Telescope Science Institute (United States)

The geometric distortion of the CCD detectors used in the HST Wide Field Camera 3 (WFC3) and Advanced Camera for Surveys (ACS) instruments is characterized by both macro and micro-scale distortions. The macro-distortion owing to the tilt of the HST optical assembly is modeled as a high-order polynomial. The micro-distortion is inherent to the CCD detectors themselves which manifests as a fine-scale systematic offset in the residuals from the best-fit polynomial solutions. Such systematic errors with a complex spatial structure across the CCD chips introduce astrometric errors at the level of about 0.2 pix (up to 3 micrometers with the 15 micrometers per pixels). These fine-scale and low-amplitude distortions arise from spatial irregularities in the pixel grids. For the WFC3/UVIS CCD chips, there is clear pattern of a periodic skew in the lithographic-mask stencil imprinted on the detector. Similar irregularities in the pixel grid of ACS/WFC CCD chips are more pronounced and their origins not yet fully understood. To remove these micro-distortions, a 2-D correction in the form of look-up table is developed using the HST images of very dense fields of stellar clusters. The post-correction of fine-scale astrometric errors can be removed down to the level of 0.05 pix (0.75 micrometers) or better. Only space-borne observations are able to provide the necessary precision to detect this small systematics in the pixel grid.

9904-253, Session PS8

Battery-powered thin film deposition process for coating telescope mirrors in space

David A. Sheikh, ZeCoat Corp. (United States)

An aluminum film manufactured in the vacuum of space may increase the broadband reflectance response of a space telescope operating in the EUV (50-nm to 115-nm) by eliminating absorbing metal-fluorides and/or metal-oxides, which typically reduce aluminum's reflectance below 115-nm and cut-off reflectance below ~90-nm. Recent developments in battery technology allow relatively large amounts of power to be discharged in a short period of time. It is therefore conceivable to power an array of resistive evaporation filaments in a space environment, using a reasonable mass of batteries and other supporting hardware. This technique may be advantageous for coating a large, broadband telescope mirror in space. This paper presents reflectance results, as well as, coating uniformity results, for aluminum films made using an array of battery-powered evaporation filaments, placed inside a vacuum chamber.

9904-242, Session PS9

Cryogenic proton irradiation of an EM-CCD for the WFIRST-AFTA coronagraph

Nathan L. Bush, David J. Hall, Andrew D. Holland, Ross Burgon, Neil J. Murray, The Open Univ. (United Kingdom); Jason P. D. Gow, Open Univ (United Kingdom); Leon K Harding, Richard Demers, Michael Hoenk, Bijan Nemati, Pavani Peddada, Jet Propulsion Laboratory (United States)

The Wide Field Infra-Red Survey Telescope (WFIRST) is a NASA observatory designed to perform wide-field surveys of the near-infrared sky and direct imaging of exoplanets in the visible. Of the two instruments on-board, a high contrast coronagraph will carry out the direct imaging and spectroscopic analysis of exoplanets, providing a means to probe the structure and composition of planetary systems.

Since the WFIRST coronagraph is expected to operate in low photon flux for long integration times, all noise sources must be kept to a minimum. The Electron Multiplication (EM)-CCD has been baselined for both the imaging and spectrograph cameras because of its low effective electronic read noise at sub-electron values with appropriate multiplication gain setting. The presence of other noise sources, however, such as thermal dark signal and Clock Induced Charge (CIC), need to be characterized and mitigated. In addition, operation within a space environment will subject the device to radiation damage that will degrade the Charge Transfer efficiency (CTE) of the device throughout the mission lifetime. Irradiation at the nominal instrument operating temperature has the potential to provide the best estimate of performance degradation that will be experienced in flight, since the final populations of silicon defects has been shown to have strong temperature dependence.

Here we present our latest results from pre-and post- cryogenic irradiation testing of the e2v CCD201-20 BI EM-CCD sensor, baselined for the WFIRST-AFTA coronagraph instrument.

9904-243, Session PS10

Zernike wavefront sensor (ZWFS) development for low order wavefront sensing (LOWFS)

Xu Wang, Fang Shi, James K. Wallace, Jet Propulsion Lab. (United States)

ZWFS measures phase via the phase-contrast method and is known to be photon noise optimal for measuring low order aberrations. Recently, ZWFS was selected as the baseline LOWFS technology on WFIST-AFTA for its good sensitivity, accuracy, and its easy integration with the starlight rejection mask. In this paper, we presents the ZWFS model validation experiment results from the fabricated ZWFS phase mask on a stand-alone LOWFS testbed and Palomar telescope.

9904-244, Session PS10

Sparse aperture mask wavefront sensor testbed results

Hari Subedi, Princeton Univ. (United States); Neil T. Zimmerman, Space Telescope Science Institute (United States); N. Jeremy Kasdin, A. J. E. Riggs, Princeton Univ. (United States)

In any future space telescope outfitted for exoplanet imaging, and in particular in the Coronagraph Instrument (CGI) for WFIRST-AFTA, it will be necessary to estimate and control low-order wavefront aberrations to maintain the desired coronagraphic starlight suppression for exoplanet detection. At the Princeton High Contrast Imaging Lab (PHCIL), we are working on a new technique that integrates a sparse-aperture mask (SAM) with a shaped pupil coronagraph (SPC) to make precise estimations of these low-order aberrations. We collect the starlight rejected from the

coronagraphic image plane and interfere it using a sparse aperture mask (SAM) at the relay pupil to estimate the low-order aberrations. In our previous work, we have numerically proven the efficacy of this technique at broadband up to 50% and we have shown that we can control these aberrations below the desired level. We also presented the initial tilt results from our testbed, which was a work on progress. In this paper, we will briefly overview the SAM wavefront sensor technique, explain the design of the completed testbed, and report the experimental estimation results of the dominant low-order aberrations.

9904-245, Session PS10

Active damping of the TALC space telescope

Christophe Collette, Univ. Libre de Bruxelles (Belgium); Simon Chesné, Institut National des Sciences Appliquées de Lyon (France); Sylvain Hellegouarch, Univ. Libre de Bruxelles (Belgium); Marc Sauvage, Commissariat à l'Énergie Atomique (France); Gilles A. Durand, Commissariat à l'Energie Atomique (France)

Further space exploration in the far-infrared requires larger telescopes, in order to improve the spatial resolution of captured images. To this purpose, several conceptual designs of future space telescopes are currently under study. One of them is the Thinned Aperture Light Collector (TALC). It consists of a 20 meter diameter deployable primary mirror, connected to a central boom through cables in tension in the manner of a bycle wheel. In the deployed configuration, structural vibrations need to be drastically reduced to collect the light.

In the first part of this paper, a dynamical model of the TALC telescope is presented, showing the modes shapes and typical structural responses. It is shown that resonances can be divided into global modes, e.g. primary miror ovalisation, and local modes, e.g. petal modes. Two control concepts are developed for damping actively these modes. The first one consists of actively modifying the tension of several cables, and the second one consists of actuating pistons placed at outer edge of petals. It is shown that the first concept is effective controlling global modes, while the second one is effective for controlling local modes. Both concepts use piezoelectric actuators, driven by robust decentralized control laws. The numerical study is completed by a parameter variation on the number/position of actuators in order to maximize the control authority with a limited number of actuators.

The second part of the paper is dedicated to an experimental validation of the proposed control concept on a 1/10 scaled prototype of tha TALC telescope. Compared to the full scale telescope, the prototype will not be deployabe, i.e. each miror segments will be connected to its neighbours through flexural hinges mimicing the kinematics of the deployed stage. Moreover, the mirors are made of aluminium honeycomb structures, and the overall mass of the optics is represented by a dummy mass attached at one end of the central carbon boom.

9904-246, Session PS10

Modeling of deformable mirror quilting orders

Dan Sirbu, Eugene A. Pluzhnik, Ruslan Belikov, NASA Ames Research Ctr. (United States)

Model-based wavefront control methods such as electric field conjugation require accurate optical propagation models to create high-contrast regions in the focal plane using deformable mirrors (DMs). Recently, it has been shown that it is possible to exceed the controllability outer-working angle imposed by the Nyquist limit based on the number of actuators by utilizing a diffraction grating. The print-through pattern on MEMS-based DMs formed during the fabrication process creates both an amplitude and a phase diffraction grating that can be used to enable Super-Nyquist wavefront control. Using high-resolution interferometric measurements of a DM-actuator, we develop a DM-diffraction grating model. We evaluate the accuracy of the model by comparison of the location and strength of the quilting orders from model predictions with experimental measurements obtained from the ACE laboratory.

9904-247, Session PS10

Active structural vibration control for high-performance space optical payload

Bowen Zhang, Xiaoyong Wang, Dewei Sun, Beijing Institute of Space Mechanics and Electricity (China)

Optical performance of high resolution space camera is severely affected by micro-vibration induced by bus disturbances, such as reaction wheel assembly (RWA), control moment gyroscope (CMG), thrusters, stepper motors, cryo-coolers, solar array drives, thermal popping, etc. As a result, vibration isolation is commonly required. The first step taken to settle this issue is often passive mechanical isolation because it is simple and reliable. For cases that the disturbance sources are excessive to the payload and the performance requirement cannot be met using passive isolators alone, additional steps like active control are taken. Recently, hybrid (passive/active) and active vibration isolation systems have been investigated broadly and demonstrated on orbit.

This paper proposed an active vibration isolation platform (AVIP) for a new agile remote sensing satellite. Agility means this satellite can acquire off-nadir scenes rapidly in a large flight envelope in the same orbit, and, at the meantime, requires very precise pointing during the exposure periods. The proposed AVIP consists of six voice coil legs with integral load cells (for feedback control). In every leg, the cylinder permanent magnet of the voice coil actuator is fixed on the base plate, with a membrane mounted inside, which is the main contributor to the axial compliance of the leg. The stinger is attached to the center of the membranes, supporting the voice coil at one end, and attaching to force sensor at the other end. One flexible joint is used to connect the leg, respectively to the base plate and to the payload plate. These six legs are arranged in a cubic Stewart platform configuration, which provides a uniform control capability and a uniform stiffness in all directions, and minimizes the crosscoupling amongst actuators and sensors of different legs. In addition, the AVIP includes gap sensors and payload side accelerometers for measurement.

An integrated framework consisting of disturbances, structure, optics, the AVIP, and their mutual interactions is created to evaluate the performance of the AVIP through numerical simulation. The disturbance data is collected by sensors located on the deck that the payload is mounted to the satellite bus in a ground-test with actuating components operating and the satellite suspended. The analysis shows that the AVIP is effective in a frequency band between 10 and 400 Hz, with a attenuation of not less than 20 dB, and proves that the AVIP is able to keep the payload in step with the bus in the course of agile imaging. An experimental test system is built on the AVIP, an optical payload, advanced multi-axis micro-vibration table, and suspension devices. The advanced multi-axis micro-vibration table is also a Stewart platform containing six voice coil legs but much bigger. Besides the calibrated accelerometers equipped to measure the transmissibility, a laser interferometer is implemented in order to measure the pointing precision of the optical payload. Result of experiment shows close agreement with that of the simulation.

9904-248, Session PS10

Unimorph piezoelectric deformable mirrors for space telescopes

Peter Rausch, Sven Verpoort, Ulrich Wittrock, Fachhochschule Münster (Germany)

Under the GSTP activity "Development of Adaptive Deformable Mirrors for Space Instruments", funded by the European Space Agency, we have developed, manufactured and tested a space-qualified unimorph deformable mirror. The goal was a generic technology development for a deformable mirror that would be used in a plane conjugate to the primary mirror of a large space telescope. The mirror we developed can be readily adapted to suite different space telescopes. For example, the mirror could be made annular such that its deformation eigenmodes resemble that of a large monolithic primary mirror. For a telescope with a segmented primary mirror, a segmented array of unimorph deformable mirrors could be designed, such that each segment of the primary mirror is imaged onto one unimorph deformable mirror. With additional piston and tip-tilt actuation, this array of unimorph mirrors could provide phasing and aberration correction of the segments of the primary mirror. This approach moves the complexity of active optics to scales where they are easier to manage: away from the large primary to a smaller mirror that needs less actuation force, has a higher temporal bandwidth, and operates in a thermally stable environment inside the telescope.

For the generic technology development, ESA had called for a mirror that had to generate low order Zernike modes with a fairly large peak-to-valley (PV) surface stroke of 30 μm in defocus mode (60 μm PV wavefront), and 5 μm PV surface stroke in trefoil mode over a clear aperture of 50 mm. The modes had to be produced with a residual RMS surface error below 30 nm. The active structure of our mirror consists of a coated mirror substrate bonded to a laser-cut piezoelectric element featuring 44 actuators. The innovative mounting allows for large stroke while at the same time providing rigid connection to the support structure. In addition, the mounting incorporates three actuators providing integrated, monolithic piston and tip/tilt functionalities. Since the mirror is based on just a few, precisely CTE-matched materials, it is insensitive to temperature fluctuations.

High spatial frequency deformations caused by the actuators, commonly referred to as print-through, is a common problem for many deformable mirrors. By suitable pre-treatment of the piezoelectric material and careful control of the manufacturing procedure, we were able to eliminate print-through to a level below 17 nm.

The mirror was successfully tested in thermal vacuum, underwent a lifetime test, and was exposed to random vibrations, sinusoidal vibrations, and to ionizing radiation. The mirror was successfully operated in thermal vacuum at 300 K, 200 K, and 100 K. It withstood sine vibration up to 20 g and random vibration loads up to 9.3 g RMS. This should render the mirror compliant to common launch vehicles. The most recent design iteration has been further optimized to provide increased resistance towards vibrations by shifting the first eigenfrequency from 253 Hz for the tested design to about 600 Hz. The optical performance has been validated by high-resolution phase shifting interferometry and the dynamic response was characterized using a fast Shack-Hartmann wavefront sensor.

9904-249, Session PS10

Hypatia and STOIC: an active optics system for a large space telescope

Nicholas Devaney, National Univ. of Ireland, Galway (Ireland); Claudia Reinlein, Fraunhofer-Institut für Angewandte Optik und Feinmechanik (Germany); Nicolas Lange, Fraunhofer-Institut für Angewandte Optik und Feinmechanik (Germany) and Friedrich-Schiller-Univ. Jena (Germany); Matthias Goy, Fraunhofer-Institut für Angewandte Optik und Feinmechanik (Germany) and Friedrich-Schiller-Univ. Jena (Germany); Alexander V. Goncharov, National Univ. of Ireland, Galway (Ireland); Pascal Hallibert, European Space Research and Technology Ctr. (Netherlands)

The next generation of UVOIR space telescopes will be required to provide excellent wavefront control despite perturbations due to thermal changes, gravity release and vibrations. The STOIC project is a response to an ESA Invitation to Tender to develop an active optics correction chain for future space telescopes. The baseline space telescope being considered is a two-mirror, 4m telescope with a monolithic primary mirror – we refer to this concept as Hypatia. The primary mirror diameter could be extended, but is limited in the near future by launch vehicle dimensions. A deformable mirror (diameter 100mm) will be an integral part of the telescope design; it is being designed for high precision and the ability to maintain a stable form over long periods of time. We demonstrate our approach to design a set-and-forget deformable mirror that is suitable for space missions positioned in L2, where no fast wavefront deformations have to be corrected, but where reliability and long-term stability are critical. The concept is based on rotary piezoLEG actuators that are self-locking and can therefore hold the position without a continuous power supply. We present an extensive study on the possible actuator positions to find the best distribution in order to correct even high-order Zernike modes with a minimized number of actuators.

The secondary mirror of the telescope will be activated to control tip-tilt, defocus and alignment with the primary. Wavefront sensing will be based on phase diversity and a dedicated Shack-Hartmann wavefront sensor. A tomographic approach is proposed to distinguish aberrations due to telescope misalignment from those due to errors in the primary mirror.

The project will develop a laboratory breadboard to demonstrate key aspects of the active correction chain. We present the current state of the preliminary design for both the Hypatia space telescope and the laboratory breadboard.

9904-250, Session PS10

High dynamic range wavefront sensing for large aperture space telescopes

Jonathan Tesch, David C. Redding, Siddarayappa Bikkannavar, Andrew Kee, Jet Propulsion Lab. (United States)

For large aperture space telescopes, end-to-end optical performance testing is rarely performed after system integration. Significant gravity-induced aberrations often prohibit the use of traditional interferometric techniques, and design constraints do not typically accommodate supplemental test instruments. In this paper we present a high dynamic range wavefront sensing approach to accurately assess telescope performance in the presence of large aberrations, such as the gravity sag of a primary mirror. The approach uses the payload imaging system directly, eliminating the need for an additional scoring instrument or non-common-path calibration. First, the pupil is divided into overlapping subapertures to reduce the wavefront aberration presented to the sensing algorithms. A parametric image-matching algorithm (IPO) is applied to images taken over each subaperture to obtain a low-spatial-resolution estimate of the wavefront error. The result forms an a priori estimate for Modified Gerchberg-Saxton (MGS), a non-parametric phase retrieval algorithm that uses defocused image pairs to produce a final, high-resolution wavefront map over the subaperture. Finally, a least squares stitching algorithm is employed to assemble the subaperture wavefront estimates into the complete pupil. Simulation results demonstrating sensing performance are presented in the context of the 2.4 meter WFIRST-AFTA telescope.

9904-252, Session PS10

Wavefront sensing in space from the PICTURE-B sounding rocket

Ewan S. Douglas, Boston Univ. (United States);

Christopher Mendillo, Glenn A. Howe, Kuravi Hewawasam, Timothy A. Cook, Susanna C. Finn, Jason Martel, Supriya Chakrabarti, Univ. of Massachusetts Lowell (United States)

NASA sounding rocket for high contrast imaging with a visible nulling coronagraph the Planet Imaging Coronagraphic Technology Using a Reconfigurable Experimental Base (PICTURE-B) mission has made two suborbital attempts to observe the warm dust disk inferred around Epsilon Eridani.

We present results from the November 2015 launch demonstrating active wavefront sensing in space with a piezoelectric mirror stage and a deformable mirror along with precision pointing and lightweight optics in space. We also discuss the testing of a new half-meter silicon carbide primary mirror for the most recent launch and lessons learned translating coronagraphy concepts into spaceflight hardware.

9904-45, Session 12

Ensuring the enduring viability of the space science enterprise: new questions, new thinking, new paradigms

Jonathan W. Arenberg, Northrop Grumman Aerospace Systems (United States)

Pursuing ground breaking science in a highly cost and funding constrained environment presents new challenges to the development of future space astrophysics missions. Within the conventional cost models for large observatories, executing a flagship “mission after next” appears to be unstainable. To achieve our nation’s space astrophysics ambitions requires new paradigms in system design, development and manufacture. Implementation of this new paradigm requires that the space astrophysics community adopt new answers to a new set of questions. This paper will discuss the origins of these new questions and the steps to their answers.

9904-46, Session 12

Risk management for small to mid-sized spaceborne telescopes

Tony B. Hull, The Univ. of New Mexico (United States)

For proposed missions, perceived risk levels often leads large margins of safety. This affects both what telescope aperture the Science Team will propose, and what Proposal Evaluators will accept. Too often the appropriate cost of the telescope and even the mission is evaluated largely on the basis of aperture. While aperture clearly is a factor in telescope cost, it is not the only one. This paper will explore some basic and early architecture decisions that may have a profound effect on both the risk and cost of a telescope. Starting with the system’s risk and cost impact of choice of materials, factors including performance margins and management of envelope will be considered. Emphasis is on small to mid-sized optical telescope assemblies relevant for Explorer and Probe class missions.

9904-47, Session 12

Configurable aperture space telescope (CAST) optical design

Kimberly Ennico, Eduardo A. Bendek, Kenny K. Vassigh, Dana H. Lynch, NASA Ames Research Ctr. (United States)

CAST, the Configurable Aperture Space Telescope, is a concept that provides access to an ultraviolet/visible-wavelength sub-arcsecond imaging platform from space, something that will be in high demand after the retirement of the astronomy workhorse, the 2.4 meter diameter Hubble Space Telescope. CAST is a concept that allows building large aperture telescopes based on small, compatible and low-cost segments mounted on autonomous cube-sized satellites. The concept merges existing technology (segmented telescope architecture) with emerging technology (smartly interconnected modular spacecraft). Requiring identical mirror segments, CAST’s optical design is a spherical primary and secondary mirror telescope with a modular three-mirror corrector placed at the system focal plane. The design enables very wide fields of view, up to as much as three degrees, while maintaining aperture growth and image performance requirements. CAST with a 0.6 meter diameter primary (3x3 segments) growing to 2.4 meter diameter (13x13 segments), with a fixed Rp=14,000 and Rs=8,750 mm curvature, yields f/22.4 and f/5.6, respectively. Its diffraction-limited design uses a two arcmin field-of-view corrector with a 7.4 arcsec/mm platescale, and can support a range of platescales as fine as 0.01 arcsec/mm. Our paper summarizes the CAST concept, presents the strawman optical design and requirements for the underlying modular spacecraft, and illustrates applications enabled by this new method in building space observatories.

9904-48, Session 12

APERTURE: a precise extremely large reflective telescope using re-configurable elements

Melville P. Ulmer, Northwestern Univ. (United States); Marie-Caroline Corbineau, Victoria L. Coverstone, Univ. of Illinois at Urbana-Champaign (United States); Yip-Wah Chung, Jian Cao, Northwestern Univ. (United States)

One of the pressing needs for the UV-Vis is a design to allow even larger mirrors than the JWST primary at an affordable cost. We report here the results of NASA Innovative Advanced Concepts phase 1 study. Our project is called A Precise Extremely large Reflective Telescope Using Reconfigurable Elements (APERTURE).

The idea is to deploy a membrane-like mirror. The mirror figure will be corrected after deployment to bring it into better or equal lambda/20 deviations from the prescribed mirror shape. The basic concept is not new. What is new is to use a different approach from the classical piezoelectric-patch technology. Instead, our concept is based on a continuous coating of a so called magnetic smart material (MSM). Then a magnetic write head will on the no reflecting side of the mirror insert magnetic field that will produce a stress in the MSM that will correct the mirror deviations from the prescribed shape.

9904-49, Session 12

ASTRO-1: a 1.8m unobscured space observatory for next generation UV/visible astrophysics and exoplanet exploration

Gary W. Matthews, Harris Corp. (United States); Jon A. Morse, BoldlyGo Institute, Inc. (United States); Robert M. Egerman, Harris Corp. (United States)

The Hubble Space Telescope has been a scientific marvel that has provided unimaginable imagery and scientific discovery. Its exquisite UV/Visible imaging performance is unmatched from the ground. In NASA’s future planning, the earliest possible successor mission would be in the 3030s, well beyond the expected lifetime of Hubble. The ASTRO-1 space telescope

is a 1.8m off-axis (unobscured) observatory that looks to fill this critical void with Hubble-like performance to continue the scientific quest while also providing the possibility for exoplanet research with a coronagraphic instrument and/or a free flying starshade. BoldlyGo Institute seeks to reach beyond NASA funding to leverage the high public interest in space research and exploration, and the search for life beyond Earth.

9904-50, Session 13

Optical telescope system-level design considerations for a space-based gravitational wave mission

Jeffrey C. Livas, Shannon R. Sankar, NASA Goddard Space Flight Ctr. (United States)

The study of the Universe through gravitational waves will yield a revolutionary new perspective on the Universe, which has been intensely studied using electromagnetic signals in many wavelength bands. Gravitational interactions dominate the behavior of systems and structures at the largest length scales. Those interactions are traceable with gravitational waves to much higher redshift ($z \approx 20$) than is possible with electromagnetic signals. A space-based gravitational wave observatory will enable access to a rich array of astrophysical sources in the measurement band from 0.1 to 100 mHz, and nicely complement observations from ground-based detectors as well as pulsar timing arrays by sampling a different range of compact object masses and astrophysical processes.

This observatory measures gravitational radiation by precisely monitoring the tiny change in the proper distance between pairs of freely falling proof masses. These masses are separated by millions of kilometers and, using a laser heterodyne interferometric technique, the change in their proper separation is detected to ~ 10 pm over timescales of 1000 seconds, a fractional precision of better than one part in 1019. Optical telescopes are essential for the implementation of this precision displacement measurement. They enable the efficient transfer of laser beams between the proof masses, but are then in-series with the measurement path. This role, quite different from image-forming telescopes, is the inherent drive behind the design of the telescope subsystem, and produces interesting design constraints that we will discuss.

We also focus our discussion towards the telescope subsystem in a mission context. We will review the flow-down of observatory level requirements to the telescope subsystem, particularly pertaining to the effects of telescopic dimensional stability and scattered light suppression on the interferometric measurement. Furthermore, we will discuss how this consideration impacts the telescope form, and also review the telescope's function in an on-orbit science-mode state. We analyze all these topics in the context of the enhanced Laser Interferometry Space Antenna mission (eLISA), a strong candidate for the European Space Agency's L3 launch opportunity in 2034. Finally, we present a nominal timeline of the telescope subsystem as we embark upon preparations for the eventual study of gravitational waves using a space-based observatory.

9904-51, Session 13

A development roadmap for critical technologies needed for TALC: a deployable 20m annular space telescope

Marc Sauvage, Gilles A. Durand, Jerome Amiaux, Commissariat à l'Énergie Atomique (France); Yann Penfornis, Samuel Napoleoni, MULTIPLAST S.A.S. (France); James Austin, North Thin Ply Technology Sàrl (Switzerland); Ulrich Wittrock, Sven Verpoort, Fachhochschule Münster (Germany); Giuseppe Valsecchi, Oberto Citterio, Media Lario Technologies S.r.l. (Italy); Sergio Molinari, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Giorgia Sironi, Giovanni Pareschi, Anna M. Di Giorgio, INAF - Osservatorio Astronomico di Brera (Italy); Christophe Collette, Univ. Libre de Bruxelles (Belgium); Simon Chesné, Institut National des Sciences Appliquées de Lyon (France)

Astronomy is driven by the quest for higher sensitivity and improved angular resolution in order to detect fainter or smaller objects. The far-infrared to submillimeter domain is a unique probe of the cold and obscured Universe, harboring for instance the precious signatures of key elements such as water. Space observations are mandatory given the blocking effect of our atmosphere. However the methods we have relied on so far to develop increasingly larger telescopes are now reaching a hard limit, with the JWST illustrating it in more than one way (e.g. it will be launched by one of the most powerful rocket, it requires the largest existing facility on Earth to be qualified). With the Thinned Aperture Light Collector (TALC) project, a concept of a deployable 20m annular telescope, we propose to break out of this deadlock by developing novel technologies for space telescopes, which are disruptive in three aspects:

- An innovative deployable mirror whose topology, based on stacking rather than folding, leading to an optimum ratio of collecting area over volume, creates a telescope with an eight times larger collecting area and three times higher angular resolution compared to JWST from the same pre-deployed volume; ?

- An ultra-light weight segmented primary mirror, based on electrodeposit Nickel, Composite and Honeycomb stacks, built with a replica process to control costs and mitigate the industrial risks.

- An active optics control layer based on piezo-electric layers incorporated into the mirror rear shell allowing controlling the shape by internal stress rather than by reaction on a structure.

We present in this paper the roadmap we have built to bring these three disruptive technologies to technology readiness level 3. We will achieve this goal through design and realization of representative elements: segment of mirrors for optical quality verification, active optics implemented on representative mirror stacks to characterize the shape correction capabilities, and mechanical models for validation of the deployment concept. Throughout the project, a strong system activity will ensure that the ultimate goal of having an integrated system can be met, especially in terms of (a) scalability toward a larger structure, and (b) verification philosophy.

9904-52, Session 13

Millimetron space observatory: progress in the development of the payload module

Andrey Smirnov, Mikhail Arkhipov, Nikolay Babakin, Evgeny Golubev, Mattheus W. M. de Graauw, Sergey Fedorchuk, Nikolay S. Kardashev, Tatyana Kosmovich, Sergey F. Likhachev, Nelly V. Myshonkova, Sergey V. Pilipenko, Dmitry Radchenko, Igor S. Vinogradov, Astro Space Ctr. (Russian Federation)

Previous and future FIR and submm space observatories have respectively inspired and promised a new outlook in our understanding of key questions in modern astrophysics. The future Millimetron Space Observatory (MSO) is based on a 10-m cryogenically cooled telescope, to be deployed in orbit after having arrived at a L2 orbit of the Earth-Sun system. The MSO will operate as a single aperture enabling high-resolution imaging and spectroscopy but also as an interferometer element in a Space-Earth VLBI regime and as such will open up new horizons of astrophysics with unprecedented sub-microarcsecond angular resolution.

The MSO will be launched at ambient temperatures and cooled down in orbit through a combination of passive and active cooling using on-board mechanical coolers. These provides cooling of the 10-m space telescope to temperatures below 10K and thus reduce by five orders of magnitude the thermal background emission from the entrance optics and thus improve the sensitivity to a level which has been unobtainable so far. MSO instruments will include a FIR photometric camera spectrometers and mm/submm receivers for interferometry. The MSO is proposed as a Russian-led mission with an extensive international consortium. The launch is foreseen for the early 2025's. Ongoing detailed analysis and verification are essential to ensure that the requirements are met. We will present an overview and progress in the development of the payload module.

9904-53, Session 14

SEL2 servicing: increased science return via on-orbit propellant replenishment

Benjamin B. Reed, Bo Naasz, Mike Kienlen, NASA Goddard Space Flight Ctr. (United States); Thomas Aranyos, NASA Kennedy Space Ctr. (United States); Joseph Pellegrino, Orbital ATK (United States)

Amongst the challenges in reach for the next generation of astrophysics missions is the direct detection of exo-Earth atmospheres. These future observatories must have tremendous sensitivity, resolution and stability. The latter will drive many observatories to Sun-Earth Lagrange point 2 (SEL2). The mass fraction dedicated to propellant for these assets will need to be allocated strategically, as it comes at the expense of instrument mass. As such, these observatories could benefit from on-orbit refueling, allowing greater dry-to-wet mass ratio at launch. The same holds true for a separate starshade spacecraft used in tandem with an observatory to externally occult starlight. Given their position many thousands of kilometers away from their observatory, every slew to a new target would require a proportional translation of the starshade. The accumulation of repeated translations would drive the delta-V and therefore the propellant mass. Even if the starshade were equipped with high-efficiency solar electric propulsion systems using xenon (Xe), a propellant-based end of life would most likely occur while the corresponding observatory is still fully operational. Moreover, complete expenditure of the observatory's chemical propellant supply will inevitably cause cessation of operation, as SEL2 orbit maintenance requires constant fuel expenditure.

The Satellite Servicing Capabilities Office (SSCO) at NASA's Goddard Space Flight Center is developing technologies and techniques to replenish Xe and chemical propellant on orbit. Since 2009, SSCO has been building a portfolio of critical and enabling servicing technologies, including dexterous robotics; sensors, avionics, and algorithms for rendezvous and proximity operations; high-speed, fault-tolerant computing; advanced robotic tools; propellant transfer systems; and cooperative servicing aids such as navigation aids, grapple features, replacement hardware latches, and fueling ports. The Robotic Refueling Mission (2011-2019) and Raven (2016-2018) on the International Space Station are demonstrating some of these capabilities on orbit. Other technologies are being tested on the ground via tests such as the Remote Robotic Oxidizer Transfer Test (2014). In parallel, SSCO has spent five years designing a notional servicing mission named Restore-L, a free-flying robotic servicer to chemically refuel a government satellite in low-Earth orbit. By the time SEL2 observatories are launched in the late 2020s, it is expected that all the enabling servicing technologies listed above will have flight heritage and be at Technology Readiness Level 8 or higher.

This paper will detail a conceptual mission design for an autonomous, robotic servicer spacecraft equipped to execute a two-sortie mission at SEL2 to extend the life of an observatory and its accompanying starshade. After recharging the Xe of the starshade, it would refuel the chemical propellant of the observatory. We will discuss the concept of operations for this two-phase mission, the servicing spacecraft design, and the cooperative servicing elements assumed to be integrated within the two clients. We will also address key mission drivers, such as servicer autonomy (necessitated due to communications latency at L2), the need to minimize initial mass impacts on the client spacecraft, and multi-sortie mission features. We hope to spur symbiotic discussions and developments to better understand the science communities' requirements, and to implement cooperative servicing elements into future missions.

9904-54, Session 14

In-space assembly and servicing infrastructures for the Evolvable Space Telescope (EST)

Charles F. Lillie, Lillie Consulting LLC (United States); Howard A. MacEwen, Reviresco LLC (United States)

The concepts for the EST provided elsewhere in this conference stand to benefit significantly from developments in in-space infrastructures now being planned and implements in support of NASA's Human Exploration plans. Among others, two documents provide particularly relevant discussions. "NASA's Journey to Mars: Pioneering Next Steps in Space Exploration" provides a recent (2015) outline of NASA thinking on human deep space exploration and the tools that will enable it, while the "On-Orbit Satellite Servicing Study: Project Report" details a few of the concepts and technologies that must be developed.

This presentation will examine the concepts in these and related documents to explore how they can best exploit the developments described therein and how systems such as EST will add credibility and support to the infrastructure needed by human exploration programs. Major topics to be addressed will include:

• Past experience with on-orbit servicing of space telescopes, notably the Hubble Space Telescope, and demonstration of the benefits that it provided. Lessons learned concerning servicing approaches both under routine maintenance conditions and when time-urgent, mission critical needs apply, and existing systems and facilities both to prepare for and execute servicing missions in the future will be described.

• Developing plans within NASA for the SLS class of heavy lift launch vehicles, notably including the Exploration Upper Stage (EUS) which may be able to co-manifest other large payloads along with a crewed Orion mission. Commercial launch vehicles will also be considered in the presentation.

• The use of crewable Deep Space Habitats (DSHs) in cislunar space as assembly and servicing bases for space telescopes as well as human exploration missions will be comparatively discussed, with similarities and differences noted (as well as synergies among them).

• Maneuverable servicing vehicles for the assembly and servicing missions, either in the vicinity of crewed bases or on autonomous missions to deep space locations of the space telescopes themselves.

• Adaptations to the serviced space telescopes that will be needed to enable servicing (such as commonality of parts and systems, modularity, accessibility, and stable maneuverability) will also be discussed.

9904-55, Session 15

FalconSAT-7: a membrane space telescope

Geoff P. Andersen, U.S. Air Force Academy (United States)

The USAF Academy Department of Physics has built FalconSAT-7, a membrane solar telescope to be deployed from a 3U CubeSat in LEO. The primary optic is a 0.2m photon sieve – a diffractive element consisting of billions of tiny circular dimples etched into a Kapton sheet. The membrane, its support structure, secondary optics, two imaging cameras and associated control/recording electronics are all packaged within half

the CubeSat volume. Once in space the supporting pantograph structure is deployed, extending out and pulling the membrane flat under tension. The telescope will then be directed at the Sun to gather images at H-alpha for transmission to the ground. We will present details of the optical configuration, operation and performance of the flight telescope which has been made ready for launch in late 2016.

9904-56, Session 15

The Australian space eye: studying the history of galaxy formation with a CubeSat

Anthony J. Horton, Australian Astronomical Observatory (Australia); Lee R. Spitler, Macquarie Univ. (Australia); Naomi Mathers, The Australian National Univ. (Australia); Roger Franzen, Research School of Astronomy & Astrophysics (Australia); Mike Petkovic, The Australian National Univ. (Australia); Sam Reisenfeld, Macquarie Univ. (Australia); Jonathon S. Lawrence, Julia Tims, Australian Astronomical Observatory (Australia)

The Australian Space Eye is a proposed astronomical telescope based on a 6U CubeSat platform. The Space Eye will exploit the low level of systematic errors achievable with a small space based telescope to enable high accuracy measurements of extragalactic background light anisotropies and low surface brightness emission around nearby galaxies. This project is also a demonstrator for several technologies with general applicability to astronomical observations from nanosatellites.

Scientific opportunities for nanosatellite space telescopes exist where measurements are typically limited by systematic errors rather than photon statistics. We propose to undertake a study of extragalactic background light anisotropies, exploiting the low levels of systematic errors achievable with small space based telescopes. The power spectrum of these spatial anisotropies contains a signature of the population of objects too faint to be detected individually. This includes high redshift galaxies whose existence is inferred from the timing of the epoch of reionisation. Measurements from Space Eye will complement those obtained and planned from the CIBER/CIBER2 sounding rocket experiments which will cover a wider wavelength range but which are limited by the short duration of sounding rocket flights and aspects of the CIBER2 telescope design. We will also look for the signatures of galaxy growth in low surface brightness structures around several nearby galaxies, complementing shorter wavelength data from ground-based facilities (e.g. Dragonfly Telephoto Array).

The Australian Space Eye is based around a 90 mm aperture telescope for broadband wide field imaging in the i' and z' bands (700-1050 nm). The use of an e2V CIS115 2000x1504 CMOS image sensor with small (7 micron) pixels allows the desired 3 arcseconds/pixel image scale to be achieved within the space constraints of the CubeSat without folding the light path, enabling the use of a clear aperture all refractive design optimised to minimise the wings of the point spread function. The field of view is 1.67 x 1.25 degrees. The spacecraft will be based on the high performance Endeavour platform developed by Tyvac Nanosatellite Systems Inc. The largest technical challenges are pointing stability, data downlink and thermal control. No commercially available CubeSat attitude determination and control systems are able to achieve the arcsecond level instrument pointing stability required for long exposures, we present a solution combining high precision star tracking in the science telescope focal plane with microthruster based attitude control. Downlinking the anticipated science data volume of 400 MB per day will be a challenge however our analysis concludes that it is possible using currently available equipment. For maximum sensitivity the science image sensor must be cooled to -40C, this will be achieved with passive cooling and stabilised using a low power Peltier device.

The Australian Space Eye concept has been developed by Macquarie University, the Australian Astronomical Observatory, the Australian National University and Tyvac Nanosatellite Systems Inc. We aim to launch into a Sun synchronous orbit in 2019 for a nominal 2 year mission.

9904-57, Session 15

Image processing in BRITE nano-satellite mission

Adam Popowicz, Silesian Univ. of Technology (Poland)

Brightest Star Explorer (BRITE) is the first Polish astronomical satellite mission carried out by Polish-Austrian-Candian consortium. The constellation of 5 nano-satellites has been created and lunched to observe the micro variability of the brightest stars intensity. Each satellite has a CCD sensor installed onboard which is employed to observe the objects through either red or blue filter. The lack of the atmosphere allows for unprecedented high photometric precision, not achievable from the ground.

Unfortunately, due to the weight and space constraints in such small satellites, the installation of heavy shielding and employing strong sensor cooling was impossible. Thereby, shortly after the lunch, the radiation induced defects appeared in CCDs making the image analysis a difficult task. The defects are visible as significantly brighter pixels, column intensity offsets and charge transfer inefficiency regions. Those problems not only affect the scientific camera, but also the star tracker sensor. As a result, the satellite suffers from temporal instabilities, thus the images are occasionally blurred and the objects move within the CCD plane from frame to frame.

In the paper, the pipeline currently established for BRITE images processing is presented. The algorithm is divided into three main parts, which include the data classification, image processing and parameters optimization.

In the first part, the images are divided into three groups: faulty, correct and dark frame candidates. While the ones from the first set are discarded from further analysis, the dark frames, obtained by intentional satellite rotations, are utilized for hot pixels identification. The chosen best classification approach involves the manual thresholding of detected star PSF area.

The second part of the pipeline is the main photometric routine, wherein the star flux is retrieved. In this section, the column offsets, originating from the readout dark current, are first compensated. Then, the PSF region is detected and initial estimation of star centroid is obtained. For this purpose, the detected hot pixels within the PSF are temporally replaced by the median of intensities of neighbouring pixels. With initial centroids positions obtained, the precise estimation of true intensities of hot pixels is calculated. It is done by the analysis of the corresponding PSF pixels in previous and following frames in the orbit. This approach utilizes the fact that the satellite stabilization is low thus star PSF changes its position within CCD plane. The final part of this stage includes the classic circular aperture photometry on processed images.

The last part of the algorithm is the optimization loop which allows for the fine tuning of outcomes by adjusting the threshold level for hot pixel identification and a radius employed in aperture photometry. The spread of results in each orbit is calculated and used as a final quality meter.

The presented algorithm was developed especially for a wide range of defects encountered in BRITE CCDs. Since it allowed for achieving high precision photometry in significantly disturbed images, it may be a vital solution for future mission of nano-satellites, for which the radiation induced noise limits the measurements accuracy.

9904-58, Session 16

The maturing of high contrast starlight suppression techniques for future NASA exoplanet characterization missions

Daniel R. Coulter, Nicholas Siegler, Stuart B. Shaklan, David B. Gallagher, Jet Propulsion Lab. (United States)

It has been almost a quarter of a century since the discovery of the first planets beyond our own solar system, so called exoplanets, and 20 years since the discovery and confirmation of 51 Peg b, the first such object discovered orbiting a main-sequence star. Since that time, over 3000 exoplanets and hundreds of exoplanetary systems have been detected primarily by the ground based radial velocity technique and ground and space based microlensing and transit studies including NASA's spectacularly successful Kepler Mission. We are now rapidly moving toward an era where the focus is shifting from detection to spectroscopic characterization of these new worlds and their atmospheres, and to that end, NASA is currently studying exoplanet characterization mission concepts for the 2020 Decadal Survey ranging from probe class to flagships. Some low-resolution spectral data on exoplanet atmospheres has been collected with the Hubble Space Telescope and the Spitzer Space Telescope using the Transit Spectroscopy technique and more is expected from JWST. In addition, the JWST NIRCAM instrument will also carry a moderate contrast coronagraph capable of imaging large exoplanets and debris disks. However, a more detailed and comprehensive exoplanet characterization leading to assessment of habitability, or indeed detection of life, will require studies with higher contrast and improved spectral resolution and sensitivity. This will be possible due to the significant advances being made in high contrast starlight suppression techniques utilizing specially shaped precision optical elements to block the light from the parent star while controlling scattering and diffraction thus revealing and enabling spectroscopic study of the orbiting exoplanets in reflected light. In this paper we describe the current status of the two primary high contrast starlight suppression techniques: 1) a coronagraph (including several of its design variations) and 2) a free flying starshade. These techniques are rapidly moving from the technology development phase to the design and engineering phase and we discuss the prospects and projected performance for future exoplanet characterization missions utilizing these techniques coupled with a moderate to large aperture space telescope.

9904-59, Session 16

A comparison of analytical depth of search metrics with mission simulations for exoplanet imagers

Dmitry Savransky, Cornell Univ. (United States); Bruce A. Macintosh, Stanford Univ. (United States); Daniel Garrett, Cornell Univ. (United States)

While new, advanced, ground-based instrumentation continues to produce new exoplanet discoveries and provide further insights into exoplanet formation and evolution, our desire to discover and characterize planets of Earth size about stars of all types and ages necessitates dedicated, imaging space instruments. Given the high costs and complexities of space observatories, it is vital to build confidence in a proposed instrument's capabilities during its design phase, and much effort has been devoted to predicting the performance of various flavors of space-based exoplanet imagers. The fundamental problem with trying to answer the question of how many exoplanets a given instrument will discover is that the number of discoverable planets is unknown, and so all results are entirely dependent on the assumptions made about the population of planets being studied. Here, we present an alternate approach, which involves explicitly separating instrumental and mission biasing from the assumptions made about planet distributions. This allows us to calculate a mission's 'depth of search'-a metric independent of the planetary population and defined as the fraction of the contrast--projected separation space reached by a given instrument for a fixed planetary radius and semi-major axis. When multiplied by an assumed occurrence rate for planets at this radius and semi-major axis (derived from an assumed planetary population), this yields the expected number of detections by the instrument for that population. Integrating over the full ranges of semi-major axis and planetary radius provides estimates of planet yield for a full mission. We use this metric to evaluate a variety of proposed space missions, including various coronagraphs under development for WFIRST-AFTA. We also compare the results of convolving the depth of search with an assumed planetary population to those derived by running full mission simulations based on that same population.

9904-60, Session 16

A direct comparison of exoEarth yields for starshades and coronagraphs

Christopher C. Stark, Space Telescope Science Institute (United States); Eric J. Cady, Jet Propulsion Lab. (United States); Mark Clampin, Shawn Domagal-Goldman, NASA Goddard Space Flight Ctr. (United States); Douglas Lisman, Jet Propulsion Lab. (United States); Avi Mandell, Michael W. McElwain, Aki Roberge, NASA Goddard Space Flight Ctr. (United States); Tyler D. Robinson, Univ. of California, Santa Cruz (United States); Dmitry Savransky, Cornell Univ. (United States); Stuart B. Shaklan, Jet Propulsion Lab. (United States); Karl R. Stapelfeldt, NASA Goddard Space Flight Ctr. (United States)

The scale and design of a future mission capable of directly imaging extrasolar planets will be influenced by the expected number of potentially Earth-like planets (exoEarth candidates) to be detected and characterized. Currently two types of high-contrast imaging instruments, coronagraphs and starshades, are being considered for such a mission. These two types of instruments both remove stellar light, enabling the detection of faint planets nearby, but operate in different regimes and are ultimately limited by different resources. We have developed a code capable of estimating yields for both starshades and coronagraphs. This code uses novel methods to optimize the observation plan and maximize the yield of exoEarth candidates for a given set of mission parameters. We will present direct comparisons of yields for starshade-based missions and coronagraph-based missions, adopting identical astrophysical assumptions, methods of calculation, mission parameters, and observational assumptions when possible. We will show yield scaling relationships for each mission type and discuss the impact of astrophysical and instrumental noise on expected yields. Although the absolute yields are dependent on yet-unknown engineering constraints, observational methods, and astrophysical parameters, we will present several limiting cases allowing us to bound the yield comparison.

9904-61, Session 16

All clear: exoplanet detection and characterization with an unobscured 2.4 m aperture space telescope

Kerri Cahoy, Massachusetts Institute of Technology (United States); Karl R. Stapelfeldt, NASA Goddard Space Flight Ctr. (United States); Keith R. Warfield, Robert T. Effinger, Geoffrey Bryden, John T. Trauger, Jet Propulsion Lab. (United States); Ruslan Belikov, NASA

Ames Research Ctr. (United States); Michael W. McElwain, NASA Goddard Space Flight Ctr. (United States); Mark S. Marley, NASA Ames Research Ctr. (United States); Victoria Meadows, Univ. of Washington (United States); Eugene Serabyn, Jet Propulsion Lab. (United States); Supriya Chakrabarti, Univ. of Massachusetts Lowell (United States)

After completing a study on the capabilities of an unobscured 1.4-meter aperture telescope dedicated to exoplanet detection and characterization [1], the NASA Exoplanet Science and Technology Definition Team for internal coronagraphs (Exo-C) has analyzed how increasing D to a 2.4-meter diameter aperture, with appropriate increases in budgeted cost and schedule, impacts exoplanet direct imaging mission scientific goals and feasibility. Mission goals are aligned with the ability to characterize super-Earths within the habitable zone of Sun-like stars, with a raw contrast of 10^-10 and stability of 10^-11 at an inner working angle (IWA) of 2 lambda/D at visible wavelengths. Our approach is to minimize modifications needed to the original Exo-C instrument, telescope, and spacecraft to support the larger aperture. We also consider the benefits of including secondary science payloads, such as a near-infrared coronagraph that overlaps the longest visible wavelength bands and improves characterization of broad features such as water. We include analysis of mission scientific yield in the new 2.4-meter configuration, and recommend technology development to enable realization of this design by the early 2020s.

9904-62, Session 16

ESA M4 mission candidate ARIEL

Ludovic Puig, Göran L. Pilbratt, Astrid Heske, Isabel Escudero Sanz, Pierre-Elie Crouzet, European Space Research and Technology Ctr. (Netherlands)

The Atmospheric Remote sensing Infrared Exoplanet Large survey (ARIEL) mission is an M-class mission candidate within the science program Cosmic Vision of the European Space Agency (ESA). It was selected in June 2015 as one of three candidates to enter an assessment phase (phase 0/A). This process involves the definition of science and mission requirements as well as a preliminary model payload, and an internal Concurrent Design Facility (CDF) study providing the input to parallel industrial studies (to be conducted in 2016). After this process, the three candidates will be reviewed and in mid-2017 one of them will be selected as the M4 mission for launch in 2026.

ARIEL is a survey-type mission dedicated to the characterisation of exoplanetary atmospheres. Using the differential technique of transit spectroscopy, ARIEL will obtain transmission and/or emission spectra of the atmospheres of a large and diverse sample of known exoplanets (≥ 500) covering a wide range of masses, densities, equilibrium temperatures, orbital properties and host-star characteristics. This will include hot Jupiters to warm Super-Earths, orbiting M5 to F0 stars.

It will employ a 0.7 m x 1.1 m off-axis three mirror telescope, feeding four photometric channels in the VNIR range (0.5-2 um) and an IR spectrometer covering 2-8 um (R~100-30).

This paper describes critical science and mission requirements, and reports on the results of the Concurrent Design Facility (CDF) study that was conducted in June / July 2015, providing a description of the resulting spacecraft design, including critical subsystems such as AOCS and thermal/cryogenics.

9904-63, Session 16

The science of ARIEL (Atmospheric Remote-sensing Infrared Exoplanet Large-survey)

Giovanna Tinetti, Univ. College London (United Kingdom); Pierre Drossart, Observatoire de Paris à Meudon (France); Paul Eccleston, STFC Rutherford Appleton Lab. (United Kingdom); Paul Hartogh, Max-Planck-Institut für Sonnensystemforschung (Germany); Astrid Heske, European Space Research and Technology Ctr. (Netherlands); Jeremy Leconte, Univ. Bordeaux 1 (France); Giuseppina Micela, INAF - Osservatorio Astronomico di Palermo Giuseppe S. Vaiana (Italy); Marc Ollivier, Institut d'Astrophysique Spatiale (France); Göran L. Pilbratt, Ludovic Puig, European Space Research and Technology Ctr. (Netherlands); Diego Turrini, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Bart Vandenbussche, KU Leuven (Belgium); Paulina Wolkenberg, Space Research Ctr. (Poland); ARIEL consortium, Institutes in EU (United Kingdom)

ARIEL is a European mission being planned to answer fundamental questions about how planetary systems form and evolve. ARIEL will investigate the atmospheres of several hundreds planets orbiting distant stars. It is one of three candidate missions selected by the European Space Agency (ESA) for its next medium class science mission, due for launch in 2026. The ARIEL mission concept has been developed by a consortium of more than 50 institutes from 12 countries, including UK, France, Italy, Germany, the Netherlands, Poland, Spain, Belgium, Austria, Denmark, Ireland, Portugal.

During its 3.5-year mission, ARIEL will observe over 500 exoplanets ranging from Jupiter- and Neptune-size down to super-Earth and Earth-size in a wide variety of environments. The main focus of the mission will be on exotic, hot planets in orbits very close to their star. Hot exoplanets represent a natural laboratory in which to study the chemistry and formation of exoplanets. In cooler planets, different gases separate out through condensation and sinking into distinct cloud layers. The scorching heat experienced by hot exoplanets overrides these processes and keeps most molecular species circulating throughout the atmosphere.

ARIEL will have a meter-class mirror to collect visible and infrared (2-8 micron) light from distant star systems. The analysis of ARIEL spectra and photometric data will allow to extract the chemical fingerprints of gases and condensates in the planets' atmospheres, including the elemental composition for the most favorable targets. It will also enable the study of thermal and scattering properties of the atmosphere as the planet orbit around the star.

ARIEL will be placed in orbit around the Lagrange Point L2 to maximise the thermal stability and field of regard, and therefore its options for observing exoplanets discovered previously by other missions.

This paper outlines the science objectives and goals for the mission, and discusses how these are translated into detailed observational and performance requirements for the mission. The data processing and calibration methodologies planned for use are also discussed.

9904-64, Session 17

Lyot coronagraph design study for large, segmented space telescope apertures

Neil T. Zimmerman, Mamadou N'Diaye, Rémi Soummer, Christopher C. Stark, Laurent Pueyo, Marshall D. Perrin, Space Telescope Science Institute (United States); Alexis Carlotti, Institut de Planétologie et d'Astrophysique de Grenoble (France); Stuart B. Shaklan, Jet Propulsion Lab. (United States); N. Jeremy Kasdin, Robert J. Vanderbei, Princeton Univ. (United States)

Recent efforts combining the optimization techniques of apodized pupil Lyot coronagraphs and shaped pupils have demonstrated the viability of a purely binary-transmission mask architecture for extremely high contrast (1E-10) exoplanet imaging. Building on the existing proofs of concept, we present a new investigation into the performance of a Lyot coronagraph optimized for a large, segmented aperture UVOIR (ultraviolet-optical-infrared) space observatory. We carry out design trials for a series of realistic telescope aperture geometries having various configurations of primary mirror segments, secondary support struts, and central obscuration. At the baseline raw contrast (1E-10) required to image a terrestrial analog, we map the performance parameter space over throughput, inner working angle, bandwidth, and image search zone geometry. Engineering metrics are translated to scientific yield by modeling a survey of nearby stars with a range of rocky planet populations. From our study, we aim to identify the most favorable segmented telescope aperture morphologies for exoplanet imaging, and to gain insights on the performance limits of Lyot coronagraphy on NASA's next flagship UVOIR space telescope.

9904-65, Session 17

PIAACMC-based coronagraphy for segmented apertures

Olivier Guyon, Univ of Arizona (United States) and Subaru Telescope, National Astronomical Observatory of Japan (United States); Brian D. Kern, Jet Propulsion Lab. (United States); Johanan L. Codona, Alexander T. Rodack, The Univ. of Arizona (United States); Ruslan Belikov, NASA Ames Research Ctr. (United States); Stuart B. Shaklan, Jet Propulsion Lab. (United States)

Future large space telescopes with segmented primary mirrors will have the sensitivity to spectrally characterize Earth-like habitable planets around other stars. While high performance coronagraphs have traditionally been developed for contiguous apertures, we show that segmented apertures are also fundamentally suitable for high contrast imaging. We have developed coronagraph solutions based on Phase-Induced Amplitude Apodization Complex Mask Coronagraph (PIAACMC) concept for several segmented and centrally obscured apertures. The PIAACMC design combines loss-less pupil apodization, performed with aspheric optics, with a multi-zone reflective or transmissive focal plane mask. The zones of the focal plane mask are computer optimized to produce a deep broadband destructive interference within the exit pupil, and can be further optimized to maintain high contrast imaging capability for partially extended stars.

We find no significant difference between PIAACMC performance on segmented and non-segmented apertures: PIAACMC can offer in both cases IWA around 1 to 1.5 l/D, near full throughput and no signiciant loss of angular resolution. The contrast at small angular separation is fundamentally limited by stellar angular size (in unit of lambda/D). On a large aperture, PIAACMC's small inner working angle enables spectroscopic observations of nearby habitable exoplanets in the near-IR, allowing atmospheric molecular composition to be measured. Thanks the the small IWA, habitable zones can be observed around later-type stars than otherwise possible, and the coronagraph can access a large number of more distant targets. We also discuss requirements and approaches for sensing small cophasing errors using either starlight rejected by the coronagraph, or bright diffraction spikes in the coronagraphic image.

9904-66, Session 17

The segmented aperture interferometric nulling testbed (SAINT) I: overview and air-side system description

Brian A. Hicks, NASA Goddard Space Flight Ctr. (United States) and Univ. of Maryland, College Park (United States); Richard G. Lyon, Matthew R. Bolcar, Mark Clampin, Jeffrey A. Bolognese, NASA Goddard Space Flight Ctr. (United States); Peter J. Dogoda, Sigma Space Corp. (United States); Daniel Dworzanski, Optimax Systems, Inc. (United States); Michael A. Helmbrecht, Iris AO, Inc. (United States); Corina Koca, Udayan Mallik, NASA Goddard Space Flight Ctr. (United States); Peter Petrone III, Sigma Space Corp. (United States)

Direct detection and characterization of exosolar planets is predicated on collecting area and angular resolution available with large telescopes, as well as the ability to suppress starlight relative to the planet at small angular separations using coronagraphic techniques. This work presents an overview of the Segmented Aperture Interferometric Nulling Testbed (SAINT), a project that will pair an actively-controlled macro-scale segmented mirror with the Visible Nulling Coronagraph (VNC). SAINT will incorporate the VNC's demonstrated wavefront sensing and control system to refine and quantify the end-to-end system performance for high-contrast starlight suppression. This pathfinder system will be used as a tool to study and refine approaches to mitigating instabilities and complex diffraction expected from future large segmented aperture telescopes. The SAINT source, collimator, and segmented mirror telescope are located on a large optical bench in air and this system is adapted from a previously demonstrated sparse aperture phased array demonstrator, the Fizeau Interferometry Testbed (FIT). These optics form one of two selectable branches of a relay, the other being a bypass that delivers a circular aperture with Gaussian intensity profile. The relay incorporates a fast steering mirror (FSM) and vacuum window port into the Vacuum Nuller Testbed (VNT), a chamber that resides on the same optical bench. Inside the VNT chamber the VNC may operate at atmospheric pressure, at reduced pressure similar to a stratospheric balloon environment, or at high vacuum to emulate system operation in a space-like environment. An overview of the SAINT system and the project goals is provided along with a more detailed description of the air-side optics and a progress report on the fabrication and testing of these components.

9904-67, Session 17

A new deformable mirror architecture for coronagraphic instrumentation

Tyler D. Groff, Aaron J. Lemmer, Princeton Univ. (United States)

Coronagraphs are a promising solution for the next generation of exoplanet imaging instrumentation. While a coronagraph can have very good contrast and inner working angle performance, it is highly sensitive to optical aberrations. This necessitates a wavefront control system to correct aberrations within the telescope. The wavefront requirements and desired search area in a deformable mirror (DM) demand control of the electric field out to relatively high spatial frequencies. Conventional wisdom leads us to high stroke, high actuator density DMs that are capable of reaching these spatial frequencies on a single surface. Here we demonstrate a different architecture, where nearly every optical surface, powered or unpowered, is a controllable element. Rather than relying on a single, high-risk, controllable surface for the success of the entire instrument we propose using a series of lower actuator count deformable mirrors to achieve the same result by leveraging the conjugate planes that exist in a

coronagraphic instrument. To make such an instrument concept effective the imaging optics themselves must become precision deformable elements, akin to the deformable secondary mirrors at major telescope facilities. Such a DM does not exist commercially; all current DMs, while not necessarily incapable of carrying optical power, are manufactured with flat nominal surfaces. This simplifies control and manufacturing, but complicates their integration into an optical system because there is oftentimes a need to pack several into collimated space. Furthermore, high actuator count DMs cannot approximate low order shapes such as focus or tip-tilt without significant mid-spatial frequency residuals, which is not acceptable for a coronagraphic high-contrast imager. To address this we have been developing a new ferrofluid-based DM at Princeton. The mirror itself has the advantage of mechanically decoupling actuators from the optical surface, which allows for a continuously supported face sheet and an additional degree of freedom that affords precision control of the mirror's focal length. Regardless of the backing technology, the ability to integrate the wavefront control system into the nominal coronagraphic optical train simplifies packaging, reduces cost and complexity, and increases optical throughput of any coronagraphic instrument. This adds redundancy, increases controllability of the complex aberrations, and mitigates both cost and risk associated with a single high-actuator count device that the entire instrument performance relies on. For the ferrofluid DM, improvements in surface quality and the decoupling of actuator failures from surface shape makes it an ideal candidate for coronagraphic instrumentation. Here we simulate an optical system with a combination of controllable imaging optics both with and without a high order DM at the pupil. The relative performance of each configuration with regard to contrast, achievable bandwidth, and redundancy is discussed. The overall performance enhancements and risk associated with actuator failures on the assumed DM technology is also evaluated.

9904-68, Session 18

High contrast imaging in multi-star systems: technology development and first lab results

Ruslan Belikov, Eduardo A. Bendek, Eugene A. Pluzhnik, Dan Sirbu, NASA Ames Research Ctr. (United States); Sandrine J. Thomas, LSST (United States)

Several starlight suppression systems have been demonstrated in the lab that can remove the leakage of light from a star down to almost 1e10 contrast, but only for single-star systems. Despite the ubiquity and importance of multi-star systems, they are typically excluded from mission target lists and multi-star imaging technology has not been strongly pursued.

We show preliminary laboratory results advancing the technology readiness of a method to directly image planets and disks in multi-star systems such as Alpha Centauri. This method works with almost any coronagraph (or external occulter with a DM) and requires little or no change to existing and mature hardware. Because of the ubiquity of multistar systems, this method potentially multiplies the science yield of many missions and concepts such as AFTA, Exo-C, Exo-S, EXCEDE, and potentially enables the detection of Earth-like planets (if they exist) around our nearest neighbor star, Alpha Centauri, with a small and cheap space telescope such as ACESat or Centaur+.

We identified two main challenges associated with double-star (or multi-star) systems and methods to solve them. The first challenge is that multi-star separation is typically beyond the outer working angle (spatial Nyquist frequency) of the deformable mirror. To address this, we are developing "Super-Nyquist Wavefront Control" (SNWC) where a mild grating or the DM itself effectively diffracts low-spatial frequency modes of the DM into higher frequencies. The second challenge is to separate and independently remove overlapping speckles from multiple stars. Speckles from each star are incoherent with respect to each other, and thus must be removed for each star independently. We solve this challenge by a new method we call "Multi-Star Wavefront Control" (MSWC), which involves partitioning the correction zone and DM modes in a way that completely decouples the wavefront control of the two stars and enables simultaneously solving for both.

We present our first lab results and model validation of: SNWC and MSWC. With SNWC, we demonstrate a high contrast speckle suppression beyond the spatial Nyquist limit of a 32x32 DM (i.e. beyond 16 l/D), and with MSWC, we demonstrate a high contrast dark zone in the presence of two stars. The demonstration is carried out at the Ames Coronagraph Experiment (ACE) testbed at NASA ARC in monochromatic as well as broadband light.

9904-69, Session 18

High-contrast imaging for complex aperture telescopes (HiCAT): testbed overview

Rémi Soummer, Mamadou N'Diaye, Laurent Pueyo, Marshall D. Perrin, Élodie Choquet, Lucie Leboulleux, Sylvain Egron, Johan Mazoyer, Space Telescope Science Institute (United States)

We present an overview of the HiCAT testbed, a project designed to integrate wavefront sensing and control with starlight suppression by coronagraphy for telescopes with complex aperture shapes (i.e. in the presence of central obstruction, support structures, or segmentation). The testbed design has the flexibility to enable studies with increasingly complex telescope aperture geometries starting with off-axis telescopes, then on-axis telescopes with central obstruction and support structures (e.g. WFIRST), up to on-axis segmented telescopes (e.g. including various concepts for a Large UV, Optical, IR telescope (LUVOIR), such as the High Definition Space Telescope (HDST)). The testbed alignment was completed in the summer of 2014, surpassing specifications with a total wavefront error of 13 nm rms over a 18 mm pupil. The testbed includes two Boston Micromachine MEMS deformable mirrors for wavefront control, and will also incorporate an Iris AO MEMS deformable mirror with 37 hexagonal segments to simulate a segmented aperture. In this communication we give an overview of the testbed design, hardware implementation, and first results. We also discuss the coronagraph designs selected for the testbed, based on our recent development of the hybrid Apodized Pupil Lyot Coronagraph (APLC) with shaped-pupil apodizations. These new APLC-type solutions using two-dimensional shaped-pupil apodizers are optimized to be quasi-insensitive to jitter and low-order aberrations, while improving the performance in terms of inner working angle, bandpass and contrast over a classical APLC.

9904-70, Session 18

Architectural considerations for starshade missions

Jonathan W. Arenberg, Tiffany M. Glassman, Steven Warwick, Northrop Grumman Aerospace Systems (United States)

We discuss the application of modern mission architecture design in support of starshade enabled exoplanet missions. Our goal is to collect into a unifying document the many considerations necessary for enabling such missions. We will examine over a decade of starshade design and how it has led to the development of mature exoplanet missions. Of particular interest to our discussion are missions that maximize the exoplanet yield and that are therefore able to provide a better characterization of the potentially habitable exoplanet candidates. For this reason we will focus on starshade design compatible with 8m or larger class space telescopes such as the ones proposed for the 2020s and beyond.

9904-71, Session 18

Starshade starlight-suppression performance with a deployable structure

Tiffany M. Glassman, Northrop Grumman Aerospace Systems (United States)

Starshades are an exoplanet direct-imaging architecture that uses a precisely-shaped screen to block the light from a star in order to achieve high-contrast imaging of exoplanets. The shape of the deployable starshade structure must precisely match the design shape in order to maintain the high level of starlight suppression. In this paper, we discuss analysis of error sources from the starshade structure including manufacturing, dynamics, and thermal distortion to show that the starshade can achieve the needed optical performance.

9904-72, Session 18

Suppression of astronomical sources using the McMath-Pierce Solar Telescope and starshades with flight-like optics

Megan C. Novicki, Steven Warwick, Daniel K. Smith, Michael C. Richards, Northrop Grumman Aerospace Systems (United States); Anthony Harness, Univ. of Colorado at Boulder (United States)

The external starshade is a method for the direct detection and spectral characterization of terrestrial planets around other stars, a key goal identified in ASTRO2010. Tests of this approach have been and continue to be conducted in the lab and in the field (Samuele et al., 2010, Glassman et al., 2014) using non-collimated light sources with a spherical wavefront and at Fresnel numbers and resolution in excess of proposed flight missions. We extend the current approach to performing night-time observations of astronomical objects using small-scale (10-30cm) starshades and the McMath-Pierce Solar Telescope at Kitt Peak National Observatory. We place a starshade directly in the path of the beam from an astronomical object in front of the main heliostat. Using only flat mirrors, we then direct the light through the observatory path and reflect it off the West heliostat to an external telescope located approximately 270m away, for an effective baseline of 420m. This configuration allows us to make measurements of stars (flat wavefront sources) with a Fresnel number close to those expected in proposed full-scale space configurations. We present the results of our engineering runs conducted in 2015.

9904-73, Session 19

PLATO: a multiple telescope spacecraft for exo-planets hunting

Roberto Ragazzoni, Demetrio Magrin, INAF - Osservatorio Astronomico di Padova (Italy); Heike Rauer, Deutsches Zentrum für Luft- und Raumfahrt e.V. (Germany); Daniele Piazza, Univ. Bern (Switzerland); Isabella Pagano, INAF - Osservatorio Astrofisico di Catania (Italy); Valerio Nascimbeni, INAF - Osservatorio Astonomico di Padova (Italy); Giampaolo Piotto, Univ. degli Studi di Padova (Italy); Patrick Levacher, Lab. d'Astrophysique de Marseille (France); Mario Schweitzer, Max-Planck-Institut für extraterrestrische Physik (Germany); Stefano Basso, INAF - Osservatorio Astronomico di Brera (Italy); Maria Bergomi, Federico Biondi, INAF - Osservatorio Astronomico di Padova (Italy); Francesco Borsa, INAF - Osservatorio Astronomico di Brera (Italy); Simonetta Chinellato, Marco Dima, Jacopo Farinato, INAF - Osservatorio Astronomico di Padova (Italy); Mauro Ghigo, INAF - Osservatorio Astronomico di Brera (Italy); Davide Greggio, Marco Gullieuszik, Luca Marafatto, INAF - Osservatorio Astronomico di Padova (Italy); Daniele Spiga, INAF - Osservatorio Astronomico di Brera (Italy); Valentina Viotto, INAF - Osservatorio Astronomico di Padova (Italy); Gisbert Peter, Deutsches Zentrum für Luft- und Raumfahrt e.V. (Germany); Ana Maria Heras, Philippe Gondoin, European Space Research and Technology Ctr. (Netherlands); Claude Catala, Observatoire de Paris (France); Pierre Bodin, Ctr. National d'Études Spatiales (France)

PLATO stands for PLAnetary Transits and Oscillation of stars and is a Medium sized mission selected as M3 by the European Space Agency as part of the Cosmic Vision program. The strategy behind is to scrutinize a large fraction of the sky collecting lightcurves of a large number of stars and detecting transits of exo-planets whose apparent orbit allow for the transit to be visible from the Earth. Furthermore, as the transit is basically able to provide the ratio of the size of the transiting planet to the host star, the latter is being characterized by asteroseismology, allowing to provide accurate masses, radii and hence density of a large sample of extra solar bodies.

In order to be able to then follow up from the ground via spectroscopy radial velocity measurements these candidates the search must be confined to rather bright stars. To comply with the statistical rate of the occurrence of such transits around these kind of stars one needs a telescope with a moderate aperture of the order of one meter but with a Field of View that is of the order of 50 degrees in diameter. This is achieved by splitting the optical aperture into a few dozens identical telescopes with partially overlapping Field of View to build up a mixed ensemble of differently covered area of the sky to comply with various classes of magnitude stars. The single telescopes are refractive optical systems with an internally located pupil defined by a CaF_2 lens, and comprising an aspheric front lens and a strong field flattener optical element close to the detectors mosaic. In order to continuously monitor for a few years with the aim to detect planetary transits similar to an hypothetical twin of the Earth, with the same revolution period, the spacecraft is going to be operated while orbiting around the L2 Lagrangian point of the Earth-Sun system so that the Earth disk is no longer a constraints potentially interfering with such a wide field continuous uninterrupted survey.

The environment, in terms of stray-light and radiation, is considered in the opto-mechanical design of the telescope, along with the need for a relatively uniform PSF size along such a huge Field of View. Details of the science aims, operations, and their implication in terms of telescope specifications and the choices adopted to cope with them are briefly given.

9904-74, Session 19

ESA CHEOPS mission: development status

Nicola Rando, Joel Asquier, Francesco Ratti, Carlos Corral, Kate Isaak, European Space Research and Technology Ctr. (Netherlands); Christopher Broeg, Univ. Bern (Switzerland)

The ESA Science Programme Committee (SPC) selected CHEOPS in October 2012 as the first S-class mission (S1) within the Agency's Scientific Programme, targeting launch readiness by the end of 2017. The CHEOPS mission is devoted to the first-step characterisation of known exoplanets orbiting bright stars, to be achieved through the precise measurement of exoplanet radii using the technique of transit photometry. It is envisaged

as a partnership between the ESA Science Programme and Switzerland, with a number of Member States delivering significant contributions to the space segment development and operations.

CHEOPS is considered as a test case for implementing ”small science missions” in ESA with the following requirements: science driven missions selected through an open Call for missions (bottom-up process); a mission implementation cycle, from the Call to launch, drastically shorter than for M and L missions; and cost-capped missions to ESA with possibly higher Member States involvement than for M or L missions.

The paper describes CHEOPS development status, focusing on the performed hardware manufacturing and test activities.

9904-75, Session 19

CHEOPS: status summary of the instrument development

Thomas Beck, Andrea Fortier, Christopher Broeg, Luca Malvasio, Virginie Cessa, Daniele Piazza, Willy Benz, Nicolas Thomas, Univ. Bern (Switzerland); Demetrio Magrin, Valentina Viotto, Maria Bergomi, Roberto Ragazzoni, INAF - Osservatorio Astronomico di Padova (Italy); Isabella Pagano, INAF - Osservatorio Astrofisico di Catania (Italy); Gisbert Peter, Maximilian Buder, Deutsches Zentrum für Luft- und Raumfahrt e.V. (Germany); Jean-Yves D. Plesseria, Univ. de Liège (Belgium); Manfred Steller, Space Research Institute (Austria); Roland Ottensamer, Univ. Wien (Austria); David Ehrenreich, Observatoire de Genève (Switzerland); Carlos Corral, Kate Isaak, Francesco Ratti, Nicola Rando, Ivan Ngan, European Space Agency (Netherlands)

CHEOPS (CHaracterizing ExOPlanets Satellite) is the first ESA Small Mission as part of the ESA Cosmic Vision program 2015-2025. The mission was formally adopted in early February 2014 with a planned launch readiness end of 2017.

The mission lead is performed in a partnership between Switzerland, led by the University of Bern, and the European Space Agency with important contributions from Austria, Belgium, France, Germany, Hungary, Italy, Portugal, Spain, Sweden, and the United Kingdom.

The mission is dedicated to searching for exoplanetary transits by performing ultrahigh precision photometry on bright starts already known to host planets whose mass has been already estimated through ground based observations. The instrument is an optical Ritchey-Chretien telescope of 30 cm clear aperture using a single CCD detector. The optical system is designed to imagine a de-focused PSF onto the focal plane with very tight stability and straylight rejection requirements providing a FoV of 0.32 degreed full cone.

The system design is adapted to meet the top-level science requirements, which asks for a photometric precision of 20ppm, in 6 hours integration time, on transit measurements of G5 dwarf stars with V-band magnitudes in the range 6≤V≤9 mag. Additionally is asks for a photometric precision of 85 ppm in 3 hours integration time of Neptune-size planets transiting K-type dwarf stars with V-band magnitudes as faint as V=12 mag.

Given the high demanding schedule and cost constrains, the mission relies mostly on components with flight heritage for the platform as well as for the payload components. Although several new developments are integrated into the design as for example the telescope structure and the very low noise, high stability CCD front end electronics.

The instrument and mission are going through critical design review in fall 2015 / spring 2016. This paper describes the current instrument and mission design with a focus on the instrument. It outlines the technical challenges and selected design implementation. Based on the current status, the instrument noise budget is presented including the current best estimate for instrument performance.

The current instrument design meets the science requirements and mass and power margins are adequate for the current development status.

9904-76, Session 19

The Transiting Exoplanet Survey Satellite (TESS): discovering exoplanets in the solar neighborhood

George R. Ricker, Massachusetts Institute of Technology (United States)

The Transiting Exoplanet Survey Satellite (TESS) will discover thousands of exoplanets in orbit around the brightest stars in the sky. In its two-year prime survey mission, TESS will monitor more than 200,000 bright stars in the solar neighborhood for temporary drops in brightness caused by planetary transits. This first-ever spaceborne all-sky transit survey will identify planets ranging from Earth-sized to gas giants, around a wide range of stellar types and orbital distances.

TESS stars will typically be 30-100 times brighter than those surveyed by the Kepler satellite; thus, TESS planets will be far easier to characterize with follow-up observations. For the first time it will be possible to study the masses, sizes, densities, orbits, and atmospheres of a large cohort of small planets, including a sample of rocky worlds in the habitable zones of their host stars.

An additional data product from the TESS mission will be full frame images (FFI) with a cadence of 30 minutes. These FFI will provide precise photometric information for every object within the 2300 square degree instantaneous field of view of the TESS cameras. These objects will include more than 1 million stars and bright galaxies observed during sessions of several weeks. In total, more than 30 million objects brighter than magnitude I=16 will be precisely photometered during the two-year prime mission. In principle, the lunar-resonant TESS orbit could provide opportunities for an extended mission lasting more than a decade, with data rates in excess of 100 Mbits/s.

An extended survey by TESS of regions surrounding the North and South Ecliptic Poles will provide prime exoplanet targets for characterization with the James Webb Space Telescope (JWST), as well as other large ground-based and space-based telescopes of the future.

TESS will issue data releases every 4 months, inviting immediate community-wide efforts to study the new planets, as well as commensal survey candidates from the FFI. A NASA Guest Investigator program is planned for TESS. The TESS legacy will be a catalog of the nearest and brightest main-sequence stars hosting transiting exoplanets, which should endure as the most favorable targets for detailed future investigations.

TESS is targeted for launch in 2017 as a NASA Astrophysics Explorer mission.

9904-77, Session 19

The TESS camera: modeling and measurements with deep depletion devices

Deborah F. Woods, MIT Lincoln Lab. (United States); Roland Vanderspek, Massachusetts Institute of Technology (United States); Robert MacDonald, MIT Lincoln Lab. (United States)

The Transiting Exoplanet Survey Satellite is a NASA Explorer-class mission to discover planets around nearby stars, with a special focus on Earth-like planets with potential for follow up characterization. The system is to be launched in 2017. The all-sky survey requires a suite of

four wide field-of-view cameras with sensitivity across a broad spectrum. Deep depletion CCDs with a silicon layer of 100 ?m thickness provide enhanced performance in the red wavelengths for sensitivity to cooler stars. The performance of the camera is critical for the mission objectives, with both the optical system and the CCD detectors contributing to the realized image quality. Expectations for image quality are studied using a combination of optical ray tracing in Zemax and simulations in Matlab to account for the interaction of the incoming photons with the 100 ?m silicon layer. The simulations include a probabilistic model to determine the depth of travel in the silicon before the photons are converted to photo-electrons, and a Monte Carlo approach to charge diffusion based on the remaining depth of travel of the photo-electron. An engineering unit camera including deep depletion CCDs was built and tested for optical performance across the full set of wavelengths and field angles. In this paper we describe the performance simulations and the corresponding measurements taken with the engineering unit camera, and discuss where the models agree well in predicted trends and where there are differences compared to observations.

9904-78, Session 20

Gaia basic angle, straylight, and focus

Alcione Mora, European Space Astronomy Ctr. (Spain) and Aurora Technology B.V. (Netherlands); Michael Biermann, Astronomisches Rechen-Institut (Germany); Alexander Bombrun, European Space Astronomy Ctr. (Spain) and HE Space Operations B.V. (Netherlands); Jacques Cande, European Space Research and Technology Ctr. (Netherlands); Lionel Carminati, Airbus Defence and Space SAS (France); François Chassat, Airbus Defence and Space (France); Philippe Corberand, Airbus Defence and Space SAS (France); Dominic Doyle, Daniel Escolar, European Space Research and Technology Ctr. (Netherlands); Thomas Guilpain, Altran Technologies (France); José Hernández, European Space Astronomy Ctr. (Spain); Volker Kirschner, Benoit Laine, European Space Research and Technology Ctr. (Netherlands); Lennart Lindegren, Lund Observatory (Sweden); Edmund Serpell, European Space Operations Ctr. (Germany) and Telespazio Vega Deutschland GmbH (Germany); Pierre Thoral, Airbus Defence and Space SAS (France)

The ESA Gaia mission is creating an all-sky astrometric survey with microarcsecond accuracy. Some payload components had stability requirements at the picometre and microkelvin levels. However, the large basic angle periodic variations found during commissioning suggest the real fluctuations are closer to the nanometre and sub-millikelvin scales. In addition, the straylight from the Sun and astronomical sources is much higher than expected. Finally, the telescope focus has not remained fixed, but evolved during the mission. These three effects are a challenge for mission operations, which had to adapt to the real conditions, and data analysis, which tries to fulfil the original requirements under substantially more unstable conditions.

A joint ESA-industry working group was created to study the straylight and basic angle variations. During more than a year, they first addressed the origin of the solar straylight and then concentrated in the basic angle. The Basic Angle Monitoring (BAM) signal and house-keeping data were analysed, both during nominal operations and spacecraft events, such as safe modes and special activities. Ad-hoc tests were carried out, introducing perturbations before one decontamination campaign. A map summarising all possible origins was created and explored. Previous finite element models were improved to provide full spacecraft thermo-elastic-optical simulations. Several levels of complexity were increasingly added to key structures to study the validity of the simulations. Sensitivity analyses were carried out including most components in the service and payload modules. The worst offenders and possible thermo- and thermo-elastic perturbation transmission mechanisms were identified.

In parallel, the scientists characterised the BAM signal in the Fourier space, obtained global astrometry solutions and independently fitted the basic angle variations using stellar measurements. The agreement between the BAM and astrometric data is remarkable at first order, demonstrating the existence of milliarcsecond payload oscillations and discontinuities due to thermal relaxation. Subtle effects, such as tens of microarcsecond variations correlated to the sky stellar density were subsequently detected. The connection between the basic angle, number of stars, laser frequency stability and on-board computer temperatures has been discussed. The potential use of house-keeping measurements to improve the data reduction has been studied. The variable solar radiation input due to the Gaia orbit and spacecraft aging has been addressed.

Contrary to pre-launch expectations, the image quality has been continuously evolving since the operations started. Monitoring tools are in place to trace it, and occasional actuations have been carried out to bring the telescopes back to focus using the secondary mirror actuators and wavefront sensors. A stable focus was an assumption for the PSF calibration, which needs to go down to the Poisson noise limit to account for many effects such as chromaticity, focal plane dependence and charge transfer inefficiency. Fortunately, the overall trend is of increased stability as the mission evolves.

In this talk, a status review of these three issued will be provided, with a focus on the mitigation schemes and the lessons learned for future space missions where extreme stability is a key requirement.

9904-79, Session 20

Enabling science with Gaia observations of naked-eye stars

Johannes Sahlmann, European Space Astronomy Ctr. (United States); Juanma Martin-Fleitas, Alcione Mora, European Space Astronomy Ctr. (Spain); Asier Abreu Aramburu, European Space Agency (Spain); Cian M. Crowley, European Space Astronomy Ctr. (Spain); Emmanuel Joliet, California Institute of Technology (United States)

ESA's Gaia mission is performing an all-sky survey of stellar objects, collecting astrometric, photometric, and spectroscopic data. It was designed to observe every star in the magnitude range G = (6.0 - 20.0]. In our previous contribution that presented results obtained during in-orbit commissioning (Proc. SPIE. 9143), we demonstrated how the bright limit can be overcome to enable Gaia observations of naked-eye stars with magnitudes G < 6, thereby completing the astrometric survey at the bright end.

Here we update on the progress of very bright star observations during the nominal mission, which began in July 2014. We present the status after more than one year of data has been obtained, which allows us to produce preliminary statistics and performance metrics for very bright stars. We discuss the data products that are generated for G<6 stars and review the expected astrometric, photometric, and spectroscopic measurements that can be made with those data. Since naked-eye stars were not part of the nominal Gaia mission goals, this fulfills the important task to inform the astronomical community on the potential content of future Gaia data releases for those stars. Eventually, the work presented here will enable the scientific exploitation of these “unexpected” Gaia observations.

Gaia does not have an input catalogue, instead its observation strategy relies on real-time detection of stellar objects as they pass in the focal plane of the spinning spacecraft. Detection, confirmation, and observation of an object is accomplished by on-board computers. The optimisation of those computers' parameter configuration allowed us to extend the autonomous bright limit to G~3. We confirm this preliminary result

obtained during commissioning with new data obtained during the nominal mission.

The adopted solution to obtain astrometric data for the 230 stars with G<3 is to force data acquisition and recording with one class of Gaia CCDs called the Sky-Mapper. We describe the procedures that make this possible in operation, which include the prediction of focal plane transits for these stars, the dedicated commanding of the payload, and the data retrieval and ingestion in the operational database. Because these data are non-nominal, they are not treated by the Gaia pipeline. We will describe the status of an independent prototype data analysis scheme to analyse the Sky-Mapper images and extract the stellar photocentres.

We will also present of a technique named virtual object synchronization, which relies on extremely precise (a few pixels in the focal plane) predictions of stellar focal plane transits. We will show results of successful tests, where we secured astrometric, photometric, and spectroscopic data for extremely bright stars that otherwise would have been lost. We present a cost-benefit estimation of this mode and the prospects for implementation in the nominal mission.

Finally, we will outline how the presented techniques could further enhance the Gaia mission. For instance, Sky-Mapper images of Baade's window and Omega Cen are already being acquired regularly, because they promise to improve Gaia's results in these extremely dense regions of the sky. Other applications are presently under study.

9904-80, Session 20

Microarcsecond astrometric observatory THEIA : from dark matter to compact objects and nearby earths

Fabien Malbet, Institut de Planétologie et d'Astrophysique de Grenoble (France); Alain M. Léger, Institut d'Astrophysique Spatiale (France); Alessandro Sozzetti, INAF - Osservatorio Astronomico di Torino (Italy); Antoine Crouzier, CEA-IRFU (France); Douglas Spolyar, Nordic Institute for Theoretical Physics (Sweden); Guillem Anglada-Escude, Queen Mary's College (United Kingdom); Renaud Goullioud, Jet Propulsion Lab. (United States); Céline Boehm, Durham Univ. (United Kingdom); Berry Holl, Observatoire de Genève (Switzerland); Michael Shao, Jet Propulsion Lab. (United States); Lucas Labadie, Univ. zu Köln (Germany)

Theia is a logical successor to Gaia, as a focused, very high precision astrometry mission which addresses two key science objectives of the ESA Cosmic Vision program: the nature of dark matter and the search for habitable planets, and addresses a number of other science cases strongly synergistic with ongoing/planned missions, such as the nature of compact objects, motions of stars in young stellar clusters, follow-up of Gaia objects of interest), Theia's "point and stare" operational mode will enable us to answer some of the most profound questions that the results of the Gaia's survey will ask. Extremely-high-precision astrometry at 1-?as level can only be reached from space. The Theia spacecraft which will carry a 0.8m telescope is foreseen to operate at L2 for 3,5 years. The preliminary Theia mission assessment allowed us to identify a safe and robust mission architecture that demonstrates the mission feasibility within the Soyuz ST launch envelope and a M-class mission cost cap. We will present these features of the mission that has been submitted at the last ESA M4 call.

9904-81, Session 21

A joint infrared space observatory: SPICA revised and upgraded

Peter R. Roelfsema, SRON Netherlands Institute for Space Research (Netherlands); Hiroshi Shibai, Osaka Univ. (Japan); Kees Wafelbakker, Willem Jellema, Bruce Sibthorpe, SRON Netherlands Institute for Space Research (Netherlands)

In the study of the various processes that govern formation evolution of planets, stars and galaxies over cosmic time the far-infrared is a truly unique wavelength domain; a major fraction of the starlight in the universe is processed through dust and gas and subsequently reemitted there - thus especially the infrared provides measurements to directly assess the physical state and energy balance of cool matter. Earlier (far) infrared space missions, although very successful, were hampered by either having a warm(ish) or a small(ish) size telescope, limiting the practically achievable sensitivity. The next step in far-infrared research can be made only with a mission with a large cold telescope, like the SPace Infrared telescope for Cosmology and Astrophysics (SPICA). This paper describes the revised mission configuration that is proposed for launch in the late 2020ies.

Over time the SPICA mission has evolved significantly from its original incarnation as proposed by the Japanese space agency JAXA. Currently SPICA is envisaged as a joint European-Japanese project to be implemented for launch and operations at the end of the next decade. Following a joint ESA-JAXA study into the technical and programmatic feasibility of possible mission configurations a new architecture has been chosen for the satellite. In this new architecture, derived from the ESA PLANCK mission, the optical axis of the 2.5 meter diameter cold telescope is perpendicular to the axis of the spacecraft. In this new concept 'V-grooves' to provide passive cooling as were used on PLANCK are be mounted between the telescope assembly and the satellite service module, resulting in an overall more effective cryogenic system. The solar cells to provide power are mounted on the bottom side of the service module, which is always oriented towards the sun.

With the redesign of the mission also the science payload has been updated. The mission will provide extremely sensitive – of order 5x10-20 W/m2 (5?/1hr) – spectroscopic capabilities from 17 through 230 ?m at resolutions ranging from R 50 through 3000. A high resolution R~30.000 capability is provided for the 12-18 ?m wavelength range. Imaging capabilities are provided for efficient broad band mapping in the 17-35 ?m domain, and spectroscopic imaging for small fields in the 35-230 ?m range. The spectroscopic sensitivity of the instrument suite will typically provide two orders of magnitude improvement over what has been attained to date corresponding to a truly enormous increase in observing speed. Such an exceptional leap in performance is bound to produce many scientific advances. Some of these are predictable today and form the core science case for SPICA and drive its design; but others are impossible to predict, and there will undoubtedly be much discovery science with SPICA.

9904-82, Session 21

New cryogenic system of the next-generation infrared astronomy mission SPICA

Hiroyuki Ogawa, Takao Nakagawa, Hideo Matsuhara, Keisuke Shinozaki, Ken Goto, Naoki Isobe, Mitsunobu Kawada, Tadahito Mizutani, Yoichi Sato, Hiroyuki Sugita, Shinsuke Takeuchi, Toshihiko Yamawaki, Japan Aerospace Exploration Agency (Japan); Hiroshi Shibai, Osaka Univ. (Japan)

We present the new design of the cryogenic system of the next-generation infrared astronomy mission SPICA under the new framework. The new design is based on the ESA-JAXA CDF study on the Next Generation Cryogenic InfraRed Telescope (NG-CryoIRTel, CDF-152(A)) with a 2 m telescope, and we modified the CDF design to accommodate the 2.5 m telescope to meet the science requirements of SPICA. The basic design concept of the SPICA cryogenic system is to cool the Science Instrument Assembly (SIA, which is the combination of the telescope and focal-plane instruments) below 8K by the combination of the radiative cooling system and mechanical cryocoolers without any cryogen. For effective radiative cooling, a series of thermal shields (V-Grooves), similar to those of the Planck mission, are adopted to reduce the heat flow from the ambient-temperature Service Module to towards SIA. Additional shield, telescope shield, which is actively cooled down to 25 K by the double-stage Stirling coolers, is placed between the V-Grooves and the telescope baffle. Some of the main structures to support SIA is to be thermally detached in orbit to reduce the heat load to SIA. Two sets of cryocoolers (4.5 K and 1.7 K Joule-Thomson coolers with Stirling coolers) are used to cool the telescope below 8 K and the focal-plane instruments and detectors to various temperature stages below 6 K. The required cooling power for cryocoolers is compatible with the cooling capability of a series of cryocoolers developed by JAXA. One of the focal-plane instruments, SPICA Far-Infrared Instrument (SAFARI) has additional sub-K cooling system. The current design enables the cryogenic observing system of SPICA without any cryogen.

9904-83, Session 21

SPICA mid-infrared instrument (SMI): technical concepts and scientific capabilities

Hidehiro Kaneda, Daisuke Ishihara, Shinki Oyabu, Mitsuyoshi Yamagishi, Nagoya Univ. (Japan); Takehiko Wada, Japan Aerospace Exploration Agency (Japan); Mitsunobu Kawada, Institute of Space and Astronautical Science (Japan); Naoki Isobe, Japan Aerospace Exploration Agency (Japan); Kentaro Asano, Institute of Space and Astronautical Science (Japan); Toyoaki Suzuki, Japan Aerospace Exploration Agency (Japan); Itsuki Sakon, The Univ. of Tokyo (Japan); Kohji Tsumura, Tohoku Univ. (Japan); Hiroshi Shibai, Taro Matsuo, Osaka Univ. (Japan)

SMI (SPICA Mid-infrared Instrument) is one of the two focal-plane scientific instruments planned for new SPICA. SMI covers the wavelength range of 12 to 36 microns, using the following three spectroscopic channels with unprecedentedly high sensitivities: low-resolution spectroscopy (LRS; R=50-120, 17-36 microns), mid-resolution spectroscopy (MRS: R=1300-2300, 18-36 microns), and high-resolution spectroscopy (HRS: R=30000, 12-18 microns).

More specifically, SMI-LRS is a multi-slit prism spectrometer of a wide field-of-view with 4 long slits of 10' in length. SMI-LRS is operated in combination with a 10' x 10' slit viewer to determine the positions of the slits on the sky. SMI-LRS has a very high continuum sensitivity (~30 microJy in 1 hr, 5 sigma). SMI-MRS is a grating spectrometer with a long slit of 1' in length, very high line sensitivity (~3 x 10-20 W/m2 in 1 hr, 5 sigma). SMI-HRS is an immersion grating spectrometer with very high line sensitivity (~2 x 10-20 W/m2 in 1 hr, 5 sigma). SMI-MRS and HRS are operated in combination with a beam-steering mirror at their common fore-optics to perform spectral mapping of relatively small areas. On the other hand, the design of SMI-LRS with the slit viewer is based on wide-area surveys in a telescope step-scan mode to produce a spectral map of ~10' x 10' area as a minimum field unit.

Scientifically, LRS enables us to study spectral bands due to dust grains such as polycyclic aromatic hydrocarbons (PAHs) from an extremely large number of star-forming galaxies at redshifts from 0.5 up to 7, and silicate grains from many planet-forming debris disks of mid-IR luminosities down to levels close to that of our solar system. As by-products, the SMI-LRS spectral surveys provide broad-band images with the slit viewer (R = 5, the central wavelength of 34 microns), which are also important as legacy datasets since the 30-40 micron region is an unexplored gap between the Spitzer 24 micron and the Herschel 70 micron surveys. Another important feature is that HRS enables us to perform velocity-resolved studies of fundamental molecular gases (H2, H2O, CO) such as those in the innermost regions of protoplanetary disks and in the energetic outflow of active galactic nuclei. Complementarily to these specific functions of LRS and HRS, MRS provides more versatile spectroscopic functions, for example, for follow-up spectroscopy of targets detected by SMI-LRS to study dust bands and gas lines in more detail.

In this presentation, we will show the technical concepts and current specifications as well as the expected scientific capabilities of SMI.

9904-84, Session 21

Achieving extreme sensitivity in the FAR-IR: the SAFARI grating spectrometer for SPICA

Peter R. Roelfsema, SRON Netherlands Institute for Space Research (Netherlands); Martin Giard, Institut de Recherche en Astrophysique et Planétologie (France) and Observatoire Midi-Pyrénées (France); Francisco Najarro de la Parra, Ctr. de Astrobiología (Spain) and Instituto Nacional de Técnica Aeroespacial (Spain); Kees Wafelbakker, Willem Jellema, Bruce Sibthorpe, Brian D. Jackson, SRON Netherlands Institute for Space Research (Netherlands)

The far-infrared spectrograph SAFARI, on the joint European-Japanese space telescope SPICA (the next step after ESA's Herschel mission), will provide the most sensitive view ever of the cool, obscured universe. By cooling the SPICA telescope to below 8 K its thermal emission is decreased to such low levels that the latest generation of ultra-sensitive Transition Edge Sensor (TES) detectors can be utilized to their full potential. With this combination of low background and extreme detector sensitivity SPICA will be able to look far deeper into space than was possible with any of its predecessors. SPICA/SAFARI is the only facility that will fill the gap in the wavelength domain between the other great observatories, and is as sensitive as both the James Webb Space telescope and the ALMA radio observatory – only with SPICA/SAFARI we will complete the view on the star-formation history of our universe.

The current baseline SAFARI design uses a beam steering mirror (BSM) that forwards the incoming signal to the dispersing and detection optics. The BSM is used to select sky or calibration signals and forward that to a nominal R~300 (low) resolution optics chain or to a R~3000 (high) resolution optics chain. The low resolution is obtained by dispersion through a diffraction grating illuminating a line of TES detectors. For the high resolution mode the signal is first pre-dispersed using Fabry-Pérot etalons before entering the grating, alternative options to achieve this pre-dispersion are being investigated. The full 35-230 ?m wavelength range is split in to several different bands, each with its own grating and TES detectors. The baseline design has for each of the bands three separate spatial pixels, to provide background reference measurements, but also to provide some imaging capability.

An earlier design for the SAFARI instrument was based on a Mach-Zehnder Fourier Transform Spectrometer. As in an FTS the detectors continuously are exposed to the full broad band signal, the sensitivity of such an architecture is fundamentally limited by photon noise, which in practice implied a sensitivity limit of around 2 x 10-19 W/m2 (5?, 1hr). With SPICA's cold, 2.5 meter telescope and the baseline TES NEP of 2x10-19 W/√Hz, for the new grating based SAFARI the sensitivity of the R~300

mode will be about 5 x 10-20 W/m2 (5?, 1hr). With the current design further improvements in TES performance will directly lead to even higher instrument sensitivity – today's state of the art TES performance is already close to 1x10-19 W/√Hz! With this high sensitivity astronomers will e.g. be able to detect the [OIV] line in relatively average galaxies out to a redshift z~3. Thus the evolution of galaxies can be followed through their most active periods in cosmic time from about 10 billion years ago to what they look like today. Additionally we will be able to observe dust features from even earlier epochs, out to redshifts of z~7-8, thus providing insight into dust formation in the very early phases of the universe.

9904-85, Session 21

The far infrared spectroscopic explorer (FIRSPEX) : probing the life cycle of the ISM in the universe

Dimitra Rigopoulou, Univ. of Oxford (United Kingdom); Giorgio Savini, Univ. College London (United Kingdom); Brian N. Ellison, Chris Pearson, STFC Rutherford Appleton Lab. (United Kingdom)

The complex processes that initiate cloud collapse enabling the onset of star formation and subsequent stellar evolution leave their imprint on the Interstellar Medium (ISM) of our Galaxy and that of external galaxies. By studying the phase structure of the ISM we can begin to unravel the processes that control the heating and cooling of the clouds that eventually regulate star formation. FIR/submm spectroscopy is essential in probing these processes since this regime contains important cooling lines of the different phases of the ISM.

The Far InfraRed Spectroscopic EXplorer (FIRSPEX) is a novel concept for an astrophysics satellite mission that will revolutionise our understanding of the life cycle of the ISM starting from our own Galaxy out to distant galaxies. To achieve this goal we aim to obtain fully sampled velocity-resolved observations of carefully chosen key far infrared lines (e.g. CII, NII, OI) each probing a different component of the ISM. The spectral range selected contains important molecular, atomic and ionic species that cannot be observed from the ground. The FIRSPEX payload consists of a number of heterodyne detection bands targeting key molecular and atomic transitions in the terahertz (THz) and Supra-Terahertz (>1 THz) frequency range. The FIRSPEX bands under consideration are: [NII] 122 microns (2.5 THz), OH 119 microns (2.45 THz), [CII] 158 microns (1.9 THz), [NII] 205 microns (1.46 THz), [CI] 370 microns (0.89 THz), CO(6-5) 433 microns (0.69 THz). The choice of the channels has been motivated by the need to study the atomic, ionized and molecular phases of the ISM both in our own Galaxy but also in external galaxies.

The mission uses a heterodyne payload and a ~1.2m primary antenna to scan the entire sky in a number of discreet spectroscopic channels from L2. While superconducting receivers operating at ~4K temperature represent the most sensitive technology for heterodyne systems in space the current FIRSPEX baseline concept relies on the use of semiconductor Schottky diode mixers as the primary detection element in each of the high spectral resolution heterodyne receivers. Each receiver will operate within a well-defined spectral range corresponding to the key species discussed above. A wide-band digitizing spectrometer will provide an instantaneous bandwidth ~10 GHz with high spectral resolution. Adequate local oscillator (LO) power, a crucial element of the heterodyne mixing process, will be provided by sub-harmonic mixer using harmonic frequency up-conversion. It is also possible to use quantum cascade laser (QCL) technology with the Schottky mixers configured in a balanced fundamental format (for the >1.5 THz receivers). The mixers and QCL LOs can operate at a 100 K, with cooling provided by previously space-qualified and demonstrated Stirling cycle mechanical cooler. FIRSPEX will perform an `unbiased' all-sky spectroscopic survey of the Galaxy and of external galaxies opening a completely new window of scientific discoveries.

9904-86, Session 21

The Space High Angular Resolution Probe for the Infrared (SHARP-IR)

Stephen A. Rinehart, NASA Goddard Space Flight Ctr. (United States); Maxime J. Rizzo, Univ. of Maryland, College Park (United States); David T. Leisawitz, Dominic J. Benford, NASA Goddard Space Flight Ctr. (United States); Johannes G. Staguhn, Johns Hopkins Univ. (United States); Michael J. DiPirro, John E. Mentzell, Roser Juanola-Parramon, NASA Goddard Space Flight Ctr. (United States); Arnab Dhabal, Lee G. Mundy, Univ. of Maryland, College Park (United States); Samuel H. Moseley Jr., John C. Mather, Deborah L. Padgett, Karl R. Stapelfeldt, Aki Roberge, NASA Goddard Space Flight Ctr. (United States)

The Space High Angular Resolution Probe for the Infrared (SHARP-IR) is a new mission currently under study. As part of the preparation for the Decadal Survey, NASA is currently undertaking studies of four major missions, but interest has also been shown in determining if there are feasible sub-$1B missions that could provide significant scientific return. SHARP-IR is being designed as one such potential probe. In this talk, we will discuss some of the potential scientific questions that could be addressed with the mission, the current design, and the path forward to concept maturation.

Conference 9905: Space Telescopes and Instrumentation 2016: Ultraviolet to Gamma Ray

Sunday - Friday 26–1 July 2016

Part of Proceedings of SPIE Vol. 9905 Space Telescopes and Instrumentation 2016: Ultraviolet to Gamma Ray

9905-1, Session 1

SMILE: a joint ESA-CAS mission to investigate the interaction between the solar wind and Earth's magnetosphere

Walfried Raab, European Space Research and Technology Ctr. (Netherlands); Graziella Branduardi-Raymont, Univ. College London (United Kingdom); Chi Wang, Lei Dai, National Space Science Ctr. (China); Eric F. Donovan, Univ. of Calgary (Canada); Philippe Escoubet, European Space Research and Technology Ctr. (Netherlands); Lei Li, Ctr. for Space Science and Applied Research (China); David Lumb, European Space Research and Technology Ctr. (Netherlands) and European Space Agency (Netherlands); Andrew M. Read, Univ. of Leicester (United Kingdom); Denis Rebuffat, European Space Agency (Netherlands) and European Space Research and Technology Ctr. (Netherlands); Jens Romstedt, European Space Research and Technology Ctr. (Netherlands) and European Space Agency (France); Steven F. Sembay, Univ. of Leicester (United Kingdom); Emma Spanswick, Univ. of Calgary (Canada); Arno A. Wielders, European Space Agency (Netherlands) and European Space Research and Technology Ctr. (Netherlands); Jianhua Zheng, Aibing Zhang, National Space Science Ctr. (China) and Chinese Academy of Sciences (China)

The Solar wind Magnetosphere Ionosphere Link Explorer (SMILE) is a collaborative science mission between ESA and the Chinese Academy of Science (CAS). SMILE is a novel self-standing mission to observe the coupling of solar wind and Earth's magnetosphere via simultaneous in-situ solar wind, magnetosheath plasma and magnetic field measurements, X-Ray images of the solar wind - magnetosphere interaction zones, and UV images of global auroral distributions. The SMILE mission proposal was submitted by a consortium of European, Chinese and Canadian scientists following a joint call for mission by ESA and CAS. It was formally selected by ESA's Science Programme Committee (SPC) as an element of the ESA Science Program in November 2015, with the goal of a launch in the 2021 - 2022 time frame.

In order to achieve its scientific objectives, the SMILE payload will comprise four instruments: the Soft X-ray Imager (SXI), which will spectrally map the Earth's magnetopause, magnetosheath and magnetospheric cusps; the UltraViolet Imager (UVI), dedicated to imaging the auroral regions; the Light Ion Analyser (LIA) and the MAGnetometer (MAG), which will establish the solar wind properties simultaneously with the imaging instruments. We will report on the status of the mission and payload developments and the findings of a design study carried out at the concurrent design facility (CDF) of ESTEC and the National Space Science Center (NSSC,CAS) in October/November 2015.

9905-2, Session 1

The solar ultraviolet imaging telescope onboard Aditya-L1

Avyarthana Ghosh, Inter-Univ. Ctr. for Astronomy and Astrophysics (India) and Indian Institute of Science Education and Research Kolkata (India); Subhamoy Chatterjee, Indian Institute of Astrophysics (India); Aafaque R. Khan, Durgesh Tripathi, A. N. Ramprakash, Inter-Univ. Ctr. for Astronomy and Astrophysics (India); Dipankar Banerjee, Indian Institute of Astrophysics (India); Pravin Chordia, Inter-Univ. Ctr. for Astronomy and Astrophysics (India); Achim M. Gandorfer, Max-Planck-Institut für Sonnensystemforschung (Germany); Dibyendu Nandi, Indian Institute of Science Education and Research Kolkata (India); Chaitanya Rajarshi, Inter-Univ. Ctr. for Astronomy and Astrophysics (India); Sami Solanki, Max-Planck-Institut für Sonnensystemforschung (Germany); S. Sriram, Indian Institute of Astrophysics (India)

The Solar Ultraviolet Imaging Telescope (SUIT) is an instrument onboard the Aditya-L1 spacecraft, the first dedicated solar mission of Indian Space Research Organization (ISRO), which will be put in an halo orbit at Sun-Earth Langrage point (L1). SUIT uses an off-axis Ritchey–Chrétien configuration telescope with a combination of 11 narrow and broad bandpass filters that will take images of the Sun in 200-400 nm. It will provide near simultaneous observations of lower and middle layers solar atmosphere, namely Photosphere, Chromosphere and lower transition region. These observations will help improving our understanding of coupling and dynamics of various layers of solar atmosphere, mechanisms responsible for stability, dynamics and eruption of solar prominences and CMEs, and possible causes for solar variability in the NUV region.

SUIT employs a 4Kx 4K UV enhanced CCD detector with a 12 micron pixel size to provide a resolution of 0.7 arcsecond/pixel with a ~48 sq. arcminutes field of view. The 11 filters consisting of 8 narrow and 3 board bandpass filters, in combination with 4 clear and neutral density filters will be employed via two independent filter wheel mechanisms. It will provide Region of Interest images in all 8 narrow band filters with a cadence of 30 seconds and full frame images in all 11 filters with a cadence of 30 minutes. The out of band solar flux i.e., the visible and IR region is rejected by an entrance aperture filter that also cuts the excessive flux in the UV region.

SUIT will autonomously operate based on preprogrammed operational sequences that will take Full frame and Region of Interest Images (500 sq. arcseconds) in different filters. During its science operations SUIT will operate in two modes: Normal and Flare mode, with an autonomous decision making capability to switch from Normal to Flare mode (and back) based on flare detection trigger from another payload onboard Aditya-L1. The massive volume of data generated from SUIT will be compressed and stored on-board and will be down linked to ground-station when the spacecraft is visible. This onboard autonomy will enable SUIT to provide 24x7 coverage of the sun even when the spacecraft is not visible from the ground-station. SUIT observations in combination with other payloads onboard Aditya-L1, E-VELC, SoLEX and HEL1OS, will provide a comprehensive perspective of different layers of solar atmosphere.

9905-3, Session 1

World Space Observatory Ultraviolet mission: status 2016

Mikhail Sachkov, Boris M. Shustov, Institute of Astronomy (Russian Federation); Ana Inés Gómez de Castro, Univ. Complutense de Madrid (Spain)

The space mission World Space Observatory - Ultraviolet (WSO-UV) is grown out the needs of the astronomical community to have access to the Ultraviolet (UV) range 115-320 nm of the spectrum in post-HST epoch. WSO-UV consists of a UV telescope of 1.7 m primary mirror diameter and a set of UV low and high spectral resolution spectrographs and UV-optical imagers.The project is in an advanced phase of creation. The current state of art of the mission will be described. The materials on selection of initial parameters of the Spacecraft, Payload, Operational orbit and Ground Segment will be presented.

9905-4, Session 1

Galaxy evolution spectroscopic explorer (GESE): a companion to high-energy observatories

Sara R. Heap (Emeritus), NASA Goddard Space Flight Ctr. (United States)

The history of the universe can be described as the continuous conversion of gas into stars. However, it is clear that star formation is impeded by “feedback” from newly formed massive stars themselves, by stellar-mass black holes and AGN’s, and by the influence of dark energy in counteracting the long-range effects of gravity. Space telescopes sensitive to far-UV radiation from massive stars, supernova explosions, and AGN’s give information that is complementary to that gained by x-ray telescopes. Using a UV mission concept called Galaxy Evolution Spectroscopic Explorer (GESE) as an example, we describe the synergy between UV and high-energy telescopes.

9905-5, Session 1

CHISL: combined high-resolution and imaging spectrograph for the LUVOIR surveyor

Kevin C. France, Brian T. Fleming, Keri Hoadley, Univ. of Colorado Boulder (United States)

NASA is currently carrying out science and technical studies to identify its next astronomy flagship mission to begin development in the 2020s. It has become clear that a Large Ultraviolet/Optical/IR (LUVOIR) Surveyor mission (dprimary ≈ 12 m, ?? ≈ 912 Å – 2 μm spectroscopic bandpass) can carry out the largest number of NASA’s exoplanet and astrophysics science goals over the coming decades. The science grasp of a LUVOIR Surveyor is broad, ranging from the direct detection of potential biomarkers on rocky planets to the flow of matter into and out of galaxies and the history of star-formation across cosmic time. There are significant technical challenges for many aspects for the LUVOIR Surveyor concept, including component level technology readiness maturation and science instrument concepts for a broadly capable ultraviolet spectrograph. We present the scientific motivation for, and a preliminary design of, a multiplexed ultraviolet spectrograph to support both the exoplanet and astrophysics goals of the LUVOIR Surveyor mission concept, the Combined High-resolution and Imaging Spectrograph for the LUVOIR Surveyor (CHISL). CHISL includes a high-resolution (R > 120,000) point-source spectroscopy channel and a medium resolution (R > 10,000) imaging spectroscopy channel for topics as broad as characterizing the composition and structure of planet-forming disks to the feedback of matter between galaxies and the intergalactic medium. We present the CHISL concept, potential science enhancing technical additions (e.g., an aperture system supporting multi-object spectroscopy), and identify the primary technological hurdles. Technical challenges include high-efficiency ultraviolet coatings and high-quantum efficiency, large-format, photon counting detectors. We are actively engaged in laboratory and flight characterization efforts for all of these enabling technologies as components on sounding rocket payloads currently under development at the University of Colorado. We describe two payloads that are designed to be pathfinder instruments for the high-resolution (CHESS) and imaging spectroscopy (SISTINE) arms of CHISL. We are carrying out this instrument design, characterization, and flight-testing today to support the new start of a LUVOIR Surveyor mission in the next decade.

9905-6, Session 2

Optical design and optical properties of a VUV spectrographic imager for ICON mission

Jérôme J. D. Loicq, Christian Kintziger, Alexandra Mazzoli, Univ. de Liège (Belgium); Tim N. Miller, Cathy Chou, Thomas Immel, Harald U. Frey, Stephen B. Mende, Univ. of California, Berkeley (United States)

The ICON mission is led by the University of California-Berkeley (Space Sciences Laboratory). In the frame of this mission the Space Center of Liege was involved into the optical design optimization and related analysis.

The ICON mission (NASA) will explore the boundary between Earth and space to understand the physical connection between our world and our space environment. Recent NASA missions have shown how dramatically variable the region of space near Earth is, where ionized plasma and neutral gas collide and react. This region, the ionosphere, has long been known to respond to space weather drivers from the sun, but in this century we have come to realize that the energy and momentum of our own low altitude atmosphere regularly affect the ionosphere with equal or greater magnitude. ICON will weigh the impacts of these two drivers as they exert change on our space environment.

During the day, photoelectrons colliding with atmospheric neutrals, N2 and O, produce emissions and by observing the limb brightness of the N2 Lyman-Birge-Hopfield (LBH) bands and of the OI 135.6 nm line, the density ratio of the neutral N2 and O atmospheric constituents can be retrieved. At night the recombination of O+ ions with ionospheric electrons also creates OI 135.6 nm emissions and the nighttime electron density can be estimated from the limb brightness of 135.6 nm. ICON FUV will measure the altitude distribution of the OI 135.6 nm and N2 LBH dayglow emissions at 157 nm and the altitude and spatial distribution of the OI 135.6 nm nightglow emissions. These quantities can then be used to determine dayside O and N2 densities and altitude profiles, and the nightside O+ densities in the F-region.

The ICON-FUV instrument is based upon the IMAGE Spectrographic Imager (SI) [Mende et al., 2000c]. Like this predecessor, ICON-FUV is a two-channel imager that uses a grating spectrometer for spectral discrimination. The two channels are required to provide the daytime profiles of two wavelengths characterizing the N2 and O species (centered at 157 nm and 135.6 nm respectively). This grating type of spectrographic imager minimizes contamination by out-of-band light leaks that are a typical problem for non-grating type FUV cameras.

In this paper the optical design and optimization process will be presented. The instrument is composed by two parts, a Czerny-Turner spectrograph selecting the science wavelengths. This spectrograph is then combined with two imagers respectively working in the two wavebands of interest. The challenge of this space instrument was to be designed for a very wide FOV (24° vertical by 18° horizontal).

The instrument has been optimized in two main steps including payload platform constrains. First the Czerny-Turner spectrograph has been designed to reduce as much as possible the astigmatism generated by the grating and to give the same spectral properties over the entire field of view, secondly the two imagers based on aspheric and off-axis mirrors have been designed.

Optical properties, instrument throughput, flat field evaluation and tolerance analysis will be presented.

9905-7, Session 2

Chromospheric LAyer SpectroPolarimeter (CLASP2)

Noriyuki Narukage, National Astronomical Observatory of Japan (Japan); Jonathan W. Cirtain, NASA Marshall Space Flight Ctr. (United States); Ryoko Ishikawa, National Astronomical Observatory of Japan (Japan); Javier Trujillo-Bueno, Instituto de Astrofísica de Canarias (Spain); Bart De Pontieu, Lockheed Martin Space Systems Co. (United States); Masahito Kubo, National Astronomical Observatory of Japan (Japan); Shin-nosuke Ishikawa, Institute of Space and Astronautical Science (Japan); Ryouhei Kano, Yoshinori Suematsu, Masaki Yoshida, National Astronomical Observatory of Japan (Japan); Ken Kobayashi, Amy R. Winebarger, NASA Marshall Space Flight Ctr. (United States); Andres Asensio Ramos, Tanausu del Pino Aleman, Instituto de Astrofísica de Canarias (Spain); Jiri Stepan, Astronomical Institute of the ASCR, v.v.i. (Czech Republic); Luca Belluzzi, Istituto Ricerche Solari Locarno (Switzerland); Juan Ignacio Larruquert, Consejo Superior de Investigaciones Científicas (Spain); Frédéric Auchère, Institut d'Astrophysique Spatiale (France); Jorrit Leenaarts, Stockholm Univ. (Sweden); Mattias J. L. Carlsson, Univ. I Oslo (Norway)

The solar chromosphere is a crucial interface region between the solar photosphere (6000 K) and the corona (more than 1 MK). Observations (e.g., with the Hinode and IRIS space telescopes) show very dynamic phenomena in the chromosphere (e.g., jets, waves, etc.), including clear hints of heating events. However, our quantitative knowledge on the magnetic field and on the dissipation of magnetic energy in the chromosphere-corona transition region is practically inexistent, since no space telescope has ever been developed to carry out spectropolarimetric measurements in the ultraviolet resonance lines that originate in the upper solar chromosphere and transition region. With this motivation in mind, the Chromospheric Lyman-Alpha SpectroPolarimeter (CLASP) was proposed, designed and launched on September 3rd, 2015, using a NASA sounding rocket. For the first time, CLASP successfully detected (with a polarization accuracy of 0.1 %) the linear polarization signals (Stokes Q and U) that scattering processes were predicted to produce in the hydrogen Lyman-alpha line (Lya; 121.567 nm). Via the Hanle effect, this unique data set may provide information about the magnetic structure and energetics in the upper solar chromosphere. The CLASP instrument was safely recovered without any damage and we have recently proposed to dedicate its second flight to observe the four Stokes profiles (intensity, linear and circular polarization) in the spectral region of the Mg II lines around 280 nm (Mg II k; 279.55 nm, and Mg II h; 280.27 nm), in order to exploit the Hanle effect in the linear polarization (Stokes Q and U) of the k line and the Zeeman effect in the circular polarization (Stokes V) of the k and h lines. This new project is called the "Chromospheric LAyer SpectroPolarimeter (CLASP2)". Essentially, for CLASP2 we will reuse, i.e., keep, the optical layout of the CLASP (Narukage et al., 2015). Nevertheless, because of the change in the wavelength target from 122 nm to 280 nm, the waveplate, grating and polarization analyzer will be re-fabricated and the narrow band filter coating on the primary mirror will be also re-coated. Additionally, we plan to develop and install a magnifying lens in front of the CCD camera for keeping the same wavelength sampling as in the CLASP. This modification will make CLASP2 suitable to detect the linear and circular polarizations signals across the Mg II lines with a 0.1 % accuracy and a wavelength sampling of 0.005 nm. The spectropolarimetric observations carried out by CLASP in Lya and by CLASP2 in Mg II h & k will be useful to constrain better the magnetic structure of the upper solar chromosphere, given the different magnetic sensitivities and formation heights of such resonance lines. Additionally, the data sets from CLASP and CLASP2 will help us decide the most suitable strategies for probing the outer solar atmosphere through spectropolarimetry from a future space telescope.

9905-8, Session 2

The miniature x-ray solar spectrometer (MinXSS) CubeSat instrument characterization techniques, instrument capabilities, and solar science objectives

Christopher S. Moore, Univ. of Colorado Boulder (United States) and Lab. for Atmospheric and Space Physics (United States) and Utah State Univ. (United States); Thomas N. Woods, Univ. of Colorado Boulder (United States); Amir Caspi, Southwest Research Institute (United States); James P. Mason, Univ. of Colorado Boulder (United States)

The Miniature X-ray Solar Spectrometer (MinXSS) is a 3U CubeSat launched in December 2015 to the International Space Station for deployment in early 2016. MinXSS will utilize a commercial off the shelf (COTS) X-ray spectrometer from Amptek to measure the solar irradiance from 0.5 – 30 keV with a nominal 0.15 keV FWHM spectral resolution at 5.9 keV and a LASP developed X-ray photometer with similar spectral sensitivity. MinXSS design and development has involved over 40 graduate students supervised by professors and professionals at the University of Colorado at Boulder.

The majority of previous solar X-ray measurements have been either at high spectral resolution with a narrow bandpass or spectrally integrating (broad band) photometers. MinXSS will conduct unique soft X-ray measurements of moderate spectral resolution over a relatively large energy range to study solar active region evolution, solar flares, and their effects on Earth's ionosphere. This paper focuses on the science instrument characterization involving radioactive X-ray sources and the National Institute for Standard and Technology (NIST) Synchrotron Ultraviolet Radiation Facility (SURF). Detector spectral response, spectral resolution, response linearity are discussed as well as future solar science objectives.

9905-9, Session 2

SISTINE: a pathfinder for far-UV imaging spectroscopy on future NASA astrophysics missions

Brian T. Fleming, Kevin C. France, James C. Green, Univ. of Colorado Boulder (United States); Oswald H. W. Siegmund, Sensor Sciences, LLC (United States); Manuel A. Quijada, NASA Goddard Space Flight Ctr. (United States); Robert Kane, Nicholas Nell, Univ. of Colorado Boulder (United States)

The University of Colorado ultraviolet sounding rocket group is finalizing the design of the Suborbital Imaging Spectrograph for Transition Region Irradiance from Nearby Exoplanet host stars (SISTINE); the first sub-arcsecond imaging, medium resolution spectrograph capable of simultaneous coverage of the entire 1000 – 1580 Angstrom bandpass. SISTINE is designed as a pathfinder instrument for maturing critical path technologies necessary for the LUVOIR surveyor. Utilizing a breakthrough advancement in broadband mirror coatings, SISTINE folds a large effective focal length into a sounding rocket envelope without a crippling loss of effective area. These enhanced lithium fluoride protected aluminum (eLiF)

coatings, developed at Goddard Space Flight Center, offer greater than 80% reflectivity from the far-ultraviolet through the near-infrared, and will be flight tested on SISTINE in preparation for implementation on future space observatories. When coupled with next-generation large-format borosilicate microchannel plate detectors developed at Sensor Sciences, SISTINE is capable of a resolving power of 10,000 over its entire band with a peak effective area of 170 cm2, representing a high throughput for an FUV instrument of > 10%. This system throughput is a factor of ~10 higher than the medium resolution far-ultraviolet imaging spectroscopy modes on HST-STIS. We present the design and an outline of the science goals of SISTINE, as well as a schedule of fabrication and calibration milestones necessary for completion of the instrument. The first flight of SISTINE is planned for 2018 to observe the energetic radiation environment of nearby low-mass exoplanet host stars.

9905-10, Session 3

Flight production of Caliste-SO: the hard x-ray spectrometers for solar orbiter/STIX instrument

Olivier Limousin, CEA-Ctr. de SACLAY (France); Aline Meuris, CEA-IRFU (France); Claire Blondel, Commissariat à l'Énergie Atomique (France); Modeste Donati, Luc Dumaye, CEA-Ctr. de SACLAY (France); Olivier Gevin, Isabelle Le Mer, Jerome Martignac, Thierry Tourrette, Commissariat à l'Énergie Atomique (France); Marie-Cécile Vassal, Mohamed Boussadia, Dominique Blain, Nicolas Fiant, Fabrice Soufflet, 3D-Plus SAS (France); Martin Bednarzik, Guy Birrer, Stefan Stutz, Christopher Wild, Paul Scherrer Institut (Switzerland); Marc Billot, Ctr. National d'Études Spatiales (France); Isabelle Fratter, Ctr. National de la Recherche Scientifique (France); Oliver Grimm, Fachhochschule NordWestschweiz (Switzerland) and ETH Zürich (Switzerland); Sam Krucker, Fachhochschule NordWestschweiz (Switzerland)

On board the Solar Orbiter mission to be flown in 2018, the Spectrometer Telescope Imaging X-rays will perform X-ray imaging spectroscopy of solar flares to study the physical properties of these eruptive events (plasma temperature, acceleration mechanisms) and the Sun-heliosphere connection (magnetic energy conversion and release). The imaging technique consists in a Fourier transform based on 32 X-ray collimators, each of them with a pair of grids and a spectrometer. Caliste-SO is the spectrometer unit designed for STIX. It is the hybridization of a 1 cm2 pixel CdTe sensor with a radiation hard low noise front-end ASIC called IDeF-X HD. With a 12 x 14 x 18 mm3 volume, a 5 g mass and a 20 mW total power, the resulting device integrates 12 high-resolution spectroscopic channels. The spectrometer is well adapted for X-ray detection from 4 keV (70 % efficiency, low-level threshold of the front-end electronics below 3 keV) to 150 keV (50 % efficiency, dynamic range of the front-end electronics up to 250 keV), allowing observations of both thermal and non-thermal emissions of the solar flares. Ninety-eight Caliste-SO units passed performance criteria (energy resolution) and quality criteria (crystal defects, metrology) to be mounted into a validation model of STIX. Energy resolution of most pixels is between 0.8 and 1 keV FWHM at 14 keV (measurements with 241Am source) when the detector is cooled down at -20°C and biased at -300V, for a peaking time of 2 μs. This performance can be achieved thanks to the hybridization process which limits the stray capacitance between the pixels and the ASIC channels to 2 pF. Even better spectral performance (< 0.7 keV) can be obtained at longer peaking times (programmable in the Caliste-SO ASIC) but that would be to the detriment of the timing performance. Photon count rate produced during solar flares can indeed vary from few photons/s/cm2 to millions of photons/s/cm2, according to the event class and evolving with time. The STIX instrument will be equipped with a removable X-ray attenuator in case of bright events but the count rate capability of Caliste-SO shall be of 20000 counts/s/cm2 at least while maintaining spectral capabilities. With 2 μs peaking time, the pile-up fraction stays below 1%. Caliste-SO qualification and further characterizations are on-going before mounting the first units on the STIX flight model in 2016.

9905-12, Session 3

Ultraviolet imaging detectors for the GOLD mission

Oswald H. W. Siegmund, Jason McPhate, Univ. of California, Berkeley (United States); John V. Vallerga, Space Sciences Lab. (United States)

The GOLD mission is an ultraviolet Earth observing spectroscopy instrument that will be flown on a telecommunications satellite in geosynchronous orbit in 2017. GOLD has two identical spectrometer channels operating in the 130 nm to 170 nm UV bandpass regime and is designed to observe atmospheric UV emission from oxygen and nitrogen. The objective is to measure the composition and temperature of the thermosphere dynamically at a cadence of the order of about 30 minutes. We will describe the microchannel plate detectors with 2D imaging cross delay line readouts and electronics have been built for each of the spectrometer channels. The two detectors are "open face" with CsI as a photocathode deposited onto the top surface of the MCPs. Each detector is enclosed in a vacuum housing with a re-closable door. The detectors provide ~500 x 500 resolution elements and are photon counting. The detector electronics are based on amplification stages followed by a time to digital converter to convert anode delay times to X and Y positions. The electronics event dead-time is ~1 μs which allows event rates of up to 100 kHz to be processed with minimal losses. The background rates are as low as 0.15 events sec-1 cm-2, and the flat field fixed pattern noise is quite low (~5%) for this generation of microchannel plates. Quantum efficiencies have been optimized and are at the same level as detector on the HST COS instrument. Image resolution, counting rates and image linearity are principally determined by the electronics system. The constraints on available power and mass in concert with the science instrument performance drivers control the design choices for the electronics package. Data for each photon detection includes a 4k x 4k position and an event pulse amplitude. The latter is also used to reject high amplitude events due to charged particles that are expected to increase the background in geosynchronous orbit. Local event rates are greater than 10 events/pore/sec and are determined by the choice of low resistance microchannel plates. This accommodates bright spectral lines and stellar calibration observations. Thermal stability and long term performance stability of the detector system will be discussed. Electronics stimulation pulses are also injected into the electronics processing chain at all times. These provide useful diagnostics on the health of the detector and electronics. The overall construction, testing and calibration of the GOLD detectors will be detailed in this paper, along with a discussion of their impact on the mission.

9905-13, Session 3

The FOXSI solar hard x-ray rocket campaigns

Lindsay Glesener, Univ. of Minnesota (United States); Sam Krucker, Univ. of California, Berkeley (United States) and Fachhochschule NordWestschweiz (Switzerland); Steven D. Christe, NASA Goddard Space Flight Ctr. (United States); Shin-nosuke Ishikawa, Institute of Space and Astronautical Science (Japan); Juan Camilo Buitrago Casas, Univ. of California, Berkeley (United States); Brian

D. Ramsey, NASA Marshall Space Flight Ctr. (United States); Tadayuki Takahashi, Shin Watanabe, Univ. of Tokyo (Japan) and Institute of Space and Astronautical Science (Japan); Mikhail V. Gubarev, NASA Marshall Space Flight Ctr. (United States); Paul Turin, William Van Shourt, Stephen McBride, Univ. of California, Berkeley (United States); Juliana Vievering, Univ. of Minnesota (United States)

The Focusing Optics X-ray Solar Imager (FOXSI) sounding rocket experiment has successfully been flown twice for 6.5 minute observations of the Sun. The experiment's goals are to develop hard X-ray (HXR) focusing optics technology for solar astrophysical purposes, and to demonstrate the use of this technology by performing novel solar investigations. To achieve these goals, FOXSI relies on grazing-incidence focusing HXR optics produced at the NASA Marshall Space Flight Center and thin, fine-pitch semiconductor detectors (Si and CdTe) provided by the JAXA Institute of Space and Astronautical Science in Japan.

The FOXSI-1 rocket flew on 2012 November 2 and imaged a solar microflare, producing the first focused images of the Sun above 5 keV. FOXSI-2 flew on 2014 December 11 and produced images and spectra of multiple flares and active regions. Several upgrades were included for the second flight, such as the addition of smaller-diameter mirrors to extend the energy range to ~20 keV, the inclusion of two 60 um pitch CdTe sensors in addition to the original 75 um Si sensors, and a new optical solar aspect and alignment system. FOXSI data have been used to measure and constrain high-temperature plasma in active regions, and have placed limits on flaring activity in the quiet Sun, both important for understanding flare contributions to coronal heating.

All FOXSI observations to date have experienced an instrumental background due to ghost rays (single-bounce photons) from sources outside the field of view. While ghost-ray backgrounds are not unique to solar science, the frequent occurrence of bright sources distributed across the solar disk means that ghost rays pose a special challenge for solar observation. Ghost rays can be highly attenuated by the addition of a pre-collimator (baffle) to the entrance of the grazing incidence optics.

In this work we present an overview of the FOXSI rocket instrument, discuss requirements for a pre-collimator to attenuate ghost rays, and outline future plans for the project.

9905-134, Session 3

The faint intergalactic medium redshifted emission balloon: FIREBall-2 ready for flight

Erika T. Hamden, D. Christopher Martin, California Institute of Technology (United States); David Schiminovich, Columbia Univ. (United States); Bruno Milliard, Observatoire Astronomique de Marseille-Provence (France); Robert Grange, Lab. d'Astrophysique de Marseille (France); Frederi Mirc, Ctr. National d'Études Spatiales (France); Patrick Morrissey, Mateusz Matuszewski, California Institute of Technology (United States); Samuel Quiret, Lab. d'Astrophysique de Marseille (France); April D. Jewell, Jet Propulsion Lab. (United States); Didier Vibert, Observatoire Astronomique de Marseille-Provence (France); Shouleh Nikzad, Jet Propulsion Lab. (United States); Jose Manuel Zorilla, Michele Limon, Columbia Univ. (United States); Nicole R. Lingner, Gillian Kyne, California Institute of Technology (United States); Albert Gomes, Ctr. National d'Études Spatiales (France); Alain Origné, Observatoire Astronomique de Marseille-Provence (France); Sandrine Pascal, Didier Ferrand, Lab. d'Astrophysique de Marseille (France)

The Faint Intergalactic Redshifted Emission Balloon (FIREBall-2) is a joint NASA/CNES collaboration that is preparing to launch in mid-summer 2016 from Palestine, TX. FIREBall-2 is a balloon-born UV multi-object spectrograph designed to detect faint emission from the circumgalactic medium (CGM) around low z galaxies. FIREBall-2 builds on the existing gondola and large optics of FIREBall-1, but has been extensively redesigned to improve performance by over an order of magnitude. To improve instrument throughput, a photon-counting delta-doped EMCCD has replaced the GALEX spare NUV micro channel plate. Custom red blocking coatings minimize out-of-band light and improve in-band transmission. FIREBall-2 will flight test these technology innovations in anticipation of the 2016 MIDEX AO. Here we discuss the final flight design, results from integration and testing in Marseille earlier in 2016, and the ongoing final preparations for flight. We also describe target fields and expected performance in flight.

9905-135, Session 3

Imaging the circumgalactic and intergalactic medium in the space ultraviolet

D. Christopher Martin, Erika T. Hamden, California Institute of Technology (United States); David Schiminovich, Columbia Univ. (United States); Bruno Milliard, Observatoire Astronomique de Marseille-Provence (France); Mateusz Matuszewski, Patrick Morrissey, California Institute of Technology (United States)

We describe the scientific case and technical approach for an Explorer designed to image the Circumgalactic Medium (CGM) and Intergalactic Medium (IGM) in the space ultraviolet. Our science method builds on discoveries made with the Palomar Cosmic Web Imager (PCWI). We will perform an imaging survey to make a complete census of Lyman alpha emitters (LAE) at redshifts 0.01< z<1.5, a period of dramatic evolution in the LAE population. We will construct a reference sample that we will map and characterize using 2D imaging spectroscopy. We will perform a survey of the bright Circum QSO Medium (CQM) emission predicted around a large fraction of QSOs, using 2D imaging spectroscopy of targeted Type I and II QSOs. We will perform a Lyman alpha, a Star Formation Rate, and a mass selected survey of the CGM of galaxies over the redshift 0.01< z<1.1 range. Finally, we will search for emission from the cosmic webusing statistical techniques to explore the deepest sensitivity levels. Our mission utilizes demonstrated UV-sensitive photon-counting CCDs, UV optimized integral field spectrographs based on proven CWI designs, and an imaging channel with a new filter.

9905-14, Session 4

Development and performance of Si-drift-based detectors and their potential capability for x-ray astronomy *(Invited Paper)*

Andrea Vacchi, Istituto Nazionale di Fisica Nucleare (Italy) and Univ. degli Studi di Udine (Italy)

The constantly evolving specifications for instrumentation to face X-ray space astronomy points towards extreme technical refinement of the

otherwise already high performances delivered by the various detectors technologies and the dedicated front end and read-out electronics. Besides the standard requirements for space applications, like the high readiness level and the probated radiation resistance, characteristics as: high efficiency in a range between few hundred eV to 10-15 KeV; high energy resolution and low leakage current at room temperature; high event rate per pixel; large sensitive areas up to more square meters; imaging capability and small pixel size, are imposing sometime contradictory constraints to the envisaged technologies. The proposed solutions will have to deepen in great details into a study of the whole harmonized detection system going from the mechanical layout to the detector's design geometry and production technology to the matching bonding techniques and not last the, on purpose, developed front-end electronics. This unavoidably leads towards specialized solutions leaving small space for generic developments. For a long time, the projects of detection systems for space applications have been profiting of the, sometime quite expensive, developments done for experiments at large accelerators. The specificity and harsh conditions on X-ray detection for astrophysics excludes at present this, in other times profitable, symbiosis. Expensive studies for dedicated detections systems shall be carefully planned in collaborative approach. Fully depleted Silicon junction detectors still offers best possible, if not ideal, solutions for soft X-ray detection. In particular the highly adaptive Silicon Drift Detectors design and production technology still plays a decisive role in the field of high performances X-rays detection systems. In this talk some recent front edge development and programmed evolutions will be discussed.

9905-15, Session 4

Properties of DePFET active pixel sensors fabricated on 200-mm wafers as monolithic focal plane detectors for x-ray astronomy missions

Lothar W. Strüder, Peter Holl, Robert Hartmann, PNSensor GmbH (Germany); Sascha Weyers, Julia Hauser, Fraunhofer-Institut für Mikroelektronische Schaltungen und Systeme (Germany); David Kalok, Dieter Schlosser, Petra Majewski, Gerhard Lutz, Stefan Aschauer, PNSensor GmbH (Germany)

DePFET active Pixel Sensors have been introduced as focal plane detectors for X-ray astronomy already in 1996, fabricated on high resistivity, back-illuminated fully depleted silicon, with fast and low noise operation. Since one year DePFET detectors are being fabricated in an industrial CMOS foundry maintaining the outstanding proven DePFET properties and adding new capabilities because of the use of state-of-the-art features of a modern CMOS fabrication process. We will highlight the additional features due to the new fabrication process (noise, speed, quantum efficiency, monolithic detector size, pixel sizes, implementation of new functions, such as gating, internal signal storage and repetitive non – destructive readout) and describe the constant progress achieved so far. In a first test technology run we have measured all device related properties, such as implantation profiles, backside protection, interface properties, leakage currents, depletion voltages etc. The most important features measured so far on the double-sided polished 725 µm thick 200 mm high resistivity float zone wafers were: (a) the thermally generated bulk leakage current was typically 500 pA per cm?, resulting in a noise contribution of less than one electron (rms) at – 60°C for a typical focal plane configuration. The operation voltage at full depletion was below 300 V reverse bias, in none of the 200 diodes measured a breakdown occurred. The surface and interface properties were excellent. The surface generated leakage current was below 400 pA per cm? at room temperature and the flat band voltage shift below 0.5 V giving hope for a very low 1/f noise contribution. The isolating gate oxides were sustaining a voltage of more than 100 V before breakdown - much more than needed. The smaller feature sizes in the chosen HV 0.35 µm CMOS process allows for pixel sizes of 20 x 20 µm? which is close to the diffusion limit for electrons in the 725 µm thick substrate. First measurements with DePFET devices will be shown from the fabrication ending early 2016.

A new fast gating and analog storage mechanism will be introduced enabling a fast switching between on and off state, (i.e. sensitive and insensitive state, gating) on the nanosecond scale. Proposals for potential focal plane configurations will be shown and their expected performance will be derived from the measured properties. We will present a concept for a device having a pixel size of 35 x 35 µm and a format of 2k x 2k pixels. It will exhibit a position resolution of better than 2 µm from 300 eV up to 20 keV resulting in 40k x 40k resolution points, still maintaining the good spectroscopic properties. A different design with 100 x 100 µm large pixels (ATHENA type), gatable with an analog storage capability will be shown as well. Being back-illuminated, the device exhibits high quantum efficiency from 100 eV up to 25 keV. A summary of the resulting new opportunities of this approach will be given.

9905-16, Session 4

Development of a Si/CdTe stacked detector system

Daniel Maier, CEA-Ctr. de SACLAY (France) and AstroParticule et Cosmologie (France); Chris Tenzer, Thomas Schanz, Eberhard Karls Univ. Tübingen (Germany); Olivier Limousin, CEA-Ctr. de SACLAY (France); Aline Meuris, Commissariat à l'Énergie Atomique (France)

At the IAAT, we have built a stacked detector system consisting of a 64x64 DePFET-Matrix in front of a CdTe-Caliste module that can be operated under laboratory conditions that approximate the expected environment in space. The detectors were developed at the Max-Planck Institute Semiconductor Laboratory (HLL) in Neuperlach and the Commissariat à l'Energie Atomique (CEA) in Saclay, respectively.

The DePFET detector is made of a Si-based active pixel matrix that provides high count-rate capabilities with a near Fano-limited energy resolution up to 15 keV. The CdTe-Caliste module consists of a 1mm thick CdTe crystal with integrated readout electronics and builds a high performance spectro-imager with event time-tagging capability in the range between 2 keV and 250 keV.

In this combined structure the DePFET detector works as Low Energy Detector (LED) while the Caliste module - as High Energy Detector (HED) - detects predominantly the high energetic photons that have passed the LED.

Besides the high energy resolution over a large energy range, the setup can be used as a Compton camera and as an X-ray polarimeter. We present results of the performance achieved so far for these two applications. In addition, we studied side-effects like fluorescence emission or Compton scattering betweeen the two detector units that can easily be identified and analyzed.

9905-17, Session 4

Novel design for medical imaging Compton camera based on pixel Si/CdTe sensor *(Invited Paper)*

Mokhtar Chmeissani, M. Kolstein, Univ. Autònoma de Barcelona (Spain)

The idea for the development of a Compton camera started in the 70s for use in astrophysics and soon after the idea was extended to the field of nuclear medicine. While the idea of the Compton camera is ingenious,

its construction is not straightforward. There are serious difficulties in constructing a fully operational camera that meets hospital standards and competes with Anger Camera. The two main problems are: an accurate reconstructions of the Compton cone, and subsequent image reconstruction. For the first problem, the Compton cone, one needs a detectors that is highly segmented, and with high energy resolution for both the scatterer and the absorber detectors. The 2nd problem is the image reconstruction from a set of Compton cones. Even with an ideal detector the image reconstruction still poses a serious limitation on the image resolution. The solution for the first problem is to use room temperature semiconductor detectors that can be high segmented into small pixels and at the same time have excellent energy resolution. Many groups have developed Compton camera prototypes based on pixel semiconductor detectors. However for such prototypes the Field Of View (FOV) is limited by the design and this poses a serious problem if one wants to increase the FOV to the nominal size of 54cm x 38 cm. The problem with image reconstruction can be minimized by using two cameras at 90 degrees.

The Voxel Imaging PET pathfinder project, has developed module detector, see image below, which is based on a stack of pixel CdTe detectors bonded to a dedicated ASIC. The module is made of a stack of 10 thin PCB layers, each with 4 detectors that constitute 4 x 100 voxel channels where each read-out voxel has a size of 1mm x 1mm x 2mm. Such a detector will provide precise and true 3D depth of interaction and high energy resolution which are fundamental parameters for defining the Compton cone. The module detector is being developed to be evaluated for use in a PET application and later for a Compton camera.

With such a module pointing to the object, under study, one can build a large FOV detector by stacking many of such modules together (next to each other and/or on top of each other). GAMOS simulations have shown that using a point source of 18F with such a camera one can achieve a sensitivity of 4.5 cps/kBq and a X,Y, and Z FWHM spatial resolution < 4mm.

9905-18, Session 4

Development of a portable Si/CdTe Compton camera for applications in diverse fields

Shin'ichiro Takeda, Okinawa Institute of Science and Technology Graduate Univ. (Japan); Atsushi Harayama, Yuto Ichinohe, Institute of Space and Astronautical Science (Japan) and Japan Aerospace Exploration Agency (Japan); Hirokazu Odaka, Kavli Institute for Particle Astrophysics & Cosmology (United States); Shin Watanabe, Tadayuki Takahashi, Institute of Space and Astronautical Science (Japan) and Japan Aerospace Exploration Agency (Japan); Hiroyasu Tajima, Nagoya Univ. (Japan); Kei Genba, Daisuke Matsuura, Munehiro Komeda, Yoshikatsu Kuroda, Mitsubishi Heavy Industries Ltd. (Japan)

The Si/CdTe semiconductor Compton camera is a gamma-ray imager covering the band from a few tens keV to MeV. The camera was originally proposed to realize high-sensitivity observation to shed light on the sensitivity gap remaining in sub-MeV band in high-energy astrophysics. The Soft Gamma-ray Detector (SGD) onboard ASTRO-H is the one that was produced by our group based on the latest achievement represented by high-energy resolution Si and CdTe imaging sensors, low-noise multi-channel analog ASICs and highly-packed assembling techniques. The detail description of the SGD is reported in Watanabe et al. (NIM.A 2014) and Ichinohe et al. (NIM.A 2015).

The design concept of the Si/CdTe semiconductor Compton camera is reflected in its structure of highly-packed accumulation of high-energy and high-position resolution Si and CdTe imaging sensors. Remarkable efficiency can be obtained with compact detection system, for example, Si and CdTe sensors with a total active volume of 40 cm^{3} and 39.3 cm^{3} are installed in roughly 10 cm x 10 cm x 10 cm region of the SGD. In addition, since the effect of Doppler broadening is smaller in the Si devices than in other semiconductor devices, the camera allows the difference between the measured and actual scattering angles to be constrained, meaning that higher angular resolution is expected. Actually, good angular resolution of 2.5 degree (FWMH) at 511 keV was measured in our preceding research (Takeda et al. SPIE 2007).

ASTROCAM is the first commercial Compton camera based on design and manufacturing resources of the SGD. Through field tests in Fukushima, we demonstrated that the camera is capable of hot spot detection and the evaluation of radioactive decontamination (Takeda et al. NIM.A 2015). The standard model of the camera consists of 8 layers of Si detectors and 4 layers of CdTe detectors. It is possible to integrate more detectors, up to 32 layers of Si and 8 layers of CdTe detectors. In addition, all four horizontal directions of the accumulated detectors are covered by 2 layers of CdTe modules. In this enhanced model, the efficiency is improved to 2.8 cps/MBq at 1 m (137-Cs, 662 keV), which is about 16 times higher than that of the standard model. The energy resolution of the camera is measured to be 2.2% (FWHM) for 662 keV gamma-rays. A moderate angular resolution of 5.4 degree (FWHM) in ARM (Angular Resolution Measure) is obtained, meaning that it has about 1 m spatial resolution at 10 m from the camera. The basic specifications of ASTROCAM are summarized in the technical review (http://www.mhi-global.com/company/technology/review/pdf/e511/e511068.pdf).

Higher angular resolution of the Si/CdTe semiconductor Compton camera than ever Compton cameras might open up new possibilities in medical imaging. The resolving power better than 3 mm was experimentally demonstrated for a 364 keV (131-I) gamma-ray with the first medical prototype camera (Takeda et al. IEEE 2009). More practical imaging with a mouse was performed and iodinated (131-I) methylnorcholestenol and 85-SrCl_{2} solution injected into the mouse are successfully visualized (Takeda et al. IEEE 2012). Now we are developing a new device for tracking of a recoiled electron by Compton scattering in order to perfectly solve Compton kinematics and change the cone-shaped probability distribution of a incident gamma-ray into single direction.

9905-19, Session 4

Fast event recognition for x-ray silicon imagers

David N. Burrows, The Pennsylvania State Univ. (United States)

New generations of X-ray observatories are being planned with collecting areas more than an order of magnitude larger than current observatories, with silicon imagers featuring high speed readout to prevent photon pileup. These detectors require rapid event processing to discriminate between X-ray events and particle background. We will discuss the design and status of a fast readout event recognition board based on a Virtex 5 FPGA we are developing with funding from NASA's Strategic Astrophysics Technology program.

9905-20, Session 4

Development of wide-field low-energy x-ray imaging detectors for HiZ-GUNDAM mission

Kazuki Yoshida, Daisuke Yonetoku, Tatsuya Sawano, Yasuaki Kagawa, Masao Ina, Kanazawa Univ. (Japan); Hirokazu Ikeda, Atsushi Harayama, Institute of Space and Astronautical Science (Japan); Makoto Arimoto, Tokyo

Institute of Technology (Japan); Satoshi Hatori, Kyo Kume, Takashi Hasegawa, Satoshi Mizushima, The Wakasa Wan Energy Research Ctr. (Japan)

We are planning a future gamma-ray burst (GRB) mission HiZ-GUNDAM to probe "the end of dark ages and the dawn of formation of astronomical objects", i.e. the physical condition of early universe beyond the redshift of z > 7. Especially we will focus on the history of first and second generation star formation activity, cosmic reionization and chemical evolution of heavy elements. We are now developing a wide field low energy X-ray imaging detectors to observe high redshift GRBs, which cover the energy range of 1 < E < 20 keV. We can obtain the X-ray images with orthogonally placed two sets of 1-dimensional coded aperture mask systems. We use silicon strip detectors (SSDs) as X-ray imaging sensor. One of the key technologies for X-ray imaging detector is multi-channel readout methods. We developed readout analog ASICs, named ALEX (ASIC for Low Energy X-ray), are specifically designed to read out small charge signals from SSDs with high gain at pre-amplifiers. ALEX can simultaneously read out 64 signal channels. It is important to understand characteristics of individual channel in order to adjust their performance to be uniform. We investigated baseline voltages, gains, and noise levels for all readout channels. Applying several adjustments with internal digital-to-analog converters, we succeeded in making the baseline voltage uniform within the standard deviation of 34 eV. We performed several radiation tolerance test for ALEX with proton and ion beams at Wakasa-wan Energy Research Center and strong gamma-ray sources at Tokyo Institute of Technology in Japan. We confirmed that ALEX can keep working during 10 years if ALEX are exposed to protons in the low earth orbit. Now we are developing a prototype model of X-ray imaging detectors with the detector area of 50 cm2, 1,024 strips, and 16 readout ALEX chips as well as dedicated digital electronics. SSD and ALEX are directly connected with short bonding wires to minimize the noise level. We achieved the detection threshold is 1.5 keV and the energy resolution of 1 keV. We also performed X-ray imaging experiments with six meter beamline in our laboratory, and confirmed the localization accuracy is 5.7 arcminutes. In this presentation, we report overview of small prototype model system of wide field X-ray imaging detector onboard HiZ-GUNDAM, and show performances of ALEX series.

9905-136, Session PS1

Correcting for distortions due to walk and geometric distortion in the COS FUV detector

David J. Sahnow, Thomas B. Ake, Justin Ely, Sean A. Lockwood, Cristina M. Oliveira, Steven V. Penton, Rachel Plesha, Charles Proffitt, Julia Roman-Duval, Paule Sonnentrucker, Space Telescope Science Institute (United States)

The Far Ultraviolet detector of the Cosmic Origin Spectrograph (COS) on the Hubble Space Telescope (HST) is subject to distortions on a range of spatial scales in its two-dimensional format due to its analog nature. Incomplete correction of these effects can lead to errors in wavelength scales and flux measurements in the calibrated spectra. Two of the largest sources of error are geometric distortion and walk. Although they are accounted for separately in the CalCOS calibration pipeline, they are highly coupled and can be considered as manifestations of the same effect.

The current calibration pipeline does not apply any walk correction in the dispersion direction even though walk-induced errors can be more than a resolution element in some cases. The current geometric correction, which was derived without considering walk effects, is also known to have inaccuracies. As part of our efforts to improve the wavelength calibration of COS, we have revisited the existing walk and geometric correction using both prelaunch and on-orbit data. We present the results of these studies, our plans for changes to CalCOS and its reference files, and the expected improvements to the final data products.

9905-137, Session PS1

In-flight performance of the polarization modulator in the CLASP rocket experiment

Shin-nosuke Ishikawa, Toshifumi Shimizu, Institute of Space and Astronautical Science (Japan) and Japan Aerospace Exploration Agency (Japan); Ryohei Kano, Takamasa Bando, Ryoko Ishikawa, Gabriel Giono, National Astronomical Observatory of Japan (Japan); Dyana L. Beabout, Brent L. Beabout, NASA Marshall Space Flight Ctr. (United States); Satoshi Nakayama, Takao Tajima, Mitsubishi Precision Co., Ltd. (Japan)

We developed a polarization modulation unit (PMU), a motor system to rotate a waveplate continuously. In polarization measurements, the continuous rotating waveplate is an important element as well as a polarization analyzer to record the incident polarization in a time series of camera exposures. High rotation uniformity for the motor is required to reduce errors in a polarization measurement. To achieve this in the next Japanese solar observation satellite SOLAR-C, the control logic of PMU was originally developed by the SOLAR-C working group. We applied this PMU for the Chromospheric Lyman-alpha SpectroPolarimeter (CLASP). CLASP is a sounding rocket experiment to observe the linear polarization of the Lyman-alpha emission (121.6 nm vacuum ultraviolet) from the upper chromosphere and transition region of the Sun with a high polarization sensitivity of 0.1% for the first time, and then to estimate their vector magnetic field by the Hanle effect. The waveplate motor (PMU-ROT) and its driver (PMU-DRV) were developed to optimize the rotation for the CLASP waveplate (12.5 rotations per minute). Rotation non-uniformity of the waveplate causes error in the polarization degree (i.e. scale error) and crosstalk between Stokes components. We confirmed that PMU has superior rotation uniformity in the ground test. In that test, we constructed the polarization measurement system similar to the CLASP instrument with a waveplate on PMU and a polarization analyzer. By obtaining a polarization modulation curve with the system and comparing to the ideal curve, we confirmed that the scale error and crosstalk of Stokes Q and U are less than 0.01 %. PMU-DRV has a function to send exposure triggers to the CCD cameras, which were developed by NASA, for synchronizing their exposures to the waveplate angle. PMU-DRV also sends the angle error signal for the telemetry, and we can check the performance by the signal. After PMU was attached to the CLASP instrument, we performed two vibration tests: once in Japan before the shipment to U.S. and the other at the launch site in U.S. We confirmed all PMU functions performance including rotation uniformity did not change after either vibration test by the angle error signal. CLASP was successfully launched on September 3, 2015, and PMU functioned well as designed. According to the PMU flight status (e.g. angle error), PMU achieved a good rotation uniformity during all of the observation period similar to the ground tests, and the high precision polarization measurement of CLASP was successfully achieved. In this presentation, we report the overview of PMU, and performance n!ot only from the ground tests but also from the flight.

9905-138, Session PS1

The re-flight of the Colorado high-resolution Echelle stellar spectrograph (CHESS): improvements, calibrations, and post-flight results

Keri Hoadley, Kevin C. France, Brian T. Fleming, Robert Kane, Nicholas Nell, Jack Swanson, Nicholas Kruczek, James C. Green, Jacob Wilson, Nicholas Erickson, Univ. of Colorado Boulder (United States)

In this proceeding, we describe the scientific motivation and technical development of the rocket-borne Colorado High-resolution Echelle Stellar Spectrograph (CHESS), focusing on the hardware advancements and testing supporting the second flight of the payload (CHESS-2). CHESS is a far ultraviolet (FUV) rocket-born instrument designed to study the atomic-to-molecular transitions within translucent cloud regions in the interstellar medium (ISM). CHESS is an objective echelle spectrograph with f/12.4 and resolving power of > 100,000 over the band pass 102 – 170 nm. The spectrograph was designed to employ an echelle grating with a groove density of 69 lines/mm. The fabrication of this grating has been an ongoing research and development (R&D) program comparing several lithographic and electron-beam etching techniques. We compare the performance of R&D echelle etching processes with mechanically-ruled echelle gratings in the FUV. Given the poor performance of the lithographic and electron-beam etched optics, CHESS-2 will utilize a mechanically-ruled, lower groove echelle density (52.9 grooves/mm – observed orders in CHESS-2: 340 – 210) fabricated at Bach Research Inc. The cross-dispersing grating, developed and ruled by Horiba Jobin-Yvon and launched on CHESS-1, is a holographically-ruled, low line density (351 grooves/mm), powered optic with a toroidal surface curvature. Both gratings were coated with Cr+Al+LiF at Goddard Space Flight Center (GSFC). We measure the reflectivity and efficiency of both the flight gratings across the 90 – 165 nm bandpass at the University of Colorado. Results from final efficiency and reflectivity measurements for the optical components of CHESS-2 will be presented, with comparison to optical performance from CHESS-1. Additionally, CHESS-2 will be the second launch of the 40mm diameter cross-strip anode readout microchannel plate (MCP) detector fabricated by Sensor Sciences to achieve high resolution over a large format (16kx16k format, 25 micron spectral resolution with 2.5 um digital pixels) with photon-counting performance at high count rates (global rates ~ 1 MHz). We will present pre-flight sensitivity and effective area calculations, as well as laboratory spectra and instrument calibration results. The launch of CHESS-2 is scheduled for February 2016 aboard NASA/CU sounding rocket mission 36.297 UG. We will observe the sightline to the hot star ? Per to diagnose the column densities, temperature, and kinematics of atomic and molecular species in the ISM.

9905-139, Session PS1

The SwRI ultraviolet reflectance chamber (SwURC): status report on a far ultraviolet reflectometer

Yang Liu, Southwest Research Institute (United States)

The Southwest Research Institute Ultraviolet Reflectance Chamber (SwURC) is a state of the art UV reflectometer chamber and data acquisition system that can measure the bidirectional reflectance from 115 to 180 nm over various reflectance angles in the principal plane. UV reflectance spectroscopy is a very important tool for studying airless planetary surfaces. However, few laboratory measurements of the far-UV spectral signatures of common minerals and ices exist, and of the measurements that do exist most were only conducted at one reflection angle with poor wavelength sampling. This lack of laboratory measurements of materials has limited the precise interpretation of remote sensed UV data from the Moon, asteroids, comets, etc. The SwURC provides laboratory-based UV reflectance measurements of water frost/ice, lunar soils, simulants, and analogs in support of interpretation of UV reflectance data from current UV space instruments, including Lunar Reconnaissance Orbiter (LRO) Lyman Alpha Mapping Project (LAMP), and New Horizons and Rosetta Alice imaging spectrographs. We report the recent radiometric calibration results from measuring the specular reflection of Al/MgF2 coated mirrors and the diffuse reflectance of Fluorilon as well as UV spectral reflectance measurements planned and in progress for water ice, lunar simulants, and Apollo soil sample 10084.

9905-140, Session PS1

Alignment and calibration of the ICON-FUV instrument: development of a vacuum UV facility

Jérôme J. D. Loicq, Pascal Blain, Christian Kintziger, Univ. de Liège (Belgium); Richard Desselle, Univ. de Liege (Belgium); Yvan G. Stockman, Isabelle Domken, Etienne Renotte, Lionel Clermont, Univ. de Liège (Belgium); Kodi Rider, Cathy Chou, Claire L. Poppett, Univ. of California, Berkeley (United States); Harald U. Frey, Space Sciences Lab. (United States); Stephen B. Mende, Univ. of California, Berkeley (United States)

In the frame of the ICON mission, CSL has developed a vacuum UV facility to align and characterize the FUV instrument. This FUV instrument is based upon the IMAGE Spectrographic Imager (SI) [Mende et al., 2000c]. Like its predecessor, ICON-FUV, is a two-channel imager that uses a grating spectrometer for spectral discrimination. The two channels are required to provide the daytime profiles of two wavelengths characterizing the N2 and O species. This grating type of spectrographic imager minimizes contamination by out-of-band light leaks that are a typical problem for non-grating type FUV cameras.

The facility developed at CSL is working under vacuum UV from 100 nm to visible light. It provides a large collimated UV beam covering the entire entrance slit of the instrument. The instrument is placed on a large tip/tilt and rotation stages. This MGSE provides the ability to rotate the instrument around the entrance pupil and covers more than the entire FOV of the instrument [24° vertical, 18° horizontal].

This paper will present the complete calibration setup and related optical simulations, the results of the alignment campaign first and the calibration next. The calibration facility is based on the combination of a double sources (Deuterium, and white laser) connected to a vacuum Mc Pherson monochromator. The light going out of the exit slit of the monochromator illuminates a pin-hole and a MgF2 diffuser to create an extended source for the collimator. The collimator is based on an off-axis parabola which produces approximately a 10 cm diameter collimated beam. Another important feature is a switchable beam divergence. This is made possible by using a wheel with different sized pinholes and a position-controllable off axis-parabola thanks to a motorized translation stage. Therefore, one or more pixels of the instrument cameras can be enlightened. The possibility to have several illuminated pixels speeds up, facilitates and improves the centroidization process.

The control of the line of sight during the thermal cycle qualification campaign is enabled by an auto-collimation process with the help of a mirror cube and CMOS camera in the visible domain. This one is using reflection by a reference cube placed on the instrument turret structure (scanning mirror). The light reflected by the reference cube returns back into the collimator and is focused into the camera.

Specific strategies have also been developed to align the instrument under vacuum to meet spectral properties and imagery requirement. Three of the instrument mirrors were actuated to align the instrument under vacuum. Simulation and alignment achievements will be presented.

9905-141, Session PS1

The qualification campaign of the EUI instrument of solar orbiter

Jean-Philippe A. Halain, Pierre Rochus, Etienne Renotte, Aline Hermans, Lionel Jacques, Alexandra Mazzoli, Univ. de Liège (Belgium); Frédéric Auchère, Institut d'Astrophysique Spatiale (France); David Berghmans, Royal Observatory of Belgium (Belgium); Louise Harra, Mullard Space Science Lab. (United Kingdom); Werner Schmutz, Physikalisch-Meteorologisches Observatorium Davos (Switzerland); Udo Schühle, Regina Aznar Cuadrado, Max-Planck-Institut für Sonnensystemforschung (Germany); Cydalise Dumesnil, Institut d'Astrophysique Spatiale (France); Manfred Gyo, Physikalisch-Meteorologisches Observatorium Davos (Switzerland); Thomas Kennedy, Mullard Space Science Lab. (United Kingdom); Francis Verbeeck, Royal Observatory of Belgium (Belgium); Philip Smith, Mullard Space Science Lab. (United Kingdom)

The Extreme Ultraviolet Imager (EUI) instrument is one of the ten scientific instruments on-board the Solar Orbiter mission to be launch in October 2018. It will provide full-sun and high-resolution images of the solar corona in the extreme ultraviolet (17.1 nm and 30.4 nm) and in the vacuum ultraviolet (121.6 nm).

The validation of the EUI instrument design has been completed with the Assembly, Integration and Test (AIT) of the instrument two-units Qualification Model (QM). Optical, electrical, electro-magnetic compatibility, thermal and mechanical environmental verifications were conducted and are here summarized. The integration and test procedures for the Flight Model (FM) instrument and sub-systems were also verified.

Following the Qualification Review, the flight instrument activities were started with the assembly of the flight units. The mechanical and thermal acceptance tests and an end-to-end final calibration in the (E)UV will then be conducted before delivery for integration on the Solar Orbiter Spacecraft by end of 2016.

9905-142, Session PS1

Full-Stokes polychromatic polarimeter design for Arago

Martin Pertenais, Coralie Neiner, Observatoire de Paris (France); Pascal Petit, Institut de Recherche en Astrophysique et Planétologie (France)

The UVMag consortium will propose the Arago space mission to the ESA call Cosmic Vision M5. This mission aims at characterizing all kind of stars and their environment simultaneously, to better understand the cycle of matter in our galaxy. It carries a single instrument, a spectropolarimeter, acquiring data from 119 nm to 888 nm and enabling the determination of the magnetic field of the stars thanks to the Zeeman effect. One of the key instrumental point of this project is the development of an efficient polarimeter over the large spectral range and in space. We chose to use a polychromatic temporal modulation to achieve a measurement of all four Stokes parameters: I the intensity, Q and U the linear polarization states, and V the circular polarization. The modulator is composed by several birefringent Magnesium Fluoride plates, optimized to achromatize the extraction efficiency of the Stokes parameters from FUV to NIR. This polarization modulator is followed by a polarization beam-splitter to analyze the state of the light. After the polarization analysis, the light goes through a high-resolution spectrograph.

The theoretical optimization and design of the polarimeter and of the whole instrument will be presented, as well as the first laboratory results on this concept.

9905-143, Session PS1

UVESP: ultraviolet visible Echelle spectropolarimeter for stellar astrophysics

Maxim Yushkin, Vladimir E. Panchuk, Special Astrophysical Observatory (Russian Federation); Gracia Belén Perea Abarca, Pablo Marcos-Arenal, Univ. Complutense de Madrid (Spain); Mikhail Sachkov, Institute of Astronomy (Russian Federation); Ana Inés Gómez de Castro, Univ. Complutense de Madrid (Spain)

In this contribution, we describe the optical design of UVESP, an efficient instrument designed for mid resolution (30,000) spectropolarimetric observations in the 119-888nm wavelength range. Spectropolarimetry introduces challenging constraints in the image quality of the echellé design that are addressed via the introduction special optical elements.

In the current design, the spectrograph is fed by the radiation of an F10 telescope that goes through an on-focus polarizer used to analyse the incident beam. The design has been optimized for the parameters of the ARAGO mission; the polarizer splits the incoming beam into two states of polarization that extend over 400 microns at the entrance of the spectrograph; ideally the spectrograph magnification must be >0.5 to guarantee a good separation between the two polarized states.

At the entrance of the instrument, a beam splitter divides the beam into the ultraviolet (UV) and the visible (VIS) channels with target wavelengths 355 nm to 888 nm for the VIS channel and 119 to 320 nm for the UV channel.

In the VIS channel the beam continues to the slit and then a collimator is placed in order to illuminate a prism with a collimated beam. After the prism an Echellé-grating is allocated. The beam has a double pass by the prism. The cross-dispersion is made with a concave diffraction grating. After the grating, objective lenses are allocated.

In the UV channel the beam continues from the slit to a collimator mirror. After, an Echelle-grating and a cross- dispersion grating are allocated.

This design is significantly optimized with respect to previous similar instruments, such as the spectrograph proposed for the UVMag mission, and it is the current baseline spectropolarimeter for the ARAGO mission.

9905-144, Session PS1

Simulations of the WUVS instrument

Pablo Marcos-Arenal, Ana Inés Gómez de Castro, Gracia Belén Perea Abarca, Univ. Complutense de Madrid (Spain); Mikhail Sachkov, Institute of Astronomy (Russian Federation)

The World Space Observatory - Ultraviolet (WSO-UV) is an international space telescope to observe in the ultraviolet (UV) range. The WSO-UV spacecraft is equipped with the instrument WUVS (WSO UltraViolet Spectrograph) that provides high resolution spectroscopy (R~55,000) in two channels: VUVES and UVES. VUVES is a far UV echelle spectrograph designed to observe point sources in the range 1020-1800 Å. UVES is the near UV echelle spectrograph, working in the range 1740-3100 Å.

The performance of these instruments can be evaluated through simulations of the expected observation.

WUVS instruments are high-precision spectrographs whose expected performance must be evaluated carefully from an appropriate overall instrument model. Since it is not feasible to build and test a prototype of a space-based instrument, numerical simulations performed by an end-to-end simulator are used to model the noise level expected to be present in the observations. The performance of the instrument can be evaluated in terms of noise source response, data quality, and fine-tuning of the instrument design for different types of configurations and observing

strategies. The simulator should also allow for testing the feasibility of the scientific programs and as a preparatory step for the scientific data processing. The WUVS simulator tool has been developed for the validation of the expected instrumental response..

In this work, we describe the implementation details of this tool and the noise models applied in the WUVS Simulator. The WUVS Simulator has been implemented as a further development of the PLATO Simulator, adapting it to an echelle spectrograph and the WUVS instrument specific characteristics.

The PLATO Simulator is an end-to-end simulation software tool designed for the performance of realistic simulations of the expected observations of the PLATO mission but easily adaptable to similar astronomical missions incorporating CCD detectors. The PLATO Simulator is an open source code developed by the Institute for Astronomy at KU Leuven. The original code required several modifications to be used for VUVES and UVES that are thoroughly described in this article.

The WUVS simulator is designed to generate synthetic time series of CCD images by including models of the CCD and its electronics, the telescope optics, the jitter movements of the spacecraft and all important natural noise sources.

We provide a detailed description of several noise sources and discuss their properties, in connection with the optical design, the quantum efficiency of the detectors, etc. The expected overall noise budget of the output spectra is evaluated as a function of different sets of input parameters describing the instrument properties.

9905-145, Session PS1

Fireball multi object spectrograph: as-built optic performances

Robert Grange, Bruno Milliard, Gerard R. Lemaitre, Samuel Quiret, Sandrine Pascal, Alain Origné, Lab. d'Astrophysique de Marseille (France); Erika T. Hamden, California Institute of Technology (United States); David Schiminovich, Columbia Univ. (United States)

Fireball (Faint Intergalactic Redshifted Emission Balloon) is a NASA/CNES balloon-borne experiment to study the faint diffuse circumgalactic medium from the line emissions in the ultraviolet (200 nm) above 37 km flight altitude. The payload and gondola have been integrated and calibrated for the 2016 flight. Fireball relies on a Multi Object Spectrograph (MOS) that takes full advantage of the new high QE, low noise 13.5 ?m pixels UV EMCCD. The MOS is fed by a 1 meter diameter parabola with an extended field (1000 arcmin2) using a highly aspherized two mirror corrector. All the optical train is working at F/2.5 to maintain a high signal to noise ratio. The spectrograph (R~ 2200 and 1.5 arcsec FWHM) is based on two identical Schmidt systems acting as collimator and camera sharing a 2400 g/mm aspherized reflective Schmidt grating. This grating is manufactured from active optics methods by double replication technique of a metal deformable matrix whose active clear aperture is built-in to a rigid elliptical contour. We will present the as-built optic performances of the Fireball instrument.

9905-146, Session PS1

Ultraviolet cosmic imager to study bright UV sources

Joice Mathew, Ajin Prakash, Mayuresh N. Sarpotdar, Margarita Safonova, Jayant Murthy, Sreejith Aickara Gopinathan, Indian Institute of Astrophysics (India)

We have designed and developed a compact ultraviolet imaging payload to fly on a range of possible platforms such as high altitude balloon experiments, cubesats, space missions, etc. The primary science goals are to study the bright UV sources (mag < 10) and also to look for transients in the Near UV (200- 300 nm) domain. Our first choice is to place this instrument on a spacecraft going to the Moon as part of the Indian entry into Google lunar X-Prize competition. The major constraints for the instrument are, it should be lightweight (< 2 Kg), compact (length < 50 cm) and cost effective. The instrument is an 80 mm diameter Cassegrain telescope with a field of view of around half a degree designated for UV imaging. In this paper we will discuss about the various science cases that can be performed by having observations with the instrument on different platforms. We will also describe the design, development and the current state of implementation of the instrument. This includes opto-mechanical and electrical design of the instrument. We have adopted an all spherical optical design which would make the system less complex to realize and a cost effective solution compared to other telescope configuration. The structural design has been chosen in such a way that it will ensure that the instrument could withstand all the launch load vibrations. An FPGA based electronics board is used for the data acquisition, processing and CCD control. We will also briefly discuss about the hardware implementation of the detector interface and algorithms for the detector readout and data processing.

9905-147, Session PS1

A near ultraviolet solar-blind telescope design using silicon CCD detectors

John W. MacKenty, Space Telescope Science Institute (United States)

We propose a novel approach to constructing a solar-blind near ultraviolet telescope using specialized mirror coating. Each mirror in a three (or four) element optical system has a coating reflective in the 200-300nm bandpass and transmissive at wavelengths longer than 300nm. This telescope can therefore use CCD detectors providing high quantum efficiency, low noise, and a large pixel count. We have procured, from Materion Corporation, sample coatings with greater than 90% reflectance in the 200-300nm bandpass and less than 10% at wavelengths longer than 300nm. With three surfaces, these coatings provide >75% in band transmission for a telescope with better than 10,000 rejection at visible wavelengths. The use of ultraviolet optimized CCD detectors, combined with a three or four element telescope, would enable an Explorer class mission with near ultraviolet survey efficiency more than 100 times that of the recent GALEX mission. We will present measured reflectance and transmission curves from 200 - 1000nm for multiple samples. We will also show simulations of the expected performance of both 3 and 4 mirror systems combined with measured e2v CCD detector performance for a conceptual space mission.

9905-148, Session PS1

Concept study for a compact homodyne astrophysics spectrometer for exoplanets (CHASE)

Sona Hosseini, Christopher R. Webster, Jet Propulsion Lab. (United States); Debra Fischer, Yale Univ. (United States); Evgenya Shkolnik, Arizona State Univ. (United States); Shouleh Nikzad, Gautam Vasisht, Wesley A. Traub, Jet Propulsion Lab. (United States)

Here, we describe the concept study for designing and developing a new compact, high-performance, high spectral resolution ultraviolet (UV) spectrometer for astrophysics science of wide applicability to NASA sounding rockets, International Space Station (ISS) and Astrophysics missions, Discovery and New Frontiers including those of cosmology and

exoplanets employing orbiting spacecraft, deep space missions, NanoSat or SmallSat deployments.

Exoplanet science is now in its full expansion, particularly after the CoRoT and Kepler space missions. However, lack of data and knowledge of temporal variations in the parent star's stellar spectra and abundance of key photochemical species (e.g., O3, H2O, CO, etc.) in exoplanets has confined our detailed understanding to develop precise models of the exoplanet atmospheric chemistry. To address this, we need simultaneous observations at more than one wavelength region especially in near-ultraviolet (NUV) and far-ultraviolet (FUV). But so far the UV observations are done by HST, and nothing is planned after HST retires in 2019.

In this study, we are targeting to build a new instrument to sequentially observe exoplanet atmospheres and their parent's stellar spectra over a significant time in NUV and FUV. The Compact Homodyne Astrophysics Spectrometer for exoplanets (CHASE) offers integrated spectra over a wide field-of-view (FOV~40arcsec) in high spectral resolution (R>105) in a miniaturized architecture using no (or a small < 1m) primary mirror. The architecture of CHASE combines the high étendue of a Fourier Transform Spectrometer (FTS) with higher optomechanical tolerance and simpler optomechanical design associated with grating spectrometers. With an all-reflective optical design, CHASE will target specific spectral features in NUV and FUV of multiple gases of exoplanet atmospheres. CHASE's wide FOV is compatible with the relaxed pointing requirements of current CubeSats and SmallSats which makes it readily qualifiable for space in a compact format and have the potential to enable major scientific breakthroughs.

Various configurations of instruments similar to CHASE have been developed as proof-of-concept laboratory prototype, ground-based instrumentation, and sounding rocket experiments in the Optical, NUV and FUV wavelengths. These studies have demonstrated high R and high sensitivity UV spectrometers can be built in ultra-compact configurations similar to CHASE with no or small aperture telescope for a variety of space science applications.

9905-149, Session PS1

Numerical simulations of space UV spectrographs

Maksim Yushkin, Timur Fatkhillin, Vladimir E. Panchuk, Special Astrophysical Observatory (Russian Federation); Mikhail Sachkov, Institute of Astronomy (Russian Federation)

The aim of our work was modelling of spectrum images of far and near UV spectrographs and Long slit low resolution spectrograph of WSO-UV mission. We pay special attention to angular energy distribution of both difraction gratings, echelle and cross dispertion. A code was realised by using C++ language and nVidiaCUDA technology. The model consists of 3 independent modules: beam trassing module, enegy efficiency estimation module and CCD image simulator. Spectrographs' optical element parameters (surface, distances, grating density, reflectance and refraction coefficients etc.) were used as input parameters. As a result we get spectrum image in FITS format for selected detector. We implemented our model for detector coating masks for WSO-UV spectrographs. The model was verified by comparing observed and simulated spectra of NES spectrograph of the Russian 6-m telescope.

9905-150, Session PS1

WSO-UV ground segment for observation optimization

Mikhail Sachkov, Institute of Astronomy (Russian Federation); Olga Basargina, Yury Kazakevich, NPO Lavochkin (Russian Federation)

The WSO-UV Ground Segment (GS) provides the means and resources to manage and control the mission, to receive and process the data produced by the instruments and to disseminate and archive the generated products.

Furthermore it provides a single interface to the users to allow optimum utilization of the system resources in line with the user needs. GS is comprised by all the infrastructure and facilities involved in the preparation and execution of the WSO-UV mission operations, which typically encompass real-time monitoring and control of the spacecraft, telescope and instruments as well as receiving, processing and storage of the scientific data. There will be two complete GS systems: in Russia and in Spain. The elements of GS are: Ground Station Monitoring and Control System, Mission Operations Center and Science Operations Center.

9905-151, Session PS1

Optical design of WUVS instrument: WSO-UV spectrographs

Vladimir E. Panchuk, Russian Academy of Sciences (Russian Federation) and ITMO Univ. (Russian Federation); Maxim Yushkin, Special Astrophysical Observatory (Russian Federation); Timur Fatkhullin, Special Astrophysical Observatory (Russian Federation); Mikhail Sachkov, Institute of Astronomy (Russian Federation)

The optical design of WSO-UV mission spectrographs (WUVS instrument) is presented. World Space Observatory - Ultraviolet project is an international space observatory for spectroscopy and imaging in 115-310 nm spectral range. The whole spectral range should be observed with the help of two high-resolution echelle spectrographs, for Far-UV (110-180 nm) and Near-UV (178-320 nm) domains accordingly. The third channel is the Long Slit Spectrograph that incorporates both the UV and VUV wavelength range. The main changes with respect to the previous design have been: a) the cross disperser in the UVES spectrograph is now similar to the VUVES spectrograph (based on the cross disperser combined with a UV camera mirror) and b) segmented toroidal gratings are implemented in the LSS design. CCDs were chosen as detectors for all 3 channels. In this optical design basic schemes of the VUVES and UVES spectrographs are quite similar.

Each of the three spectrographs has its own entrance slit, lying in the focal plane of the T-170M telescope on a circle with diameter of 100 mm. The three optical trains are not used for simultaneous observation, but in sequential mode. This is managed by satellite motion.

9905-152, Session PS1

Design of a wide field far-UV spectrometer for a mission to Mars

Edward H. Wishnow, Tim Miller, Matthew Fillingim, Jerry Edelstein, Robert Lillis, Space Sciences Lab. (United States); Eric J. Korpela, Univ. of California, Berkeley (United States); Scott England, William Van Shourt, Space Sciences Lab. (United States); Oswald H. W. Siegmund, Jason McPhate, Univ. of California, Berkeley (United States); Sasha Courtade, Space Sciences Lab. (United States); David W. Curtis, Univ. of California, Berkeley (United States); Justin Deighan, Michael Chaffin, Univ. of Colorado Boulder (United States)

An imaging spectrometer for observations of the Martian corona and the

Martian thermosphere is presented. The corona extends over 10 Martian radii and its measurement requires observations over a very wide field. The spectrometer covers the wavelength region 120-170 nm where this band includes coronal spectral lines of Ly alpha and oxygen, and thermospheric spectral lines from ionized oxygen and carbon and the 4th positive band of CO. Stellar occultation observations will provide atmospheric density measurements. These scientific requirements are fulfilled by an Offner-type spectrometer with a 110 degree instantaneous field of view and no moving mechanisms. Both the spectral and imaging resolution vary across the field, from higher resolution across the planet body, to lower resolution required at the diffuse outer parts of the corona. This Offner-type design has not been previously used in the FUV.

9905-153, Session PS1

Near UV imager with an MCP-based photon counting detector

Ambily Suresh, Joice Mathew, Mayuresh N. Sarpotdar, Sreejith Aickara Gopinathan, Nirmal K., Margarita Safonova, Jayant Murthy, Indian Institute of Astrophysics (India)

Small Scientific payloads below 10 kg can be designed and developed easily and flown on available flight opportunities like high-altitude balloons or CUBESATs. We are developing a compact UV Imager using a light weight optical system and a photon counting detector with off-the-shelf MCPs, CMOS sensor and electronics. The lens system is designed in such a way that it provides an aberration free image over a wide field of view. Micro channel plate (MCP) based detectors are widely used in the ultraviolet region due to their low noise levels, high sensitivity and better spatial and temporal resolution. We are using a Z stack MCP with a compact High Voltage Power Supply and the readout is done using a phosphor screen anode. The scientific goals behind the payload are to observe bright solar system objects and transient detection. In addition the photocathode of the MCP has good spectral response till below 2000 A°, which makes it possible to study some of the extinction features like the 2175 A° bump with suitable designed optics and filters. The detector is designed to be capable of working in direct frame transfer mode as well in photon-counting mode for single photon event detection. The identification and centroiding of each photon event is done using an FPGA (Field-Programmable Gate Array)-based data acquisition and a real-time processing system.

9905-154, Session PS1

Response of a spaceborne lightweighted optical system to various forms of thermal expansion inhomogeneity

Tony B. Hull, The Univ. of New Mexico (United States); Thomas Westerhoff, Guenter Weidmann, Rule Kirchhoff, Antoine Leys, SCHOTT AG (Germany)

Elsewhere we have discussed the role of thermal expansion and thermal diffusion in materials for spaceborne mirrors. In these cases, we assumed an ideal material with perfect homogeneity for example in thermal expansion. Some materials considered for these mirrors exhibit inhomogeneity of thermal characteristics, and this manifests into optical figure errors when exposed to thermal transients and offsets operational temperatures. We will examine the effect on optical figure as several different forms of inhomogeneity of thermal expansion are considered. We will address both slab mirrors and lightweighted mirrors.

9905-155, Session PS1

Spectral calibration of CCDs and multilayer filters intended for future space applications

Eugene A. Vishnyakov, Alexey S. Kirichenko, Anton A. Reva, P.N. Lebedev Physical Institute (Russian Federation); Artem A. Rizvanov, Jurii A. Plastinin, Central Research Institute of Engineering (Russian Federation); Sergei V. Kuzin, P.N. Lebedev Physical Institute (Russian Federation)

We have examined spectral sensitivity of CCD matrices (typically 1024?2048 pixels, 13 ?m pixel size) in a wide wavelength range: from 110 nm to 600 nm. Some of the CCD matrices under study apply to VUV operating range, and some will handle soft X-ray spectral images. The distant goal is to employ the CCD matrices as a part of future telescopes for remote Earth ionosphere observations and for soft X-ray solar missions. Therefore, it is meaningful to understand which spectral sensitivity the CCD detectors have in a wide spectral range.

In the range of 300-600 nm we used a prism monochromator with a halogen lamp as a source of light. We also took an IRD silicon detector with known quantum efficiency as a calibrated detector. The results of calibration have relative error about 5% that is enough to estimate total power of useful or unwanted radiation in the waveband accounted.

In the 250-300 nm UV spectral range we also used a prism monochromator, here employing a deuterium lamp as a source of radiation. We used a photomultiplier tube as a detector to calibrate the CCDs in the current spectral region with reasonable spectral resolution.

All measurements in the waveband 110-250 nm we have conducted inside the IKAR vacuum chamber due to significant absorption of the VUV radiation in the air. The inner dimensions of the vacuum chamber are Ø 0.9 m ? 3.8 m. It is equipped with a turbopump enabling 'dry' evacuation to a residual pressure of ~ 5·10–5 Torr.

We have developed a VUV spectrograph and mounted it on a 0.6 m ? 3.6 m optical table inside the IKAR vacuum chamber. We employed a laser-driven plasma source of VUV radiation emerging under irradiation of a tungsten target by laser pulses (Nd:YAG, 1 J, 8 ns, 1064 nm). A heavy flint lens in the scheme focuses the laser beam onto the target into a focal spot with effective area Seff ~ 10–4 cm2. The peak radiation intensity reaches 10^12 W/cm2. Such laser-plasma radiation source possesses a quasicontinuous spectrum covering wavelengths from 5 nm to the visible spectral range. We have blocked the XUV radiation in the waveband 5-110 nm using a MgF2 spectral filter.

The VUV spectrograph inside the vacuum chamber comprises an entrance slit, a MgF2 spectral filter, a wide-aperture transmission diffraction grating with noticeable supporting structure, and a detector. In the stage of CCD calibration in the waveband 110-250 nm we used an IRD UV photodiode as a reference detector. The electrical output of the photodiode led to an oscillograph outside the vacuum chamber.

Having the CCD calibrated, we have measured the initial spectral effectivity of our tungsten laser-plasma radiation source in the 110-250 nm waveband using the same spectrograph. Then we employed the calibrated spectrograph to measure spectral transmittance functions of several VUV multilayer filters intended for use inside the future telescopes for remote Earth ionosphere observations. Each filter has a multilayer structure deposited on MgF2 glass plate Ø 40 mm.

9905-157, Session PS1

Advanced telescope mirror coatings for ultra violet astronomy: challenges and opportunities

Kunjithapatham Balasubramanian, John J. Hennessy, Shouleh Nikzad, Jet Propulsion Lab. (United States); Nasrat A. Raouf, Jet Propulsion Lab (United States); Manuel A. Quijada, NASA Goddard Space Flight Ctr. (United States)

Advanced space telescopes to study astrophysical phenomena in the far ultraviolet to near infrared require mirror coatings that will gather enough light in the entire spectrum. While coatings for the optical and near IR part of the spectrum are fairly well developed with proven systems, the far ultraviolet presents significant challenges. Typical Aluminum mirrors protected with MgF_2 fall short of the requirements below 120nm. Therefore new and improved coatings are sought to protect aluminum from oxidation that causes severe absorption. Besides choice of materials, the process of applying coatings has to be optimized and controlled accurately and reliably to ensure the coatings preserve the expected optical characteristics. This challenge is addressed here with experimental investigations at JPL and at GSFC. Conventional and atomic layer deposition processes are explored. We present the progress achieved to date and discuss the path forward to achieve high reflectance in the spectral region from 90 to 130nm without degrading performance in the visible and NIR regions, taking into account durability concerns when the mirrors are exposed to normal laboratory conditions.

9905-158, Session PS1

A technique for selectable band imaging in the ultraviolet and optical

James C. Green, Kevin C. France, Univ. of Colorado Boulder (United States)

We present a design concept that provides selectable band imaging in the optical and ultraviolet. The bandpass is created through reconstructive spectroscopy, utilizing crossed gratings, and creates an image, not a spectrum. The bandpass depends upon the field of view, the object location within that field, and the illuminated area of the second grating. All three factors are in principle selectable in real time, so that an instrument utilizing this technique is extremely flexible in its application. The technique utilizes no transmitting optics, and therefore is usable down to the limits of normal incidence reflectivity (~ 400 Å).

9905-159, Session PS1

Optical alignment of the chromospheric Lyman-Alpha spectropolarimeter using sophisticated methods to minimize activities under vacuum

Gabriel Giono, Yukio Katsukawa, Ryoko Ishikawa, Noriyuki Narukage, Ryouhei Kano, Masahito Kubo, National Astronomical Observatory of Japan (Japan); Shin-nosuke Ishikawa, Institute of Space and Astronautical Science (Japan); Takamasa Bando, Hirohisa Hara, Yoshinori Suematsu, National Astronomical Observatory of Japan (Japan); Amy R. Winebarger, Ken Kobayashi, NASA Marshall Space Flight Ctr. (United States); Frédéric Auchère, Institut d'Astrophysique Spatiale (France); Javier Trujillo Bueno, Instituto de Astrofísica de Canarias (Spain)

The Chromospheric Lyman-Alpha Spectro-Polarimeter (CLASP) is an international sounding-rocket project aiming to achieve polarimetry of the Lyman-alpha line (121.6nm) with unprecedented 0.1% polarization accuracy. However, achieving the spatial and spectral resolutions (3.2'' and 0.01nm, respectively) are also crucial to resolve the fine structures of the solar upper-chromosphere and lower transition region, as well as resolving the Lyman-alpha line profile. A careful alignment of the optical elements composing the Cassegrain telescope and the inverse Wadsworth mount spectro-polarimeter was required, but aligning an instrument at Lyman-alpha implies working under vacuum condition since this wavelength is absorbed by air, which makes any experiments difficult. Therefore, an alignment procedure was investigated to minimize the activities under vacuum.

The telescope (270mm aperture diameter and 2614mm focal length) was aligned by measuring its wavefront error in a double-pass configuration with a He-Ne (632.8nm) laser-interferometer. Interference fringes were obtained even though the "cold mirror" coating on the primary mirror reflected only 3.5% of the visible light on each of the two reflections. The secondary mirror tilt and despace were adjusted in order to remove the coma and defocus aberrations at the center of the slit. After the alignment, the wavefront error was measured in "zero-g" condition by performing measurements with different orientations of the telescope to cancel the effect of gravity, and was used to estimate the point spread function at the center of the slit. Additional wavefront error measurements were also conducted across the field of view by adjusting the position of the laser interferometer with a 6-axis table. As a result, a 8.0 microns RMS spot radius was evaluated even at the edge of the slit (requirement: 13.0 microns).

The spectro-polarimeter is composed of a grating that diffracts the incident light from the slit to the +/– first order light in Lyman-alpha, two off-axis parabola mirrors that focuses the diffracted light, and two cameras imaging the Lyman-alpha spectra. The optical alignment aimed to adjust the tilts and rotation of the grating, the tilts of the off-axis mirrors and the CCD camera positions (i.e. focus adjustment). The off-axis mirrors were aligned at first in visible-light using a custom grating (hereafter alignment grating) specially designed with the same diffraction angle in the He-Ne wavelength as that for the flight grating in the Lyman-alpha. The tilt of the off-axis mirrors was adjusted by estimating the misalignment from the shape of the spot images formed by a pinhole array located at the slit position and illuminated by a He-Ne laser. The resulting RMS spot radius at the edge of the slit was estimated around 11.0 microns (requirement: 13.5 microns). The alignment grating was then replaced by the flight grating. The rotation of the grating and the camera focus positions were adjusted at Lyman-alpha by using motorized jigs. The final spatial and spectral resolutions were confirmed to be within the requirements.

CLASP was successfully launched on September 3rd 2015. It has been confirmed that the required image quality was kept during the flight.

9905-160, Session PS1

An optimized Fresnel array for a test space mission in UV

Wilhem Roux, Laurent Koechlin, Institut de Recherche en Astrophysique et Planétologie (France)

The Fresnel Diffractive Imager is an optical concept dedicated to astronomy, developed by Institut de Recherche en Astrophysique et Planétologie (IRAP) in Toulouse, France. A nominal mission aims at an aperture of 6 meters for astrophysics in the Ultra-Violet, yielding an angular resolution of 0.005 arcseconds in the Lyman-? line. The feasibility of apertures up to 30 meters has been studied, yielding arc-millisecond resolutions.

Instead of a classical primary mirror to focus light, we propose a light-weight diffractive optics : the Fresnel array. This project has already proved its performances in terms of resolution and high dynamics in the laboratory, in the visible domain and at longer wavelengths. It has been successfully tested on high contrast astrophysical sources using a ground-based prototype 20cm-aperture.

Today, this project has reached the stage where a probatory mission is needed to validate its operation in space, and thus increase the Technological Readiness Level (TRL). In collaboration with institutes in Spain and Russia, we will propose this mission for the ISS with a UV astronomy program. The last progresses are a new configuration to decrease the diffusion through materials in the instrument, and the optimization of the Fresnel array. We will present that at the conference.

We have worked on improving the Fresnel array to get a better Point Spread Function (PSF) in two different ways.

First, opaque Fresnel zones were maintained with an orthogonal bars mesh, previously spaced in relation with Fresnel zones. We have shown that the PSF becomes better when bars are spaced uniformly.

Second, to further improve their performances, these optics were apodized, increasing the contrast of resulting images. More precisely, to apodize a binary mask (such as a Fresnel array) we modulate the Fresnel zones thickness from center to edge. Previously, Fresnel arrays were apodized circularly but it is more efficient when this apodization is orthogonal. We have developed a new way to apodize them.

These new improvements were tested with numerical simulations of the whole Fresnel Imager. They are leading to the production of a new array, that will be tested during a measurement campaign in order to confirm these results, before proposing it for a mission to the ISS.

9905-161, Session PS1

Development of a flight qualified 100 x 100 mm MCP UV detector using advanced cross strip anodes and associated ASIC electronics

John V. Vallerga, Jason McPhate, Anton Tremsin, Oswald H. W. Siegmund, Space Sciences Lab. (United States); Rick Raffanti, Techne Instruments, Inc. (United States); Andrej Seljak, Harley Cumming, Gary Varner, Univ. of Hawai'i at Manoa (United States)

Photon counting microchannel plate (MCP) imagers have been the detector of choice for most UV astronomical missions over the last three decades (e.g. EUVE, FUSE, COS on Hubble etc.). Using cross strip anodes, improvements in the MCP laboratory readout technology have resulted inbetter spatial resolution (x10), temporal resolution (x 1000) and output event rate (x100), all the while operating at lower gain (x 10) resulting in lower high voltage requirements and longer MCP lifetimes.

A crossed strip anode MCP readout starts with a set of orthogonal conducting strips (e.g. 80 x 80), typically spaced at a 635 micron pitch onto which charge clouds from MCP amplified events land. Each strip has its own charge sensitive amplifier that is sampled continuously by a dedicated analog to digital (ADC) converter (ADC). All of the ADC digital output lines are fed into a field programmable gate array (FGPA) which can detect charge events landing on the strips, measure the peak amplitudes of those charge events and calculate their spatial centroid along with their time of arrival (X,Y,T) and pass this information to a downstream computer.

Laboratory versions of these electronics have demonstrated < 20 microns FWHM spatial resolution, count rates on the order of 2 MHz, and temporal resolution of ~ 1ns. In 2012 our group at U.C. Berkeley, along with our partners at the U. Hawaii, received a NASA Strategic Astrophysics Technology (SAT) grant to raise the TRL of a cross strip detector from 4 to 6 by replacing most of the19" rack mounted, high powered electronics with application specific integrated circuits (ASICs) which will lower the power, mass, and volume requirements of the detector electronics. We were also tasked to design and fabricate a "standard" 50mm square active area MCP detector incorporating these electronics that can be environmentally qualified for flight (temperature, vacuum, vibration).

The first ASICs designed for this program have been successfully fabricated and are undergoing extensive testing. We will present the latest progress on these ASIC designs and their performance and show imaging results from the 50mm XS detector using the new low power and mass ASIC electronics. We will also show our preliminary work on scaling these designs (detector and electronics) to a flight qualified 100 x 100 mm cross strip detector, which has recently been funded through another SAT grant.

9905-162, Session PS1

Ultraviolet detector with CMOS-coupled microchannel plates for future space missions

Go Murakami, Institute of Space and Astronautical Science (Japan); Masaki Kuwabara, Kazuo Yoshioka, Reina Hikida, Fumiharu Suzuki, Ichiro Yoshikawa, The Univ. of Tokyo (Japan)

The extreme ultraviolet (EUV) telescopes and spectrometers have been used as powerful tools in a variety of space applications, especially in planetary science. For example, an EUV telescope onboard Japan's lunar orbiter KAGUYA first took a global meridian image of the Earth's plasmasphere. In addition, the EUV spectrometer EXCEED (Extreme Ultraviolet Spectroscope for Exospheric Dynamics) onboard the Japan's small satellite SPRINT-A was launched in 2013 and it has observed tenuous gases and plasmas around the planets in the solar system (e.g., Mercury, Venus, Mars, Jupiter, and Saturn). These EUV instruments adopted microchannel plate (MCP) detection systems with resistive anode encoders (RAEs). An RAE is one of the position sensitive anodes suitable for space-based applications because of its low power, mass, and volume coupled with very high reliability. However, this detection system with RAE has limitations of resolution (up to 512 x 512 pixels) and incident count rate (up to ~104 count/sec). Concerning the future space and planetary missions, a new detector with different position sensitive system is required in order to a higher resolution and dynamic range of incident photons. One of the solutions of this issue is using a CMOS imaging sensor. The CMOS imaging sensor with high resolution and high radiation tolerance has been widely used. Here we developed a new CMOS-coupled MCP detector for future UV space and planetary missions. It consists of MCPs followed by a phosphor screen, fiber optic plate, and a windowless CMOS. We manufactured a test model of this detector and performed vibration, thermal vacuum, and performance tests. In this paper, we report the concept of this detector and initial results of our tests.

9905-163, Session PS1

Optical and structural characterization of reflective quarter wave plates for EUV range

A. E. H. Gaballah, Piergiorgio Nicolos, Paola Zuppella, Alain Jody Corso, IFN-CNR LUXOR Lab. (Italy)

The knowledge of the state of polarization of the light is one of the requirements in many basic experiments in physics which is being used as a probe in the experiment. In space, polarimetry play an important role to understand the interpretation role of the coronal plasma in the energy transfer processes from the inner parts of the Sun to the outer space. Synchrotron radiation is also highly polarized, giving additional motivation to the search for a polarization analyzer. In analyzing the polarization

properties of those emission sources, the quarter wave retarder (QWR) is one of the basic tools.

In this paper a new effective multilayer design based on a combination of Aluminum with other materials have been studied to obtain a quarter wave retarder, our design approach can be used for any other angle of incidence which can work with a wider spectral range of wavelengths at lines of a particular interest in space application like Lyman series of Hydrogen (121.6 - 91.2 nm) and Oxygen VI (103.2 nm) with high, matched reflectance for both S and P polarization and at the same time a phase difference between these two states of nearly 90 degree with uncertainty ± 2 degree.

Aluminum could be a potential candidate for multilayer quarter wave retarder in the far UV range with high reflectivity because the characteristics of the Al mirror seemed to be favorable. However, aluminum mirrors tend to highly oxidize and form an Al_2O_3 layer which has very high absorption below 170 nm, reducing the reflectance of the aluminum in this region. We are making a good progress to produce and testing a new (QWRs) consisting of Al with 30 nm thickness capped with different materials that Based on preliminary theoretical results TiO_2, MgF_2, Pt and InP with different capping layer thickness ranging from 1 to 5 nm, the various samples will be prepared by the technique of electron beam evaporation and grown on Si (100) substrates, the films are deposited at a substrate temperature of 150°C with a deposition rate of 0.3 - 0.5 A/sec. The thickness of the films are designed such that to obtain a Quarter Wave Retarder working at different FUV wavelengths, and are characterized by profilometry. Selection of the working wavelength and optimization of the phase difference between s and p components is obtained by changing the angle of incidence on the sample. Reflectance measurements of the samples are performed in FUV and EUV spectral regions from 14.5 to 6 eV using synchrotron radiation at the BEAR beamline Elettra, Triest, Italy.

This system is used on the EUV reflectometer facility available in LUXOR-CNR Padova, Italy in order to realize a system to retrieve the complete state of polarization of an electromagnetic wave. The system mounts polarizer, retarder and analyzer based on the previously described design. Full characterization of the system performances will be presented.

9905-164, Session PS1

Design and improvements of the attitude control system (ACS) of the Fireball balloon experiment

Johan Montel, Frederi Mirc, Isabelle Zenone, Ctr. National d'Études Spatiales (France); Etienne Perot, Thales (France)

FIREBALL (the Faint Intergalactic Redshifted Emission Balloon) is a balloon-borne 1m telescope coupled to an ultraviolet fiber-fed spectrograph, designed to study the faint and diffuse emission of the intergalactic medium. The third flight of the experiment is planned in summer 2016. The goal of this paper is to describe the accurate pointing system of the 5-metre high / 1000kg gondola - that has been designed to cope with severe pointing specifications: less than 1'' in elevation and cross elevation, and about 1' around the line of sight axis, for a duration of about 1h. The pointing system is based on a multi stages - 4 DOF- closed loop system, involving an azimuth control of the gondola, a dual axis pivot assembly controlling the 1.2-meter plano siderostat, and a rotation stage that allows to control the field rotation of the instrument. The attitude measurements are given by a 3- axis gyrometer measurement, a large FOV star tracker and an accurate star camera integrated inside the instrument. The manuscript presents the design of the ACS, the limitations related to stability considerations - mainly due to of the pendulum motion and torsion modes of the flight chain-, to the actuators and sensors accuracy, and to the disturbance torques.

9905-165, Session PS1

The effects of dust outbursts on the anomalistic features observed by Rosetta Alice around 67P/Churyumov-Gerasimenko

John Noonan, Eric R. Schindhelm, Joel W. Parker, Andrew Steffl, Michael W. Davis, S. Alan Stern, Southwest Research Institute (United States); Zuni Levin, Sascha Kempf, Mihaly Horanyi, Univ. of Colorado Boulder (United States)

Beginning on August 7th of 2014, just after orbital insertion of the Rosetta spacecraft around comet 67P/Churyumov-Gerasimenko, the UV spectrometer (UVS) Alice on Rosetta began to return images containing a curved feature near the 850Å portion of the detector. This anomalistic feature (AF) was similar in appearance to a scattered light feature that had been seen before with the Lyman Alpha Mapping Project UVS on board the Lunar Reconnaissance Orbiter, as well as on Alice during the Rosetta Mars flyby, and so it initially was considered to be normal scattered light during this appearance in early August. Less than a month later, on August 29th, the feature began to quickly change in shape and intensity, earning it the nickname the ''Chameleon''. By late December 2014, the frequency of the Chameleon in science images rose to nearly 100% at comet separations less than 450 km, with the AF only disappearing in dark calibrations and 80% of stellar calibrations, causing concern among the team that it might be harming the instrument and could create problems with science analysis if it persisted. In an effort to try and determine the cause of the AF two simulations were made to model potential culprits; ions and dust particles. The ion simulations tested protons, OH^+,H_2O^+, H_3O^+, and OH^- using the SIMION program to model the interior of the Alice instrument. The dust simulation modeled the paths of charged dust particles of varying sizes, velocity vectors and charges after passing through the slit using electrostatic equations. The results found by the team indicate that the AF is most likely caused by a combination of ion and charged dust particles in the nanograin size range. The overall effect to the instrument has been in the form of a increased gain sag in the area the Chameleon most often appears in, though some exposures have to be ignored due to the Chameleon's presence and strength, which can overwhelm emission lines below the wavelength of Lyman Alpha.

Analog and mixed-signal front-end ASICs for high-energy detectors in space *(Invited Paper)*

Olivier Gevin, CEA-Ctr. de SACLAY (France)

Analog and mixed-signal front-end ASICs for high-energy detectors in space.

In most of embedded imaging systems for space applications, the increase of granularity and size of focal planes has made the use of integrated circuits almost always mandatory. To fulfill spatial and energy resolution challenging requirements these circuits have to be well suited to the sensor and to the system in terms of noise, geometry and architecture. In addition, to be accepted onboard, these electronics have to exhibit very low power consumption and must be able to survive to radiations in space. Thus, in order to be part of an optimized detection system for space, the integrated circuit has to be specifically designed for each application and becomes an Application Specific Integrated Circuits (ASIC).

The paper will focus on analog and mixed signal ASICs for spectro-imaging systems in the keV-MeV region.

It will begin with a review of the main different kinds of front-end electronic architectures:

The first task of the front-end electronics is to convert the charge coming from de detector into voltage. For most of the Silicon detectors (CCD, DEPFET, DSSD) this is done in the detector itself. For other sensor materials, charge preamplifiers operate the conversion. The paper will shortly describe the different parameters of charge preamplifiers and what drives their design.

To increase the signal to noise ratio or to reduce the duration of the signal, filtering is generally mandatory. The paper will review the main noise sources and the filtering techniques that are mostly used to reduce them.

To be space-qualified, ASICs have to be radiation hardened in terms of single event effect and total ionizing dose. The paper will shortly describe some of the typical hardening techniques.

The final noise performances of the detection systems are most often dominated by the way sensors and ASICs are connected together. The second part of the paper will take the geometry of the detector as a story line to explore different kinds of ASIC structures and architectures. From the simple mono-channel ASIC to readout CCDs to 3D ASIC prototypes to build dead-space free imaging systems, the paper will review different families of circuits for spectro-imaging systems and describe different choices that have been done all around the word for different space missions.

9905-22, Session 6

Developments in time-division, code-division, and microwave-SQUID multiplexed readout of arrays of x-ray and gamma-ray microcalorimeters

Joel Ullom, National Institute of Standards and Technology (United States) and Univ. of Colorado Boulder (United States); Joseph S. Adams, Simon R. Bandler, NASA Goddard Space Flight Ctr. (United States); Douglas A. Bennett, National Institute of Standards and Technology (United States); Gabriele L. Betancourt-Martinez, NASA Goddare Space Flight Ctr. (United States); James A. Smith, NASA Goddard Space Flight Ctr. (United States); Daniel T. Becker, National Institute of Standards and Technology (United States)

Large arrays of cryogenic microcalorimeters are an enabling technology for x-ray and gamma-ray imaging spectrometers. For example, ESA's Athena mission will incorporate an array of ~4,000 transition-edge sensor (TES) microcalorimeters. Microcalorimeters are typically operated at temperatures near 0.1 K so multiplexed readout approaches in which one amplifier chain contains the signals from many sensors are desirable to reduce the thermal and mechanical loads on the focal plane. Successful readout schemes must preserve the exquisite energy sensitivity of cryogenic detectors. Here, we discuss recent progress developing multiplexing readout technology as part of the U.S. contribution to the Athena mission.

We are presently pursuing three multiplexing techniques for x-ray and gamma-ray microcalorimeters. First, we describe recent progress on time-division SQUID multiplexing (TDM) in which the sensor signals from a single column are sampled sequentially. This work includes efforts to increase the analog and digital bandwidth of the readout chain, to reduce cross-talk within the cryogenic SQUID circuitry, and to reduce the input noise of the readout SQUIDs. We have already demonstrated a co-added energy resolution of 2.55 +/- 0.01 eV full-width-at-half-maximum (FWHM) for 6 keV x-rays using TES detectors in a 1-column by 32-row format. Further, we anticipate presenting a new 3-column by 32-row result.

Second, we describe recent progress on code-division SQUID multiplexing (CDM). CDM shares many implementation details with TDM but CDM also eliminates the aliased SQUID noise penalty found in TDM. We anticipate presenting new CDM results in a 1-column by 32-row format. TDM and CDM are backup readout approaches for the Athena mission.

Third, we describe recent progress on microwave SQUID multiplexing (uSQUID). This readout approach provides several GHz of useful bandwidth, a roughly 100-fold increase compared to lower frequency time-, code-, and frequency-division techniques. The increased readout bandwidth provided by uSQUID readout will enable substantially higher multiplexing factors and faster sensors. We have recently completed an end-to-end demonstration of uSQUID readout using four TES gamma-ray detectors and scalable room temperature electronics based on the ROACH2 electronics. We show an average energy resolution of 47 eV FWHM at 97 keV with performance undegraded by the readout circuitry. We also describe recent work to greatly increase the number of sensors per amplifier by using the full bandwidth made available by this readout approach.

In addition to advancing the performance of multiplexing technology, we are presently building a 24-column by 40-row test platform at NIST compatible with TDM and CDM readout. The test platform will enable the characterization of TES arrays being developed at Goddard Space Flight Center for the Athena satellite mission. The test platform will also increase the readiness level of TDM and CDM readout. We will provide a status update on the assembly of this test platform. Finally, we will briefly describe the future potential of TDM, CDM, and uSQUID readout.

9905-23, Session 6

Development of x-ray microcalorimeter imaging spectrometers for the X-ray Surveyor mission concept

Simon R. Bandler, NASA Goddard Space Flight Ctr. (United States) and National Institute of Standards and Technology (United States) and Stanford Univ. (United States); Joseph S. Adams, Manuel A. Balvin, James A. Chervenak, Kevin Denis, Archana Devasia, Megan E. Eckart, NASA Goddard Space Flight Ctr. (United States); Fred M. Finkbeiner, National Institute of Standards and Technology (United States); Richard L. Kelley, Caroline A. Kilbourne, Peter Nagler, Frederick S. Porter, John E. Sadleir, Stephen J. Smith, Thomas R. Stevenson, Edward J. Wassell, Wonsik Yoon, NASA Goddard Space Flight Ctr. (United States); Daniel T. Becker, Douglas A. Bennett, William B. Doriese, Johnathan D. Gard, Gene C. Hilton, National Institute of Standards and Technology (United States); John A. B. Mates, Univ. of Colorado Boulder (United States) and National Institute of Standards and Technology (United States); Carl D. Reintsema, Daniel S. Swetz, Joel N. Ullom, Leila R. Vale, National Institute of Standards and Technology (United States); Kent D. Irwin, Sang-Jun Lee, Stanford Univ. (United States); Alexey A. Vikhlinin, Smithsonian Astrophysical Observaotry (United States)

While requirements for instruments on the X-ray Surveyor are still under study, an initial straw-man design includes an X-ray microcalorimeter instrument with a field-of-view of 5'x5', and pixel sizes corresponding to 1". Thus a nominal array of 300 x 300 pixels (90k pixels) on a 50 ?m pitch is required over an area of 1.5 x 1.5 cm. In general, the best energy resolution possible is desirable, however, it is considered acceptable to sacrifice some energy resolution in order to meet the rather challenging pixel number requirements.

We have developed strawman designs utilizing transition-edge sensors (TES) and magnetically coupled calorimeters (MCC) as the sensors that have the potential to meet these requirements. To reduce the number of sensors read out to a plausible scale, the most promising detector geometries are those in which a thermal sensor such a TES or MCC can read out a sub-array of 20-25 individual 1" pixels. Position discrimination is achieved through the different pulse shapes produced, since each absorber is connected by a different strength thermal connection. This "hydra" geometry is very attractive when the pixel pitch desired is this fine, and thus the combined heat capacity of the entire sub-array is therefore sufficiently small to maintain very high energy resolution. If this scale of "hydra" design is successful, then the number of sensors that are needed to be read out is the same as is currently proposed for the X-ray Integral Field Unit instrument on ESA's Athena mission (~3840). Therefore the multiplexing technologies currently being developed for Athena could be directly transferable to this spectrometer.

Alternative read-out approaches also exist that utilize dissipationless microwave SQUIDs coupled to each sensor in resonator circuits in the GHz frequency range. The resonators are spaced closely in frequency space, in principle allowing hundreds of resonators to be read out with each amplifier chain. This technology has not yet reached the same level of technical maturity. However, if successfully developed, this read-out has the potential for meeting and even exceeding the straw-man read-out requirements with just a handful of signal chains. In this presentation I will review the current state-of-the art for the detector and read-out approaches described.

9905-24, Session 6

The transition-edge EBIT microcalorimeter spectrometer

Gabriele L. Betancourt-Martinez, NASA Goddard Space Flight Ctr. (United States) and Univ. of Maryland, College Park (United States); Joseph S. Adams, Simon R. Bandler, NASA Goddard Space Flight Ctr. (United States); Peter Beiersdorfer, Gregory V. Brown, Lawrence Livermore National Lab. (United States); James A. Chervenak, NASA Goddard Space Flight Ctr. (United States); William B. Doriese, National Institute of Standards and Technology (United States); Megan E. Eckart, NASA Goddard Space Flight Ctr. (United States); Natalie Hell, Lawrence Livermore National Lab. (United States); Kent D. Irwin, Stanford Univ. (United States); Richard L. Kelley, Caroline A. Kilbourne, Maurice A. Leutenegger, Frederick S. Porter, NASA Goddard Space Flight Ctr. (United States); Carl D. Reintsema, National Institute of Standards and Technology (United States); Stephen J. Smith, NASA Goddard Space Flight Ctr. (United States); Joel N. Ullom, National Institute of Standards and Technology (United States)

The Transition-edge EBIT Microcalorimeter Spectrometer (TEMS) is a 1000-pixel array to be delivered to the Electron Beam Ion Trap (EBIT) facility at Lawrence Livermore National Laboratory (LLNL) in 2016. It will be the first fully operational array of its kind. TEMS will utilize the unique capabilities of the EBIT to verify and benchmark atomic theory that is critical for the analysis of data observed from the high resolution microcalorimeter spectrometers aboard the next generation of X-ray observatories such as Athena.

The TEMS detector will achieve 3 eV spectral resolution at 6 keV while being multiplexed, and will be sensitive to 0.05-10 keV. With the current generation of readout electronics, it will be able to read out 256 pixels at once. TEMS will allow count rates of up to several thousand counts per second over the entire array.

The cryogenic platform is complete and operates as expected. We have installed the wiring for all 8 multiplexer columns, along with the magnetic shielding which will shield the detectors and SQUID amplifiers from external magnetic fields and the 4T adiabatic demagnetization refrigerator magnet. The final focal plane array is nearing completion, a new 32x32 test detector array has been installed, and 1x32 and 2x16 channel columns have been demonstrated with average spectral resolution below 3.5 eV at 6 keV.

The EBIT at LLNL enables fundamental laboratory measurements that no other technique can achieve. We present some of the ongoing work with the EBIT facility measured with the EBIT Calorimeter Spectrometer (ECS), which includes benchmarking atomic theory for charge exchange, measuring absolute cross sections of the L-shell transitions for astrophysically abundant elements from Mg to Ni, and studying K-shell emission in He-like Si, S, Ar, Ni, and Fe. We also present recent laboratory spectra from TEMS and progress made in developing the focal plane assembly and cryogenic platform.

9905-25, Session 6

Toward large μ-calorimeters x-ray matrices based on metal-insulator sensors and HEMTs/SiGe cryo-electronics

Jean-Luc Sauvageot, Claude Pigot, Xavier de la Broïse, Thomas Charvolin, Hamza Sahin, Francis Lugiez, Alain Le

Coguie, Commissariat à l'Énergie Atomique (France)

The launch of the X-ray Japanese/US mission early in 2016 with μ-calorimeters based on Metal- Insulator-Sensors (M.I.S) experiment with a 4.5eV spectral résolution, generates renewed interest on these high impedance M.I.S based on Si P:B. Starting from 2009, we are involved in a large program to build a camera consisting of a 2x2 mosaic of 32x32 pixel matrices using this sensor type. Since we rely on very similar approach of ASTRO-H design, we have concentered our efforts on the use of collective all-silicon technologies only. In the last SPIE conferences, we have presented the building block such as thermometers, sensors and cryo-electronics. Now, thanks to our new 32x32 CAD, we are today in the process of building 4 32x32 matrices per wafer. Due to our use of superconducting wiring and composite superconducting Tantalum absorber, this matrix will have a spectral resolution that should be much improved than that of ASTRO-H. Moreover, our development has a ultra low power consumption Cryo-Electronics chain, based on High Electron Mobility Transistors (HEMTs, with an AsGa/AlAsGa hetero-junction) and SiGe ASICs, that handle 34:1 multiplexing tested under cryogenic conditions. The composite Tantalum absorber have been successfully tested in 6keV X-rays, and our M.I.S. exhibit good and homogeneous sensitivity. To be compatible with the 1μW@50mK thermal budget allowed in present day spatial cryo-coolers, we have developed new thermal insulation techniques that will allow us to easily handle more than 4000 independent pixels within this limit.

9905-26, Session 6

MKIDs for x-rays: thermal kinetic inductance detectors (TKIDs)

Gerhard Ulbricht, Benjamin Mazin, Paul Szypryt, Alex B. Walter, Clint Bockstiegel, Univ. of California, Santa Barbara (United States)

We will present our project to develop Thermal Kinetic Inductance Detectors (TKIDs) for the 0.5 to 20 keV band, with a projected energy resolution of 0.1 %. TKIDs are very promising detectors for X-ray imaging spectroscopy as many spectroscopic applications profit tremendously from further improving single pixel energy resolution or detector array size. Many established detector types however have started to reach their physical limits, especially when both high pixel count and high energy resolution are required. Microwave Kinetic Inductance Detectors (MKIDs) are an emerging superconducting detector technology that promises to meet that challenge: They provide an easy, passive way of multiplexing very large detector arrays while still offering high individual pixel energy resolution, single photon counting and no read noise. TKIDs modify the MKID working principle in order to detect high energy photons. In a TKID, the sensitive part of the pixel (the superconducting inductor) and a separate X-ray absorber are suspended on a freestanding membrane. TKIDs operate as microcalorimeters as they measure that membrane's temperature change after absorbing a photon. They have the potential to achieve time and energy resolutions that can compete with transition edge sensors (TESs) while avoiding their multiplexing complexity, promising a feasible way to kilo- or even mega-pixel detector arrays. This unique combination of high pixel number and energy resolution makes TKIDs ideal for X-ray astronomy and many other applications.

We will present our most recent progress with our TKID prototypes and report on fabrication and operating conditions. In 2015, our first working TKIDs showed an energy resolution of 75 eV at 5.9 keV, and we will elaborate on their dynamic range and the achieved progress in time and energy resolution. We will also compare different materials for superconductors and absorbers and explain challenges in pixel design and the data analysis necessary to extract photon energies.

9905-97, Session PS2

The design, implementation, and performance of the ASTRO-H SXS calorimeter array and anti-coincidence detector

Caroline A. Kilbourne, Regis P. Brekosky, James A. Chervenak, Meng P. Chiao, Megan E. Eckart, NASA Goddard Space Flight Ctr. (United States); Enectali Figueroa-Feliciano, Northwestern Univ. (United States); Massimiliano Galeazzi, Univ. of Miami (United States); Christine A. Jhabvala, Richard L. Kelley, Daniel P. Kelly, Maurice A. Leutenegger, NASA Goddard Space Flight Ctr. (United States); Dan McCammon, Univ. of Wisconsin-Madison (United States); Frederick S. Porter, NASA Goddard Space Flight Ctr. (United States); Andrew E. Szymkowiak, Yale Univ. (United States); Tomomi Watanabe, NASA Goddard Space Flight Ctr. (United States); Christopher Grein, Jun Zhao, EPIR Technologies, Inc. (United States)

The calorimeter array of the Astro-H Soft X-ray Spectrometer (SXS) will provide unprecedented spectral resolution of extended cosmic x-ray sources (e.g. supernova remnants and galaxy clusters) and of all cosmic x-ray sources in the Fe-K band (around 6 keV), which will enable essential plasma diagnostics. The SXS has a square array of 36 microcalorimeters at the focal plane. These calorimeters consist of ion-implanted silicon thermistors and HgTe thermalizing x-ray absorbers. These devices have demonstrated a resolution of better than 4.5 eV at 6 keV when operated at a heat-sink temperature of 50 mK. We will discuss the basic physical parameters of this array, including the array layout, thermal conductance of the link to the heat sink, thermistor size, resistance function, absorber details, and means of attaching the absorber to the thermistor bearing element. We will present representative performance data, breaking out the contributions from other systems and from the test environment to estimate the intrinsic detector performance. A synthesized detector model will also be presented and compared to measurements.

We will also present the thermal characterization of the whole array, including thermal conductance and crosstalk measurements and the results of pulsing the frame temperature via alpha particles, heat pulses, and the environmental background.

A silicon ionization detector is located behind the calorimeter array and serves to reject events due to cosmic rays. We will briefly describe this anti-coincidence detector and its performance in conjunction with the array.

Although performance at the component level is the focus of this presentation, with system, instrument, and satellite performance to be discussed in other presentations, some in-orbit data will presented to illustrate effects at the component level.

9905-98, Session PS2

System design and implementation of the detector assembly of the Astro-H soft x-ray spectrometer

Meng P. Chiao, Phillip A. Goodwin, Clair Hobson, Richard L. Kelley, Caroline A. Kilbourne, Daniel McGuinness, Samuel J. Moseley, Frederick S. Porter, Sandy A. Shuman, NASA Goddard Space Flight Ctr. (United States); Tomomi Watanabe, NASA Headquarters (United States) and

NASA Goddard Space Flight Ctr. (United States)

The soft x-ray spectrometer (SXS) onboard Astro-H presents to the science community unprecedented capability (< 7 eV at 6 keV) for high resolution spectral measurements in the range of 0.5 – 12 keV to study extended celestial sources. At the heart of this SXS is the x-ray calorimeter spectrometer (XCS) where detectors (calorimeter array and anti-coincidence detector) operate at 50 mK, the bias circuit operates at nominal 1.2 K, and the first stage amplifiers operate at 130 K, all within a nominal 20 cm envelope. The design of the detector assembly in this XCS originates from Astro-E XRS and lessons learned from Astro-E and Suzaku, some of which was published in 2010 during the development of our engineering model. We have made more changes and improvements based on prototype tests since then in order to improve our flight assembly process for better reliability and overall performance. We will provide in this poster an update, present the final design and implementation of the flight detector assembly, show comparison of parameters and performance to Suzaku's XRS, and list susceptibilities to other subsystems as well as our lessons learned.

9905-99, Session PS2

Cryogen-free operation of the soft x-ray spectrometer instrument

Gary A. Sneiderman, Thomas Bialas, Kevin R. Boyce, Meng P. Chiao, Michael J. DiPirro, Megan E. Eckart, Leslie Hartz, Richard L. Kelley, Caroline A. Kilbourne, Candace Masters, Frederick S. Porter, Peter J. Shirron, NASA Goddard Space Flight Ctr. (United States); Kazuhisa Mitsuda, Institute of Space and Astronautical Science (Japan); Ryuichi Fujimoto, Kanazawa Univ. (Japan); Yoh Takei, Noriko Y. Yamasaki, Institute of Space and Astronautical Science (Japan); Masahiro Tsujimoto, Institute of Space and Astronautical Science (Japan); Yoshitaka Ishisaki, Tokyo Metropolitan Univ. (Japan)

The Soft X-ray Spectrometer (SXS) instrument is the first space-based instrument featuring sub-Kelvin temperature control capability without the need for consumed cryogens. After the LHe supply is exhausted, cryogen-free control can continue or restart SXS operations achieving the same instrument performance. This control mode utilizes all of the SXS active cooling devices in a different arrangement. Control of three Adiabatic Demagnetization Refrigerators (ADR) stages and four active heat switches contributed by NASA, and five cryo-coolers contributed by JAXA, provide this capability. Cryo-coolers include two pairs of double-stage Stirling coolers (Shield Coolers (SC) and JT Pre-coolers (PC)), and one Joule-Thompson (JT) cooler.

The SXS Dewar Main Shell (DMS) structure suspends four interior shields and helium tank where the detectors and ADRs are mounted. The thermal stages and nominal temperatures include: Outer, Middle, and Inner Vapor Cooled Shields (OVCS, 135K; MVCS, 105K; IVCS, 35K); the JT Shield (JTS, 4.5K); helium tank, 1.525 K; and detectors, 50mK. The MVCS is thermally isolated and not controlled, but the OVCS and IVCS are cooled by the two stages of the SC, and the JTS is cooled by the JT cooler which is assisted by the PC coolers. Each cooler is voltage controlled and operates at fixed settings during cryogen-free operation.

The SXS detectors are controlled to 50mK with stability <1.0 ?K RMS for 14.3 hours by the 1st stage ADR. During this time, the 2nd stage ADR stabilizes the empty helium tank at 1.525K while the 3rd stage ADR cycles continuously every ~ 25 minutes to alternately remove heat from the 1.525K stage and transfer it to the JT cooler at ~4.5K. When the 1st stage ADR current runs out, a 2.5 hour recycle of the first two ADR stages, synchronized by the 3rd stage ADR, is performed. This process is run from the ADR Controller (ADRC) using an FPGA based state machine sequencer, repeating indefinitely and automatically.

The ADRC drives a peak of 2.0A through each ADR magnet during its recycle. The period and amplitude of current (heating) varies: the 3rd stage averages ~1A but cycles continuously with a ~25 minute period, the 2nd stage controls the helium tank using ~1A and recycles with the 1st stage which controls the detector temperature using <~0.1A and recycles every 16.8 hours. The heat from the non-superconducting portions of the magnet leads is dumped to the OVCS and IVCS representing their primary time-varying loads; the exception being orbital variation of the DMS and related effects.

Ground cryogen-free tests always began with sub-cooled shields caused by evaporating residual LHe following other tests. The time constant of the shields is about 7 days, producing a changing environment that affects the IVCS and JTS temperatures and the 3rd stage ADR period used to synchronize recycling of the other ADR stages. In lieu of very long tests, shorter tests and correlated models were used to verify the operation.

The paper describing the details of cryogen-free operation, its development and verification, will be presented on behalf of the entire SXS team.

9905-100, Session PS2

Design and on-orbit operation of the adiabatic demagnetization refrigerator on the ASTRO-H soft x-ray spectrometer instrument

Peter J. Shirron, Mark O. Kimball, Bryan James, Theodore Muench, Edgar R. Canavan, Michael J. DiPirro, Thomas Bialas, Gary A. Sneiderman, Caroline A. Kilbourne, Frederick S. Porter, Richard L. Kelley, NASA Goddard Space Flight Ctr. (United States); Ryuichi Fujimoto, Kanazawa Univ. (Japan); Yoh Takei, Institute of Space and Astronautical Science (Japan); Seiji Yoshida, Sumitomo Heavy Industries, Ltd. (Japan); Kazuhisa Mitsuda, Institute of Space and Astronautical Science (Japan)

The Soft X-ray Spectrometer (SXS) on Astro-H contains a 6x6 array of x-ray microcalorimeters, which is cooled to 50 mK by an adiabatic demagnetization refrigerator (ADR). The ADR consists of three stages in order to provide stable detector cooling using either a 1.2 K superfluid helium bath or a 4.5 K Joule-Thomson (JT) cryocooler as its heat sink. If the cryogenic system performs nominally, the liquid helium will last for at least 3 years on-orbit, during which time two of the ADR's stages are used to single-shot cool the detectors while rejecting heat to the helium. After the helium is depleted, the ADR changes operating mode to cool both the helium tank (to about 1.5 K) and the detectors (to 50 mK) using the JT cryocooler as its heat sink. The Astro-H satellite completed its pre-launch environmental testing (thermal vacuum, vibration and acoustics) in September 2015, and has been shipped to Tanagashima Space Center, Japan, for launch in early 2016. This paper will discuss the basic operation of the ADR and its initial on-orbit performance.

9905-101, Session PS2

Porous plug phase separator and superfluid film flow suppression system for the soft x-ray spectrometer onboard ASTRO-H

Yuichiro Ezoe, Tokyo Metropolitan Univ. (Japan); Kumi Ishikawa, RIKEN (Japan); Ikuyuki Mitsuishi, Nagoya Univ. (Japan); Takaya Ohashi, Tokyo Metropolitan Univ. (Japan);

Kazuhisa Mitsuda, Institute of Space and Astronautical Science (Japan); Ryuichi Fujimoto, Kanazawa Univ. (Japan); Masahide Murakami, Univ. of Tsukuba (Japan); Kenichi Kanao, Seiji Yoshida, Shoji Tsunematsu, Sumitomo Heavy Industries, Ltd. (Japan); Michael J. DiPirro, Peter J. Shirron, NASA Goddard Space Flight Ctr. (United States)

The sixth Japanese X-ray astronomy satellite, ASTRO-H (Takahashi et al. 2014, SPIE), carries the Soft X-ray Spectrometer (SXS, Mitsuda et al. 2014 SPIE). The SXS consists of an X-ray telescope and an X-ray microcalorimeter system operated at 50 mK. It was developed by an international collaboration lead by JAXA and NASA with European participation. The cooling chain of the SXS is composed of an adiabatic de-magnetization refrigerator (50 mK), 30 L superfluid liquid He (1.15 K), a 4He Joule-Thomson cryocooler and four 2-stage Stirling cryocoolers.

Under zero gravity, the superfluid He must be kept in the He tank. Superfluid film flow must be strictly suppressed to avoid loss of liquid. For these purposes, a porous plug phase separator and film flow suppression system is installed in the SXS dewar (Ezoe et al. 2015, Space Cryogenics Workshop[to be published in Cryogenics?]). The expected He flow rate varies from ~30 ug/s to ~3 mg/s depending on the operational case. The required film flow in the nominal operational case must be less than 2 ug/s.

The porous plug phase separator is made of porous sintered stainless steel and is installed between the dewar and the vent line. It separates vapor and liquid He using thermomechanical effect. The film flow suppression system consists of an orifice or a small diameter tube, a heat exchanger, and a pair of knife edge devices. The orifice has a small inner diameter of 1.4 mm to suppress the film flow whose flow rate is proportional to perimeter of the vent line. The heat exchanger fixed on the He tank evaporates the film flow and cools the He tank using the temperature difference between the He tank and the flowing film. The knife edge devices stop the remaining film flow by introducing atomically sharp edges into the film flow path.

Flow rate and film flow measurements have been conducted on the ground at various He temperatures from ~1.15 K to ~2.0 K, both at component level and after installing the system inside the flight dewar. For the measurements inside the flight dewar, the porous plug was wet by tilting the dewar to test the phase separation. The results meet the requirements in the various operational cases and are consistent with each other. In this presentation, we report on ground test results and in-orbit performance.

9905-102, Session PS2

The design, implementation, and performance of the Astro-H SXS aperture assembly and blocking filters

Caroline A. Kilbourne, Joseph S. Adams, Petar Arsenovic, Meng P. Chiao, Megan E. Eckart, John D. Kazeva, Richard L. Kelley, NASA Goddard Space Flight Ctr. (United States); Kari L. Kripps, Univ. of Wisconsin-Madison (United States); Maurice A. Leutenegger, NASA Goddard Space Flight Ctr. (United States); Dan McCammon, Univ. of Wisconsin-Madison (United States); Daniel McGuinness, Samuel J. Moseley, Frederick S. Porter, Andrea Schweiss, Rosemary S. Thorpe, Tomomi Watanabe, NASA Goddard Space Flight Ctr. (United States); Travis Ayers, Heidi Lopez, Bruce Lairson, Luxel Corp. (United States)

The calorimeter array of the Astro-H Soft X-ray Spectrometer (SXS) will provide unprecedented spectral resolution of extended cosmic x-ray sources (e.g. supernova remnants and galaxy clusters) and of all cosmic x-ray sources in the Fe-K band (around 6 keV), which will enable essential plasma diagnostics. The properties that make the SXS array a powerful x-ray spectrometer also make it sensitive to photons from the entire electromagnetic band, and particles as well. (If characterized as a bolometer, it would have a noise equivalent power (NEP) of < 4 E-18 W/sqrt(Hz)). Thus it was imperative to shield the detector from thermal radiation from the instrument and optical and UV photons from the sky. Additionally, it was necessary to shield the coldest stages of the instrument from the thermal radiation emanating from the warmer stages. Both of these needs are addressed by a series of five thin-film radiation-blocking filters anchored to the nested temperature stages that block long-wavelength radiation while minimizing x-ray attenuation (subject to other design constraints). The aperture assembly is a system of barriers, baffles, filter carriers, and filter mounts that supports the filters and inhibits their potential contamination. The three warmer filters also have been equipped with thermometers and heaters for decontamination. We will present the requirements, design, implementation, and performance of the SXS aperture assembly and blocking filters.

9905-103, Session PS2

Thermal analyses for initial operations of the soft x-ray spectrometer (SXS) onboard ASTRO-H

Hirofumi Noda, RIKEN (Japan); Kazuhisa Mitsuda, Noriko Y. Yamasaki, Yoh Takei, Institute of Space and Astronautical Science (Japan); Atsushi Okamoto, Japan Aerospace Exploration Agency (Japan); Ryuichi Fujimoto, Kanazawa Univ. (Japan); Takaya Ohashi, Yoshitaka Ishisaki, Yuichiro Ezoe, Tokyo Metropolitan Univ. (Japan); Kumi Ishikawa, RIKEN (Japan); Ikuyuki Mitsuishi, Nagoya Univ. (Japan); Seiji Yoshida, Sumitomo Heavy Industries, Ltd. (Japan); Michael J. DiPirro, Peter J. Shirron, NASA Goddard Space Flight Ctr. (United States)

The Soft X-ray Spectrometer (SXS; Mitsuda et al. 2014, SPIE, 9144E, 2A) is an X-ray microcalorimeter array onboard the Japanese X-ray satellite ASTRO-H (Takahashi et al. 2014, SPIE, 9144E, 25), which is planned to be launched at the end of Japanese 2015 fiscal year. It achieves an unprecedentedly high energy resolution of <7 eV in the 0.3-10 keV band by cooling the detectors to very low temperature, ~50 mK. The instrument uses superfluid helium stored in a helium tank as a heat sink for the sub-kelvin cooler. To achieve the required hold time of 3 years, the helium tank is surrounded by multiple shields, which are cooled not only by the venting helium vapor, but also by several Stirling coolers and a Joule-Thomson cooler. The temperature of the helium is predicted to be less than ~1.2K in orbit (Fujimoto et al. 2010, SPIE, 7732E, 3H).

In the helium vent system, we employ a porous plug phase separator (Ezoe et al. 2012, Cryogenics, 52, S4-6, 178-182), which divides gas and liquid helium in zero gravity, and vents only boiloff gas. Because the porous plug functions only when the liquid helium is in the superfluid phase, the helium temperature must always be kept lower than the lambda point at ~2.17K. Hence, we need to carefully verify that the highest helium temperature in orbit, which is predicted to occur approximately 1-2 days after launch, never reaches the lambda point.

After the final topoff on the launch pad, the liquid will be pumped to low temperature (~1.3 K) with the cryocoolers operating. Leading up to launch, the pumping must be stopped so that the external plumbing can be removed. From that point, the sequence is as follows: (1) the mechanical coolers continue operating, but there is no vapor cooling of the shields, (2) within a few hours of launch, the cryocoolers are powered down, (3) after launch, opening of the vent valve begins helium vapor cooling of the shields with the coolers still off, and (4) after approximately several hours the cryocoolers are turned on. The impact of this sequence is not only warming of the liquid prior to launch, but some continued warming after launch. In order to predict the maximum helium temperature, we constructed a thermal mathematical model, which includes nodes for the helium, helium tank and the shields, and implemented effects of the helium vapor cooing and the mechanical coolers as negative heat loads at some nodes. By assuming initial temperature at each node resulted by the operation (1), we numerically simulated temperature variations of the helium, the helium tank, and the shields in the operation (2), (3), and (4). As a result, we successfully confirmed that the helium temperature can be anytime kept lower than the lambda point. In our presentation, we report the simulation results, and comparisons with actual measurements obtained in the initial operation of the SXS.

The Soft X-ray Spectrometer (SXS) is a cryogenic high resolution X-ray spectrometer utilizing an X-ray microcalorimeter array onboard the X-ray astronomy satellite ASTRO-H, that achieves the energy resolution better than 7 eV at 6 keV in orbit. The detector array is cooled down to 50 mK using adiabatic demagnetization refrigerators (ADRs). The cooling chain from room temperature to the ADR heat-sink is composed of superfluid liquid helium, a 4He Joule-Thomson cryocooler, and 2-stage Stirling cryocoolers. It is designed to keep 30 L of liquid He for more than 3 years in the nominal case. It is also designed with redundant subsystems throughout from room temperature to the ADR heat-sink, to alleviate failure of a single cryocooler or loss of liquid helium.

The detector array, ADRs, and the aperture assembly developed by NASA were integrated, the Dewar assembly was completed in September 2014. Then thermal performance tests, function tests, and mechanical environment tests were carried out at Niihama works of Sumitomo Heavy Industries and JAXA's Tsukuba Space Center. The heat load on the helium tank was measured and it was verified that it is small enough to satisfy the lifetime requirement, in the case of nominal cryocooler operation. It was also verified that the minimum lifetime requirement can be satisfied even if one of the cryocoolers fails. The vibration isolation system against the Stirling compressors was installed during the subsystem test phase at Tsukuba Space Center, and it was verified that the detector performance satisfies the requirement. The Dewar was mounted on the spacecraft in April 2015, and have joined the a series of system-level tests (the function tests, the thermal vacuum test, and the mechanical environment test). One of the critical thermal design to use cryocoolers is the heat exhaust from them, which was verified in the system-level thermal vacuum test, when the Dewar and the cryocoolers were operated in the environment similar to that in orbit. As of December 2015, the remaining activity is the post-shipment test at the launch site (Tanegashima Space Center), and the final helium transfer and top-off operation just before the launch.

In this paper, we present the performance of the flight helium Dewar and the cryocoolers of the SXS, and initial results of the in-orbit operation.

9905-105, Session PS2

In-flight performance of pulse processing system of the ASTRO-H soft x-ray spectrometer

Yoshitaka Ishisaki, Shinya Yamada, Hiromi Seta, Tokyo Metropolitan Univ. (Japan); Makoto S. Tashiro, Sawako Takeda, Saitama Univ. (Japan); Masahiro Tsujimoto, Kazuhisa Mitsuda, Institute of Space and Astronautical Science (Japan); Makoto Sawada, Aoyama Gakuin Univ. (Japan); Kevin R. Boyce, Meng P. Chiao, Tomomi Watanabe, Megan E. Eckart, Maurice A. Leutenegger, Frederick S. Porter, Caroline A. Kilbourne, Richard L. Kelley, NASA Goddard Space Flight Ctr. (United States)

The PSP (Pulse Shape Processor) is a digital signal processing electronics for the microcalorimeter instrument, SXS (Soft X-ray Spectrometer), onboard the X-ray astronomy satellite, ASTRO-H.

The SXS has 36 sensor pixels, which are operated at 50 mK to measure heat input of X-ray photons and realize energy resolution of < 7 eV FWHM in the range 0.3–12.0 keV. Receiving digitized wave-form (14 bit, 12.5 kHz sample) from 2-18 channels, two identical units of PSP-A and -B trigger X-ray events, assign an event grade, and perform optimal filtering to measure energy deposit on the microcalorimeter pixels.

We tested performance of PSP for high count rate X-ray irradiation up to ~ 2000 c/s/array on ground.

The rate of 2000 c/s/array corresponds to very bright celestial target for SXS, e.g., point-like source with X-ray flux of 1 Crab unit.

It is demonstrated that PSP can process more than ~200 events/s/array, including X-ray events and electrical crosstalk events. The electrical crosstalk events originate in wiring of the detector signal output, which have fast rise-time and easily screened out by offline processing.

We need to tune the pulse thresholds in orbit for the electrical crosstalk and possible interference with other instruments of the spacecraft.

PSP begins to discard events when the input rate exceeds the processing limit of ~200 c/s/array, namely ~50 c/s/CPU. Discarding events is usually done by flushing the waiting FIFO for each pixel.

PSP reports the time tags of the first- and last-event discarded, mixing into the normal events.

When the count rate is not uniform among the pixels, almost 100% of events are processed for pixels with count rate less than ~5 c/s/pixel, while dead time fraction increases in proportion to the count rate for pixels with higher count rate.

Non-uniform irradiation is usually the case for a point-source observation with SXS, because the X-ray from the target is focused by Soft X-ray Telescope (SXT) with half power diameter of ~ 1 arcmin, which is comparable to the SXS field of view of 3.05 arcmin. This automatic adjustment is useful for observation of bright X-ray targets, because central high rate pixels are mostly low-grade events which have degraded energy resolution, while 0outermost pixels with moderate count rate are expected to have better energy resolution.

This paper describes the results of the initial in-orbit performance of the PSP.

The Soft X-ray Spectrometer (SXS) onboard the Astro-H orbiting x-ray observatory features an array of 36 silicon thermistor x-ray calorimeters optimized to perform high spectral resolution x-ray imaging spectroscopy of astrophysical sources in the 0.3-12 keV band. Extensive pre-flight calibration measurements are the basis for our modeling of the pulse-height-energy relation and energy resolution for each pixel and event grade, telescope collecting area, detector efficiency, and pulse arrival time. Onboard radioactive and fluorescent x-ray sources are used inflight to monitor drift in the energy scale due to variations in the thermal boundary conditions of the detectors. The energy scale is interpolated non-linearly between curves measured pre-flight at fixed reference conditions, using the reference energy from the drift monitoring. The energy scale and energy resolution are explicitly validated using observations of emission line rich sources with well-understood properties. We also characterize orbital variation in energy resolution and energy scale caused by variation in the flux of particles incident on the instrument. We use observations of broadband continuum sources and sources with constant line fluxes to validate our models of the telescope area and detector efficiency, as well as monitoring for possible contamination.

9905-107, Session PS2

First in-flight performance results of the calibration sources for the soft x-ray spectrometer instrument on ASTRO-H

Cor P. de Vries, Paul Lowes, Jan-Willem A. den Herder, Daniel Haas, SRON Netherlands Institute for Space Research (Netherlands); Stephane Paltani, ISDC Data Ctr. for Astrophysics (Switzerland); Noriko Y. Yamasaki, Institute of Space and Astronautical Science (Japan); Richard L. Kelley, Caroline A. Kilbourne, Megan E. Eckart, Meng P. Chiao, Maurice A. Lautenegger, Frederick S. Porter, Keith C. The Soft X-ray Spectrometer instrument (SXS) on the ASTRO-H satellite contains a novel type of calibration sources. These active Modulated X-ray Sources (MXS) generate electrons by means of light pulses incident on a photo cathode, which in turn are accelerated onto a target to generate a suitable X-ray spectrum.

These sources are part of the filterwheel structure.

Here we report on the first few weeks of operations of these sources and the filterwheel, in space, on board the recently launched satellite.

9905-108, Session PS2

Ground calibration of the ASTRO-H soft x-ray spectrometer

The Soft X-ray Spectrometer (SXS) will launch aboard Astro-H in early 2016, enabling high-resolution non-dispersive spectroscopy in the soft x-ray waveband (0.3-12 keV). We present the suite of ground calibration measurements acquired from 2012 through 2015, including characterization of the detector system, anti-coincidence detector, optical blocking filters, and filter-wheel filters.

The calibration of the 36-pixel silicon thermistor microcalorimeter array includes parametrizations of the energy gain scale and line spread function for each event grade over a range of instrument operating conditions, as well as event timing and quantum efficiency data. We also describe sources of interference seen during ground testing and discuss the effects

on detector calibration.

The x-ray transmission of the set of five Al/polyimide thin-film optical blocking filters mounted inside the SXS dewar has been modeled based on measurements at synchrotron beamlines, including with high spectral resolution at the C, N, O, and Al K-edges. In addition, we present the x-ray transmission of the filters mounted on the SXS filter wheel (external to the dewar), including beryllium, polyimide contamination-blocking, and neutral density filters.

9905-109, Session PS2

Point spread function of ASTRO-H soft x-ray telescope (SXT)

Takayuki Hayashi, Nagoya Univ. (Japan) and NASA Goddard Space Flight Ctr. (United States); Toshiki Sato, Naomichi Kikuchi, Ryo Iizuka, Yoshitomo Maeda, Manabu Ishida, Sho Kurashima, Nozomi Nakaniwa, Institute of Space and Astronautical Science (Japan); Takashi Okajima, Hideyuki Mori, Yang Soong, Peter J. Serlemitsos, NASA Goddard Space Flight Ctr. (United States)

ASTRO-H satellite will be launched in February 2016. It equips two Soft X-ray Telescopes (SXTs), one of which is coupled to Soft X-ray Spectrometer (SXS) while the other is coupled to Soft X-ray Imager (SXI). Although SXTs are lightweight of ~42 kg/module and have large on-axis effective area (EA) of ~450 cm2 at 4.5 keV/module by themselves, their angular resolutions are moderate ~1.2 arcmin in half power diameter. The SXT angular resolution varies from 1.2 arcmin to 1.5 arcmin by energy to energy as well as EA. Field Of View (FOV) of SXS and SXI are considerably different, and 3.05x3.05 arcmin2 and 38x38 arcmin2, respectively, which means that characteristics important for the observation are different for the two detectors.

It is difficult that contamination amount into the SXS FOV from nearby sources through the PSF tail of SXT is evaluated with accuracy in orbit because SXS has only 6x6 pixels and SXT angular resolution is comparable to the SXS FOV. Therefore, the contamination amount was measured in the ground-based calibration at the beam line in Institute of Space and Astronautical Science. The contamination at 4.5 keV were measured with sources one width of the FOV distant from the FOV center in perpendicular and diagonal directions, that is, 3 and 4.5 arcmin off, respectively. The average EA of the contamination in the four directions with the 3 and 4.5 arcmin off were measured to be 2 and 0.6% of the SXS on-axis EA of 412 cm2, respectively. The contamination from a source two FOV widths distant, that is, 8.6 arcmin off in only one diagonal direction was also measured to be 0.1% of the on-axis at 4.5 keV.The contamination amounts were also measured at 1.5 keV and 8.0 keV at the 3 and 4.5 arcmin off in only one direction, which indicated that the fractional contamination amounts to each of the on-axis EA (535 cm2 at 1.5 keV and 340 cm2 at 8.0 keV) hardly depend on the source energy.

On the other hand, SXI FOV is wide comparing to the SXT angular resolution and it?has 1280x1280 pixels which are sufficiently fine. Therefore, the image variation associated with the off-axis and stray image arrived at SXI will be seen in orbit. The off-axis images from 4.5 to 27 arcmin in diagonal direction were acquired at intervals of 4.5 arcmin in the ground-based calibration. The image became asymmetric about normal to the off-axis direction and shrinks in that direction as the off-axis angle increased. Moreover, at off-axis angle more than 13.5 arcmin, stray clearly appeared in the off-axis direction. As for on-axis image, stray appeared at the edge of SXI of ~35 arcmin distant from the image center.

We will report the contamination from the nearby source into the SXS FOV and various off-axis images in the wide FOV of SXI.

9905-110, Session PS2

The ASTRO-H SXT performance to the large off-set angles

Toshiki Sato, Institute of Space and Astronautical Science (Japan) and Tokyo Metropolitan Univ. (Japan); Ryo Iizuka, Institute of Space and Astronautical Science (Japan); Hideyuki Mori, NASA Goddard Space Flight Ctr. (United States); Takayuki Hayashi, NASA Goddard Space Flight Ctr. (United States) and Nagoya Univ. (Japan); Yoshitomo Maeda, Manabu Ishida, Institute of Space and Astronautical Science (Japan); Naomichi Kikuchi, Sho Kurashima, Nozomi Nakaniwa, Institute of Space and Astronautical Science (Japan) and Tokyo Metropolitan Univ. (Japan); Takashi Okajima, Yang Soong, Peter J. Serlemitsos, NASA Goddard Space Flight Ctr. (United States)

The ASTRO-H, which is currently planed as launched in 2015 JFY, is the first mission to carry out high resolution spectroscopy of extended sources. The ASTRO-H's Soft X-ray Telescopes : SXT-I for a CCD camera (SXI) & SXT-S for a calorimeter (SXS), which adopt the conically approximated Wolter type-I optical system, play a role of concentrating and imaging up to ~12 keV. In this optics, X-rays usually are doubly reflected and focused by "primary" and "secondary" reflectors. However, X-rays from a large off-set angle rarely reaches the face of the detector without the normal double reflection. That is called "stray light". When we observe a target which has a large structure (like the nearby clusters of galaxies) or a faint source near a bright source, the stray lights contaminate the real signals significantly. Therefore, it is inevitable to reduce the amounts of the stray lights for the precision observations by the ASTRO-H.

Main components of the stray lights are X-rays reflected by only secondary reflectors (secondary reflection) and those reflected on the mirror substrates (backside reflection). Bare aluminum is used as the substrates. Since the critical angle of the reflection at the aluminum surface is about an order of magnitude smaller that that of the gold, the backside reflection is about one order of magnitude fainter than the secondary reflection. In order to reduce the secondary reflection, the SXTs have a "pre-collimator" (Mori et al. 2012). The pre-collimator, which is composed of cylindrical aluminum thin-foils (~120 ?m), is equipped on top of the optics so that only stray light is cut before arriving at the reflectors.

In this study, we measured the effective area of the SXTs at several off-axis angles by using the ISAS X-ray beam line (Hayashi et al. 2015) in order to estimate the level of the stray light. In particular, it is important to reveal the stray light to the SXS in order to support the high-resolution spectroscopy for diffuse X-ray emission. In the results, we found the effective area in the SXS's field of view (~3'x3') at the 30' off-axis is as small as (2.1±0.2)x10^-3 cm^2 at 1.49 keV, and those of the stray light at off-axis larger than 15' are smaller than ~10^-5 times of the effective area at on-axis (~590 cm^2). Thus, even if there is a contamination source which is 1000 times brighter than the target at 15' off-axis, we can observe less than ~ 1% contribution of the stray light with SXS. In this poster, we will also present other detail informations of the stray light of the SXTs.

9905-111, Session PS2

Reflectivity around the gold M-edges of x-ray reflector of the soft x-ray telescope onboard ASTRO-H

Sho Kurashima, Tokyo Metropolitan Univ. (Japan) and Institute of Space and Astronautical Science (Japan); Akihiro Furuzawa, Nagoya Univ. (Japan); Toshiki Sato, Naomichi Kikuchi, Nozomi Nakaniwa, Tokyo Metropolitan Univ. (Japan) and Institute of Space and Astronautical Science (Japan); Yoshitomo Maeda, Manabu Ishida, Ryo Iizuka, Institute of Space and Astronautical Science (Japan); Takashi Okajima, Hideyuki Mori, NASA Goddard Space Flight Ctr. (United States); Hironori Matsumoto, Keisuke Tamura, Kazunori Ishibashi, Nagoya Univ. (Japan); Takayuki Hayashi, Nagoya Univ. (Japan) and NASA Goddard Space Flight Ctr. (United States); Takuya Miyazawa, Masato Maejima, Shun Yoshikawa, Nagoya Univ. (Japan)

The X-ray astronomy satellite ASTRO-H equips two Soft X-ray Telescopes (SXT-I and SXT-S) which cover 0.3 to ~12 keV. The SXT-I and SXT-S focuses their images on the focal plane detectors of the CCD camera (SXI) and the micro-calorimeter (SXS), respectively. A surface of an X-ray reflector of the SXTs is a gold monolayer fabricated by a replica method (Okajima et al. in this volume). The replicated method used in the SXT is a basically similar to that in the Suzaku X-Ray Telescope (XRT). Gold M absorption edges in the 2-4 keV band cause complex structures in the effective area of the SXTs. In the 2-4 keV energy band, there are emission lines from Si, Ar and S that are important in astronomy. The effective area is known as drastically changed around M-edges. Because the SXS has unprecedented high energy resolution, it is hence inevitable for making the response function of the SXTs with the fine energy pitch to quantify the reflectivity precisely around the M-edges. From Nov. 14 to Nov. 20, 2014, we measured the reflectivity around the gold M-edges in detail using the synchrotron radiation facility KEK PF BL11-B. This beamline supplies monochromatic X-rays with a double crystal monochromator with a wide energy band of the 2-4 keV band. In our experiment, Si(111) was used for the monochromating. A witness sample was used that was fabricated with the same process to those of SXT. We measured reflectivity with 2 eV energy pitch in 2100 eV to 4100 eV band including the M-I to M-V absorption edges at grazing angles of 0.5, 0.8, 1.0, 1.2, 1.4 degree around the critical angle of gold. We measured reflectivity with the finer energy pitch of the 0.25 eV in the 2200 eV to 2350 eV band included M-IV, M-V edges that were deeper absorption edges. In the reflectivity, we clearly identified the fine structures of the M-edges of the M-I to M-V. In addition, some weak but artificial structures due to the systematic errors were remained in the reflectivity those might be due to the uncontrolled beam angle and divergence into the sample. Using the measurements, we calculated atomic scattering factor f1. The f1 was determined by the curve fitting to the reflectivity at the incident angles of 0.5, 0.8, 1.0, 1.2, 1.4 degrees. Since the f1 values contains some systematic uncertainties, we also checked the residuals using the Suzaku XIS data. We found that the residuals around the M-edges to the Suzaku spectra of 4U1630-472 (BH transient) and the Crab nebula are better reduced than those with the official Suzaku response. However, there still exist small residuals around the edges. The residuals are likely originated from the systematic errors of our measurements and will be checked with the in-flight data of the ASTRO-H SXS.

9905-112, Session PS2

Reflectivity around the gold L-edges of x-ray reflector of the soft x-ray telescope onboard ASTRO-H

Yoshitomo Maeda, Institute of Space and Astronautical Science (Japan); Naomichi Kikuchi, Sho Kurashima, Tokyo Metropolitan Univ. (Japan); Ryo Iizuka, Manabu Ishida, Institute of Space and Astronautical Science (Japan); Toshiki Sato, Tokyo Metropolitan Univ. (Japan); Hideyuki Mori, Takashi Okajima, Takayuki Hayashi, NASA Goddard Space Flight Ctr. (United States); Hironori Matsumoto, Ikuyuki Mitsuishi, Shigetaka Saji, Sasagu Tachibana, Nagoya Univ. (Japan); Nicolai F. Brejnholt, Lawrence Livermore National Lab. (United States); Finn E. Christensen, Technical Univ. of Denmark (Denmark); Kiyofumi Nitta, Tomoya Uruga, Japan Synchrotron Radiation Research Institute (JASRI) (Japan)

Two Soft X-ray telescopes (SXT-I and SXT-S) are mounted on the ASTRO-H mission.

The SXT-I and SXT-S focuses their images on the focal plane detectors of the CCD camera (SXI) and the micro-calorimeter (SXS), respectively.

Since the incident angle to the light along the on-axis direction is at minimum 0.15 degrees, the SXT can reflect the incident X-rays above 10 keV effectively.

Although the primary energy is 6-7 keV at the Fe-K lines, this gives us a bonus of the X-ray spectroscopy above 10 keV.

The Wolter-I type optics are adopted on the SXT with a gold surface. Therefore, the effective area show the complex structures around the gold L-edges in 11-15 keV.

The optical constant of the SXT's gold surface must be measured for making the response function of these energies.

In 2014, we measured the reflectivity around the gold L-edges in detail using the synchrotron radiation facility Spring-8 BL01B1.

An Si(311) double-crystal monochromator was used for the incident beam.

An energy resolution of the beam is about 3e-5 (FWHM) which corresponds to 0.3 eV at 10 keV and 0.5 eV at 15 keV.

The second mirror is designed to focus the beam at the sample which is located at 4.9~m away. The mirrors work to focus the beam in ~0.3 mm height at the the sample.

The mirrors are tilted to cut high energy photons by tuning the tilt angle within the critical angle at the energy of ~20 keV (=3 micro rad).

A witness sample of the SXT reflector was then illuminated at the constant incident-angle at any energies in the 11--15 keV within ~0.3 mm height and~0.04~degree diverging angle with negligible higher harmonics.

Using the measurements, we calculated atomic scattering factor f1 and f2 by the curve fitting to the reflectivity at several energies.

We identified the edges associated with the L-I, II, and III transitions. We also found that the depth of these energies are roughly 60% shallower than that listed in the Henke's 1993 optical constant table.

9905-113, Session PS2

Measurements of reflectivity around the Pt L and K absorption edges of Pt/C multilayer reflector for calibration of the ASTRO-H hard x-ray telescope (HXT)

Akihiro Furuzawa, Shigetaka Saji, Sasagu Tachibana, Takayuki Hayashi, Hironori Matsumoto, Ikuyuki Mitsuishi, Kazunori Ishibashi, Keisuke Tamura, Nagoya Univ. (Japan); Hideyuki Mori, Takashi Okajima, NASA Goddard Space Flight Ctr. (United States); Naomichi Kikuchi, Sho Kurashima, Ryo Iizuka, Yoshitomo Maeda, Institute of Space and Astronautical Science (Japan); Manabu Ishida, Institute of Space and Astronautical Science (Japan); Shigeo Yamauchi, Nara Women's Univ. (Japan); Hisamitsu Awaki, Ehime Univ. (Japan); Finn E. Christensen, Technical Univ. of Denmark (Denmark); Nicolai F. Brejnholt, Regina Soufli, Michael J. Pivovaroff, Lawrence Livermore National Lab. (United States); Kiyofumi Nitta, Tomoya Uruga, Japan Synchrotron Radiation Research Institute (JASRI) (Japan)

We present the results of the reflectivity measurement of Pt/C multilayer for calibration of the ASTRO-H Hard X-ray telescope.

Japan's 6th X-ray satellite mission ASTRO-H will carry two hard X-ray telescopes (HXT) using depth-graded multilayer reflectors which provide us the capability of hard X-ray imaging observation up to 80 keV. The ASTRO-H HXT is the light-weight hard X-ray telescope using Pt/C depth-graded multilayer and high-throughput thin-foil optics. The effective area of the ASTRO-H HXT is estimated by calculation with the geometry and reflectivity of reflectors. It is difficult to calculate actual reflectivity of a multilayer reflector accurately with optical constants in literatures, because a reflectivity of a multilayer depends not only on optical constants but also on density, interfacial roughness and thickness of each layer, which are heavily dependent on a method and condition of a multilayer deposition. Furthermore, those parameters are strongly coupled to each other, thus they are hard to be determined independently. The actual reflectivity needs to be measured with the reflector fabricated by the same method and facility as that of the HXT, and then set of parameters to represent it should be derived.

For the purpose of deriving the set of parameters, reflectivity measurements of a Pt/C multilayer reflector have been done at the beamline BL01B1 of the synchrotron radiation facility SPring-8 in 2014. BL01B1 is the beamline with the bending magnet and Si Double Crystal Monochrometer which E/dE is ~ 30000 in energy range from 3.8 keV to 113 keV. The design parameters of the measured multilayer sample are the number of bilayers (N) of 15, period thickness (d) of 30 angstrom and the multilayer thickness ratio (gamma) of 0.5. The multilayer has been deposited onto the super-smooth surface of the substrate by using the fabrication facility used for reflector production of the ASTRO-H HXT. With that sample, energy scans at fixed incident angles were performed in several energy ranges; from 11.2 to 15.4 keV with 0.5 eV step including the Pt-L absorption edges, from 50 to 100 keV with 10 keV step for broad band reflectivity, from 77.5 to 80.5 keV with 0.5 keV step and from 78.1 to 78.7 keV with 0.025 keV step for detailed study of the K edge absorption feature. The reflectivity curves in the energy band of 11 to 15 keV and 50 to 100 keV including fine structures of L and K absorption edges have been obtained with high accuracy and enough energy resolution. We report the results of reflectivity measurements and the parameter set for the Pt/C multilayer reflector fabricated at the ASTRO-H HXT production facility.

The Hard X-ray Telescope (HXT) onboard ASTRO-H is a Wolter-I X-ray telescope utilizing Pt/C multilayer supermirrors. ASTRO-H carries two HXTs (HXT1 and HXT2), and each of them can reflect X-rays up to 80 keV onto each of the Hard X-ray Imagers (HXI). We have developed a ray-trace simulation code for the HXT. The code can take into account the tilt and twist of the mirrors, the roughness of each layer of the supermirror, and the scattering profile of each mirror. We have tuned these parameters based on the results of the characterization of HXT conducted mainly at the synchrotron facility SPring-8 Beam Line 20B2. For example, if we simulate the effective area as a function of X-ray energy with a unique roughness common to all multi-layers, the simulation tends to predict the larger effective area above 50 keV. This problem is known as a throughput problem. We have done various simulations, and found that the throughput problem can be resolved if we apply different roughness values to different mirrors; the roughness of the innermost mirror is about 10.0 A, while that of the outermost radius is about 7.0 A. So far our simulation is consistent with the measurement of the effective area within +/- 7 % in the case of the HXT1, and within +9/-3% in the case of the HXT2. The measurements of the point spread function, the half power diameter, the encircled energy function, and the vignetting function have been also compared with our simulation. We will compare the simulation with the in-flight X-ray data obtained after the launch of ASTRO-H to evaluate the in-orbit performance of the HXT. This will also clarify the effect of the launch on the status of the HXT.

9905-115, Session PS2

A laboratory test setup to study the stability of operation of the CdTe detectors within Astro-H HXI

Daniel Maier, CEA-Ctr de SACLAY (France); Benoit Horeau, Commissariat à l'Énergie Atomique (France); Philippe Laurent, Olivier Limousin, CEA-Ctr. de SACLAY (France); Diana Renaud, CEA-Ctr. de SACLAY (France)

Astro-H is the next JAXA/NASA X-ray satellite that will be launched at the beginning of 2016.

The hard X-ray imager (HXI) is a Si/CdTe stacked detector system which is placed in the focus of a hard x-ray telescope. HXI constitute one of the four different instruments onboard Astro-H.

We are presenting the current status of a stacked detector setup which consists of two mini-HXI double sided CdTe strip detectors---similar to those used in HXI---that are read out with the low-noise readout ASIC Idef-X BD.

We describe the configuration of the setup, its spectroscopic performance, and a long-term operation of the setup.

The long-term test simulates the orbital operation of HXI using identical detector temperatures, bias voltages, and switch-on/switch-off cycles with the goal to study the detector stability and the evolution of its performance during operation.

9905-116, Session PS2

Summary of the ground-based calibration for the ASTRO-H hard x-ray telescopes (HXTs)

Ikuyuki Mitsuishi, Nagoya Univ. (Japan); Hideyuki Mori, NASA Goddard Space Flight Ctr. (United States); Takuya Miyazawa, Nagoya Univ. (Japan); Hisamitsu Awaki, Ehime Univ. (Japan); Shigetaka Saji, Yasunori Babazaki, Masato Maejima, Ren Nakamichi, Shun Yoshikawa, Ayako Bandai, Naoki Shima, Hiroaki Kobayashi, Yusuke Miyata, Takayuki Hayashi, Akihiro Furuzawa, Nagoya Univ. (Japan); Ryo Iizuka, Institute of Space and Astronautical Science (Japan) and Japan Aerospace Exploration Agency (Japan); Kazunori Ishibashi, Hideyo Kunieda, Hironori Matsumoto, Nagoya Univ. (Japan); Satoshi Sugita, Ehime Univ. (Japan); Yoshio Suzuki, The Univ. of Tokyo (Japan); Keisuke Tamura, NASA Goddard Space Flight Ctr. (United States); Yuzuru Tawara, Nagoya Univ. (Japan); Kentaro Uesugi, Japan Synchrotron Radiation Research Institute (JASRI) (Japan)

ASTRO-H, the 6th Japanese X-ray satellite, equips identical two Hard X-ray Telescopes (HXTs) to carry out imaging spectroscopy in the hard X-ray energy band between 5 and 80 keV (Awaki et al. 2013). Conically-approximated thin-foil Wolter-I optical system with a focal length of 12 m is employed and Pt/C depth-graded multilayer structures are formed on the HXT mirrors in order to realize higher effective area also in the hard energy band. The HXT consists of tightly-nested 213 shells divided azimuthally into three segments and the aluminum foils with a thickness of 0.2 mm, a length of 200 mm, and a diameter of 120-450 mm are installed in the housing.

Before the launch, the HXT performance, e.g., angular resolution, effective area, vignetting function, and field of view, has been investigated extensively on ground at both SPring-8 BL20B2, 3rd generation synchrotron facility, and the X-ray pencil beam line facility of ISAS/JAXA. Consequently, angular resolutions of 1.9 and 1.8 arcmin in HPD at 30 keV are achieved for HXT-1 and HXT-2, respectively and improve up to 1.5 arcmin at 70 keV. This energy dependency in the angular resolution is explained by the difference of the waviness of the mirror reflectors. Considering the facts that the waviness of the mirror reflectors at the inner radius is smaller than that of the outer radius and high-energy photons can be reflected only at a smaller grazing angle, the angular resolution is expected to depend on energy and improve with increasing energy. The effective areas of HXT-1 and HXT-2 at 30 keV are 170 and 178 cm2, respectively. The throughput is ~0.75. The effective area decreases down to ~20 cm2 at 70 keV. The effective area as a function of an off-axis angle, i.e., the mirror vignetting function, was also measured and the resulting mirror field of views corresponding to the FWHM values in the vignetting curve are 9.9 arcmin at 8 keV and 5.6 arcmin at 50 keV. In this paper, we will report on the summary of ground-based calibration for the HXTs.

9905-117, Session PS3

Cross-calibration of the x-ray instruments onboard the Chandra, Suzaku, Swift, and XMM-Newton observatories using the SNRs 1E 0102.2-7219 and N132D

Paul Plucinsky, Smithsonian Astrophysical Observatory (United States); Andrew P. Beardmore, Univ. of Leicester (United Kingdom); Frank Haberl, Max-Planck-Institut für extraterrestrische Physik (Germany); Eric D. Miller, Massachusetts Institute of Technology (United States); Andrew M. T. Pollock, European Space Astronomy Ctr. (Spain); Steven F. Sembay, Univ. of Leicester (United Kingdom)

We report on our continuing efforts to compare the absolute effective areas of the current generation of CCD instruments onboard the recently active observatories, specifically: Chandra ACIS, XMM EPIC (MOS and pn), Suzaku XIS, and Swift XRT, using 1E~0102.2-7219, the brightest supernova remnant (SNR) in the Small Magellanic Cloud, and N132D, the brightest SNR in the Large Magellanic Cloud. E0102 has strong lines of O, Ne, and Mg below 1.5 keV and little Fe emission to complicate the spectrum, while N132D has strong emission lines of Si, S, Ar, and Fe-K. The spectrum of both SNRs has been well-characterized using the RGS grating instrument on XMM and the HETG grating instrument on Chandra. We have developed empirical models that includes Gaussians for the identified lines, absorption components in the Galaxy and the MCs, and continuum components. In our E0102 fits, the model is highly constrained in that only the normalizations of the four brightest line complexes (the O VII triplet, O VIII Ly alpha line, the Ne IX triplet, and the Ne X Ly alpha) and an overall normalization are allowed to vary, while all other components are fixed. In our N132D fits, only the normalizations of the the Si XIII triplet, the S XV triplet, and the Ar XVII triplet, and an overall normalization are allowed to vary. We adopted this approach to provide a straightforward comparison of the measured line fluxes at these energies. We compare these measured line fluxes to provide an estimate of the consistency of the absolute effective area of the respective missions in the energy range from 0.5 to 3.5~keV.

9905-118, Session PS3

Evolution of temperature-dependent charge transfer inefficiency correction for ACIS on the Chandra X-ray Observatory

Catherine E. Grant, Marshall W. Bautz, Massachusetts Institute of Technology (United States); Nick Durham, Paul Plucinsky, Smithsonian Astrophysical Observatory (United States)

As the Advanced CCD Imaging Spectrometer (ACIS) on the Chandra X-ray Observatory enters its seventeenth year of operation on orbit, it continues to perform well and produce spectacular scientific results. The response of ACIS has evolved over the lifetime of the observatory due to, among other factors, radiation damage and aging of the spacecraft. The ACIS instrument team developed a software tool which applies a correction to each X-ray event and mitigates charge transfer inefficiency and spectral resolution degradation (Grant et al. 2004). The behavior of the charge traps that cause CTI are temperature dependent, however, and warmer-than-nominal focal plane temperatures reduce the effectiveness of the correction algorithm. As the radiator surfaces on Chandra age, ACIS cooling has become less efficient at some spacecraft orientations and the focal plane temperatures can increase by a few degrees. A temperature-dependent component was added to the CTI correction algorithm in 2009. We present an evaluation of the effectiveness of this algorithm as the radiation damage and thermal environment continue to evolve and suggest updates to improve the calibration fidelity.

9905-119, Session PS3

Development of the front-end readout ASIC for charged particle counting with the RADEM instrument on the ESA JUICE mission

Dirk X. Meier, Philip Påhlsson, Amir Hasanbegovic, Hans Kristian Otnes Berge, Mehmet Akif Altan, Jörg Ackermann, Bahram Najafiuchevler, Suleyman Azman, Jahanzad Talebi, Alf Olsen, Codin Gheorghe, David Steenari, Petter Øya, Timo A. Stein, Tor Magnus Johansen, Gunnar Maehlum, Integrated Detector Electronics AS-IDEAS (Norway)

This work describes the development of the front-end readout IDE3466 for RADEM on JUICE. The readout has been implemented in an application specific integrated circuit (ASIC) to meet the RADEM specifications. The ASIC has been designed for the p-side readout of silicon charged particle sensors. RADEM will use three instances of the ASIC for its protons and ions detector, its electrons detector, and its directional detector, respectively. The ASIC has 36 charge sensitive pre-amplifiers (CSA), 36 counters of 22-bits each, and one analogue output for multiplexing the pulse heights from all channels. A predecessor of the IDE3466 without counters is used in the ESA Next Generation Monitor (NGRM). The counters count pulses from charged particles in the silicon sensors depending on the charge magnitude and the programmable coincidence conditions among the 36 channels. The ASIC can be operated with an external controller for programming the ASIC registers after power-on and reading out the counter data in regular intervals. Out of the 36 channels, 32 have a high gain with saturation at 2.6 pC, and 4 have a low gain with saturation at 26 pC. The high-gain counters energy thresholds are 10-bit programmable in the range from 2.2 fC to 100 fC and also in the range from 2.2 fC to 1 pC. The low-gain counters energy thresholds are also 10-bit programmable in the range from 100 fC to 26 pC. This allows for energy binned counting of electrons from 0.3 MeV to 40 MeV, and protons from 5 MeV to 250 MeV. The ASIC operates with positive voltage supplies (+1.8V and +3.3V) and one external reference bias current. The total power consumption is less than 180 mW, depending on settings and readout rate. The ASIC has a serial peripheral interface (SPI) for programming its register settings and for the count data readout. All amplifier inputs are protected by diodes against over-voltage and electro-static discharge (ESD). The ASIC is designed in 0.35-µm CMOS process and has been manufactured at a European foundry. We have manufactured test devices and validated the design with respect to radiation. We measure a single-event-upset threshold of 50 MeVcm2/mg and we do not observe any latch-up up to the maximum tested energy of 135 MeVcm2/mg. We are currently validating the RADEM ASIC with respect to the requirements and aim for flight readiness in the year 2017.

9905-120, Session PS3

Developments in calibration of EUV and VUV detectors for solar orbiter instrumentation using synchrotron radiation

Thomas Reichel, Alexander Gottwald, Udo Kroth, Christian Laubis, Frank Scholze, Physikalisch-Technische Bundesanstalt (Germany)

Space-based missions exploring the spectral ranges of extreme- and vacuum-ultraviolet radiation (EUV, VUV) require on-ground at-wavelength calibration of their detectors and imaging systems to be able to provide reliable spectral intensity data. For wavelengths shorter than 200 nm monochromatized synchrotron radiation is an ideal calibration tool since it is tunable, stable in operation and inherently debris-free from its source. At the Metrology Light Source, the electron storage ring of the Physikalisch-Technische Bundesanstalt in Berlin, Germany, different beamlines cover the complete EUV and VUV spectral range for spectrally dispersed measurements. Detector systems ranging from devices like photodiodes, over imaging devices like CCD or APS to complete radiometers (or spectrometers) can be calibrated and characterized with monochromatized radiation traceable to cryogenic electrical substitution radiometers as primary detector standards. Thus it is possible to quantify the spectral responsivity (or quantum efficiency) of detectors in SI-units. Different illumination conditions are possible (e.g. beam sizes, intensities), thus allowing the determination of detector uniformity, linearity, etc. At these beamlines, also detector aging and degradation effects can be investigated. At dedicated high-flux beamlines it is possible to test up to the expected life-time dose for the devices under test.

The detector-based approach (with traceability of the radiometric quantities to a primary detector standard) is an alternative approach to the characterization of complete spectrometer systems by undispersed radiation of the storage ring, operated as a source standard. Besides our standard experimental chambers which can accommodate single detector devices, a dedicated vacuum chamber designed for instruments up to 100 kg in weight and 1.2 m length is available for instruments like, e.g., completely mounted spectrometers. The instruments are loaded into the chamber from a clean room facility which matches ISO class 5 specifications.

This chamber is capable to be used at monochromator beamlines for detector-based calibrations as well as at a beamline for undispersed radiation for source-based calibrations.

Currently the work is focused on instruments for Solar Orbiter, in particular the EUI (Extreme Ultraviolet Imager) instrument. This concerns the detector modules (for EUV as well as for Lyman-alpha), several other components (filters, mirrors) as well as the complete instrument. The full instrument calibration comes with several challenges: In contrast to the Sun, the synchrotron radiation source point is not at infinity, and the instrument's aperture is typically larger than the beam size. This applies for all imaging systems, and has to be taken into account for detector- and source based calibration procedures. Thus, precise alignment must be ensured, and measurement procedures shall include tests for angular variations as well as for non-uniform response over the entrance aperture.

We report on the current status of PTB's space instrument calibration facilities and recently developments for the radiometric characterization of components and instruments in particular for the Extreme Ultraviolet Imager (EUI) of the Solar Orbiter.

9905-121, Session PS3

Bright eruptive events polarimeter nanosatellite project: definition and performances of a spectro-imaging instrument onboard a nanosatellite payload for solar flares studies

Henri E. Triou, Aline Meuris, Olivier Limousin, Laura Gosset, Commissariat à l'Énergie Atomique (France)

Nanosatellites are currently essentially aimed at training students in the frame of university projects or used as technological demonstrators. As for now, less than one fifth of the nanosatellites have a scientific interest. However, due to the standardization and miniaturization of satellite subsystems such as AOCS and RF systems (onboard X and S band antennas), the nanosatellite platforms can reach performances in terms of attitude control, pointing stability and data transfer at the level needed for scientific missions.

In this talk, we present the "Bright Eruptive Events Polarimeter" (BEEP) project that is motivated by the opportunity of having high performance

and miniaturized X-rays detectors operate on a space mission for solar studies. The properties of Caliste HD detectors (size, mass, power consumption) make these detectors a good candidate for nanosatellite missions, allowing reduced cost and development time.

The Scientific goals of the BEEP mission are to perform firstly spectroscopy and secondly polarimetry on solar flares. Even if it shall be further possible to adapt a grid to perform coded mask imaging, no imaging capabilities are required at this stage for the BEEP mission. The BEEP mission is intended to operate simultaneously as the Solar Obiter/STIX mission in order to optimize the scientific return of both instruments, benefitting from the use of the same family of detectors (Caliste) and thanks to the possibility to perform stereoscopic observations of the same events. The use of Caliste HD detectors will allow high performance photometry and spectroscopy measurements. Spectroscopy with BEEP will trigger with single hits and will cover a lower energy range (say 3-150 keV), allowing to study the transition between thermal and non-thermal emissions of solar flare events. Compton diffusion within the Caliste HD detector will allow BEEP to perform polarization measurements. Polarimetry will trigger with double hits and will be efficient for incoming photons energies greater than about 100 keV. Polarimetry without imaging will be possible only for those flares near the solar limb with a single footpoint in the field of view of the instrument.

We have defined and studied a scientific payload, based on very high performance miniaturized X-rays detectors (Caliste HD), well adapted to the observation of all kind of solar flares. We demonstrated, thanks to a system analysis, that this payload can be accommodated on a 3U CubeSat and will meet the constraints (mass, power, telemetry budgets) associated with the use of such nanosatellites.

9905-122, Session PS3

Source-based calibration of space instruments using synchrotron radiation at the metrology light source

Roman M. Klein, Rolf G. Fliegauf, Simone Kroth, Wolfgang Paustian, Thomas Reichel, Mathias Richter, Reiner Thornagel, Physikalisch-Technische Bundesanstalt (Germany)

PTB has been involved in the calibration of many space-based instruments. The observation of solar VUV radiation is of increasing importance for various scientific questions, such as the verification of solar models, atmospheric research or space weather forecasts. These investigations often require the absolute measurement of radiometric quantities. Based on synchrotron radiation (SR), PTB can perform these absolute measurements traceable to the primary national standards. Over the past decades, PTB has performed calibrations for numerous space missions within scientific co-operations and has become an important partner for activities in this field [1].

New instrumentation in the PTB laboratory at the Metrology Light Source (MLS) has been put into operation that opens up extended calibration possibility within this context. A new facility for the calibration of radiation transfer sources in the 7 nm to 400 nm spectral range has been set-up. Also an existing VUV transfer calibration source [2] was upgraded to cover the extended spectral range from 16 nm to 350 nm.

A new large vacuum vessel is available at the MLS now, which allows the handling of complete space instruments, opening up the way for calibration of space instruments directly to the primary source standard MLS. Before its availability, the calibration of the complete space instruments was only possible by using transfer sources. These sources have been calibrated traceable to the primary source standard by PTB and have then be used at the home-institute of the corresponding cooperation partner for the calibration of the space instrument. Prominent examples for such calibrations are the calibration of transfer sources that have been used for the calibration of the CDS and SUMER spectrographs of the SOHO mission, using hallow cathode based transfer sources built and calibrated by PTB [2]. Now, also this scheme of calibration via transfer sources, which may be in some circumstances advantageous compared to the direct calibration, can be performed in-house at PTB. This respective transfer source can be rather easily recalibrated at short notice in the same laboratory at a neighbouring station, which also was put into operation recently and allows the traceable calibration of transfer sources in the spectral range from 7 nm to 400 nm [3].

9905-123, Session PS3

The PixDD project

Yuri Evangelista, Marco Feroci, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Alexander Rachevski, Irina Rashevskaya, Andrea Vacchi, Gianluigi Zampa, Nicola Zampa, Istituto Nazionale di Fisica Nucleare (Italy); Riccardo Campana, Claudio Labanti, Fabio Fuschino, INAF - IASF Bologna (Italy); Mahadi Ahangarianabhari, Giuseppe Bertuccio, Massimo Gandola, Politecnico di Milano (Italy); Piero Malcovati, Univ. degli Studi di Pavia (Italy); Pierluigi Bellutti, Claudio Piemonte, Antonino Picciotto, Nicola Zorzi, Fondazione Bruno Kessler (Italy)

The PixDD (Pixel Drift Detector) project is aimed at realizing of a fast, single-photon, pixelated focal plane detector for X-ray optics, operating in the energy range 0.5-10 keV with nearly Fano-limited energy resolution and pixel size smaller than 500 um x 500 um. The science driver is to overcome the count rate limitation related to imaging sensors (e.g., CCD) for application in X-ray astronomy and in synchrotron beamlines. The PixDD project started in early 2015 and it is being carried out in two phases. The first prototype will be a 4x4 Silicon Drift Detector with 500 um x 500 um pixels, 450 um thick. The read-out will be based on a 2D layout, where the 16 pixels will be read-out by SIRIO preamplifiers surrounding the detector. The second phase will produce a 32x32 pixel detector, 300 um x 300 um, and it will be read-out by a dedicated ASIC, developed in the context of the PixDD project, in a flip-chip configuration. In this paper we will describe the PixDD project and present its status and current results.

9905-124, Session PS3

Development of a pixelated CdTe detector module for a hard-x and gamma-ray imaging spectrometer application

José L. Galvèz, Consejo Superior de Investigaciones Científicas (Spain); Gabriel Artigues, Institut de Ciències de l'Espai (Spain); Margarita Hernanz, Laura Álvarez, Institut de Ciències de l'Espai (Spain)

Stellar explosions are relevant and interesting astrophysical phenomena. Since long ago we have been working on the characterization of novae and supernovae in X and gamma-rays, with the use of space missions. We have been also involved in feasibility studies of future instruments in the energy range from several keV up to a few MeV, in collaboration with other

research institutes. High sensitivities are essential to perform detailed studies of cosmic explosions and cosmic accelerators, e.g., Supernovae, Classical Novae, Supernova Remnants (SNRs), Gamma-Ray Bursts (GRBs), Pulsars, Active Galactic Nuclei (AGN).

In order to fulfill the combined requirement of high detection efficiency with good spatial and energy resolution, an initial module prototype based on CdTe pixel detectors is being developed. The detector dimensions are 12.5mm x 12.5mm x 2mm and with a pixel pitch of 1mm x 1mm. Two kinds of CdTe pixel detectors with different contacts have been tested: ohmic and Schottky. Each pixel is bump bonded to a fanout board made of Sapphire substrate and routed to the corresponding input channel of the readout VATAGP7.1 ASIC, to measure pixel position and pulse height for each incident gamma-ray photon. The study is complemented by the simulation of the CdTe module performance using the GEANT 4 and MEGALIB tools, which will help us to optimize the detector design, e.g. pixel size vs angular resolution.

We will report the spectroscopy characterization of the CdTe detector module as well as the study of the charge sharing.

9905-125, Session PS3

Development of a 32-detector CdTe matrix for the SVOM ECLAIRs x/gamma camera: test results of first flight models

Karine Lacombe, Carine Amoros, Jean-Luc Atteia, Institut de Recherche en Astrophysique et Planétologie (France); Marc Billot, Ctr. National d'Études Spatiales (France); Sandra Bordon, Institut de Recherche en Astrophysique et Planétologie (France); Bertrand Cordier, Commissariat à l'Énergie Atomique (France); Simon Delaigue, Jean-Pascal Dezalay, Maël Galliano, Institut de Recherche en Astrophysique et Planétologie (France); Olivier Gevin, Commissariat à l'Énergie Atomique (France); Olivier Godet, Institut de Recherche en Astrophysique et Planétologie (France); François Gonzalez, Philippe Guillemot, Ctr. National d'Études Spatiales (France); Baptiste Houret, Institut de Recherche en Astrophysique et Planétologie (France); Olivier Limousin, CEA-Ctr. de SACLAY (France); Francis Lugiez, Commissariat à l'Énergie Atomique (France); Karine Mercier, Ctr. National d'Études Spatiales (France); Guillaume Nasser, Roger Pons, Damien Rambaud, Pascale Ramon, Vincent Waegebaert, Institut de Recherche en Astrophysique et Planétologie (France)

ECLAIRs, a 2-D coded-mask imaging camera on-board the Sino-French SVOM space mission, will detect and locate Gamma-ray bursts (GRBs) in near real time in the 4 - 150 keV energy band. The design of ECLAIRs has been mainly driven by the objective of achieving an unprecedented low-energy threshold of 4 keV for this type of instrument. The detection plane is an assembly of 6400 Schottky CdTe semiconductor detectors of size 4x4x1 mm3 organized on elementary hybrid matrices of 4 x 8 detectors named XRDPIX, biased from -200V to -500V and operated at -20°C to minimize the leakage current and maximize the polarization time due to Schottky barrier lowering. The remarkable low-energy threshold required for the space detection plane is achieved thanks to an extensive characterization of the detectors, the development of a specific low-noise 32-channel ASIC, the realization of an innovative hybrid module composed of a thick film ceramic holding 32 CdTe detectors with their high voltage grid ("Detectors Ceramics"), associated to an HTCC ceramic housing the ASIC chip within an hermetic cavity ("ASIC Ceramics"). Finally we selected the coupling of each Detectors Ceramics with each ASIC Ceramics in order to enhance the uniformity of performance.

In this paper, we start describing the complete hybrid matrix, and then the manufacturing of a first set of 50 XRDPIX flight models (SAGEM company). Afterwards, we show tests results obtained on Detectors Ceramics, on ASIC Ceramics and on the whole modules. We analyze the different sources of noise such as design capacitances, leakage currents and ENC measurements to validate the specific technologies used for this hybridization. Then, in order to check the good pairing of each channel, we compare and confront all these values with the energy threshold and FWHM measured on spectral measurements made at the regulated temperature of -20°C in vacuum chambers by using a calibrated radioactive source of 241Am. We identify the best conditions of polarization and electronics parameters to ensure the optimum performance. We study of homogeneity of spectral properties of the 32-detector hybrid matrices and we present the ratio of more 1000 channels which could reach the key goal of a low-energy threshold of 4 keV. To finish, we conclude on the general performance required at the SVOM mission for almost a quarter of the future space camera.

9905-126, Session PS3

Directly-deposited blocking filters for high-performance silicon x-ray detectors

Marshall W. Bautz, Steven E. Kissel, Rebecca A. Masterson, Massachusetts Institute of Technology (United States); Kevin K. Ryu, Vyshnavi Suntharalingam, MIT Lincoln Lab. (United States)

Silicon X-ray detectors often require blocking filters to mitigate noise and out-of-band signal from UV and visible backgrounds. Such filters must be thin to minimize X-ray absorption, so direct deposition of filter material on the detector entrance surface is an attractive approach to fabrication of robust filters. On the other hand, the soft (E < 0.5 keV) X-ray spectral resolution of the detector is sensitive to the charge collection efficiency in the immediate vicinity of its entrance surface, so it is important that any filter layer is deposited without disturbing the electric field distribution there. We have successfully deposited aluminum blocking filters, ranging in thickness from 70 to 220nm, on high-performance CCD X-ray detectors. We report on the visible and X-ray response of filter-equipped devices.

Our methods have been used to deposit filters on the detectors of the REXIS instrument scheduled to fly on OSIRIS-ReX. REXIS has completed environmental testing and has been delivered for spacecraft integration. We discuss the current technology readiness level of this filter deposition technology.

9905-127, Session PS3

Generation of response matrix for multi-pixel CZT detectors

Tanmoy Chattopadhyay, Santoshv V. Vadawale, Physical Research Lab. (India); A. R. Rao, Tata Institute of Fundamental Research (India); Dipankar Bhattacharya, Inter-Univ. Ctr. for Astronomy and Astrophysics (India); Mithun N. P. S., Physical Research Lab. (India); Varun Bhalerao, Inter-Univ. Ctr. for Astronomy and Astrophysics (India)

Cadmium Zinc Telluride (CZT) detectors have been the workhorse in hard X-ray astronomy for a decade now, implemented in many X-ray observatories e.g. SWIFT, NuSTAR and more recently in ASTROSAT. Response matrix for CZT detectors requires precise modelling of the X-ray lines as a function of energy. Instead of showing simple Gaussian feature, these lines exhibit a long tail at lower energies because of trapping of the charge carriers due to their low mobility (μ) and lifetime (?). The effect is

found to be more significant for high energy photons as the probability of charge loss increases with the depth of interaction. Therefore, precise line modelling in case of CZT detectors needs accurate measurement of μ values for electrons and holes. For pixelated detectors, other significant components in the line modelling come from the crosstalk between the pixels due to charge sharing, fluorescence photons and Compton scattering. Charge sharing is expected to be quite significant making the CZT line profile further complicated. We have developed a numerical model taking into account all these physical processes to predict the CZT line shapes properly. The model is written in S-LANG and incorporated in spectral fitting package ISIS. Here we present the details of the numerical model and experimental measurements of mobility and lifetime of the charge carriers and the inter-pixel charge sharing fractions for 4 cm X 4 cm and 5 mm thick CZT detectors with pixel dimension of 2.5 mm X 2.5 mm, procured from Orbotech Medical Solutions (similar to the modules used in CZTI, Astrosat). In order to understand the charge sharing in the detectors in more detail, we did further experiments, results and implications of which will be discussed in this presentation.

Two possible configurations of a Compton effect polarimeter for hard x-rays in the framework of the COMPASS project

Ettore Del Monte, Alda Rubini, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Armando Brandonisio, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy) and Sapienza Univ. di Roma (Italy); Fabio Muleri, Paolo Soffitta, Enrico Costa, Giuseppe Di Persio, Sergio Di Cosimo, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Enrico Massaro, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy) and Sapienza Univ. di Roma (Italy); Alfredo Morbidini, Ennio Morelli, Luigi Pacciani, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Sergio Fabiani, Istituto Nazionale di Fisica Nucleare (Italy); Daniele Michilli, Astronomical Institute Anton Pannekoek (Netherlands) and ASTRON (Netherlands); Salvatore Giarrusso, Osvaldo Catalano, Domenico Impiombato, Teresa Mineo, Giuseppe Sottile, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Sergio Billotta, INAF - Osservatorio Astrofisico di Catania (Italy)

COMpton Polarimeter with Avalanche Silicon readout (COMPASS) is a research and development project that aims to measure the polarization of X-ray photons through Compton Scattering. The measurement is obtained by using a set of small rods of fast scintillation materials with both low-Z (as active scatterer) and high-Z (as absorber), all read-out with Silicon Photomultipliers. By this method we can operate scattering and absorbing elements in

coincidence, in order to reduce the background.

We are studying two configurations of satellite-borne instruments: i) a focal plane polarimeter with a single scattering element surrounded by an array of absorbers, to be coupled with a multilayer telescope for hard X-rays; ii) a large area and wide field of view polarimeter for transients and Gamma Ray Bursts composed of an array of scattering and absorbing elements, on hexagonal pattern.

In this paper we describe the two configurations of Compton Effect polarimeters and we report about the estimation of the scientific performances by means of analytical calculations and simulations.

Caliste-MM: a spectro-polarimeter for soft x-ray astrophysics based on the micromegas concept

Paul Serrano, David Attié, Esther Ferrer Ribas, Fabien Jeanneau, Olivier Limousin, Commissariat à l'Énergie Atomique (France)

Performing soft X-ray polarimetry in astrophysics is a topic of groing interest, giving strong information about the magnetic field of the observed sources. Only few flying experiments have been dedicated to it, and those experiments had a low sensitivity. Thanks to the development of gaseous detectors in the late 90s it became possible to use them to perform soft X-ray polarimetry, as a soft X-ray photon conversion in a gaseous detector uses the photo-electric effect : the photon is converted into a photo-electron which is ejected in a prefered azimuthal direction depending on the direction of the polarisation vector of the incident beam. By performing an histogram of the azimuthal direction of all the ejected photo-electrons, it is possible to recover the polarization direction of the source.

We used a gaseous detector based on the Micromegas concept, called the piggyback detector. Using the bulk technology, its particularity is its anode consisting only in a resistive layer spread on a ceramic plate : there are no readout electronics inside the gaseous detector, and the signal is read through the ceramic plate. Having the readout electronics outside the detector makes it easily interchangeable, and naturally protected from cosmic sparks without the need of using a protection card. The readout electronics used to read the signal must be low noise and sensitive enough to recover the signal through the ceramic, and finely pixelised to be able to recover the tracks of the photo-electrons. We decided to use the electronics called Caliste, initially developed for semi-conductor applications, but perfectly suited to read the signal of a piggyback, on top of being already space qualified.

The coupling of the piggyback detector and the Caliste readout electronics has been called Caliste-MM and various parameters, such as the gain, the influence of the distance between the ceramic and the readout electronics, or the influence of the resistivity of the detector, have been studied and modelised analytically, and the detector shows good performances. Its energy resolution in a mixture of Argon is less than 18 % FWHM at 6 keV which is the best that can be expected when using a gaseous detector based on the bulk technology : even with an outer and contactless electronics, we manage to recover the resolution of the gaseous detector alone and our device works as a spectrometer. But Argon being a high Z and high K-edge gas it is not suitable for soft X-ray polarimetry if it is used at atmospheric pressure, so it has been replaced by a mixture of Helium, and with it we are able to see good photo-electrons' tracks at 8 keV, and the reconstruction algorithm developed allows a good recovery of the ejection-direction of the photo-electrons, meaning that performing polarimetry with Caliste-MM is possible. The detector will soon be brought to a 100% polarized beam in order to measure the Q-factor of the detector, giving a last caracterization of our spectro-polarimeter with an outer and contactless electronics.

9905-130, Session PS4

Development of x-ray spectroscopic polarimetry with bent Si crystals and CFRP substrate

Ryo Iizuka, Institute of Space and Astronautical Science (Japan); Takanori Izumiya, Yohko Tsuboi, Chuo Univ. (Japan)

The light from celestial objects includes four important quantities; images, time variation, energy spectrum, and polarization. In the field of X-ray astronomy, the capabilities of the former three have remarkably developed. On the other hand, the progress for the polarimetry is considerably delayed because of technical difficulties. In order to make a breakthrough in the field of X-ray polarimetry, we have developed a new type of optics for X-ray polarimetry. The system is collecting Bragg crystal with large area and very high sensitivity for the polarization dedicated to Fe-K lines. We adopt the 400 reflection of Si(100) crystals with high sensitivity for the polarization around Fe-K lines (6 keV), and bent the crystals with the wide X-ray band and high S/N ratio. Furthermore, to install small area of CCD to non-focal plane, it also has the spectroscopic capability with the better resolution than that of general X-ray CCD.

Our previous development was to bent Si crystals to the cylindrical shape of circle and parabola with the DLC deposition. However, for the better optics for the X-ray polarimetry, the shape should be the paraboloid of revolution to collect X-rays with high S/N ratio. We searched for the method to bent the Si crystals to the shape of the paraboloid of revolution. We devised the method to mold the crystal and the CFRP substrate?simultaneously pushed to the sophisticated foundation with the paraboloid of revolution. We developed the prototype of about 8 inch in radius of one-quater size. The crystals was also bent in the circumferential direction. Therefore, the image capability examined with optical parallel beam is 0.5 degree. In this thesis, we discussed the new design for X-ray spectroscopic polarimetry, the evaluation of image capability, and comparison of other mission.

9905-131, Session PS4

Monte Carlo study of a 3D CZT spectro-imager used as scattering polarimeter for a balloon borne experiment

Ezio Caroli, Giovanni De Cesare, INAF - IASF Bologna (Italy); Rui M. Curado da Silva, Univ. de Coimbra (Portugal); Natalia Auricchio, INAF - IASF Bologna (Italy); Carl Budtz-Jørgensen, DTU Space (Denmark); Stefano Del Sordo, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Philippe R. Ferrando, CEA-Ctr. de SACLAY (France); José L. Gàlvez, Margarita Hernanz, Jordi Isern, Consejo Superior de Investigaciones Científicas (Spain); Irfan Kuvvetli, DTU Space (Denmark); Philippe Laurent, Olivier Limousin, CEA-Ctr. de SACLAY (France); Jorge M. Maia, M. Moita, Univ. de Coimbra (Portugal); Nicolas Produit, ISDC Data Ctr. for Astrophysics (Switzerland); John B. Stephen, INAF - IASF Bologna (Italy); Andrea Zappettini, Consiglio Nazionale delle Ricerche (Italy)

The measurement of the polarisation of the high-energy emission from cosmic sources has now become a key observational parameter for understanding the production mechanisms and the geometry of the regions involved. Therefore, a mandatory requirement for new instrumentation operating in this energy regime will be to provide high sensitivity for polarimetric measurements. In this framework, we describe the concept of a small high-performance imaging spectrometer optimized for polarimetry between 100 and 600 keV suitable for use as a stratospheric balloon-borne payload and as a pathfinder for a future satellite mission. The detector, with 3D spatial resolution, is a CZT based spectrometer in a highly segmented configuration designed to operate simultaneously as a high performance scattering polarimeter. Herein, we report on the results of a Monte Carlo study devoted to optimize the configuration of the detector for polarimetry and to evaluate the achievable performance in term of minimum detectable polarisation (MDP). In particular, we present the results for some feasible geometrical configurations (thickness and pixel/voxel scales) in presence of different background models and by using various event filters in order to maximize the MDP. Furthermore, to assess the reliability of the implemented numerical model, we compare Monte Carlo results with experimental data obtained with the high performance CZT spectro-imager module Caliste.

9905-132, Session PS4

Performances of the gas pixel detector: an x-ray imaging polarimeter for upcoming missions of astrophysics

Fabio Muleri, INAF - IASF Roma (Italy)

The Gas Pixel Detector allows for making imaging X-ray polarimetry resolved in energy and time in the classical energy band for X-ray Astronomy. It is already built in a configuration suitable for flight and in this paper we present its main characteristics, including a measurement of stability in almost three years of operation, for both the energy resolution and the modulation factor. We also show energy dependent position resolution, modulation factor and energy resolution all obtained at the calibration and test facility at IAPS-INAF. The results of these measurements show that the performances are such to fulfill already the requirements for XIPE, a mission under study for ESA M4 and for IXPE a mission in phase A for NASA/SMEX.

9905-133, Session PS4

The on-board calibration system of XIPE

Silvia Zane, Berend Winter, Mullard Space Science Lab. (United Kingdom)

The calibration system for XIPE is aimed at providing a way to check and correct possible variations of performances of the Gas Pixel Detector during the three years of operation in orbit, while facilitating the observation of the celestial sources. This will be performed by using a filter wheel with a large heritage having a set of positions for the calibration and the observation system. In particular it will allow for correcting possible gain variation, for measuring the modulation factor using a polarized source, for removing non interesting bright sources in the field of view and for observing very bright celestial sources. The on-board calibration system is composed of three filter wheels, one for each detector and it is expected to operate for a small number of times during the year. Moreover, since it operates once at a time, within the observation mode, it allows for simultaneous calibration and acquisition from celestial sources. In this paper we present the scope and the requirements of the on-board calibration system, its design, and a description of its possible use in space.

The ASTRO-H x-ray astronomy satellite

Tadayuki Takahashi, Motohide Kokubun, Kazuhisa Mitsuda, Institute of Space and Astronautical Science

(Japan) and Japan Aerospace Exploration Agency (Japan); Richard L. Kelley, NASA Goddard Space Flight Ctr. (United States); Takaya Ohashi, Tokyo Metropolitan Univ. (Japan)

ASTRO-H, the new Japanese X-ray Astronomy Satellite following Suzaku, is an international X-ray mission, planed for launch in Feb, 2016. ASTRO-H is a combination of wide band X-ray spectroscopy (3 - 80 keV) provided by focusing hard X-ray mirrors and hard X-ray imaging detectors, and high energy-resolution soft X-ray spectroscopy (0.3 - 10 keV) provided by thin-foil X-ray optics and a micro-calorimeter array. The mission will also carry an X-ray CCD camera as a focal plane detector for a soft X-ray telescope and a non-focusing soft gamma-ray detector based on a narrow-FOV semiconductor Compton Camera. With these instruments, ASTRO-H covers very wide energy range from 0.3 keV to 600 keV. The simultaneous broad band pass, coupled with high spectral resolution of <7 eV by the micro-calorimeter will enable a wide variety of important science themes to be pursued. The ASTRO-H mission objectives are to study the evolution of yet-unknown obscured super massive Black Holes in Active Galactic Nuclei; trace the growth history of the largest structures in the Universe; provide insights into the behavior of material in extreme gravitational fields; trace particle acceleration structures in clusters of galaxies and SNRs; and investigate the detailed physics of jets. In this presentation, we will describe the mission, scientific goal and report the initial performance on the orbit.

9905-28, Session 7

The ASTRO-H high-resolution soft x-ray spectrometer

Richard L. Kelley, NASA Goddard Space Flight Ctr. (United States); Kazuhisa Mitsuda, Institute of Space and Astronautical Science (Japan); SXS Team, NASA/JAXA (United States)

We describe the overall design and performance of the Soft X-Ray Spectrometer (SXS) for the JAXA Astro-H mission, to be launched in February 2016. The instrument is based on a 36-pixel array of semiconductor microcalorimeters designed for high resolution over the 0.3-12 keV energy band at the focus of a high throughput, grazing-incidence x-ray mirror. The instrument was designed to provide high-resolution, non-dispersive spectroscopy over a large simultaneous bandpass, and is a joint collaboration between the JAXA Institute of Space and Astronautical Science and many partners in Japan, and the NASA/Goddard Space Flight Center and collaborators in the US. The principal components of the spectrometer are the microcalorimeter detector system, a low-temperature anticoincidence detector, a 3-stage adiabatic demagnetization refrigerator (ADR) to maintain 50 mK operation under both cryogen and cryogen-free operation, a hybrid liquid helium/cryogen-free dewar with both Stirling and Joule Thomson coolers, and electronics for reading out the array, processing the x-ray data for spectroscopy, and operating the ADR and cryocoolers. The dewar is closed out by a complex aperture system that has five thin-film filters designed to provide high x-ray transmission with low heat loads to the dewar and detector system, and prevent contamination from condensing on the filters.

The instrument was designed to have better than 7 eV energy resolution, and was demonstrated to achieve 4-5 eV resolution across the array at the full level of spacecraft integration during extensive ground testing prior to launch. The overall cooling chain was designed to provide a lifetime of at least 3 years in orbit, and continue to operate without liquid helium to provide redundancy and the longest operational lifetime for the instrument. The instrument was tested in both modes prior to launch, and provides about 43 hours of hold time at 50 mK in cryogen mode (1.2K He temperature) with a 45 min recycle time, and about 14.7 hours at 50 mK in cryogen-free mode with a 2.5 hour recycle time (He tank maintained at 1.525K by the third stage ADR).

Among the many challenges for the instrument is maintaining an end-end knowledge of the absolute energy scale of the instrument to better than 2 eV. This has been done on the ground using an extensive series of calibration measurements over a very wide energy range, and at multiple array temperatures. The in-flight energy scale is maintained using controllable x-ray sources mounted just above the entrance to the dewar aperture that can be used simultaneously with celestial observations.

In this presentation, we will describe the SXS instrument and cover its main design elements, and give an overview of the ground and early in-flight performance.

This presentation is being given on behalf of the very large international team that developed this complex instrument.

9905-29, Session 7

In-flight performance of the soft x-ray spectrometer detector system on ASTRO-H

Frederick S. Porter, Kevin R. Boyce, Meng P. Chiao, Megan E. Eckart, NASA Goddard Space Flight Ctr. (United States); Ryuichi Fujimoto, Kanazawa Univ. (Japan); Richard L. Kelley, Caroline A. Kilbourne, Maurice A. Leutenegger, NASA Goddard Space Flight Ctr. (United States); Yoshitaka Ishisaki, Tokyo Metropolitan Univ. (Japan); Dan McCammon, Univ. of Wisconsin-Madison (United States); Kazuhisa Mitsuda, Institute of Space and Astronautical Science (Japan); Makoto Sawada, Aoyama Gakuin Univ. (Japan); Gary A. Sneiderman, NASA Goddard Space Flight Ctr. (United States); Andrew E. Szymkowiak, Yale Univ. (United States); Yoh Takei, Institute of Space and Astronautical Science (Japan); Makoto S. Tashiro, Saitama Univ. (Japan); Masahiro Tsujimoto, Japan Aerospace Exploration Agency (Japan); Tomomi Watanabe, NASA Goddard Space Flight Ctr. (United States); Shinya Yamada, Tokyo Metropolitan Univ. (Japan)

The SXS instrument will be launched aboard the Astro-H observatory in early February, 2016. The SXS spectrometer is based on a high sensitivity x-ray calorimeter detector system that has been successfully deployed in many ground and sub-orbital spectrometers. However, the SXS will be the first long-term implementation in space. The instrument will provide essential diagnostics for nearly every class of x-ray emitting objects from the atmosphere of Venus to the outskirts of galaxy clusters, without degradation for spatially extended objects. The SXS detector system consists of a 36 pixel cryogenic microcalorimeter array operated at a heat sink temperature of 50mK. In pre-flight testing, the detector system demonstrated a resolving power of better than 1300 at 6 keV with a simultaneous bandpass from below 0.3 keV to above 12 keV with a timing precision below 100 us. In addition, a solid stage anti-coincidence detector is placed directly behind the detector array for background suppression. The detector error budget includes the measured interference from the SXS cooling system and the spacecraft. Additional margin for on-orbit gain-stability, and on-orbit spacecraft interference are also included in the error budget predicting an on-orbit performance that meets or exceeds the 7 eV FWHM at 6 keV requirement. Here we discuss the actual on-orbit performance of the SXS detector system and compare this to performance in pre-flight testing and the on-orbit predictions. We will also discuss the on-orbit gain stability, any additional on-orbit interference, and early measurements of the on-orbit background.

9905-30, Session 7

Vibration isolation system for cryocoolers of xoft x-ray spectrometer onboard ASTRO-H

Yoh Takei, Susumu Yasuda, Japan Aerospace Exploration Agency (Japan); Kosei Ishimura, Institute of Space and Astronautical Science (Japan); Naoko Iwata, Atsushi Okamoto, Yoichi Sato, Mina Ogawa, Japan Aerospace Exploration Agency (Japan); Makoto Sawada, Aoyama Gakuin Univ. (Japan); Taro Kawano, Shingo Obara, Japan Aerospace Exploration Agency (Japan); Chikara Natsukari, Institute of Space and Astronautical Science (Japan); Atsushi Wada, Japan Aerospace Exploration Agency (Japan); Shinya Yamada, Tokyo Metropolitan Univ. (Japan); Ryuichi Fujimoto, Kanazawa Univ. (Japan); Motohide Kokubun, Institute of Space and Astronautical Science (Japan); Noriko Y. Yamasaki, Hiroyuki Sugita, Kenji Minesugi, Yasuo Nakamura, Kazuhisa Mitsuda, Tadayuki Takahashi, Japan Aerospace Exploration Agency (Japan); Seiji Yoshida, Shoji Tsunematsu, Kenichi Kanao, Katsuhiro Narasaki, Kiyomi Otsuka, Sumitomo Heavy Industries, Ltd. (Japan)

The design and performance of vibration isolation system used for Soft Soft X-ray Spectrometer (SXS) onboard Astro-H will be presented. SXS onboard Astro-H is a microcalorimeter-type spectrometer. A microcalorimeter is a thermometer-based detector, measuring X-ray energy of a X-ray photon as temperature increase by each X-ray photon input. SXS detector is installed in a dewar and cooled at 50~mK to have a good sensitivity in measuring temperature increase with high resolution. It is also sensitive to any other energy input, including micro-vibration. This kind of stray energy input could increase the noise of the detector and cause gain variation, both of which could significantly degrade the energy resolution of the detector. The energy resulution of the SXS engineering model indeed suffered from micro-vibration from cryocoolers (two-stage Stirling coolers) used for cooling the dewar. The microvibration in the frequency of several hundred Hz was transmitted to inside the dewar, stimulating the vibration of detector cold stage, and inducing a variable heat input on to the detector heat sink. This variation in heat load caused significant gain variation of the detector, resulting in unacceptable degradation in energy reslution; five times worse than the requirement. This influence of microvibration was mitigated in flight model program, by introducing vibration isolation system between the cryocoolers and the dewar. The vibration isolation system consists of flexure springs that isolates the vibration from cryocoolers, bumpers that restricts the displacement by mechanical load at launch, and thermal straps that compensates the reduced thermal connection between each cryocooler and the dewar by introducing the vibration isolation system. The vibration isolation system was carefully designed to achieve two conflicting requirements: to have small transmissibility for microvibration in several hundred Hz range, requiring low natural frequency of the flexure, and to avoid too large amplification for launch vibration, requiring not-too-low natural frequency. The detector performance with the vibration isolation system was verified in both ambient condition and thermal-vac condition, showing no detectrable degradation in energy resolution.

ASTRO-H is an X-ray observatory scheduled to be launched in Feb 2016. The soft X-ray spectrometer (SXS) onbaord the satellite is one of the payloads using an X-ray calorimeter array at a focus of X-ray telescope. SXS has an unprecedented spectroscopic performance particularly in the about 2-15 keV band. The sensor working temperature is controlled at 50 mK by a multiple cooling chain using adiabatic demagnetization refrigerators, mechanical cryo-coolers, and liquid He.

SXS is a cold-launch system, which is launched without power. However, it is powered just before launch and soon after launch to prevent warm-up of the system and immediate He venting in the orbit. A series of time-critical operations is planned in the first few weeks for the first light as early as possible. In this presentation, we summarize the result of the in-orbit operation covering from the launch to the transition to the normal observing operation.

9905-32, Session 7

First peek of ASTRO-H soft x-ray telescope (SXT) in-orbit performance

Takashi Okajima, Yang Soong, Peter J. Serlemitsos, Hideyuki Mori, Lawrence G. Olsen, David Robinson, Richard G. Koenecke, William Chang, NASA Goddard Space Flight Ctr. (United States); Devin Hahne, Johns Hopkins Univ. Applied Physics Lab., LLC (United States); Ryo Iizuka, Manabu Ishida, Yoshitomo Maeda, Institute of Space and Astronautical Science (Japan); Toshiki Sato, Naomichi Kikuchi, Sho Kurashima, Nozomi Nakaniwa, Institute of Space and Astronautical Science (Japan) and Tokyo Metropolitan Univ. (Japan); Takayuki Hayashi, Nagoya Univ. (Japan) and NASA Goddard Space Flight Ctr. (United States); Kazunori Ishibashi, Takuya Miyazawa, Kenji Tachibana, Keisuke Tamura, Akihiro Furuzawa, Yuzuru Tawara, Nagoya Univ. (Japan); Satoshi Sugita, Ehime Univ. (Japan)

ASTRO-H is a Japanese X-ray astrophysics satellite under the development led by Japan and US. It has been completed and is scheduled to be launched in February, 2016, from Tanegashima, Japan by a JAXA H-IIA launch vehicle. It has two Soft X-ray Telescopes (SXTs), among other instruments, that were developed by NASA's Goddard Space Flight Center. One is for an X-ray micro-calorimeter instrument and the other for an X-ray CCD camera, both covering the X-ray energy band up to ~15 keV. The SXT employs a conically approximated Wolter I grazing incidence optic with 203 nested shells. The SXT design builds on the legacy of Suzaku mirrors and has a focal length of 5.6 m and a diameter of 45 cm. Each shell is segmented and its gold reflecting surface is replicated from a Pyrex glass tube onto a 0.15-0.3 mm thick shell substrate with an epoxy buffer layer.

The two flight SXTs have been completed and delivered to ISAS/JAXA in Japan for full X-ray characterization at their X-ray beamline, and then transported to JAXA Tsukuba Space Center for the spacecraft integration. The SXT has been successfully installed and aligned to the spacecraft observing axis as well as the calorimeter/CCD instrument. The SXT performance, such as on/off-axis effective area, on/off-axis point spread function (PSF) was measured on ground. Amount of the stray light from off-axis angles was also measured.

Furthermore, local effective area and PSF across the mirror were measured in order to optimize a ray-tracing simulator to reproduce the SXT performance as well as possible, which will be used to generate a SXT response for astronomical observations. According to the ground calibration, the on-axis angular resolution is about 1.2 arcmin (HPD), independent of energy, and the on-axis effective area is about 590 and 380 cm^2 at 1.5 and 8 keV, respectively, yet the SXT weighs only 42 kg. The amount of the stray light is found to be much less than that of the Suzaku telescope. All the measured performance met the project requirement and actually exceeded the goal in the original proposal. In this paper, we will present the overview of the SXT design as well as the in-flight SXT performance for the first time, by comparing with the ground calibration results and the ray-tracing simulations, particularly the PSF and the end-end effective area for the calorimeter and the CCD instrument. Due to the extremely high energy resolution of the calorimeter system (~5 eV), a prominent feature may be seen in a observed spectrum around the gold M and L absorption edges. We will also discuss such a feature by comparing with ground measurement results of individual reflectors obtained at a synchrotron facility.

9905-33, Session 8

Soft x-ray imager (SXI) onboard ASTRO-H

Hiroshi Tsunemi, Kiyoshi Hayashida, Hiroshi Nakajima, Naohisa Anabuki, Ryo Nagino, Osaka Univ. (Japan); Takeshi Go Tsuru, Takaaki Tanaka, Hiroyuki Uchida, Kyoto Univ. (Japan); Masayoshi Nobukawa, Nara Univ. of Education (Japan); Tadayasu Dotani, Hiroshi Tomida, Masanobu Ozaki, Chikara Natsukari, Shutaro Ueda, Institute of Space and Astronautical Science (Japan); Koji Mori, Makoto Yamauchi, Isamu Hatsukade, Yusuke Nishioka, Univ. of Miyazaki (Japan); Junko S. Hiraga, Kwansei Gakuin Univ. (Japan); Hiroshi Murakami, Tohoku Gakuin Univ. (Japan); Takayoshi kohmura, Tokyo Univ. of Science (Japan); Aya Bamba, Aoyama Gakuin Univ. (Japan); SXI Team, SXI team (Japan)

We have developed an X-ray CCD camera, the Soft X-ray Imager (SXI) onboard the ASTRO-H satellite. The SXI consists of 4 CCDs with an effective area of 60mm square. The CCD is a P-channel type, back-illumination, resulting in a depletion layer of 200um. The physical pixel size is 24um square while we will run the SXI in 2x2 pixel binning mode that allows us to employ a similar method for event detection to those developed for ASCA and Suzaku. Since we demonstrated the validation of the artificial charge injection on the CCD against the CTI degradation in space, we apply it to the SXI from the beginning of the mission. We have designed the surrounding electronics for the CCD based on those developed for ASCA and Suzaku. We introduce an analog ASIC in the front-end electronics so that we can reduce the weight, size and power. We employ two mechanical coolers to cool CCDs around -110C. We can cool CCDs more in case that we notice a degradation of the CCDs due to the radiation damage.

There are two types of soft X-ray detectors onboard ASTRO-H: SXI and an X-ray calorimeter (SXS). Both of them are placed at the focal plane for individual soft X-ray telescope (SXT) that are looking at the same direction. The SXI has a large field of view (FOV, 38' square), ten times larger than that of the SXS although the SXS has an excellent energy resolution. Therefore, we can obtain a detailed spectrum at the aim point by the SXS and an image around it by the SXI. The SXI covers the energy range from 0.4keV to 12keV. There are a few absorbing materials above the CCD: a thermal shield of the SXT, a contamination blocking filter for the SXI and a SiO_2 layer on the CCD. They determine the low energy end of the SXI. The high energy end is limited by the SXT.

ASTRO-H passed the final review at the end of 2015 and will be launched in the beginning of 2016. It will be commissioned soon after the initial check-out phase. In the SPIE symposium, we will be able to report the first light of the SXI. Based on the previous satellites, we notice that there are some ambiguities in the CCD spectrum due to its insufficient energy resolution. Sometimes, we have to add an extra emission line around 1.2keV that must come from Fe-L transitions. We do not know how much fraction below 1keV is contributed by the continuum component since there are so many emission lines clustered there in thin thermal plasma. By combining the SXI and SXS results, we will be able to practically demonstrate what generates the CCD spectrum. We expect that this knowledge will help us to know the detailed spectrum whole through the entire FOV of the SXI.

9905-34, Session 8

The hard x-ray imager (HXI) onboard ASTRO-H

Kazuhiro Nakazawa, The Univ. of Tokyo (Japan); Goro Sato, Motohide Kokubun, Institute of Space and Astronautical Science (Japan) and Japan Aerospace

Exploration Agency (Japan); Teruaki Enoto, Kyoto Univ. (Japan); Yasushi Fukazawa, Hiroshima Univ. (Japan); Kouichi Hagino, Atsushi Harayama, Katsuhiro Hayashi, Institute of Space and Astronautical Science (Japan) and Japan Aerospace Exploration Agency (Japan); Jun Kataoka, Waseda Univ. (Japan); Junichiro Katsuta, Hiroshima Univ. (Japan); Madoka Kawaharada, Japan Aerospace Exploration Agency (Japan); Philippe Laurent, CEA-Ctr. de SACLAY (France); François Lebrun, AstroParticule et Cosmologie (France); Olivier Limousin, CEA-Ctr. de SACLAY (France); Kazuo Makishima, RIKEN (Japan); Daniel Maier, CEA-Ctr. de SACLAY (France); Tsunefumi Mizuno, Hiroshima Univ. (Japan); Kunishiro Mori, Institute of Space and Astronautical Science (Japan) and Japan Aerospace Exploration Agency (Japan); Takeshi Nakamori, Yamagata Univ. (Japan); Toshio Nakano, The Univ. of Tokyo (Japan); Hirofumi Noda, RIKEN (Japan); Hirokazu Odaka, Kavli Institute for Particle Astrophysics & Cosmology (United States); Masanori Ohno, Hiroshima Univ. (Japan); Masayuki Ohta, Institute of Space and Astronautical Science (Japan) and Japan Aerospace Exploration Agency (Japan); Shinya Saito, Rikkyo Univ. (Japan); Rie Sato, Institute of Space and Astronautical Science (Japan) and Japan Aerospace Exploration Agency (Japan); Hiroyasu Tajima, Nagoya Univ. (Japan); Tadayuki Takahashi, Institute of Space and Astronautical Science (Japan) and Japan Aerospace Exploration Agency (Japan); Shin'ichiro Takeda, Okinawa Institute of Science and Technology Graduate Univ. (Japan); Yukikatsu Terada, Saitama Univ. (Japan); Hideki Uchiyama, Shizuoka Univ. (Japan); Yasunobu Uchiyama, Rikkyo Univ. (Japan); Shin Watanabe, Institute of Space and Astronautical Science (Japan) and Japan Aerospace Exploration Agency (Japan); Kazutaka Yamaoka, Nagoya Univ. (Japan); Yoichi Yatsu, Tokyo Institute of Technology (Japan); Takayuki Yuasa, RIKEN (Japan)

ASTROH is the sixth of a series of Japanese X-ray astronomy satellite, to be launched into orbit in early 2016. The 2.5 t large mission is designed for; (1) high-resolution soft X-ray spectroscopy (at 0.3-12 keV), with resolving power >1000 at 6 keV using X-ray micro-calorie-meter (SXS) coupled with a soft X-ray telescope (SXT), and (2) wide-band coverage up to 600 keV. Among them, 5—80 keV imaging spectroscopy is achieved with the hard X-ray imaging spectrometers (HXIs) coupled with hard X-ray telescopes (HXTs), with angular resolution of 2' half-power diameter (HPD). Soft energy band is covered with a X-ray CCD (SXI) coupled with another SXT, and two soft gamma-ray detectors (SGDs, non-imaging) cover up to 600 keV.

The hard X-ray imager (HXI) is located at the bottom of the satellite, at the 12 m long focal position of the HXT. ASTRO-H carries 2 set of this system, providing in total of 300 cm2 effective area at 30 keV. It has a field-of-view 9'.2x9'.2 wide and are designed to detect sources as dim as a few times 1/1000,000 of the Crab nebula. To obtain a good overlap with the SXI (working up to 12 keV) and also cover the Fe-K line complex, it is required to able to observe down to 5 keV.

The HXI imager is made of 5 layers of semiconductor double-sided strip detectors (DSDs); 4 layers of Si (DSSDs) at the top, and a CdTe layer (CdTe-DSD) at the bottom. The strip pitch is 250 um, covering 3.2x3.2 cm2 area with 128x128 strips orthogonally oriented in the cathode and anode sides. In total 1280 ch of signals are read-out via specially designed analog ASICs, VA32TAs, featuring low power and good energy resolution of 1 keV (full width at half maximum; FWHM) for the DSSDs and 2 keV for the CdTe-DSD.

The semiconductor imagers are covered almost in 4-pi direction with ~3 cm thick BGO scintillators. There are 9 BGO units all read out via avalanche photo-diode to provide anti-coincidence signal to the imager, in order to reduce in-orbit background signals generated from cosmic and albedo X-rays, as well as cosmic-rays protons and material activations from them.

Flight model detectors of the HXI was manufactured in 2014, and mounted, integrated and tested on the satellite throughout 2015. The system successfully went through all the mechanical, thermal and electrical tests. The energy resolution, lower threshold, and low background were verified to meet the requirement, and all system is ready for launch. After the launch, the satellite will be activated gradually. The extendable optical bench equipped at the HXI-mounted plate will be deployed by ~6 m long prior to the HXI power on. Then, all the operation parameters and bias will be applied for actual observations of high-energy celestial targets, the first lights and continue observations afterwards.

9905-35, Session 8

Performance of ASTRO-H hard x-ray telescope (HXT)

Hisamitsu Awaki, Ehime Univ. (Japan); Hideyo Kunieda, Nagoya Univ. (Japan); Manabu Ishida, Institute of Space and Astronautical Science (Japan); Hironori Matsumoto, Akihiro Furuzawa, Nagoya Univ. (Japan); Yoshito Haba, Aichi Univ. of Education (Japan); Takayuki Hayashi, Nagoya Univ. (Japan) and NASA Goddard Space Flight Ctr. (United States); Ryo Iizuka, Institute of Space and Astronautical Science (Japan); Kazunori Ishibashi, Nagoya Univ. (Japan); Masayuki Itoh, Kobe Univ. (Japan); Tatsuro Kosaka, Kochi Univ. of Technology (Japan); Yoshitomo Maeda, Institute of Space and Astronautical Science (Japan); Ikuyuki Mitsuishi, Takuya Miyazawa, Nagoya Univ. (Japan); Hideyuki Mori, NASA Goddard Space Flight Ctr. (United States); Hosei Nagano, Nagoya Univ. (Japan); Yoshiharu Namba, Chubu Univ. (Japan); Yasushi Ogasaka, Japan Science and Technology Agency (Japan); Keiji Ogi, Satoshi Sugita, Ehime Univ. (Japan); Yoshio Suzuki, Japan Synchrotron Radiation Research Institute (JASRI) (Japan); Keisuke Tamura, Yuzuru Tawara, Nagoya Univ. (Japan); Kentaro Uesugi, Japan Synchrotron Radiation Research Institute (JASRI) (Japan); Shigeo Yamauchi, Nara Women's Univ. (Japan); Takashi Okajima, NASA Goddard Space Flight Ctr. (United States)

The Japanese X-ray Astronomy Satellite, ASTRO-H carries hard X-ray imaging system, covering the energy band from 5 keV to 80 keV.

The hard X-ray imaging system consists of two hard X-ray telescopes (HXT) and the focal plane detectors (HXI). The HXT employs tightly-nested, conically-approximated thin foil Wolter-I optics. The mirror surfaces of HXT are coated with Pt/C depth-graded multilayers.

We carried out ground calibrations of HXTs at the synchrotron radiation facility SPring-8/ BL20B2 Japan, and found that total effective area of two HXTs was about 350 cm2 at 30 keV, and the half power diameter of HXT was about 1.9 arcmin. The calibration data on ground is used to make parameter files of the raytrace program which simulates the X-ray performance of XRTs onboard ASTRO-H. The pre-launch parameters files are going to be archived in the ASTRO-H calibration database. We will perform in-flight calibrations of HXTs in order to perform a fine tuning of the parameter files.

9905-36, Session 8

The soft gamma-ray detector (SGD) onboard ASTRO-H

Shin Watanabe, Institute of Space and Astronautical Science (Japan); Hiroyasu Tajima, Nagoya Univ. (Japan); Yasushi Fukazawa, Hiroshima Univ. (Japan); Roger D. Blandford, Stanford Univ. (United States); Katsuhiro Hayashi, Institute of Space and Astronautical Science (Japan); Jun Kataoka, Waseda Univ. (Japan); Junichiro Katsuta, Takao Kitaguchi, Hiroshima Univ. (Japan); Motohide Kokubun, Institute of Space and Astronautical Science (Japan); Philippe Laurent, CEA-Ctr. de SACLAY (France); François Lebrun, CEA-IRFU (France); Olivier Limousin, CEA-Ctr. de SACLAY (France); Grzegorz M. Madejski, Kavli Institute for Particle Astrophysics & Cosmology (United States); Kazuo Makishima, RIKEN (Japan); Tsunefumi Mizuno, Hiroshima Univ. (Japan); Kunishiro Mori, Institute of Space and Astronautical Science (Japan); Takeshi Nakamori, Yamagata Univ. (Japan); Kazuhiro Nakazawa, The Univ. of Tokyo (Japan); Hirokazu Odaka, Kavli Institute for Particle Astrophysics & Cosmology (United States); Masanori Ohno, Hiroshima Univ. (Japan); Masayuki Ohta, Goro Sato, Rie Sato, Institute of Space and Astronautical Science (Japan); Shin'ichiro Takeda, Okinawa Institute of Science and Technology Graduate Univ. (Japan); Hiromitsu Takahashi, Hiroshima Univ. (Japan); Tadayuki Takahashi, Institute of Space and Astronautical Science (Japan); Takaaki Tanaka, Kyoto Univ. (Japan); Yasuyuki Tanaka, Hiroshima Univ. (Japan); Yukikatsu Terada, Saitama Univ. (Japan); Hideki Uchiyama, Shizuoka Univ. (Japan); Yasunobu Uchiyama, Rikkyo Univ. (Japan); Kazutaka Yamaoka, Nagoya Univ. (Japan); Yoichi Yatsu, Tokyo Institute of Technology (Japan); Daisuke Yonetoku, Kanazawa Univ. (Japan); Takayuki Yuasa, RIKEN (Japan)

ASTRO-H is the next generation X-ray satellite in Japan, and intended to carry instruments with broad energy coverage and exquisite energy resolution. The Soft Gamma-ray Detector (SGD) is one of ASTRO-H instruments and will feature wide energy band (60--600 keV) with a lower background level by a factor of 10 than the past observatories. The SGD achieves low background by combining two technologies; a Compton camera scheme where Compton kinematics is utilized to reject backgrounds and a narrow field-of-view active shield which was realized by the Suzaku HXD. The Compton camera in the SGD is realized as a hybrid semiconductor detector system which consists of silicon and CdTe (cadmium telluride) sensors. Good energy resolution of semiconductor sensors and readout ASICs leads to a good background rejection capability with better constraints on Compton kinematics. Utilization of Compton kinematics also enable the SGD to measure the gamma-ray polarization, opening up a new window to study cosmic gamma-ray emission processes. In this paper, we will present the evaluation test results of the flight model during the ground calibration test and the final thermal vacuum test. Moreover, we will also present the on-orbit observation results.

9905-37, Session 8

ASTRO-H data analysis, processing, and archive

Lorella Angelini, NASA Goddard Space Flight Ctr. (United States)

Astro-H is the next major international X-ray/Gamma-ray mission set to launch in February 2016. The complex payload consists of four different types of instruments (SXS, SXI, HXI and SGD) that operate simultaneously and provide data in the 0.3 keV- 600 keV energy band. After an initial PV phase, Astro-H operates as an observatory with time open to the astronomy community via competitive proposals. This paper presents the analysis software created to calibrate and analyze the data along with the plan for the archive and user support. This has been a collaborative effort shared between scientists and software engineers working in Japan and USA.

Data are translated in FITS event format, directly from the telemetry. The software, built under the FTOOLs environment, operates directly on the event FITS files and calibrates the time, energy and coordinate domains using calibration information stored in an external calibration database (CALDB). The calibration database is updated throughout the mission to account variation of the instruments performance. The software has been trained with data taken during the integration and test of satellite.

A common approach across the instruments has been used to assign time and coordinate information and a new ray-tracing code can model both the low energy telescopes used in conjunction with the SXS and SXI instruments as well as the high-energy telescope used in conjunction with the HXI. Many of the existing general FTOOLs are used via scripts to extract source light curve, images and spectrum. The package also includes a new graphical user interface aimed to help in the energy line recognition detected by the calorimeter instrument, SXS, as well as a simulator for proposal preparation that may be used in conjunction with the ray-tracing.

The software is distributed to the community via the HEASARC, together with CALDB, and it is also integrated in the processing pipeline. The products of the processing pipeline are calibrated events as well as 'filtered' data and high level products. The Astro-H data, outputs of the pipeline processing, are archived both in Japan and USA.

9905-38, Session 9

XIPE: the x-ray imaging polarimetry explorer

Paolo Soffitta, Istituto Nazionale di Astrofisica (Italy)

XIPE the X-ray Imaging Polarimetry Explorer has been selected for Study Phase for ESA M4 along with other two missions operating in very different fields. It is expected to re-open the window of X-ray polarimetry after 40 years from the last positive measurement of the Crab Nebula made by OSO-8 by means of Bragg diffraction, but now exploiting the photoelectric effect in gas. Its payload consists of only three Gas Pixel Detectors at the focus of three large area, low weight but having a good angular resolution, electroformed mirror shells.

Now, thanks to its moderate resources, it will be possible to measure X-ray polarization in hundreds of sources for studying in a novel way almost all the classes in high energy Astrophysics, since they are polarized at least as at some extent. XIPE is supposed to operate for three years. 75 % of the data will be available worldwide, through a competitive Guest Observer program, while the remaining 25 % will be exploited from the team, as core program to guarantee its minimum science return. All data will be made public after one year.

9905-39, Session 9

The polarimeter for relativistic astrophysical x-ray sources

Keith M. Jahoda, Timothy R. Kallman, NASA Goddard Space Flight Ctr. (United States); Chryssa Kouveliotou, The George Washington Univ. (United States); Lorella Angelini, J. Kevin Black, Joanne E. Hill, NASA Goddard Space Flight Ctr. (United States); Theodore Jaeger, Johns Hopkins Univ. Applied Physics Lab., LLC (United States); Philip E. Kaaret, The Univ. of Iowa (United States); Craig B. Markwardt, Takashi Okajima, Robert Petre, Jeremy Schnittman, Yang Soong, Tod E. strohmayer, NASA Goddard Space Flight Ctr. (United States); Toru Tamagawa, RIKEN (Japan); Yuzuru Tawara, Nagoya Univ. (Japan)

The Polarimeter for Relativistic Astrophysical X-ray Sources (PRAXyS) is one of three Small Explorer (SMEX) missions selected by NASA for Phase A study, with a launch date in 2020. The PRAXyS Observatory exploits grazing incidence X-ray mirrors and Time Projection Chamber Polarimeters capable of measuring the linear polarization of cosmic X-ray sources in the 2-10 keV band. PRAXyS combines well characterized instruments with spacecraft rotation to ensure low systematic errors. The PRAXyS payload is developed at the Goddard Space Flight Center with readout components from the JHU Applied Physics Laboratory and JAXA. The LeoStar-2 spacecraft bus is developed by Orbital ATK, which also supplies the extendable optical bench that enables the Observatory to be compatible with a Pegasus class launch vehicle.

A nine month primary mission will provide sensitive observations of multiple black hole and neutron star sources where theory predicts polarization is a strong diagnostic as well as exploratory observations of other high energy sources. The PRAXyS team is committed to releasing the primary mission data to the community rapidly as well as to vigorous support for a Guest Observer driven extended mission.

9905-40, Session 9

The Imaging X-ray Polarimetry Explorer (IXPE)

Martin C. Weisskopf, NASA Marshall Space Flight Ctr. (United States)

IXPE is a mission undergoing a Phase-A study as a possible NASA Small Explorer. IXPE uses X-ray polarimetry to expand dramatically observation space and to provide new input to our understanding as to how X-ray emission is produced in objects where physics under extreme conditions dominates: neutron stars, pulsar wind nebulae, and stellar and supermassive black holes. The mission is very low-risk, making use of mature flight elements combined in a system with conservative resource margins and run by a team with extensive mission experience, in X-ray astronomy, especially X-ray polarimetry. Not only will the mission expand observation space by adding both degree of polarization and position angle to the list of observational parameters, it will also add imaging capability in a significant number of important contexts such as jets in active galaxies. The mission combine 30-arcseond half-power-diameter optics with high precision gas pixel detectors whose two-dimensional symmetry is devoid of any significant systematic effects.

9905-41, Session 9

Opening the field of soft x-ray polarimetry

Herman L. Marshall, Norbert S. Schulz, Massachusetts Institute of Technology (United States); David L. Windt, Reflective X-Ray Optics LLC (United States); Eric M. Gullikson, Lawrence Berkeley National Lab. (United States)

We present continued development of a telescope for measuring linear X-ray polarization over the 0.2-0.8 keV band. We employ multilayer-coated mirrors as Bragg reflectors at the Brewster angle. By matching to the dispersion of a spectrometer, one may take advantage of high multilayer reflectivities and achieve polarization modulation factors over 95%. We have constructed a source of polarized X-rays that operates at a wide range of energies with a selectable polarization angle. We will present results from measurements of new laterally graded multilayer mirrors and new gratings essential to the design. Finally, we will present a design for a small telescope for suborbital or orbital missions. A suborbital mission could measure the polarization of a blazar such as Mk 421 to 5-10 percent while an orbital version could measure the polarizations of neutron stars, active galactic nuclei, and blazars.

Support for this work was provided by the National Aeronautics and Space Administration through grant NNX15AL14G and by Research Investment Grants from the MIT Kavli Institute.

9905-42, Session 9

POLIX: a Thomson x-ray polarimeter

Biswajit Paul, Rishin Puthiya Veetil, M. R. Gopala Krishna, Raman Research Institute (India)

POLIX is a medium energy Thomson X-ray polarimeter for a small astronomy satellite of ISRO. It uses a collimator, a scatterer and a set proportional counters to detect the scattered X-rays. This instrument will provide unprecedented opportunity to measure X-ray polarisation in the energy range of 5-30 keV in a large number of sources of different classes with a minimum detectable linear polarisation degree of 2-3%. The prime objects for observation with this instrument are the bright X-ray sources: accretion powered neutron stars, accreting black holes in different spectral states, rotation powered pulsars, magnetars, and active galactic nuclei. We will describe the design details of POLIX and its sensitivity for polarization measurement of cosmic X-ray sources.

9905-43, Session 9

Hard x-ray imaging polarimeters for Polaris

Kiyoshi Hayashida, Juyong Kim, Osaka Univ. (Japan); Shuichi Gunji, Yamagata Univ. (Japan); Tatehiro Mihara, RIKEN (Japan); Daisuke Yonetoku, Kanazawa Univ. (Japan); Hiromitsu Takahashi, Tsunefumi Mizuno, Hiroshima Univ. (Japan); Hidetoshi Kubo, Kyoto Univ. (Japan); Tomokage Yoneyama, Yuki Ikeyama, Fumiyoshi Kamitsukasa, Osaka Univ. (Japan)

Hard X-ray polarimetry is complementary to the soft X-ray polarimetery, such as planned with PRAXyS, IXPE, XIPE. Although the number of hard X-ray photons is not larger than in the soft X-ray regime, polarization degrees are in general expected to be higher than in the soft X-ray band. This is due to the fact that non thermal radiation is prominent in the hard X-ray band. For example, reflection component from the accretion

disks around black holes, which should have high polarization degree, is dominant in the hard X-ray band.

We thus plan hard X-ray polarmetry mission, PolariS, for a small satellite. Its target is tens of sources brighter than 1/100 Crab. It would employ three modules of hard X-ray mirrors and scattering type imaging polarimeters installed on their focal plane.

We show the current status of the PolariS mission, and recent development of the imaging polarimeters.

The imaging polarimeter consists of two kinds of scintillator pillars and multi anodes photomultiplier tubes (MAPMT). Incident position and scattered direction is measured with this system. We have already built bread board models of the PolariS imaging polarimeter in which 50% of the surrounding unit to catch scattered X-rays are employed. We performed X-ray irradiation tests at a synchrotron facility. We confirmed the system has polarization sensitivity with as modulation factor M of 0.5-0.6 to 10-80keV X-rays. The detection efficiency is higher than 1% at 20keV, and about 20% at 80keV. The efficiency would be doubled if we employ full coverage of the surround units. We are also optimizing data processing techniques to gain high efficient for low energy incidence.

9905-44, Session 9

The x-ray polarimeter instrument on board the Polarimeter for Relativistic Astrophysical X-ray Sources (PRAXyS) mission

Joanne E. Hill, NASA Goddard Space Flight Ctr. (United States); J. Kevin Black, NASA Goddard Space Flight Ctr. (United States) and Rock Creek Scientific (United States); Keith M. Jahoda, NASA Goddard Space Flight Ctr. (United States); Toru Tamagawa, Asami Hayato, Wataru Iwakiri, Takao Kitaguchi, RIKEN (Japan); Teruaki Enoto, RIKEN (Japan) and Kyoto Univ. (Japan); Yoko Takeuchi, Megu Kubota, RIKEN (Japan) and Tokyo Univ. of Science (Japan); Philip E. Kaaret, Ross McCurdy, The Univ. of Iowa (United States); Takashi Okajima, NASA Goddard Space Flight Ctr. (United States); Yang Soong, NASA Goddard Space Flight Ctr. (United States) and Univ. of Maryland (United States)

The Polarimeter for Relativistic Astrophysical X-ray Sources (PRAXyS) is one of three Small Explorer (SMEX) missions selected by NASA for Phase A study. The PRAXyS observatory carries an X-ray Polarimeter Instrument (XPI) capable of measuring the linear polarization from a variety of high energy sources, including black holes, neutron stars, and supernova remnants.

The XPI is comprised of two identical mirror-Time Projection Chamber polarimeter telescopes with effective area TBD at 3 keV, capable of photon limited observations for sources as faint as 1 mCrab. The XPI is built with well-established technologies. This paper will describe the performance of the XPI flight mirror and the protoflight polarimeter.

9905-45, Session 10

Large area x-ray proportional counter (LAXPC) instrument onboard ASTROSAT

J. S. Yadav, H. M. Antia, Dhiraj K. Dedhia, Javierdhan Chauhan, Tilak B. Katoch, P. Madhwani, Parag Shah, Tata Institute of Fundamental Research (India); Ranjeev Misra, Mayukh Pahari, Inter-Univ. Ctr. for Astronomy and Astrophysics (India); Prahlad C. Agrawal, R. K. M. Manchanda, Univ. of Mumbai (India); Biswajit Paul, Raman Research Institute (India)

ASTROSAT India's first dedicated astronomy space mission was launched on September 28, 2015. The Large Area X-ray Proportional Counter (LAXPC) is one of the major payloads on ASTROSAT. A cluster of three co-aligned identical LAXPC detectors provides large area of collection of about 8000 cm2.. The large detection volume (15 cm depth) filled with mixture of xenon gas (90(%) and methane (10%) at ~ 2 atmospheres pressure, results in detection efficiency greater than 50%, above 30 keV. The LAXPC instrument is best suited for X-ray timing and spectral studies over energy range of 3-80 keV. It will provide the largest effective area among all the satellite missions flown so far worldwide and will remain so during next 5-10 years for X-ray studies in the given energy range. The LAXPC detectors have been calibrated using radioactive sources in the lab. GEANT4 simulation for LAXPC detectors was carried out to understand detector background and its response. The LAXPC instrument became fully operational on 19th October 2015 for the first time in space. We have performed detector calibration in orbit. The LAXPC instrument is functioning well and has achieved all detector parameters proposed initially. In this paper, we will describe LAXPC detector calibration in lab as well as in orbit along with first results.

9905-46, Session 10

In-orbit performance of SXT aboard AstroSat

Kulinder Pal Singh, K. Mukerjee, Tata Institute of Fundamental Research (India); G. C. Stewart, Univ. of Leicester (United Kingdom); Sunil Chandra, Somnath Bhattacharyya, Vinita Navalkar, Tata Institute of Fundamental Research (India)

A soft X-ray Imaging Telescope (SXT) built in India was launched in a near Earth near equatorial orbit aboard the AstroSat on September 28th, 2015. The X-ray optics was built in the Tata Institute of Fundamental Research, India and mated to a Focal Plane camera containing a cooled CCD built in collaboration with the Space Research Centre of the University of Leicester, UK. The electronics for the camera including the temperature control, telemetry and telecommand system for various modes of operation was also built in-house in TIFR, and it was switched on within 3 days of the launch. The first light with SXT was seen on October 26th, 2015 after a sequence of operations. Several cosmic targets have been observed since then during the Performance Verification phase lasting until March 31, 2016. A few near-simultaneous observations have also been carried out with the Swift observatory.The in-orbit performance of the SXT based on these observations and its comparison with the limited ground based tests will be presented,

9905-47, Session 10

In-orbit performance of UVIT on AstroSat

Annapurni Subramaniam, Shyam Tandon, Indian Institute of Astrophysics (India); John Hutchings, National Research Council Canada (Canada); Swarna K. Ghosh, National Ctr. for Radio Astrophysics (India); Koshy George, Indian Institute of Astrophysics (India); V. Girish, Indian Space Research Organisation (India); P. U. Kamath, S. Kathiravan, Amit Kumar, J. Paul Lancelot, P. K. Mahesh, Rekhesh Mohan, Jayant Murthy, S. Nagabhushana, Ashok K. Pati, Indian Institute of Astrophysics (India); Joe Postma, Univ. of Calgary (Canada); N.K. Rao, Indian

Institute of Astrophysics (India); Kasiviswanathan Sankarasubramanian, Indian Space Research Organisation (India); P. Sreekumar, S. Sriram, Cheliah S. Stalin, Firoza Sutaria, Yuvraj Harsha Sreedhar, Indian Institute of Astrophysics (India)

The Ultraviolet Imaging telescope on ASTROSAT is a twin telescope (each of aperture 375 mm) capable of imaging in three channels. The FUV(130-180 nm) detector along with a filter wheel is mounted on one of the telescopes. The NUV (200-300 nm) and VIS (320-550 nm) detectors, along with one filter wheel each, are mounted on the second telescope, where a beam splitter is used to direct the NUV to the side port. The NUV and FUV detectors are used in the Photon counting mode and the VIS in the integration mode.

The filter wheels for FUV and NUV channels also carry gratings for slitless spectroscopy with low resolution.

The in-orbit calibrations are expected to estimate the spatial resolution, flat field corrections, photometric zero-points of the filter systems and the calibration of the grating.

9905-48, Session 10

In-orbit performance AstroSat CZTI

Santosh V. Vadawale, Physical Research Lab. (India); A. R. Rao, Tata Institute of Fundamental Research (India); Dipankar Bhattacharya, Varun B. Bhalerao, Inter-Univ. Ctr. for Astronomy and Astrophysics (India); Mithun N. P. S., Tanmoy Chattopadhyay, Physical Research Lab. (India); S. S. Sreekumar, Vikram Sarabhai Space Ctr. (India)

The Cadmium-Zinc-Telluride Imager (CZTI) is one of the five payloads onboard recently launched Indian astronomy satellite Astrosat. CZTI is primarily designed for simultaneous hard X-ray imaging and spectroscopy of celestial X-ray sources. It employs the technique of coded mask imaging for measuring spectra in the energy lange of 20 – 150 keV. The detector plane of CZTI consists of total 64 CZT detector modules arranged in four identical quadrants. Each detector module has an active area of 16 cm2 and further divided into an array of 16 ? 16 pixels, each having size of 2.5 ? 2.5 mm2, resulting in total 16384 pixels over entire detector plane. As an added advantage, the fine pixilated nature of the detector plane of CZTI is also helpful in extending useful energy range to ~250 keV as well as possibly to measure polarization in hard X-rays, by identifying the X-ray photons interacting by means of Compton scattering. CZTI was the first scientific payload of Astrosat to be switched on after one week of the launch and was made operational during subsequent week. First phase of the CZTI performance verification observations consisted of deep imaging observations of the standard candle source, the Crab nebula as well as a black hole binary Cygnus X-1. Here we present preliminary results form the performance verification phase observations and discuss the in-orbit performance of CZTI.

9905-49, Session 11

The Neutron star Interior Composition Explorer (NICER): design and development

Keith C. Gendreau, Zaven Arzoumanian, Phillip W. Adkins, Cheryl L. Albert, NASA Goddard Space Flight Ctr. (United States); John F. Anders, ASRC Federal InuTeq (United States); Andrew T. Aylward, Charles L. Baker, NASA Goddard Space Flight Ctr. (United States); Erin R. Balsamo, Univ. of Maryland, Baltimore County (United States); William A. Bamford, Emergent Space Technologies (United States); Suyog S. Benegalrao, Daniel L. Berry, Shiraz Bhalwani, NASA Goddard Space Flight Ctr. (United States); Joel K. Black, Forbin Scientific (United States); Carl A. Blaurock, Nightsky Systems, Inc. (United States); Gary L. Brown, Jason G. Budinoff, NASA Goddard Space Flight Ctr. (United States); Thoniel Cazeau, NASA Goddard Space Flight Ctr (United States); Phillip T. C. Chen, NASA Goddard Space Flight Ctr. (United States); Thomas G. Clement, ASRC Federal Space and Defense (United States); Andrew T. Colangelo, SGT, Inc. (United States); Gerald S. Coleman, Orbital Sciences Corp. (United States); William E. Dehaven, Honeywell International Inc. (United States); John P. Doty, Noqsi Aerospace, Ltd. (United States) and Massachusetts Institute of Technology (United States); Mark D. Egan, MIT Kavli Institute for Astrophysics and Space Research (United States); Teruaki Enoto, Kyoto Univ. (Japan); Wei-Ming Fan, NASA Goddard Space Flight Ctr (United States); Deneen Ferro, SGT, Inc. (United States); Richard Foster, Massachusetts Institute of Technology (United States); Luis D. Gallo, NASA Goddard Space Flight Ctr. (United States); Nicholas M. Galassi, SGT (United States); Christopher M. Green, NASA Goddard Space Flight Ctr. (United States); David Grosh, Raytheon Co. (United States); Kong Q. Ha, Monther A. Hasouneh, NASA Goddard Space Flight Ctr. (United States); Kristofer B. Heefner, Honeywell International Inc. (United States); Phyllis Hestnes, Lisa J. Hoge, Tawanda M. Jacobs, NASA Goddard Space Flight Ctr. (United States); Michael A. Kaiser, ATA Aerospace, LLC (United States); James W. Kellogg, Steven J. Kenyon, NASA Goddard Space Flight Ctr. During 2014 and 2015, NASA's Neutron star Interior Composition Explorer (NICER) mission proceeded successfully through Phase C, Design and Development. An X-ray (0.2–12 keV) astrophysics payload destined for the International Space Station, NICER is manifested for launch in the second half of 2016 on the Commercial Resupply Services SpaceX-11 flight. Its scientific objectives are to investigate the internal structure, dynamics, and energetics of neutron stars, the densest objects in the universe. During Phase C, flight components including optics, detectors, optical bench, pointing actuators, electronics, and others were subjected to environmental testing and integrated to form the flight payload. A custom-built facility was used to co-align and integrate the X-ray "concentrator" optics and silicon-drift detectors. Ground calibration provided robust performance measures of the optical (at NASA's Goddard Space Flight Center) and detector (at the Massachusetts Institute of Technology) subsystems, while comprehensive functional tests prior to payload-level environmental testing met all instrument performance requirements. We describe here the implementation of NICER's major subsystems, summarize their performance and calibration, and outline the component-level testing that was successfully applied.

9905-50, Session 11

NICER instrument detector subsystem: description and performance

Gregory Y. Prigozhin, MIT Kavli Institute for Astrophysics and Space Research (United States); Keith C. Gendreau, NASA Goddard Space Flight Ctr. (United States); Zaven Arzoumanian, NASA Goddard Space Flight Ctr. (United States) and The Ctr. for Research and Exploration in Space and Technology (United States) and Universities Space Research Association (United States); John P. Doty, Noqsi Aerospace, Ltd. (United States); Richard F. Foster, Ronald Remillard, Andrew Malonis, MIT Kavli Institute for Astrophysics and Space Research (United States); Beverly J. LaMarr, Massachusetts Institute of Technology (United States); Michael L. Vezie, Mark D. Egan, Jesus N. S. Villaseñor, Wayne H. Baumgartner, MIT Kavli Institute for Astrophysics and Space Research (United States); Alan C. Huber, Amptek, Inc. (United States); Frank Scholze, Christian Laubis, Michael Krumrey, Physikalisch-Technische Bundesanstalt (Germany)

NICER (Neutron star Interior Composition Explorer) is an instrument that is planned to be deployed on the International Space Station. Its goal is to detect soft X-ray emission (0.2 - 12 keV) of neutron stars with unprecedented timing resolution of about 100 ns. The focal plane of the instrument is comprised of 56 Silicon Drift Detectors (SDD) manufactured by Amptek. Detectors form 7 groups of 8 SDDs, each group is controlled by an independent electronics box called MPU - Measurement and Power Unit. Signal from each SDD is fed to fast shaper with 84ns peaking time, and, in parallel, to slow shaper with 465ns peaking time. Fast shaper allows for accurate time stamping of the arriving photons, while slow shaper enables good energy resolution for spectroscopy. Ratio of fast to slow amplitudes also provides additional information about distance of the photon interaction from the detector center, thus helping to reject undesirable events at the periphery.

We will describe the main features of the system and will present the results of the measurements of the key parameters, such as quantum efficiency, energy resolution, timing properties, and other details of the instrument performance in the preflight testing.

9905-51, Session 12

Status of ART-XC/SRG instrument

Mikhail N. Pavlinsky, Valeriy V. Akimov, Vasiliy Levin, Alexander Krivchenko, Alexey Rotin, Maria M. Kuznetsova, Igor Y. Lapshov, Alexey Tkachenko, Nikolay P. Semena, Mikhail Buntov, Alexander Glushenko, Vadim Arefiev, Alexander Yaskovich, Sergei Grebenev, Sergey Sazonov, Mikhail Revnivtsev, Alexander Lutovinov, Sergey Molkov, Roman Krivonos, Dmitry Serbinov, Mikhail Kudelin, Tatyana Drozdova, Sergey Voronkov, Space Research Institute (Russian Federation); Rashid Sunyaev, Eugene Churazov, Marat Gilfanov, Space Research Institute (Russian Federation) and Max-Planck-Institut für Astrophysik (Germany); Vladimir Babyshkin, Ilya Lomakin, Alexander Menderov, NPO Lavochkin (Russian Federation); Mikhail V. Gubarev, Brian D. Ramsey, Kiranmayee Kilaru, Stephen L. O'Dell, Jeffery J. K. Kolodziejczak, Ronald Elsner, NASA Marshall Space Flight Ctr. (United States); Vyacheslav Zavlin, Douglas A. Swartz, Universities Space Research Association (United States)

Spectrum Roentgen Gamma (SRG) is an X-ray astrophysical observatory, developed by Russia in collaboration with Germany. The mission will be launched in 2017 from Baikonur and placed in a 6-month-period halo orbit around L2. The scientific payload consists of two independent telescope arrays – a soft-x-ray survey instrument, eROSITA, being provided by Germany and a medium-x-ray-energy survey instrument ART-XC being

developed by Russia. ART-XC will consist of seven independent, but co-aligned, telescope modules. The ART-XC flight mirror modules have been developed and fabricated at the NASA Marshall Space Flight Center (MSFC). Each mirror module will be aligned with a focal plane CdTe double-sided strip detector which will operate over the energy range of 6-30 keV, with an angular resolution of <1?, a field of view of ~34? and an expected energy resolution of about 12% at 14 keV. The current status of the ART-XC/SRG instrument will be present.

9905-52, Session 12

eROSITA on SRG

Peter Predehl, Max-Planck-Institut für extraterrestrische Physik (Germany)

eROSITA (extended ROentgen Survey with an Imaging Telescope Array) is the core instrument on the Russian/German Spectrum-Roentgen-Gamma (SRG) mission which will be launched next year. eROSITA is now near its completion; The entire system is qualified, all flight components are finished and tested. All eight flight mirrors and flight cameras (including flight spares) underwent the final calibration. All subsystems and components are well within their expected performances. The end-to-end test with the complete telescope in our PANTER facility will be last step before shipment to Russia.

9905-53, Session 13

Localization algoritms for micro-channel x-ray telescope on board SVOM space mission

Laura Gosset, Diego Götz, Commissariat à l'Énergie Atomique (France)

SVOM is a French-Chinese space mission to be launched in 2021, and whose goal is the study of Gamma-Ray Bursts, the most powerful stellar explosions in the Universe. The Micro-channel X-ray Telescope (MXT) is an X-ray focusing telescope, on board SVOM, with a field of view of 1° (working in the 0.2-10 keV energy band), dedicated to the rapid follow-up of the Gamma-Ray Bursts counterparts and to its precise localization (smaller than 2 arc minutes). In order to reduce the optics mass and to have an angular resolution of few arc minutes, a configuration in "Lobster-Eye" has been chosen.

Using a numerical model of the MXT point spread function (PSF) we simulated MXT observations of point sources in order to develop and test different localization algorithms to be implemented on board MXT. We included preliminary estimations of the instrumental and sky background, as well as the effect of satellite stabilization after slew and potential detector defects such as dead columns and bright pixels.

The algorithms on board have to be a combination of speed and precision (the brightest sources are expected to be localized at a precision better than 10 arc seconds in the MXT reference frame). We present the comparison between different methods such as barycenter, PSF fitting in one or two dimensions.

The temporal performance of the algorithms is being tested using the X-ray afterglow data base of the XRT telescope on board the NASA Swift satellite.

9905-54, Session 13

THESEUS: the transient high-energy sky and early universe surveyor

Lorenzo Amati, INAF - IASF Bologna (Italy)

The Transient High Energy Sky and Early Universe Surveyor (THESEUS) is a mission concept developed by a large international collaboration aimed at exploiting Gamma-Ray Bursts for investigating the early Universe. The main scientific objectives of THESEUS include: investigating the star formation rate and metallicity evolution of the ISM and IGM up to redshift 10, detecting the first generation (pop III) of stars, studying the sources and physics of re-ionization, detecting the faint end of galaxies luminosity function. These goals will be achieved through a unique combination of instruments allowing GRB detection and arcmin localization over a broad FOV (more than 1sr) and an energy band extending from several MeVs down to 0.3 keV with unprecedented sensitivity, as well as on-board prompt (few minutes) follow-up with a 0.6m class IR telescope with both imaging and spectroscopic capabilities. Such instrumentation will also allow THESEUS to unveil and study the population of soft and sub-energetic GRBs, and, more in geeneral, perform monitoring and survey of the X_ray sky with unprecedented sensitivity.

9905-55, Session 13

DIOS: the Dark Baryon Exploring mission

Takaya Ohashi, Yoshitaka Ishisaki, Yuichiro Ezoe, Shinya Yamada, Tokyo Metropolitan Univ. (Japan); Yuzuru Tawara, Ikuyuki Mitsuishi, Nagoya Univ. (Japan); Kazuhisa Mitsuda, Noriko Y. Yamasaki, Yoh Takei, Institute of Space and Astronautical Science (Japan) and Japan Aerospace Exploration Agency (Japan); Naomi Ota, Nara Women's Univ. (Japan)

DIOS (Diffuse Intergalactic Oxygen Surveyor) is planned for a JAXA's small mission to be launched by Epsilon rocket around 2022. The purpose is to search for dark baryons through detecting red-shifted oxygen emission lines from warm-hot intergalactic medium (WHIM). The payload will consist of a TES microcalorimeter array, with energy resolution of a few eV, cooled with cryogen free refrigerators, and a 4-reflection X-ray telescope. The instrument will cover an energy range of 0.3 - 2 keV with a field of view of 30 - 50 arcmin diameter and an angular resolution of about 3 arcmin. The large field of view and very low background will give a high sensitivity for largely extended X-ray mission from earth's neighborhood, supernova remnants, galaxies and clusters of galaxies. The design of the spacecraft is in progress including the satellite bus system and thermal design of the payload. We also study to use a larger telescope up to about 1000 cm^2 at 1 keV, combined with a fast repointing function, to allow measurements of absorption lines from gamma-ray bursts. We report on the status of the design and expected science from DIOS.

9905-56, Session 13

A broadband x-ray imaging spectroscopy with high-angular resolution: the FORCE mission

Koji Mori, Univ. of Miyazaki (Japan); Takeshi Go Tsuru, Kyoto Univ. (Japan); Kazuhiro Nakazawa, The Univ. of Tokyo (Japan); Yoshihiro Ueda, Kyoto Univ. (Japan); Takashi Okajima, NASA Goddard Space Flight Ctr. (United States); Hiroshi Murakami, Tohoku Gakuin Univ. (Japan); Hisamitsu Awaki, Ehime Univ. (Japan); Hironori Matsumoto, Nagoya Univ. (Japan); Yasushi Fukazawa, Hiroshima Univ. (Japan); Hiroshi Tsunemi, Osaka Univ. (Japan); Tadayuki Takahashi, Institute of Space and Astronautical Science (Japan); William W. Zhang, NASA Goddard Space Flight Ctr. (United States)

We are proposing FORCE (FOcusing Relativistic universe and Cosmic Evolution) as a next Japanese X-ray mission in the early 2020s. FORCE will be a medium-class mission after upcoming large-class X-ray mission ASTRO-H. ASTRO-H possesses a suite of sensitive instruments realizing the highest energy-resolution spectroscopy, a broadband X-ray imaging spectroscopy, and more. FORCE will take over a concept of the broadband X-ray imaging spectroscopy from ASTRO-H and reinforce it by significantly higher angular resolution. The current design of FORCE defines energy band pass of 1-80 keV with angular resolution of <15", achieving a 10 times higher sensitivity compared to previous missions above 10 keV with simultaneous soft X-ray coverage.

Our primary scientific objectives are to trace the cosmic evolution of black holes in various mass-scales, and to hunt for the nature of relativistic particles at various astrophysical shocks. How many heavily obscured (Compton-thick) Active Galactic Nuclei (AGNs) exist in the universe and what are their contributions to the total growth of supermassive black holes (SMBHs) are key questions to establish a complete picture of AGN evolution. Hard X-ray surveys above 10 keV are essential to census the Compton-thick AGN population and have started find a part of this population in the local universe. Our sensitive hard X-ray survey will prove more distant population and trace the cosmological growth. While it is believed that SMBHs gained most of their masses by accretion, the question how their ``seed'' black holes formed remains a big mystery. Ultra luminous X-ray sources in external galaxies are good candidates of such seed black holes. We will tackle their nature by tracing the state transition into dimmer X-ray regime that have not been explored ever. Searching for orphan stellar-mass blackholes in our Galaxy is also our scope. Non-thermal X-ray emission from relativistic particles at various astrophysical shocks provide us with essential information their nature and origin. Measuring time variability and small-scale structure above the synchrotron cut-off energy is a key to understand the particle acceleration mechanism in young supernova remnants. Detection of non-thermal X-ray emission from clusters of galaxies has long been awaited but not so far been successful. FORCE are going to open a new era in these fields.

FORCE will be launched with the Epsilon vehicle that is a Japanese solid-fuel rocket. FORCE carries three identical pairs of Super-mirror and wide-band X-ray detector. The focal length is currently assumed to be 10 m. The silicon mirror with multi-layer coating is our primary choice to achieve lightweight, good angular optics. The detector is a descendant of hard X-ray imager onboard ASTRO-H replacing its silicon strip with SOI-CMOS silicon pixel detector, allowing the low energy threshold down to 1 keV.

9905-57, Session 13

The X-Ray Surveyor mission concept study

Jessica A. Gaskin, Gregg K. Gelmis, Douglas A. Swartz, NASA Marshall Space Flight Ctr. (United States); Harvey D. Tananbaum, Alexey A. Vikhlinin, Smithsonian Astrophysical Observatory (United States); Martin C. Weisskopf, NASA Marshall Space Flight Ctr. (United States)

The X-Ray Surveyor is a successor to Chandra, with orders of magnitude improvements in sensitivity, field of view for sub-arcsec imaging, and effective area for grating spectroscopy and with high spectral resolution capabilities for extended objects. An X-ray observatory with such capabilities, operating in concert with other major astronomical facilities of the 2020-2030s, is required to address and solve some of the greatest challenges in modern astrophysics. The X-Ray Surveyor mission concept was recently selected by the NASA Astrophysics Director one of four missions to study for prioritization in the 2020 Astrophysics Decadal Survey. A formal concept study will be led by a NASA Center, selected by the Astrophysics Director, and executed under the guidance of a nominated Science and Technology Definition Team. The Study will be carried out over the next 3 to 4 years and products will include the science case for the mission, observatory performance requirements, a design reference mission, technology assessment, cost and top-level schedule for all of the major phases of the development. We will report on previous work to define a strawman concept for the X-Ray Surveyor and will summarize the plan forward.

9905-58, Session 13

eXTP: Enhanced X-ray Timing and Polarization mission

Shuang-Nan Zhang, Institute of High Energy Physics (China); Marco Feroci, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy)

eXTP - enhanced X-ray Timing and Polarization mission

eXTP is a science mission designed to study the state of matter under extreme conditions of density, gravity and magnetism. Primary goals are the determination of the equation of state of matter at supra-nuclear density (QCD theory), the measurement of QED effects in highly magnetized environments,and the test of predictions of General Relativity in strong-field regime of gravity. Primary targets include isolated and binary neutron stars, strong magnetic field systems like magnetars, and stellar-mass and supermassive black holes. The mission carries a unique and unprecedented suite of state-of-the-art scientific instruments enabling for the first time ever the simultaneous spectral-timing-polarimetry study of cosmic sources in the energy range 0.5-30 keV. Key elements of the payload are: the low-energy Focusing Array (LFA) - a set of 11 X-ray optics (PSF 1') for a total effective area of 1 and 0.6 m2 at 2 keV and 6 keV, respectively, equipped with Silicon detectors offering <180 eV spectral resolution; the large Area Detector (LAD) - a deployable set of 640 Silicon drift detectors, for a total effective area of 3.4 m2 and spectral resolution of beteer than 250-300 eV, with field of view collimated to 1 degree by capillary plate technologies; the Gas Pixelated Detector (GPD) – a set of 2 X-ray optics (PSF 15"), for a total effective area of 1700 cm2 and 1100 cm2 at 2 keV and 6 keV, respectively, equipped with imaging gas-pixelated detector photo-electric polarimeters; and the Wide Field Monitor (WFM) – a set of 6 coded-mask, wide field camera units, equipped with position-sensitive Silicon drift detectors, each covering a 90 degrees x 90 degrees field of view.

The eXTP international consortium is primarily made of major institutions of the Chinese Academy of Sciences and universities in China, as well as several major institutions in several European countries. The predecessor of eXTP is the XTP mission, selected and funded as one of the so-called background missions in the Strategic Pioneering Space Science Program of the Chinese Academy of Sciences since 2011. The strong European participation has enhanced the scientific capabilities of eXTP significantly. Given the core objectives of the mission, eXTP is fully complementary to ESA's ATHENA mission. The planned launch time of eXTP is between 2023 and 2025.

The presentation is made on behalf of the whole eXTP consortium.

9905-59, Session 13

The LOFT mission concept: a status update

Marco Feroci, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy)

The Large Observatory For x-ray Timing (LOFT) is a mission concept which was proposed to ESA as M3 and M4 candidate in the framework of the Cosmic Vision 2015-2025 program. Thanks to the unprecedented combination of effective area and spectral resolution of its main instrument, and the uniquely large field of view of its wide field monitor, LOFT will study the behaviour of matter in extreme conditions such as the strong gravitational field in the innermost regions close to black holes and neutron stars, and the supranuclear densities in the interiors of neutron stars. The science payload is based on a Large Area Detector (LAD, >8m2 effective area, 2-30 keV, 240 eV spctral resolution, 1 degree collimated field of view) and a Wide Field Monitor (WFM, 2-50 keV, 4 steradian field of view, 1 arcmin source location accuracy, 300 eV spectral resolution). The WFM is equipped with an on-board system for bright events (e.g. GRB) localization. The trigger time and position of these events are broadcast to the ground within 30 s from discovery. In this paper we will present the current technical and programmatic status of the mission.

9905-60, Session 14

High-resolution lightweight x-ray optics

William W. Zhang, NASA Goddard Space Flight Ctr. (United States)

Optics plays a uniquely important role in determining the capability of an observatory. Future observatories must be qualitatively better than current ones in angular resolution and/or effective area. In this paper we report on an effort whose objective is to eventually achieve diffraction-limited x-ray optics that is both lightweight and affordable, enabling future x-ray observatories that are a match to optical observatories such as HST and JWST in image quality. Our program has five technical elements: substrate fabrication, coating, alignment, bonding, and systems engineering. We have made significant and steady progress in each of these five areas in the last few years, culminating in progressively better angular resolution and technical readiness while keeping the mirror lightweight. We are well on our way to realize x-ray astronomers' dream of a high-resolution (~1" or better) and large effective area (>1 m2) telescope, such as the x-ray surveyor being studied by NASA.

9905-61, Session 14

Beyond Chandra: problems, solutions, and perspectives for the implementation of very high angular resolution x-ray telescopes in the new millennium

Giovanni Pareschi, INAF - Osservatorio Astronomico di Brera (Italy)

An important challenge for the X-ray astronomy of the new millennium is represented by the implementation of an X-ray telescope able to maintain the exquisite angular resolution of Chandra (sub-arcsec on axis) but, at the same time, being characterized by a much larger throughput and grasp. A mission with similar characteristics is represented by the X-ray Surveyor Mission, recently proposed in USA at a level of concept. The mission is an effective area of more than 2 square meters at 1 keV (i.e. 30 greater than Chandra) and a 15-arcminute diameter field-of-view with one-arcsecond or better half-power diameter (versus the 4 arcmin diameter of Chandra). While the scientific reasons for implementing a similar mission are clear, being related to compelling problems like e.g. the formation and subsequent growth of black hole seeds at very high redshift or the identification of the first galaxy groups and proto-clusters, the realization of an optics system able to fulfil these specs remain challenging. Different technologies are being envisaged, like the use of adjustable segmented mirrors (with use of piezoelectric or magneto-restrictive film actuators on the back surface) or the direct polishing of a variety of thin substrates or the use of innovative correction methods like the differential deposition, the ion-figuring removal of error profile or the correction via controlled stress films. In this paper the problematic will be deeply discussed, comparing pros and cons of the different technological approaches and configurations (including the question of monolithic versus segmented optics options). Finally, an update will be given on the progresses achieved on direct polishing of thin SiO_2 substrates (monolithic and segmented).

9905-62, Session 14

Development of 0.5 arcsecond adjustable x-ray optics: status update

Paul B. Reid, Ryan Allured, Vincenzo Cotroneo, Edward Hertz, Vanessa Marquez, Stuart McMuldroch, Sagi Ben-Ami, Daniel A. Schwartz, Alexey A. Vikhlinin, Harvard-Smithsonian Ctr. for Astrophysics (United States); Susan Trolier-McKinstry, Margeaux L. Wallace, Thomas N. Jackson, The Pennsylvania State Univ. (United States); Harvey D. Tananbaum, Harvard-Smithsonian Ctr. for Astrophysics (United States)

Adjustable grazing incidence X-ray optics represent a candidate technology for the development of the successor to the Chandra X-ray Observatory. The adjustable optics, produced by depositing a thin film of piezoelectric material on the back surface of a Wolter mirror segment, represents a way in which mirror figure errors resulting from fabrication and mounting can be corrected once on the ground. After launch, it may also be feasible to make on-orbit corrections for figure changes due to thermal effects. This powerful technology does not require massive reaction structures, and will make possible the simultaneous achievement of very large effective area and sub-arcsecond X-ray imaging.

We describe recent progress in our continuing development of adjustable X-ray optics. We discuss development of a mirror segment alignment approach consistent with sub-arcsecond imaging, demonstration of deterministic figure correction on cylindrical test mirrors, the use of strain gauges for in situ monitoring of piezoelectric performance, and progress towards X-ray testing of a mounted, aligned, and corrected pair of mirrors.

9905-63, Session 14

Development of the a direct fabrication technique for full-shell x-ray optics

Mikhail V. Gubarev, Jeffery J. K. Kolodziejczak, Charles W. Griffith, Jacqueline M. Roche, W. Scott Smith, Thomas J. Kester, NASA Marshall Space Flight Ctr. (United States); Carolyn Atkins, The Univ. of Alabama in Huntsville (United States); William R. Arnold Sr., a.i. solutions, Inc. (United States); Brian D. Ramsey, NASA Marshall Space Flight Ctr. (United States)

The Chandra observatory demonstrated that modern fabrication techniques can provide sub-arcsecond-resolution grazing-incidence optics if thick mirror substrates are used. The challenge to meet the optics requirements for future astrophysical missions is to develop the optical fabrication technology capable of producing Chandra-like optics but with an order of magnitude lighter mirror shells and at an affordable price. Towards realizing this goal at MSFC we are using full-shell thin-metal substrates to provide the necessary stiffness and a modern robotic polishing machine which can converge to a low level of surface error quickly.

Ideally, the mirror shell has low density, low coefficient of expansion (CTE), high modulus of elasticity and high yield strength. It should also be a material that is not too difficult to figure and polish. Beryllium has excellent mechanical properties for an optic substrate. Also beryllium can be coated with Nickel/Phosphorous (NiP) alloy, a hard material which can be easily figured and polished/superpolished. The CTE of beryllium alloy can be matched to the NiP by adding aluminum to the alloy and is very close to stainless steel, so for future telescopes such mirrors would be easy to mount in a thermally stable system. However, while highly desirable as a substrate the cost of beryllium is quite high and so we are using aluminum substrates coated with NiP as mechanical surrogates during our early development.

One of the challenges for thin-shell fabrication is to support the shell during processing so that, at one extreme, it cannot fracture or microyield, but also cannot deflect enough to affect the polishing itself. The optics backing systems developed for diamond turning of inner and outer surfaces of the substrate and for the polishing will be presented along with the ex-situ and in-situ metrology techniques used.

To perform the mirror surface error correction deterministically using the computer controlled polishing machine the measured surface figure profiles need to be converted into the polishing tool path profile. The wear patterns are characterized for a specific slurry and polishing pad material and these data area used to generate the appropriate polishing-tool velocity profile to apply the necessary figure correction. The polishing tool model is developed to streamline the optimization of the polishing tool generation process. Results of polishing experiments to validate the model using NiP plated samples will be presented. The validated model has been used for the generation of polishing tool paths to reduce the surface errors of the x-ray optics to sub-arcsecond levels. Results of these polishing experiments will be also presented.

9905-64, Session 14

Advancements in x-ray reflection gratings for space-based applications

Randall L. McEntaffer, The Univ. of Iowa (United States)

Many of the key science goals in X-ray astronomy require spectroscopy in the soft energy band, 0.2 - 2.0 keV. The performance requirements placed on spectrometers typically have spectral resolving powers in the thousands with effective areas in the hundreds of square centimeters. Obtaining both of these requirements in a single instrument is a challenge for a variety of reasons. Here, we discuss the development tasks specific to off-plane reflection gratings. We detail the requirements that drive our technical challenges such as fabrication, alignment, and integration. Finally, we summarize the plans for utilizing off-plane grating arrays on suborbital rockets and Explorers, in addition to discussing their applicability to Probe and Observatory class missions.

9905-65, Session 14

Critical-angle x-ray transmission grating spectrometer with high resolving power and extended bandpass

Ralf K. Heilmann, MIT Kavli Institute for Astrophysics and Space Research (United States); Alexander R. Bruccoleri, Izentis, LLC (United States); Mark L. Schattenburg, MIT Kavli Institute for Astrophysics and Space Research (United States)

A number of high priority questions in astrophysics can be addressed by a state-of-the-art soft x-ray grating spectrometer, such as the role of Active Galactic Nuclei in galaxy and star formation, characterization of the Warm-Hot Intergalactic Medium and the "missing baryon" problem, characterization of halos around the Milky Way and nearby galaxies, as well as stellar coronae and surrounding winds and disks. An Explorer-scale, large-area (> 1,000 cm2), high resolving power (R ??lambda/delta_lambda > 3,000) soft x-ray grating spectrometer is highly feasible based on Critical-Angle Transmission (CAT) grating technology. Still significantly higher performance can be provided by a CAT grating spectrometer on an X-ray-Surveyor-type mission. CAT gratings combine the advantages of blazed reflection gratings (high efficiency, use of higher diffraction orders) with those of conventional transmission gratings (low mass, relaxed alignment tolerances and temperature requirements, transparent at higher energies) with minimal mission resource requirements. They are high-efficiency blazed transmission gratings that consist of freestanding, ultra-high aspect-ratio grating bars fabricated from silicon-on-insulator (SOI) wafers using advanced anisotropic dry and wet etch techniques. Blazing is achieved through grazing-incidence reflection off the smooth grating bar sidewalls. The reflection properties of silicon are well matched to the soft x-ray band. Nevertheless, CAT gratings with sidewalls made of higher atomic number elements allow extension of the CAT grating principle to higher energies and larger dispersion angles. We show x-ray data from metal-coated CAT gratings and demonstrate efficient blazing to higher energies and larger blaze angles than possible with silicon alone. We also report on measurements of the resolving power of a breadboard CAT grating spectrometer consisting of a Wolter-I slumped-glass focusing mirror pair from Goddard Space Flight Center and CAT gratings, performed at the Marshall Space Flight Center Stray Light Facility.

9905-215, Session PS7

Thermal forming of glass substrates for X-ray Surveyor optics

Vincenzo Cotroneo, Ryan Allured, Paul B. Reid, Alexey A. Vikhlinin, Harvard-Smithsonian Ctr. for Astrophysics (United States); Giovanni Pareschi, Marta M Civitani, Bianca Salmaso, Astronomical Observatory of Brera (Italy)

The X-ray surveyor mission concept aims to the construction of an observatory with Chandra-like angular resoution and 30 times more effective area or larger. The technology under development at SAO is based on the deposition of piezoelectric material on the back of thermally formed Wolter segments made of thin glass. About 8000 mirror segments, with initial quality of 10 arcseconds or better are required for the telecope. In this paper we review the progress and current status of thermal forming activities conducted in last years at SAO, highlighting the most relevant technical problems and the way to solve them.

9905-216, Session PS7

The SVOM/GRM mass model and background monte-carlo simulations

Bobing Wu, Fei Xie, Yongwei Dong, Institute of High Energy Physics (China)

The Space multi-band Variable Object Monitor (SVOM) mission is a wide band observatory designed for making observations of Gamma Ray Bursts (GRB) from the visible band to gamma ray band, which is expected to launch around year of 2021.

GRM (Gamma Ray Monitor) is a GRB trigger detector on aboard SVOM. GRM detects a large portion of the sky in the hard X-ray and soft gamma-ray band with a PS/NaI(Tl) phoswich detector. The energy range is 15-5000 keV. GRM has 3 GRD (Gamma Ray Detector) units.The elevation angle of each GRD relative to the symmetry axis is set to 30° and the interval in azimuth angle of 3 GRDs is 120°. Rough localization can be achieved in a large Field of View using only 3 GRDs, which may contribute to the gravitational wave measurement.

In order to evaluate the number of bursts detected and the GRB spectrum description, we have some research on the background of GRM. Also simulated background level is necessary for the signal noise ratio (SNR) calculation. We make use of the mass modeling technique to estimate the total background. It consists of three steps. First, we built a fine geometric model of GRM and a coarse model of the other payloads. Then based on the investigation about the space environment concerning SVOM low-earth orbit, in our simulation we considered cosmic rays, cosmic X-ray background (CXB), South Atlantic Anomaly (SAA) trapped particles, the albedo gamma, and neutrons from interaction of cosmic rays with the Earth's atmosphere. Finally, the Shielding Physics List supplied by Geant4

collaborations was adopted. According to our simulation, we find that CXB dominates the total background because of GRM's large field of view (for each GRD, the FOV is +/-60 degree with respect to its symmetry axis). When the Earth locates behind the SVOM, the total background of each GRD is approximately 1081 count/s on average over 15–5000 keV energy band after 100 days in orbit, and approximately 800 count/s comes from the CXB. As SVOM adopts the anti-sun pointing strategy, the Earth will in the FOV of GRM in some situation definitely. When the GRD observes facing the Earth, the total background reduces to approximately 659 count/s because of the Earth shielding, and CXB induced background reduces to 290 count/s. So we got a function about the total background level with respect to the Earth-SVOM pointing angle by fitting 12 discrete data in different pointing angels. We also find that in the energy band larger than 300 keV, delayed background come from the SAA trapped particles become prominent.

9905-217, Session PS7

The SVOM microchannel x-ray telescope status

Diego Götz, CEA-Ctr. de SACLAY (France)

We present the PDR design status Microchannel X-ray Telescope (MXT), a new telescope that will be flying on the Sino-French space mission SVOM dedicated to Gamma-Ray Burst (GRB) science. SVOM will carry a multi wavelength payload, which includes 2 instruments provided by France (ECLAIRs and MXT) and two provided by China (GRMs and VT). ECLAIRs is a wide field of view (2 sr) coded mask telescope, triggering in the 4 - 250 keV, and providing the initial GRB alerts. ECLAIRs is complemented by the GRMs, a set of three wide field non-imaging gamma-ray (30 keV - 5 MeV) NaI spectrometers. Two narrow field instruments, a visible telescope, VT, and the MXT, will point the GRB location, after an autonomous slew of the satellite, in order to study in detail the GRB afterglows, and to pinpoint the GRB locations.

MXT is being developed under the responsibility of CNES Toulouse, in tight collaboration with CEA-Irfu, MPE Garching, and the University of Leicester. Its current design is based on the coupling of square 40 microns micro-pore optics (MPOs) with an actively cooled (-65°C) pnCCD (made of 256 x 256 pixels of 75 microns) developed at MPE/HLL in the context of the DUO mission.

MXT is a compact and light (<35 kg) focussing X-ray telescope with a 1 m focal length, which will provide an effective area of about 50 square cm on axis. Its point spread function (PSF) is expected to be better than 4.5 arc min (FWHM), and its sensitivity (~2e-12 erg/cmsq/s for a 10 ks observation) adequate to detect practically all the X-ray afterglows of the SVOM GRBs.

MXT is expected to localize 90 (50)% of SVOM GRB afterglows to better than 60 (20) arc sec (90% confidence radius, no systematic errors included) after five minutes of observation from the satellite stabilisation. We present MXT the status of the design of the different MXT sub-systems, as well as, the associated preliminary bread-board results.

9905-218, Session PS7

Arcus: the x-ray grating spectrometer explorer

Randall K. Smith, Ryan Allured, Nancy S. Brickhouse, Peter N. Cheimets, Adam R. Foster, Edward Hertz, Scott J. Wolk, Harvard-Smithsonian Ctr. for Astrophysics (United States); Jörn Wilms, Friedrich-Alexander-Univ. Erlangen-Nürnberg (Germany); Lynne A. Valencic, Johns Hopkins Univ. (United States); Richard Willingale, Univ. of Leicester (United Kingdom); Catherine E. Grant, Marshall W. Bautz, Ralf K. Heilmann, David P. Huenemoerder, Eric D. Miller, Michael A. Nowak, Mark L. Schattenburg, Norbert S. Schulz, Massachusetts Institute of Technology (United States); Vadim Burwitz, Kirpal Nandra, Jeremy Sanders, Max-Planck-Institut für extraterrestrische Physik (Germany); Jay A. Bookbinder, Rodolphe DeRosee, NASA Ames Research Ctr. (United States); Robert Petre, Andrew F. Ptak, Alan Smale, NASA Goddard Space Flight Ctr. (United States); David N. Burrows, The Pennsylvania State Univ. (United States); Katja Poppenhaeger, Queen's Univ. Belfast (United Kingdom); Elisa Costantini, Jelle S. Kaastra, SRON Netherlands Institute for Space Research (Netherlands); Casey T. DeRoo, Randall L. McEntaffer, The Univ. of Iowa (United States); Richard Mushotzky, Univ. of Maryland, College Park (United States); Joel Bregman, Jon M. Miller, Univ. of Michigan (United States)

Arcus will be proposed to the NASA Explorer program as a free-flying satellite mission that will enable high-resolution soft X-ray spectroscopy with unprecedented sensitivity - effective areas of >500 sq cm and spectral resolution up to 3000. The Arcus key science goals are (1) to measure the effects of structure formation imprinted upon the hot baryons that are predicted to lie in extended halos around galaxies, groups, and clusters, (2) to trace the propagation of outflowing mass, energy and momentum from the vicinity of the black hole out to large scales as a measure of their feedback and (3) to understand how stars, circumstellar disks and exoplanet atmospheres form and evolve.

Arcus relies upon grazing-incidence silicon pore X-ray optics with the same 12m focal length (achieved using an extendable optical bench) that will be used for the ESA Athena mission. The focused X-rays from these optics will then be diffracted by high-efficiency off-plane reflection gratings that have already been demonstrated on sub-orbital rocket flights, imaging the results with flight-proven CCD detectors and electronics. The power and telemetry requirements on the spacecraft are modest. Mission operations are not complex, as most observations will be long (~100 ksec), uninterrupted, and pre-planned, although there will be limited ToO capabilities to observe sources such as tidal disruption events or supernovae. After the end of prime science, we plan to allow guest observations to maximize the science return of Arcus to the community.

9905-219, Session PS7

Multi-directional measurements of high energy particles from the Sun-Earth L1 point with STEPS

Shiv Kumar Goyal, Shanmugam Munuswamy, Arpit R. Patel, Tinkal Ladiya, Neeraj K. Tiwari, Swaroop B. Banerjee, Santosh V. Vadawale, P. Janardhan, D. Chakrabarty, Physical Research Lab. (India); A. R. Srinivas, Space Applicaton Ctr. (India); Piyush Shukla, Space Application Ctr. (India); Prashant Kumar, K. P. Subramanian, Physical Research Lab. (India); B. Bapat, Indian Institute of Science Education and Research Pune (India); P. R. Adhyaru, Physical Research Lab. (India)

Supra Thermal Energetic Particle Spectrometer (STEPS) is an independent sub system of the ASPEX experiment. ASPEX (Aditya Solar Wind Particle EXperiment) has been selected as one of the possible experiments onboard the Aditya - L1 mission (forthcoming Indian solar mission), which is to be placed in a halo orbit around the L1 Lagrangian point, lying between the Sun and the Earth at a distance of 1.5 million km from the Earth. Primary objective of the ASPEX experiment is to make in - situ, multi - directional measurements of solar wind supra-thermal and high

energy particles in the energy range of 100 eV/n to 5 MeV/n. The ASPEX payload has two independent subsystems – STEPS, which will measure the energy spectrum of high energetic particles from six multiple directions, in the energy range of 20 keV/n to 5 MeV/n; and SWIS (Solar Wind Ion Spectrometer), which will measure the angular and energy distributions of Solar wind ions in the energy range of 100 eV to 20 keV, using the technique of electro-static analysis (ESA) followed by magnetic separation of particles.

The STEPS instrument has been configured into three packages: viz. the STEPS - 1 detector package, the STEPS - 2 detector package and the processing electronics package. The STEPS - 1 detector package has 4 detector units, pointing in 4 different directions with each having a different field of view. In this package, 2 detector units will provide particle species differentiated (proton and alpha) energy spectra while other 2 detector units will provide particle species integrated energy spectra. Similarly STEPS - 2 detector package has 2 detector units, one detector will provide species differentiated energy spectra, while other unit will provide species integrated energy spectra.

The detector units of STEPS measuring species differentiated energy spectra, will use a specially designed Si detectors along with plastic Scintillators for particle detection. Si detectors are fabricated in a single package with two different thicknesses of dead layers (0.1 ?m and 1.0 ?m) of high Z material. The Plastic Scintillator is placed below the Si detector package, which provides a possibility of measuring particles up to very high energy (~50 MeV/n) along with particle identification using ?E-E mode. The detector units of STEPS measuring species integrated spectra will use a standard Si-PIN detector.

In this paper, we will describe the overall configuration of the STEPS subsystem and present the salient feature of STEPS. We will present the development status of the bread - board model with some preliminary results.

9905-220, Session PS7

Optical design considerations and raytracing results for the Arcus grating spectrometer concept

Ryan Allured, Harvard-Smithsonian Ctr. for Astrophysics (United States); Randall L. McEntaffer, The Univ. of Iowa (United States); Edward Hertz, Laura Brenneman, Peter N. Cheimets, Randall K. Smith, Harvard-Smithsonian Ctr. for Astrophysics (United States)

Arcus is a mission concept for a next generation X-ray grating spectrometer. It will offer spectral resolution greater than 2000 combined with over 500 cm^2 of effective area at the 2.1-2.4 nm bandpass. These capabilities will elucidate the cycle of baryonic matter in and out of galaxies, the means by which supermassive black holes influence their surroundings, and the early formation and evolution of solar systems. We present the overall optical design of the mission, which features four arrays of silicon pore optics modules with four matching arrays of off-plane reflection grating modules. These optics disperse the incident X-rays over the 12 m focal length in four separate conical diffraction patterns onto CCD arrays at the focal plane. Each array of optics is an azimuthal sub-aperture of the typical Wolter telescope design, enabling enhanced spectral resolution due to an asymmetric point spread function. Coatings for the silicon pore optics and gratings featuring B4C have been baselined to optimize throughput in the 0.8-5 nm mission bandpass. The theoretical spectral resolution, effective area, and alignment tolerances have been determined via a high fidelity raytrace model. This model has been optimized using an observation time metric derived from the mission science program.

9905-221, Session PS7

Exploring the formation and evolution of clusters, galaxies, and stars with Arcus

Laura Brenneman, Smithsonian Astrophysical Observatory (United States); Randall K. Smith, Harvard-Smithsonian Ctr. for Astrophysics (United States); Jay A. Bookbinder, NASA Ames Research Ctr. (United States); Joel Bregman, Univ. of Michigan (United States); Jelle S. Kaastra, SRON Netherlands Institute for Space Research (Netherlands); Nancy S. Brickhouse, Harvard-Smithsonian Ctr. for Astrophysics (United States); Lynne A. Valencic, Johns Hopkins Univ. (United States) and NASA Goddard Space Flight Ctr. (United States); Robert Petre, NASA Goddard Space Flight Ctr. (United States); Ryan Allured, Adam R. Foster, Scott J. Wolk, Harvard-Smithsonian Ctr. for Astrophysics (United States); Jörn Wilms, Friedrich-Alexander-Univ. Erlangen-Nürnberg (Germany); Richard Willingale, Univ. of Leicester (United Kingdom); Catherine Grant, Marshall W. Bautz, Ralf K. Heilmann, David P. Huenemoerder, Eric Miller, Michael A. Nowak, Mark L. Schattenburg, Norbert S. Schulz, Massachusetts Institute of Technology (United States); Vadim Burwitz, Kirpal Nandra, Jeremy Sanders, Max-Planck-Institut für extraterrestrische Physik (Germany); Andrew F. Ptak, Alan Smale, NASA Goddard Space Flight Ctr. (United States); David N. Burrows, The Pennsylvania State Univ. (United States); Katja Poppenhaeger, Queen's Univ. Belfast (United Kingdom); Elisa Costantini, SRON Netherlands Institute for Space Research (Netherlands); Casey T. DeRoo, Randall L. McEntaffer, The Univ. of Iowa (United States); Richard Mushotzky, Univ. of Maryland, College Park (United States); Jon Miller, Univ. of Michigan (United States)

I will discuss the scientific research objectives of Arcus, a NASA/MIDEX mission under development in response to the 2017 call for proposals. It is a free-flying, soft X-ray grating spectrometer with the highest-ever spectral resolution in the energy range. The Arcus bandpass includes the most sensitive tracers of diffuse million-degree gas, spectral lines from O VII and O VIII, along with many other diagnostics, such as H- and He-like lines of C, N, Ne and Mg, and unique density- and temperature-sensitive lines from Si and Fe ions. These capabilities enable an advance in our understanding of the formation and evolution of baryons in the Universe that is unachievable with any other present or planned observatory. The mission will address multiple key questions posed in the Decadal Survey and NASA's 2013 Roadmap: How do baryons cycle in and out of galaxies? How do black holes and stars grow and influence their surroundings and the cosmic web via feedback? How do stars, circumstellar disks and exoplanet atmospheres form and evolve? Arcus data will answer these questions by measuring X-ray emission and absorption spectra at high resolution from a wide range of sources within and beyond the Milky Way. This will be accomplished by leveraging recent technical developments in off-plane gratings and silicon pore optics. CCDs with strong Suzaku heritage combined with electronics based on the Swift mission will detect the dispersed X-rays. Arcus will support a broad astrophysical research program, and its superior resolution and sensitivity in soft X-rays will complement the forthcoming Astro-H and Athena calorimeters that have high resolution above 2 keV.

9905-222, Session PS7

End-to-end simulations for Arcus

Jörn Wilms, Friedrich-Alexander-Univ. Erlangen-Nürnberg (Germany); Andrew F. Ptak, NASA Goddard Space Flight Ctr. (United States); Ryan Allured, Harvard-Smithsonian Ctr. for Astrophysics (United States); Randall L. McEntaffer, The Univ. of Iowa (United States); David P. Huenemoerder, MIT Kavli Institute for Astrophysics and Space Research (United States); Jay A. Bookbinder, NASA Ames Research Ctr. (United States); Randall K. Smith, Harvard-Smithsonian Ctr. for Astrophysics (United States); Marshall W. Bautz, Massachusetts Institute of Technology (United States); Catherine E. Grant, Eric D. Miller, Herman L. Marshall, MIT Kavli Institute for Astrophysics and Space Research (United States); Robert Petre, NASA Goddard Space Flight Ctr. (United States); Peter N. Cheimets, Harvard-Smithsonian Ctr. for Astrophysics (United States)

We present an overview of the end to end simulation software developed for the proposed Arcus mission. Consisting of off-plane gratings behind silicon pore optics, Arcus will provide a resolution of >2000 in the soft 0.25-1.5keV X-ray regime with a high effective area of >500cm^2, recovering a substantial fraction of the X-ray gratings science originally envisioned for the International X-ray Observatory.

As part of the Arcus concept study we have developed a full simulation chain for Arcus that is able to model in a realistic way all properties of the Arcus instrument that are relevant for its measurement process. We use the SIXTE Monte-Carlo modeling and simulation framework (http://www.sternwarte.uni-erlangen.de/sixte) to model as-detected X-ray source photon distributions. We employ such simulations both for simulation of observations, but also to generate instrument responses (effective areas and line spread functions) which may not be explicitly known a priori. Models of the expected particle background will also be included. We illustrate the simulation chain using several typical applications and demonstrate the feasibility of the envisaged Arcus design. These simulations will also establish both diffuse X-ray and particle background requirements and thus potentially impact the choice of orbit. These tools can be easily generalized for use with other X-ray gratings mission concepts such as an X-ray gratings probe or the “X-ray Surveyor” concept.

9905-223, Session PS7

The protoMIRAX hard x-ray balloon experiment: a pathfinder for MIRAX

João Braga, Flavio D ‘Amico, Instituto Nacional de Pesquisas Espaciais (Brazil)

We present the development status of the protoMIRAX hard X-ray balloon experiment, which is a prototype designed to test in near-space environment several subsystems of the MIRAX satellite mission. The main instrument is a wide-field (20 x 20 degrees) hard X-ray (10-200 keV) imaging camera that utilizes an array of 169 (13x13) planar CdZnTe detectors with dimensions 10mm x 10mm x 2mm, a collimator and a coded mask. The angular resolution in the balloon configuration is 1.5 degrees. The coded mask employs an extended 13x13 MURA pattern and is built with Pb-Sn-Cu layers supported by an acrylic frame. We show laboratory calibration results and detailed Monte Carlo GEANT4 simulations of the performance of the instrument at balloon altitudes and also at the expected near-equatorial circular low-Earth orbit of MIRAX. The simulations results allowed us to redesign the shielding and collimator materials and geometry in order to minimize the background and make the spatial distribution of background counts uniform across the detector plane. We also present the electronics solutions we have developed for the data acquisition system and the data handling on-board computer. protoMIRAX will be launched for the first time in late 2016.

9905-224, Session PS7

Update on the micro-X sounding rocket x-ray telescope

David Goldfinger, Massachusetts Institute of Technology (United States); Enectali Figueroa-Feliciano, Northwestern Univ. (United States)

Micro-X is a sounding rocket borne X-ray telescope that utilizes Transition Edge Sensors in order to do imaging spectroscopy with a high level of energy resolution. The detectors are held at 75 mK via an Adiabatic Demagnetization Refrigerator which uses a Ferric Ammonium Alum salt pill. The detector array has 128 pixels and an effective area of 300 cm2, with a field of view of 11.8 arcmin in its present layout. We present an update of ongoing progress in preparation for the upcoming launch of the instrument.

9905-225, Session PS7

Alignment and metrology of a high fidelity grating module prototype for the Arcus mission concept

Ryan Allured, Edward Hertz, Peter N. Cheimets, Harvard-Smithsonian Ctr. for Astrophysics (United States); Casey T. DeRoo, Randall L. McEntaffer, The Univ. of Iowa (United States); David L. Windt, Reflective X-Ray Optics LLC (United States); Randall K. Smith, Harvard-Smithsonian Ctr. for Astrophysics (United States)

Arcus is a mission concept for a next generation X-ray grating spectrometer. It will offer spectral resolution greater than 2000 combined with over 500 cm^2 of effective area at the 2.1-2.4 nm bandpass. To demonstrate the technical feasibility of such a mission, we have designed and fabricated a prototype grating module. The alignment tolerances of the grating module are reviewed and the metrology techniques used to achieve these tolerances are covered in detail. We describe the gratings used to populate this module and the results of the alignment and figure metrology during alignment. The module will be tested along with a prototype 12 m focal length silicon pore optics module at the PANTER beamline this summer.

9905-226, Session PS7

The CubeSat imaging x-ray solar spectrometer (CubIXSS) mission concept

Amir Caspi, Southwest Research Institute (United States); Albert Y. Shih, NASA Goddard Space Flight Ctr. (United States); Glenn T. Laurent, Craig DeForest, Southwest Research Institute (United States); Harry Warren, U.S. Naval Research Lab. (United States); James P. Mason, Thomas N. Woods, Scott E. Palo, Univ. of Colorado Boulder (United States); Marek Steslicki, Janusz Sylwester, Space Research Ctr. (Poland); Jan J. Sojka, Utah State Univ. (United States); Phillip C. Chamberlin, NASA Goddard Space Flight Ctr. (United States)

The CubeSat Imaging X-ray Solar Spectrometer (CubIXSS) is a nanosatellite mission concept to measure spectrally- and spatially-resolved soft X-ray (SXR) emission from the quiescent and flaring Sun using a 6U CubeSat platform in low-Earth orbit during a nominal 1-year mission. The CubIXSS instrument suite comprises two spectrometers and a slitless imaging spectrograph: the Small Assembly for Solar Spectroscopy (SASS) and the Multi-Order X-ray Spectral Imager (MOXSI), respectively. The copious solar SXR flux allows for precise measurements even with pinhole apertures, ideal for the limited resources of a CubeSat envelope.

The ~1 MK solar corona is ~100x hotter than the underlying chromosphere, and can reach ~50 MK or higher during solar flares. Exactly how the corona attains such high temperatures remains one of the fundamental unanswered questions in solar physics. There has been a general lack of spectrally-resolved observations of solar SXRs from ~0.2 to 5 keV (~0.25-6 nm), an energy range dominated by emission from hot coronal plasma. These SXRs also drive dynamical processes in Earth's ionosphere that affect communications, atmospheric composition, and satellite drag. Accurate SXR measurements in this range would thus provide crucial diagnostics of plasma heating during both solar flares and quiescent times, and aid in modeling and understanding Earth's atmospheric response to these X-rays.

SASS utilizes the Amptek X123-SDD silicon drift detector, a low-noise, commercial off-the-shelf (COTS) instrument enabling spatially-integrated solar SXR spectroscopy from ~0.5 to ~30 keV with ~0.15 keV FWHM spectral resolution and ~few-sec cadence with low power, mass, and volume requirements. Two detectors with tailored filters and pinhole aperture sizes provide sensitivity over all activity levels, from solar minimum to >X5 flares, from only ~0.03 mm^2 total illuminated area. Two X123-CdTe cadmium-telluride detectors, with ~50 mm^2 total illuminated area, provide ~5-100 keV hard X-ray (HXR) spectroscopy with ~0.5-1 keV FWHM resolution to extend the high-energy response during flares. The precise spectra from SASS will provide detailed measurements of the coronal temperature distribution during flares and quiescent times, along with context information of HXR-emitting flare-accelerated electrons.

MOXSI is a novel spectro-spatial imager -- the first ever solar imager on a CubeSat -- utilizing a custom pinhole camera and Chandra-heritage X-ray transmission diffraction grating to provide spatially-resolved, full-Sun imaging spectroscopy from ~1 to ~55 Å (~0.2-10 keV) with ~25 arcsec and ~0.25 Å FWHM spatial and spectral resolutions, respectively, and cadence of ~few tens of sec. MOXSI's unique capabilities enable SXR spectroscopy and temperature diagnostics of individual flares and active regions.

Through these new measurements, CubIXSS will improve our physical understanding of thermal plasma processes and impulsive energy release in the solar corona, from quiet Sun to solar flares, and the impact of solar X-rays on Earth's upper atmosphere.

9905-227, Session PS7

Fast simulation of the NICER instrument

John P. Doty, Noqsi Aerospace, Ltd. (United States) and MIT Kavli Institute for Astrophysics and Space Research (United States); Matthew P. Wampler-Doty, Noqsi Aerospace, Ltd. (United States); Gregory Y. Prigozhin, MIT Kavli Institute for Astrophysics and Space Research (United States); Takashi Okajima, Zaven Arzoumanian, Keith C. Gendreau, NASA Goddard Space Flight Ctr. (United States)

The NICER mission uses a complicated physical system to collect information from objects that are, by x-ray timing science standards, rather faint. To get the most out of the data we will need a rigorous understanding of all instumental effects. We are in the process of constructing a very fast, high fidelity simulator that will help us to assess instrument performance, support simulation-based data reduction, and improve our estimates of measurement error. We will combine and extend existing optics, detector, and electronics simulations. We will employ the Compute Unified Device Architecture (CUDA) to parallelize these calculations. The price of suitable CUDA-compatible multi-gigaflop cores is about $0.20/core, so this approach will be very cost-effective.

9905-228, Session PS7

Ground calibration of the SDDs for NICER

Beverly J. LaMarr, Massachusetts Institute of Technology (United States) and MIT Kavli Institute for Astrophysics and Space Research (United States); Gregory Y. Prigozhin, Ronald Remillard, Andrew Malonis, MIT Kavli Institute for Astrophysics and Space Research (United States); Keith C. Gendreau, Zaven Arzoumanian, Craig B. Markwardt, Wayne H. Baumgartner, NASA Goddard Space Flight Ctr. (United States)

The Neutron star Interior Composition ExploreR (NICER) is set to be deployed on the International Space Station (ISS) in early 2017. It will use an array of 56 Silicon Drift Detectors (SDDs) to detect soft X-rays (0.2 - 12 keV) with 100 nanosecond timing resolution. Here we describe the effort to calibrate the detectors in the lab primarily using a Modulated X-ray Source (MXS).

9905-229, Session PS7

Performance of NICER flight x-ray concentrator

Takashi Okajima, Yang Soong, NASA Goddard Space Flight Ctr. (United States); Erin R. Balsamo, NASA Goddard Space Flight Ctr. (United States) and Univ. of Maryland, Baltimore County (United States); Teruaki Enoto, Kyoto Univ. (Japan); Richard G. Koenecke, Lawrence G. Olsen, Steven J. Kenyon, Zaven Arzoumanian, Keith C. Gendreau, NASA Goddard Space Flight Ctr. (United States)

Neutron star Interior Composition ExploreR (NICER) is a NASA instrument proposed to the Mission of Opportunity (MoO) and will be delivered to the International Space Station (ISS) by SpaceX-11 Falcon 9 launch vehicle in August, 2016. NICER is dedicated to the study of the extraordinary gravitational, electromagnetic, and nuclear-physics environments embodied by neutron stars. It features a high timing resolution of less than a few hundred nsec with a large collecting area twice as much as XMM-Newton at the 1-2 keV band. The NICER timing instrument consists of 56 X-ray optic and detector pairs, an X-ray Concentrator (XRC) and a silicon drift detector. Each XRC is based on an epoxy replicated thin aluminum foil X-ray mirror, similar to those of Suzaku and ASTRO-H, but only single stage parabolic grazing incidence optic. Each has a focal length of 1.085 m and a diameter of 100 mm, with 24 confocally aligned parabolic shells.

Grazing incident angles to individual shells range from 0.4 to 1.4 deg. The flight 56 XRCs have been completed and successfully delivered to the payload integration. All the XRC was characterized at the GSFC 100-m X-ray beamline using 1.5 and 4.5 keV X-rays. The XRC performance, effective area and point spread function, was measured by a CCD camera and a proportional counter. The average effective area is about 44 cm^2 at 1.5 keV and about 18 cm^2 at 4.5 keV, which is consistent with a micro-roughness of 5 A from individual shell reflectivity measurements. The XRC focuses about 91% of X-rays into a 2 mm aperture at the focal plan, which is the NICER detector window size. Each XRC weighs only 325 g. These performance met the project requirement. In this paper, we will present summary of the flight XRC

performance as well as co-alignment results of the 56 XRCs on the flight payload as it is important to estimate the total effective for astronomical observations. We are also developing a ray-tracing simulator in order to reproduce the XRC performance and generate a response, which will be used in astrophysical discussion. We will present comparison between the measured performance and the ray-tracing simulations.

9905-230, Session PS7

Large observatory for x-ray timing (LOFT-P): a probe-class mission concept study

Colleen Wilson-Hodge, NASA Marshall Space Flight Ctr. (United States); Paul S. Ray, U.S. Naval Research Lab. (United States); Deepto Chakrabarty, MIT Kavli Institute for Astrophysics and Space Research (United States); Marco Feroci, INAF - IASF Roma (Italy)

LOFT-P is a mission concept for a NASA Astrophysics Probe-Class (<$1B) X-ray timing mission, based on the LOFT M-class concept originally proposed to ESA's M3 and M4 calls. LOFT-P requires very large collecting area, high time resolution, good spectral resolution,broadband spectral coverage (2-30 keV), highly flexible scheduling, and an ability to detect and respond promptly to time-critical targets of opportunity. It addresses science questions such as: What is the equation of state of ultra dense matter? What are the effects of strong gravity on matter spiraling into black holes? It would be optimized for sub-millisecond timing of bright Galactic X-ray sources including X-ray bursters, black hole binaries, and magnetars to study phenomena at the natural timescales of neutron star surfaces and black hole event horizons and to measure mass and spin of black holes. These measurements are synergistic to imaging and high-resolution spectroscopy instruments, addressing much smaller distance scales than are possible without very long baseline X-ray interferometry, and using complementary techniques to address the geometry and dynamics of emission regions. LOFT-P would have an effective area of >6 m2, >10x that of the highly successful Rossi X-ray Timing Explorer (RXTE). A sky monitor (~2-50 keV) acts as a trigger for pointed observations, providing high duty cycle, high time resolution monitoring of the X-ray sky with ~20 times the sensitivity of the RXTE All-Sky Monitor, enabling multi-wavelength and multi-messenger studies. A probe-class mission concept would employ lightweight collimator technology and large-area solid-state detectors, segmented into pixels or strips, technologies which have been recently greatly advanced during the ESA M-3 Phase A study of LOFT. Given the large community interested in LOFT (>800 supporters, (http://www.isdc.unige.ch/loft/index.php/loft-team/community-members), the scientific productivity of this mission is expected to be very high, similar to or greater than RXTE (~2000 refereed publications.) In 2016, MSFC's Advanced Concepts Office will perform a study of a US-led probe-class LOFT concept. We will report on the current status of this study of LOFT-P. NRL's work on X-ray astrophysics is funded by the Chief of Naval Research (CNR)

9905-231, Session PS7

Verification and in-orbit-prediction of the eROSITA thermal control system

Maria Fürmetz, Max-Planck-Institut für extraterrestrische Physik (Germany)

The X-ray telescope eROSITA is the core instrument on the Russian Spektrum-Roentgen-Gamma mission, accompanied by the Russian ART-XC telescope. Besides an all-sky survey, also pointed observations will be performed in the energy range between 0.1-10 keV. Main goal of the mission is the detection of 100.000 galaxy clusters in order to constrain cosmological parameters, such as the density and evolution of dark energy.

With launch scheduled for 2017, the project is in its final stage, with the calibration ongoing. All major environmental tests with the qualification model have been performed successfully. Especially the thermal control system was qualified in a space simulation test, and meanwhile also the flight components have been manufactured and tested extensively.

All test results, gained over the years, can now be combined to an overall picture of the thermal behavior of the instrument. Not only operational and non-operational temperature ranges have been identified, also uncertainty analysis has been done.

Finally, accurate in-orbit predictions are possible. With the given boundary conditions at the Lagrangian point 2 (L2), we expect a rather stable performance, only modified by different positions on the orbit around L2. Different load cases have been examined to have reliable data for the mission.

9905-232, Session PS7

ART-XC/SRG: results of qualification thermo-vacuum test

Nikolay P. Semena, Mikhail N. Pavlinsky, Mikhail Buntov, Dmitry Serbinov, Vasily Levin, Vladislav Tambov, Alexey Rotin, Space Research Institute (Russian Federation); Alexander Krivchenko, Space Researche Institute (Russian Federation)

ART-XC – a medium-x-ray-energy survey instrument of SRG project is being developed in Russia under the leadership of the Space Research Institute (IKI).

Main requirements to the telescope temperature control system are provided by two key elements – module of seven semiconductor DSSD CdTe detectors which have to operate at the temperature -22.5±2.5 C to prevent CdTe crystals fast polarization (large polarization time allows to keep detector energy spectral characteristics during continuous 2 – 3 days expositions) and the module of seven mirror systems which have to operate at a temperature 20±2 C (which is the temperature used in the on Earth mirror systems calibration tests).

Thermal control system ART-XC consists of 36 variable film heaters placed in different places on the telescope structure and controlled according to indications of thermal sensors. The maximum power of each heater is 10 W. There are 21 heaters located on seven mirror systems. Each mirror system case is equipped with two heaters, additional one is located on the mirror system baffle. Seven heaters are placed on detectors. Remaining eight heaters are placed in different telescope parts – one on the protective cover, one on the explosive pin, one under the star tracker, three on the mirror system and star tracker mount plate, one on the detector block mount plate and one on the calibration sources control system block. Thermal control system constantly checks temperature from 36 thermal sensors and regulate the heater's power supply. There is one passive thermal control element in the telescope – radiator, which is connected to detectors via three heat pipes and cools them down.

The QM (qualification model) of ART-XC was manufacture and tests of it were operated. QM completely corresponds to flight model. Conditions of thermo-vacuum tests were corresponded to real external thermal conditions in flight. The vacuum, cold of space, temperature of mounting planes and shielding by eRosita telescope were reproduced at this test. During test various thermal telescope modes include orbital injection were simulated.

Results of the QM thermo-vacuum test are presented in this paper.

9905-233, Session PS7

Results of ground tests and calibration of x-ray focal plane detectors for ART-XC/SRG instrument

Vasily Levin, Mikhail N. Pavlinsky, Valeriy V. Akimov, Maria M. Kuznetsova, Alexey Rotin, Alexander Krivchenko, Igor Y. Lapshov, Alexey Tkachenko, Vladimir A. Oleynikov, Space Research Institute (Russian Federation)

The Russian Space Research Institute (IKI) has developed seven flight models and three spare models of the X-ray detectors for the ART-XC/SRG telescope.

Each detector situated in the focal plane of ART-XC X-ray optics and includes CdTe die, front-end electronics, data processing, storage and telemetry units.

CdTe dies manufactured by Acrorad (Japan). Each die has a double side strip electrodes configuration (48 strips and guard ring on top side and 48 strips and guard ring on bottom side of the die). The die dimensions is 30?30?1 mm.

We used VA64TA1 ASICs manufactured by Ideas (Norway) as front-end electronics. We need two ASICs per one detector (one for bottom side and one for top side). Due to nature of the double side strip detectors, we obtain spectroscopy from both sides of the die.

In the Space Research Institute performed a vibration, thermal cycling and thermal vacuum tests of X ray detectors. During this tests have been studied the leakage current stability, polarization rate, spectroscopic and imaging performance in the working temperature range.

The current status of the X-ray detectors development and testing will be presented.

9905-234, Session PS7

An updated approach to the study of proton propagation in the eROSITA mirror system

Emanuele Perinati, Eberhard Karls Univ. Tübingen (Germany); Teresa Mineo, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Michael J. Freyberg, Max-Planck-Institut für extraterrestrische Physik (Germany); Sebastian Diebold, Eberhard Karls Univ Tübingen (Germany); Andrea Santangelo, Chris Tenzer, Eberhard Karls Univ. Tübingen (Germany)

In this paper we review the analysis of proton transmission through the eROSITA telescope and present simulations performed with an updated version of the ray tracing code where soft (10 keV-1 MeV) protons impinging onto the entrance pupil are propagated to the focal plane following the Remizovich's scatter distribution. Laboratory measurements on eROSITA mirror samples are used to validate the model and select ad-hoc parameters

9905-235, Session PS7

The high definition x-ray imager (HDXI) instrument on the X-ray Surveyor mission concept

Abraham D. Falcone, The Pennsylvania State Univ. (United States); Ralph P. Kraft, Smithsonian Astrophysical Observatory (United States); Mark W. Bautz, Massachusetts Institute of Technology (United States); David N. Burrows, The Pennsylvania State Univ. (United States); Almus T. Kenter, Smithsonian Astrophysical Observatory (United States); Zachary R. Prieskorn, The Pennsylvania State Univ. (United States); Alexey A. Vikhlinin, Smithsonian Astrophysical Observatory (United States)

By utilizing optics that couple fine angular resolution (<0.5 arcsec) with large effective area (~2.3 m^2 at 1keV), the X-ray Surveyor mission would enable exploration within a unique scientific parameter space. One of the primary soft X-ray imaging instruments being baselined for this mission concept is the High Definition X-ray Imager, HDXI. This instrument would achieve this fine angular resolution imaging over a wide field of view (22 x 22 arcmin) by using a silicon sensor array with small pixels. Silicon sensors enable large-format/small-pixel devices, radiation tolerant designs, and high quantum efficiency across the entire soft X-ray bandpass. To fully exploit the X-ray Surveyor's large collecting area (~30x Chandra) without X-ray event pile-up, the HDXI will be capable of much faster frame rates than current X-ray imagers. The planned requirements and capabilities of the HDXI will be described.

9905-236, Session PS7

Laboratory demonstration of the piezoelectric figure correction of a cylindrical slumped glass optic

Ryan Allured, Edward Hertz, Vanessa Marquez, Vincenzo Cotroneo, Harvard-Smithsonian Ctr. for Astrophysics (United States); Margeaux L. Wallace, The Pennsylvania State Univ. (United States); Bianca Salmaso, Marta M. Civitani, INAF - Osservatorio Astronomico di Brera (Italy); Susan Trolier-McKinstry, The Pennsylvania State Univ. (United States); Alexey A. Vikhlinin, Harvard-Smithsonian Ctr. for Astrophysics (United States); Giovanni Pareschi, INAF - Osservatorio Astronomico di Brera (Italy); Paul B. Reid, Harvard-Smithsonian Ctr. for Astrophysics (United States)

The X-ray Surveyor is a mission concept for a next generation X-ray observatory. This mission will feature roughly 30 times the effective area of the Chandra Observatory while matching its sub-arcsecond angular resolution. The key to meeting these requirements is lightweight, segmented optics. To ensure these optics achieve and maintain sub-arcsecond performance, we propose to use piezoelectric coatings for post-bonding and on-orbit figure correction. We have fabricated a cylindrical prototype optic with piezoelectric adjusters and measured its performance using optical metrology. We present the results of this laboratory figure correction and discuss their implications for an observatory featuring adjustable X-ray optics.

9905-237, Session PS7

An alignment budget for the X-Ray Surveyor telescope

Jonathan W. Arenberg, Northrop Grumman Aerospace Systems (United States); Ryan Allured, Smithsonian Astrophysical Observatory (United States); Edward Hertz, Smithsonian Astrophysical Observatory (United States);

Paul B. Reid, Smithsonian Astrophysical Observatory (United States)

This paper presents a first proposal of an error budget for the image quality of the X-ray Surveyor (XRS) Telescope. The XRS telescope is proposed to be a Wolter-Schwarzchild prescription consisting up of many modules. The resulting budget is the set of intermodule alignment tolerances that give a specific image quality, considering both on and off axis imaging performance. The tolerance space that yields imaging performance in the sub-arcsecond class is examined for trades and sensitivities.

9905-238, Session PS7

Ray-tracing critical angle transmission gratings for the X-ray Surveyor mission

Hans Moritz Günther, Marshall W. Bautz, Massachusetts Institute of Technology (United States); Ralf K. Heilmann, David P. Huenemoerder, MIT Kavli Institute for Astrophysics and Space Research (United States); Herman L. Marshall, Michael A. Nowak, Norbert S. Schulz, Massachusetts Institute of Technology (United States)

The X-ray surveyor mission will feature a large collecting area and provide sub-arcsecond imaging resolution over a wide X-ray band. In addition to direct imaging, it will feature an X-ray grating spectrometer designed for a spectral resolving power of order 5000, significantly higher than flown on any other X-ray mission. This new technology will allow us to resolve kinematic components in absorption and emission lines of galactic and extragalactic matter down to unprecedented dispersion levels.

In this work, we study a critical angle transmission (CAT) grating spectrograph that could fulfill these design goals. We perform ray-trace simulations to characterize the performance depending on the angle of inclination between the grating and the ray and the placement of the Rowland-torus in relation to the optical axis. For each design we study the influence of finite-size effects for the grating facets and how performance degrades with increasing misalignments of the grating facets and readout CCDs.

Our newly developed ray-trace code is a tool suite to simulate the performance of X-ray observatories. It is primarily aimed at astronomical X-ray telescopes and sounding rocket payloads, but can be used to ray-trace experiments in the laboratory as well. The simulator code is written in python, because the use of a high-level scripting language allows modifications of the simulated instrument design in very few lines of code. This is especially important in the early phase of mission development, when the performances of different configurations are contrasted. To reduce the run-time and allow for simulations of a few million photons in a few minutes on a desktop computer, the simulator code uses tabulated input (from theoretical models or laboratory measurements of samples) for grating efficiencies and mirror reflectivities.

Based on these simulations we analyze strategies to improve the spectral resolution such as sub-aperturing. We define the error budget for grating facet misalignments, grating constant variations and other uncertainties that are inevitable in the manufacturing process of any instrument.

9905-239, Session PS7

A new type of multiple image x-ray interferometer for arcseconds and sub-arcsecond sources

Kiyoshi Hayashida, Hiroshi Nakajima, Hiroyuki Kurubi, Osaka Univ. (Japan)

A new type of X-ray interferometer using an X-ray grating and an X-ray imaging spectrometer, such as X-ray CCDs or X-ray pixel detectors, is proposed. This interferometer does not employ any mirrors. Instead, multiple images (self images of the grating) generated with the Talbot effect are extracted and employed.

If we use a 5um pitch X-ray grating and X-ray with the wavelength of 0.1nm (12keV), the first self images are expected to focused at the distance of 25cm from the grating. The width of each self image corresponds to the angular size of 2 arc seconds. It means we can measure the X-ray source size of this order or smaller. One of the advantages of this methods is we only need to measure the self images of the identical profiles. We can sample the profile with X-ray detectors with lower position resolution as for moire imaging.

Although our method use similar configuration to X-ray Talbot interferometer with which phase contrast imaging of light material such as human body, and inspired by that method, different information is extracted. The X-ray Talbot interferometer measures the distortion of wave front by the sample material located in front of the grating. Our X-ray multiple image interferometer does not place the sample material, but measure the size of the X-ray source.

We consider possible improvement of the angular resolution of this system to obtain sub-arcsecond resolution, with future prospect of this method.

9905-240, Session PS7

Direct imaging of star vicinity using a miniaturized distributed occulter/telescope in Earth orbit

Adam W. Koenig, Simone D'Amico, Bruce A. Macintosh, Stanford Univ. (United States)

Distributed occulter/telescope systems hold great promise in the field of direct exoplanet imaging. However, proposed missions using this concept such as the New Worlds Observer and Exo-S (NASA) are exceptionally large with occulter diameters of tens of meters and inter-spacecraft separations of tens of megameters, requiring deployment in deep space. These missions are characterized by exorbitant costs in the order of billions of dollars and high risk due to the low technological readiness of the involved technologies. In order to mitigate the risks associated with these missions, this paper presents new findings from optical and orbit design studies of a novel concept recently proposed by the authors, namely a Miniaturized Distributed Occulter/Telescope (mDOT) based on two micro-/nano-satellites in earth orbit. The proposed mission serves two key purposes: 1) demonstrate key technologies required by future large-scale space observatories including light suppression performance of the occulter and precise guidance, navigation, and control, and 2) detect, map, and characterize a set of scientifically valuable targets such as exozodiacal dust formations and large exoplanets. The envisioned mission includes a nano-satellite telescope of 10cm aperture separated from a micro-satellite occulter by a few hundred kilometers in earth orbit. Because detection and imaging of scientifically interesting targets requires starlight suppression of 10^?7 or better, the occulter is designed to suppress some bandwidth in the ultraviolet spectrum (150-400nm) to compensate for its limited size. Additionally, the occulter is designed such that optical performance is insensitive to separation deviations of 1%. The required observation time for a 10cm telescope in the ultraviolet spectrum is on the order of tens of hours or larger and can only be achieved with an optimal orbit design. The proposed formation design leverages the separation insensitivity to minimize the total delta-v (propellant) cost via a two-stage operations concept. The science phase is centered about the apogee of a highly elliptical orbit such as a geosynchronous transfer orbit. Here, a low-thrust, quasi-continuous control system is used to maintain decimeter-level relative position control perpendicular to the line-of-sight while the telescope images the target from within the shadow of the occulter. The formation design aligns the relative acceleration with the observation axis to minimize delta-v cost. Using this strategy, continuous observations

of over one hour without control input along the observation axis can be achieved. The reconfiguration phase takes place after each science phase and consists of a sequence of impulsive maneuvers to ensure that the formation is properly aligned at the start of the next science phase. Preliminary design results show great promise. The total delta-v cost of accumulating 10 hours of observation time is well within the capacity of current propulsion systems. The required manufacturing precision to achieve starlight suppression of 10^?7 is comparable to specifications for large-scale occulters. Finally, a preliminary system design for the telescope spacecraft suggests that a 6U CubeSat telescope spacecraft can meet key design parameters (power, data, and delta-v) with ample margins. Overall, these studies suggest that an mDOT in earth orbit is both feasible and scientifically valuable.

9905-241, Session PS7

iWF-MAXI: a soft x-ray transient monitor on the ISS

Nobuyuki Kawai, Tokyo Institute of Technology (Japan); Hiroshi Tomida, Japan Aerospace Exploration Agency (Japan); Yoichi Yatsu, Tokyo Institute of Technology (Japan); Shiro Ueno, Japan Aerospace Exploration Agency (Japan); Tatehiro Mihara, RIKEN (Japan); Hiroshi Tsunemi, Osaka Univ. (Japan); Makoto Arimoto, Tokyo Institute of Technology (Japan); Motoko Serino, RIKEN (Japan); Takanori Sakamoto, Atsumasa Yoshida, Aoyama Gakuin Univ. (Japan); Takayoshi Kohmura, Tokyo Univ. of Science (Japan); Hitoshi Negoro, Nihon Univ. (Japan); Yoshihiro Ueda, Kyoto Univ. (Japan); Yohko Tsuboi, Chuo Univ. (Japan); Ken Ebisawa, Japan Aerospace Exploration Agency (Japan); Mikio Morii, The Institute of Statistical Mathematics (Japan); Takayuki Yuasa, RIKEN (Japan); Tadayasu Dotani, Japan Aerospace Exploration Agency (Japan); Takashi Nakamura, Takahiro Tanaka, Kyoto Univ. (Japan); Michitoshi Yoshida, Hiroshima Univ. (Japan); Nobuyuki Kanda, Osaka City Univ. (Japan); Mark Vagins, Kavli Institute for the Physics and Mathematics of the Universe (Japan)

iWF-MAXI is an X-ray transient monitor mission proposed as an experiment payload on the JEM/EF (Japanese Experiment Module Exposed Facility) of the International Space Station.

It has four main scientific goals:

(1) To find and localize the X-ray counterparts of gravitational wave events, which are expected to be detected by the next generation gravitational wave detectors such as Advance LIGO and KAGRA in late 2010's.

(2) To detect short soft X-ray transients such as stellar flares, nova ignitions, and supernova shock breakouts, and promptly notify the world.

(3) To trigger on short high-energy transients such as gamma-ray bursts and tidal disruption events, and promptly disseminate their locations to the community.

(4) To detect the onset of activities from black hole binaries, neutron star binaries, and active galactic nuclei (AGN), and issue alerts to the astronomical community of the world.

Its main scientific instrument is the Soft X-ray Large Solid Angle Camera (SLC).

It is sensitive in the energy range of 0.7–10 keV with a localization accuracy of $0.1.

It will detect short transient events like GRBs with durations from a fraction of a second to minutes that occur in its large large field of view (>10% of the entire sky).

With the orbital revolution of the ISS, iWF-MAXI scans much larger sky area in 90 minutes, and looks for slower events such as outbursts of X-ray binaries.

iWF-MAXI uses iSEEP, a medium-size multi-use bus system developed at JAXA in order to save the cost and development time. Missions on the ISS benefits from its infrastructure. The availability of real-time ground contact during 70% of the in-orbit time is particularly favorable for monitor missions that issue prompt alerts for explosive astrophysical transients. On the other hand, iWF-MAXI has to live with various constraints of the ISS/iSEEP payload, such as volume envelope, mass, power, thermal environment, radiation, and safety requirements.

In 2015, iWF-MAXI has been proposed to the small-scale project category of ISAS/JAXA, and has passed the review by the Advisory Committee for Space Science. We are currently working on the design study to accommodate the mission within theses constraints.

9905-242, Session PS7

Opportunities for the high energy astrophysics community by the AHEAD European Infrastructure Project

Lorenzo Natalucci, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Paul O'Brien, Univ. of Leicester (United Kingdom); Luigi Piro, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Salvatore Sciortino, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); José Miguel Torrejon, Univ. de Alicante (Spain)

AHEAD (Integrated Activities in the High Energy Astrophysics Domain) is a project approved in the framework of the European H2020 program. Its main objective is to integrate European key research infrastructures for the domain by offering free-of-cost transnational access to a wide choice of facilities. Two distinct programs aim at opening access to facilities for test and calibration of space-based sensors and optics, and to institutes or data centres for mentoring/tutorial sessions on data analysis of the best high-energy astrophysical observatories. Moreover, our visitor program provides financial support for visits of experienced scientists and engineers to scientific institutes in Europe and EU associated countries. We will discuss the expected impact in relation to the current astrophysics mission programs, along with the specific opportunities given by the second, recently opened, AO. We will also describe the first results and lessons learned from the previous call.

9905-243, Session PS7

The AHEAD Horizon 2020 Program for the high energy astrophysics domain

Luigi Piro, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy)

The overall objective of AHEAD (Integrated Activities in the High Energy Astrophysics Domain) is to integrate national efforts in High-Energy Astrophysics, keeping its community at the cutting edge of science and technology and ensuring that space observatories are at the state of the art. AHEAD will integrate key research infrastructures including facilities for on-ground test and calibration and for data analysis of high-energy astrophysical observatories, by opening them to the space science community through its transnational access program. The technological development will focus on the improvement of selected critical technologies, background modeling, cross calibration, and feasibility studies of space-based instrumentation. Other programs include grants for collaborative studies, dissemination and public outreach and promotion of

workshops. Strong connections between institutes and industry will enable the development of new technologies and the associated market growth.

9905-269, Session PS7

Compact hard x-ray imaging system with large FOV

Miho Katsuragawa, ISAS - JAXA (Japan) and The Univ. of Tokyo (Japan); Shin'ichiro Takeda, OIST (Japan); Goro Sato, Atsushi Harayama, ISAS - JAXA (Japan); Shin Watanabe, Tadayuki Takahashi, ISAS - JAXA (Japan) and The Univ. of Tokyo (Japan)

9905-66, Session 15

Aberrations in square pore micro-channel optics used for x-ray lobster eye telescopes

Richard Willingale, James F. Pearson, Adrian Martindale, Charlotte H. Feldman, Univ. of Leicester (United Kingdom); Raymond Fairbend, Emile Schyns, PHOTONIS France S.A.S. (France); Julian T. Osbourne, Paul O'Brien, Univ. of Leicester (United Kingdom)

We identify all the significant aberrations that limit the performamce of square pore micro-channel plate optics (MPOs) used as an X-ray lobster eye.

These aberrations are incorporated into a comprehensive software model of the X-ray response of the optics and the predicted imaging and efficiency response is compared with the measured performance obtained from a breadboard lobster eye X-ray optic constructed for the SVOM MXT program.

The results reveal the manufacturing tolerances which limit the current performance of MPOs and enable us to identify particular intinsic aberrations which will limit the ultimate performance we can expect from MPO-lobster eye telescopes.

9905-67, Session 15

Development of the four-stage x-ray telescope (FXT) for the DIOS mission

Yasunori Babazaki, Ren Nakamichi, Ayako Bandai, Yuzuru Tawara, Ikuyuki Mitsuishi, Nagoya Univ. (Japan); Nozomi Nakaniwa, Yoshitomo Maeda, Institute of Space and Astronautical Science (Japan) and Japan Aerospace Exploration Agency (Japan)

A small satellite mission, the Diffuse Intergalactic Oxygen Surveyor (DIOS), is designed to carry out X-ray observations for detecting the warm-hot intergalactic medium (WHIM), which is a candidate of missing baryons, and revealing the large scale structure of the nearby universe (z < 0.3). In order to achieve the scientific goals, a telescope for the DIOS is required to possess high sensitivity for diffuse sources (grasp > 100 cm2 deg2 @ 0.6 keV) and an angular resolution of 5 arcmin. A Four-stage X-ray Telescope (FXT) has been developed as the best-fit optics for the DIOS mission because a four-stage optical system makes it possible to realize short focal length and large aperture at the same time.

We fabricated a third demonstration model of the FXT which consists of a quadrant housing, 3 sets of four-stage mirrors with a diameter of ~500 mm, a length of 36 mm, a thickness of 0.22 mm, and a focal length of 700 mm, and alignment plates. A new alignment system which adjusts radial positions of alignment plates is introduced. Platinum with a thickness of 1000 A was coated on the mirrors in the replication process. The FXT performance was investigated at the ISAS 30-m X-ray pencil beam facility using a monochromatic energy of 1.5 keV after tuning of radial positions of the alignment plates in optical. The best angular resolution for one set of four-stage mirrors is about 6 arcmin in HPD which is about 1 arcmin better than that of the previous samples. We confirmed that the resulting effective area is consistent with that of the expected in the ray-tracing simulation. The FXT mirrors with a focal length of 1200 mm and a diameter of 240 mm were also designed to obtain higher reflectivity at a higher energy range above 2 keV and prepared. We conducted an X-ray irradiation test also for the samples using a monochromatic energy of 4.5 keV. Consequently, the best angular resolution for one set of four-stage mirrors is ~ 5 arcmin in HPD and we confirmed that the effective area increases significantly as expected.

9905-68, Session 15

Development of x-ray multilayer telescope optics for XTP mission

Zhengxiang Shen, Xiaoqiang Wang, Kun Wang, Bin Ma, Qiushi Huang, Zhong Zhang, Tongji Univ. (China); Haifeng Wang, Donghua Univ. (China); Ying Dai, Pengfei He, Zhanshan Wang, Tongji Univ. (China)

The X-ray Timing and Polarization (XTP) satellite is dedicated to study black hole, neutron star and magnetar and then get more information in the physics under extreme gravity, density and magnetism. With an effective area of about 1 square meter and angular resolution of 1 arcminute, XTP is expected to make the most sensitive temporal and polarization observations with good energy resolution in 1-30 keV. Large collecting areas are obtained by tightly nesting layers of grazing incidence mirrors in a conical approximation Wolter-I design. The segmented mirrors that form these layers are formed by thermally slumping glass substrates coated with depth-graded W/Si multilayers for enhanced reflectivity in higher energy region. In order to force the overall shape of the nominally cylindrical substrates to the appropriate conic form, an over-constraint method was used to assemble the mirrors to a telescope. We will present performance on the XTP optics and report the current status of the telescope production.

9905-69, Session 15

Progress on the fabrication of high resolution and lightweight monocrystalline silicon x-ray mirrors

Raul E. Riveros, NASA Goddard Space Flight Ctr. (United States) and Univ. of Maryland, Baltimore County (United States); Michael P. Biskach, Kim D. Allgood, James R. Mazzarella, SGT, Inc. (United States); Marton V. Sharpe, SGT, Inc. (United States); William W. Zhang, NASA Goddard Space Flight Ctr. (United States)

Monocrystalline silicon could be an excellent X-ray mirror substrate material due to its high stiffness, low density, high thermal conductivity, zero internal stress, and commercial availability. Our work at NASA Goddard Space Flight Center focuses on identifying and developing a manufacturing process to produce high resolution and lightweight X-ray mirror segments in a cost and time effective manner. Previous

efforts focused on demonstrating the feasibility of cylindrical silicon mirror polishing and lightweighting. Present efforts are aimed towards producing true paraboloidal and hyperboloidal mirror surfaces on the lightweight silicon segments. This paper presents results from these recent investigations.

9905-70, Session 15

Gas bearing slumping and figure correction of x-ray telescope mirror substrates

Brandon D. Chalifoux, Heng Zuo, Michael D. DeTienne, Graham Wright, Ralf K. Heilmann, Mark L. Schattenburg, Massachusetts Institute of Technology (United States)

Figure correction of thin x-ray telescope mirrors may be critical for future missions that require high angular resolution and large collecting areas. One promising method of providing figure correction is to use stress generated via ion implantation. Since stress-based figure correction strategies cannot correct high spatial frequency errors, it is critical to obtain glass with only low spatial frequency error. One method is thermal gas bearing slumping, where glass is softened while floating on thin films of gas. This method avoids introducing mid- or high- spatial frequency errors by eliminating contact between the glass and mandrel. Together, our methods are a promising approach to fabricating mirrors for a high angular resolution, large-area x-ray observatory. In this paper we report on progress in advancing the air bearing slumping to higher gas pressures and curved geometry. We also report on continued progress on advancing the ion implantation technology toward correcting flight-sized mirror substrates.

9905-71, Session 15

Slumped glass optics development with pressure assistance

Bianca Salmaso, Stefano Basso, Marta M. Civitani, Mauro Ghigo, Joanna Holyszko, Daniele Spiga, Gabriele Vecchi, Giovanni Pareschi, INAF - Osservatorio Astronomico di Brera (Italy)

Thin glass mirrors are a viable solution to build future X-ray telescopes with high angular resolution and large collecting area. This approach is very attractive for the optics implementation of future X-ray astronomy projects like the X-ray Surveyor Missions in USA, the XTP mission in China and the NGHXT mission in Japan (all this projects could have an European participation). In the case of the X-ray Surveyor Mission, where a sub-arcsec angular resolution is requested, the use of actuators or post correction with sputtering deposition is envisaged. The hot slumping assisted by pressure is an innovative technology developed in our laboratories to replicate a mould figure. Our hot slumping process is based on thin substrates of Eagle XG glass to be thermally formed on Zerodur K20 moulds. This technology is coupled with an integration process able to damp low frequency errors. A continuous improvement in the reduction of the mid-frequency errors led to slumped glass foils with a potential angular resolution evaluated from the metrological data of a few arcsec, HEW. High frequency errors have been for a long time a critical point of our technology. In particular, the pressure assistance was leading to a partial replication of the mould micro-roughness, causing a quite relevant contribution to the PSF of a few arcsec (depending on the incidence angle and photon energy). Therefore, we developed a new process to further reduce the micro-roughness of slumped glass foils, making the technology now attractive for telescopes sensitive also in the hard X-tray band. This paper provides the latest status of our research.

9905-72, Session 15

New lithographic techniques for x-ray spectroscopy

Jake A. McCoy, Casey T. DeRoo, Randall L. McEntaffer, The Univ. of Iowa (United States)

X-ray spectroscopy has been proven to be an extremely important aspect of high energy astrophysics. In addition to providing a powerful tool for performing diagnostics in astrophysical plasmas, high-resolution X-ray spectroscopy has direct applications to several key scientific issues including making measurements of the warm-hot intergalactic medium, determining elemental abundances in the local interstellar medium and studying dynamics in active galactic nuclei. The majority of astrophysically abundant X-ray spectral lines exist below 2 keV, at soft X-ray energies, necessitating the use of diffraction gratings to perform high-resolution spectroscopy. The grating spectrometers on board XMM-Newton and the Chandra X-ray Observatory have resolving powers on the order of several hundred and have provided large amounts of scientific return. Future X-ray observatories will require advanced spectrometers with resolving powers of a few thousand to make significant improvements in X-ray spectroscopy and to address future scientific problems. Reflection gratings can be integrated into a grazing incidence optical system of an X-ray telescope by being positioned to intercept the radiation coming to a focus. When compared to the standard in-plane geometry of reflection gratings, the off-plane design has several attractive features. First, there is minimal groove shadowing at grazing incidence angles resulting in high diffraction efficiency. In addition, off-plane gratings feature lower scatter, have better spectral coverage than in-plane gratings, and have the potential for high resolving power. Further, off-plane gratings can be tightly packed into an array, offering an efficient way for them to be paired with Wolter-I optics in an X-ray telescope. To maximize spectral resolution and diffraction efficiency, these gratings must feature a high-precision custom groove profile. Gratings with parallel grooves lead to aberrations when dispersing a spectrum from a converging beam of radiation. To remedy this, these gratings must be radially ruled such that groove density increases in the direction that radiation travels to the focal plane of the telescope. Further, gratings with groove facets blazed to a triangular saw-tooth profile will preferentially disperse X-rays to one side of zero order, effectively doubling signal-to-noise in the detected spectrum with half the number of necessary detector elements. As a result, the development of radially ruled off-plane gratings, with high groove densities and blazed groove facets, that can be compactly stacked and aligned in array will be critical to push the state-of-the-art for instruments in the future. This paper describes the development of a novel fabrication method to produce these gratings using techniques in electron-beam lithography (EBL) and presents preliminary results. In this approach, approximating the idealized radially ruled groove profile to high fidelity requires the use of an EBL tool with a sufficiently small minimum step size. Further, producing blazed groove facets requires carefully controlling e-beam doses to create multilevel staircase structures in the resist and using thermal reflow to smooth them to inclines.

9905-73, Session 16

ATHENA: the advanced telescope for high energy astrophysics *(Invited Paper)*

Kirpal Nandra, Max-Planck-Institut für extraterrestrische Physik (Germany)

Athena is the next generation X-ray astronomy facility, currently under Phase A study by the European Space Agency for a launch in 2028. The scientific objectives and current status of the Athena project will be reviewed, as well as the activities of the Athena Science Study study team and the scientific community that supports the mission.

9905-74, Session 16

ATHENA: system studies and optics accommodation

Mark R. Ayre, Marcos Bavdaz, Ivo Ferreira, Eric Wille, Sebastiaan Fransen, Alexander Stefanescu, Martin Linder, European Space Research and Technology Ctr. (Netherlands)

ATHENA is currently in Phase A, with a view to formal adoption upon a successful System Requirements Review in 2019. After a brief presentation of the reference spacecraft design, this paper will focus on the functional and environmental requirements, the thermo-mechanical design and the Assembly, Integration & Test (AIT) considerations related to the very large Mirror Assembly Module (MAM) housing the Silicon Pore Optics (SPO).

Initially functional requirements on the optics accommodation are presented, with the Effective Area and Half Energy Width (HEW) requirements leading to a MAM comprising (depending on final mirror size selected) between ~700-1000 Mirror Modules (MM), co-aligned with exquisite accuracy to provide a common focus. A preliminary HEW budget allocated across the main contributors is presented, and this is then used as a reference to derive subsequent requirements and engineering considerations, including: The procedures and technologies under consideration for AIT to achieve the required alignment; stiffness requirements and handling scheme required to constrain deformation under gravity during x-ray testing; temperature control to constrain thermo-elastic deformation during flight; and the capability to focus using the Instrument Switching Mechanism (ISM).

Next, our best understanding of the launch mechanical environment imposed by the forthcoming Ariane-64 launch vehicle is presented along with the mechanical requirements of the MMs, and the need to minimise shock-loading of the MMs is stressed. Methods to achieve this are presented, including: Modal-tuning of the MAM to act as a low-pass filter during launch shock events; the possibility to deploy a passive vibration solution in the launcher interface plane to reduce loads.

9905-75, Session 16

The ATHENA optics development

Marcos Bavdaz, Eric Wille, Brian Shortt, Sebastiaan Fransen, European Space Agency (Netherlands); Maximilien J. Collon, Nicolas M. Barrière, cosine B.V. (Netherlands); Alexei Yanson, Giuseppe Vacanti, cosine Science & Computing B.V. (Netherlands); Jeroen Haneveld, Micronit Microfluidics B.V. (Netherlands); Coen van Baren, SRON Netherlands Institute for Space Research (Netherlands); Karl-Heinz Zuknik, OHB AG (Germany); Finn E. Christensen, DTU Space (Denmark); Michael Krumrey, Physikalisch-Technische Bundesanstalt (Germany); Vadim Burwitz, Max-Planck-Institut für extraterrestrische Physik (Germany); Giovanni Pareschi, Daniele Spiga, INAF - Osservatorio Astronomico di Brera (Italy); Giuseppe Valsecchi, Media Lario Technologies S.r.l. (Italy); Dervis Vernani, RUAG Space AG (Switzerland)

ATHENA (Advanced Telescope for High ENergy Astrophysics) is being studied by the European Space Agency (ESA) as the second large science mission, with a launch slot in 2028. System studies and technology preparation activities are on-going.

The optics of the telescope is based on the modular Silicon Pore Optics (SPO), a novel X-ray optics technology significantly benefiting from spin-in from the semiconductor industry. Several technology development activities are being implemented by ESA in collaboration with European industry and institutions. The related programmatic background, the status of the SPO technology and the associated planning will be presented in the paper.

9905-76, Session 16

Silicon pore optics for the ATHENA telescope

Maximilien J. Collon, Giuseppe Vacanti, Ramses Günther, Alexei Yanson, Nicolas M. Barrière, Boris Landgraf, Mark Vervest, Abdelhakim Chatbi, Marco W. Beijersbergen, cosine B.V. (Netherlands); Marcos Bavdaz, European Space Agency (Netherlands); Eric Wille, European Space Research and Technology Ctr. (Netherlands); Jeroen Haneveld, Arenda Koelewijn, Micronit Microfluidics B.V. (Netherlands); Coen van Baren, SRON Netherlands Institute for Space Research (Netherlands); Peter Müller, Michael Krumrey, Physikalisch-Technische Bundesanstalt (Germany); Vadim Burwitzz, Max-Planck-Institut für extraterrestrische Physik (Germany); Marta M. Civitani, INAF - Osservatorio Astronomico di Brera (Italy); Daniele Spiga, Giovanni Pareschi, Istituto Nazionale di Astrofisica (Italy); Sonny Massahi, Finn E. Christensen, DTU Space (Denmark); Giuseppe Valsecchi, Media Lario Technologies S.r.l. (Italy)

Silicon Pore Optics is a high-energy optics technology, invented to enable the next generation of high-resolution, large area, X-ray telescopes such as the ATHENA observatory, an European large (L) class mission with a launch date of 2028. The technology development is carried out by a consortium of industrial and academic partners and focuses on building an optic with a focal length of 12 m that shall achieve an angular resolution better than 5". So far we have built optcs with with a focal length of 50 m and 20 m.

This paper presents details of the work carried out to build silicon stacks for a 12 m optic and to integrate them into mirror modules. It will also present results of x-ray tests taking place at the BESSY synchrotron and the PANTER test facility.

9905-77, Session 16

Mass production of silicon pore optics for ATHENA

Eric Wille, Marcos Bavdaz, European Space Agency (Netherlands); Maximilien J. Collon, cosine B.V. (Netherlands)

Silicon Pore Optics (SPO) provide high angular resolution with low effective area density as required for the Advanced Telescope for High Energy Astrophysics (ATHENA). The x-ray telescope consists of several hundreds of SPO mirror modules. During the development of the process steps of the SPO technology, specific requirements of a future mass production have been considered right from the beginning. The manufacturing methods heavily utilise off-the-shelf equipment from the semiconductor industry, robotic automation and parallel processing. This allows to upscale the present production flow in a cost effective way, to produce hundreds of mirror modules per year.

Considering manufacturing predictions based on the current technology status, we present an analysis of the time and resources required for the ATHENA flight programme. This includes the full production process starting with Si wafers up to the integration of the mirror modules. We present the times required for the individual process steps and identify the equipment required to produce two mirror modules per day. A preliminary timeline for building and commissioning the required infrastructure, and for flight model production of about 1000 mirror modules, is presented.

9905-166, Session PS5

Observing the WHIM with ATHENA

Jörn Wilms, Thorsten Brand, Thomas Dauser, Friedrich-Alexander-Univ. Erlangen-Nürnberg (Germany); Philippe Peille, Institut de Recherche en Astrophysique et Planétologie (France); Beatriz Cobo, Maite Ceballos, Univ. de Cantabria (Spain); Jelle S. Kaastra, SRON Netherlands Institute for Space Research (Netherlands); Paul O'Brien, Univ. of Leicester (United Kingdom); Xavier Barcons, Univ. de Cantabria (Spain); Luigi Piro, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Jan-Willem A. den Herder, SRON Netherlands Institute for Space Research (Netherlands); Didier Barret, Institut de Recherche en Astrophysique et Planétologie (France)

We present the results of simulations of the detection probability for absorption lines from ions in the warm and hot ionized medium with ATHENA in the spectra of Gamma-ray burst afterglows. Performed using the end to end simulation framework SIXTE, the simulations are based on Swift XRT lightcurves of afterglows. We simulate both the case of single and multiple lines, as well as results for line searches in absorption structures from a more complex medium.

9905-167, Session PS5

Detectability of exoplanet transits with ATHENA's WFI instrument: testing for white and correlated noise

Stefania Carpano, Max-Planck-Institut für extraterrestrische Physik (Germany); Jörn Wilms, Friedrich-Alexander-Univ. Erlangen-Nürnberg (Germany); Arne Rau, Max-Planck-Institut für extraterrestrische Physik (Germany)

One of the science goals of the Athena X-ray observatory is to detect and characterize the X-ray transits of hot Jupiter-like planets orbiting their parent stars. To date, the only suitable source for these studies is HD 189733b, a Jupiter-size planet in a 2 d orbit, for which a transit depth of 6-8% has been found from the accumulation of several Chandra and XMM-Newton observations.

Here, we simulate realistic light curves of exoplanet transits using the SIXTE Athena end-to-end simulator and derive the expected signal-to-noise ratio (SNR) for different configurations of the Wide Field Imager (WFI) instrument and for different planetary system parameters. We first generate flat light curves for different source fluxes to derive the (white noise) standard deviation. Next, moderate level of correlated noise and transits of different depths are added to the light curves.

For pure white noise, the SNR is proportional to the square root of the flux, of the light curve bin size and of the number of co-added transits, and by definition proportional to the transit depth. When correlated noise starts to be significant, re- binning the data will only slightly increase the SNR, depending on the noise characteristics. Considering only white noise, a transit from a source like HD 189733, with a source flux around 5e-13 erg s^-1 cm^-2 and a transit depth of about 5% can be detected with a SNR>3 in a unique transit with Athena. With correlated noise, stacking of the observations of multiple transits may be necessary.

9905-168, Session PS5

Silicon pore optics mirror module assembly method

Nicolas M. Barrière, Abdelhakim Chatbi, Maximillien J. Collon, Ramses Günther, Boris Landgraf, Giuseppe Vacanti, Roy van der Hoeven, Mark Vervest, Alexei Yanson, cosine B.V. (Netherlands); Marcos Bavdaz, Eric Wille, European Space Agency (Netherlands)

Silicon Pore Optics are produced as stacks of mirror plates, which are then paired to form X-ray Optics Units (XOUs). For Athena, in the current scheme, two XOUs are glued together in between a set of brackets, leading to mirror modules made of 4 stacks. Mirror modules are integrated at the XPBF beamline of PTB (BESSY synchrotron, Berlin), using a pencil X-ray beam; The relative orientation of the secondary stack with respect to the primary stack is fitted using the positions of the reflected beamspots onto the camera. This provides a deterministic way of orienting stacks with respect to each other within a XOU, and allows meeting with the stringent angular accuracy requirements. The same operation is then repeated for the second XOU composing a mirror module, with the additional constraint that it needs to be confocal with the first one. In this talk we review the method that is used to integrate stacks into mirror modules.

9905-169, Session PS5

Predicting silicon pore optics

Giuseppe Vacanti, Nicolas M. Barrière, Abdelhakim Chatbi, Ramses Günther, cosine Science & Computing B.V. (Netherlands); Maximilien J. Collon, cosine B.V. (Netherlands); Roy van der Hoeven, Boris Landgraf, Mark Vervest, Alexei Yanson, cosine Science & Computing B.V. (Netherlands); Marcos Bavdaz, Eric Wille, European Space Research and Technology Ctr. (Netherlands)

While X-ray characterization of Silicon Pore Optics provides the ultimate validation of their performance, modelling and simulation also have an important role in the development efforts. We report on the latest results on this front, and in particular on the developments aiming at making the models understand possibly every piece of metrology available during the production process. Besides understanding how the optics behave, this effort also aims at being able to assess the X-ray performance of stacks without making use of actual X-ray measurements.

9905-170, Session PS5

Characterizing silicon pore optics stacks

Giuseppe Vacanti, Nicolas M. Barrière, Abdelhakim Chatbi, Ramses Günther, cosine Science & Computing B.V. (Netherlands); Maximilien J. Collon, cosine B.V. (Netherlands); Roy van der Hoeven, Boris Landgraf, Mark Vervest, Alexei Yanson, cosine Science & Computing B.V. (Netherlands); Marcos Bavdaz, Eric Wille, European Space Research and Technology Ctr. (Netherlands)

Every Silicon Pore Optics stack made is characterized at the PTB's X-ray Pencil Beam Facility (BESSYII). We describe how the stacks are measured, and the data analyzed by means of an automatic analysis pipeline. The pipeline can be run in live mode, while the measurement is is progress, so that a few minutes after completion a complete characterization is available. This provides immediate feedback on the quality of the stacks and comparison with the available metrology.

9905-171, Session PS5

X-ray mirror coating design, development, and testing for the ATHENA mission

Desirée Della Monica Ferreira, Finn E. Christensen, Anders C. Jakobsen, Sonny Massahi, David Girou, DTU Space (Denmark); Brian Shortt, European Space Research and Technology Ctr. (Netherlands); Jørgen Garnæs, Antoni T. Rosell, Danish Fundamental Metrology Institut (Denmark); Michael Krumrey, Levent Cibik, Stefanie Marggraf, Physikalisch-Technische Bundesanstalt (Germany)

We present results on X-ray mirror coating optimisation based on the latest optics geometry adopted for ATHENA along with the development and testing of coatings on silicon pore optics (SPO) substrates.

This study include pre and post coating characterisation of the x-ray mirrors using Atomic Force Microscopy (AFM), X-ray reflectometry (XRR) and scatter measurements performed at the 8 keV X-ray facility at DTU Space and with synchrotron radiation in the laboratory of PTB at BESSY II.

We report our findings on surface roughness, coating reflectivity, environmental tests and long term stability of coatings considering the grazing incidence angles and energies of ATHENA.

9905-172, Session PS5

Upgrades to the PANTER x-ray test facility for future missions

Vadim Burwitz, Max-Planck-Institut für extraterrestrische Physik (Germany)

Activities at the Max-Planck-Institute for extrateréstial Physics PANTER X-ray test facility to develop and test X-ray optics and telescopes for new missions will be described. Currently upgrades to the test facility are beeing made to allow detailed thermo-optical studies of X-ray optics in the X-ray beamline, especially for baseline Silicon Pore Optics for the ATHENA and ARCUS missions. Also the accomodation in the test facility of the large up to 3 m diameter ATHENA optic is beeing studied. Furthermore plans for tests of the soft X-ray telescope for the SVOM mission, the XIPE

X-ray polarimetry telescope will be presented.

9905-173, Session PS5

Measuring SPOs at the PANTER x-ray test facility: the alignment

Benedikt Menz, Vadim Burwitz, Gisela D. Hartner, Max-Planck-Institut für extraterrestrische Physik (Germany)

The development and calibration of silicon pore optics (SPOs) as proposed for ATHENA is supported by continuous measurements at the PANTER X-ray test facility.

To obtain comparable measurement results for the SPOs robust alignment procedures are needed to place the mirror module with respect to the optical axis.

In this work we examine, how the angular resolution and the effective area of the SPOs are influenced by the alignment.

By means of ray tracing simulations and X-ray measurements the influence of the alignment is investigated.

Based on these results it is demonstrated how the characteristics of these influences can be used to align the SPOs at the PANTER X-ray test facility.

9905-174, Session PS5

New x-ray pencil beam facility for the characterization of silicon pore optics

Michael Krumrey, Physikalisch-Technische Bundesanstalt (Germany); Peter Müller, Physikalisch Technische Bundesanstalt (Germany); Levent Cibik, Physikalisch-Technische Bundesanstalt (Germany); Maximilien J. Collon, cosine B.V. (Netherlands); Marcos Bavdaz, European Space Research and Technology Ctr. (Netherlands)

A new X-ray pencil beam facility (XPBF 2.0) has been installed in the laboratory of the Physikalisch-Technische Bundesanstalt at the synchrotron radiation facility BESSY II in Berlin to characterize silicon pore optics (SPOs) for the future X-ray observatory ATHENA. As the existing XPBF which is operated since 2005, the new beamline provides a pencil beam of very low divergence, a vacuum chamber with a hexapod system for accurate positioning of the SPO to be investigated, and a vertically movable CCD-based camera system to register the direct and the reflected beam. In contrast to the existing beamline, a multilayer-coated toroidal mirror is used for beam monochromatization and collimation, enabling the use of beam diameters between about 100 μm and several mm at a photon energy of 1.6 keV. The new beamline features increased travel ranges for the hexapod to cope with larger SPOs and a sample to detector distance of 12 m corresponding to the envisaged focal length of ATHENA.

9905-175, Session PS5

Advancement status of the Beam Expanded Testing X-ray facility (BEaTriX)

Carlo Pelliciari, Daniele Spiga, Bianca Salmaso, Giovanni Pareschi, Gianpiero Tagliaferri, INAF - Osservatorio Astronomico di Brera (Italy)

We report the advancement of the realization of the BEaTriX (Beam Expander Testing X-ray facility) project, an X-ray apparatus to generate an expanded (200x60 mm2), uniform and low divergent (~1.5 arcsec HEW) soft X-ray beam within a small lab (6x15 m2). BEaTriX will be used to directly perform the quality control of focusing modules of large X-ray optics such as those for the ATHENA X-ray observatory, based on either Silicon Pore Optics (baseline) or Slumped Glass Optics (alternative). Given the large number of modules to be integrated (>1000) and the stringent requirement of 5 arcsec in the final angular resolution of the telescope, an even larger number of modules has to be produced and tested in series, without relying on outer metrology tools or large X-ray facilities such as synchrotron light sources. BEaTriX is being built at INAF/OAB, but due to its small size it can be replicated at the industrial site where the mirror modules will be manufactured, with the additional possibility of aligning the parabolic and the hyperbolic segments directly in X-ray illumination. The basic requirement is a beam with divergence below 1-2 arcsec HEW to characterize mirror modules that have to reach an angular resolution of about 3-4 arcsec HEW. In this paper we report design of the facility and the ongoing fabrication of the optical components including: a microfocus X-ray source, a grazing incidence paraboloidal mirror to parallelize the beam, a crystal monochromation system, and an asymmetrically-cut diffracting crystal used to perform the beam expansion to the desired size. A detailed performance simulation of the system is also shown.

9905-176, Session PS5

Simulation and modeling of silicon pore optics for the ATHENA x-ray telescope

Daniele Spiga, INAF - Osservatorio Astronomico di Brera (Italy); Finn E. Christensen, DTU Space (Denmark); Marcos Bavdaz, European Space Agency (Netherlands); Marta M. Civitani, Paolo Conconi, INAF - Osservatorio Astronomico di Brera (Italy); Desirée Della Monica Ferreira, Sonny Massahi, DTU Space (Denmark); Giovanni Pareschi, INAF - Osservatorio Astronomico di Brera (Italy); Brian Shortt, European Space Agency (Netherlands); Kashmira Tayabaly, INAF - Osservatorio Astronomico di Brera (Italy) and Politecnico di Milano (Italy); Niels Joergen S. Westergaard, DTU Space (Denmark); Eric Wille, European Space Agency (Netherlands)

The ATHENA X-ray observatory is a large-class ESA approved mission, with launch scheduled in 2028. The technology of Silicon Pore Optics (SPO) was been selected as the baseline to assemble ATHENA's optic with more than 1000 mirror modules, obtained by stacking wedged and ribbed silicon wafer plates onto silicon mandrels to form the Wolter-I configuration. Even if the current baseline design fulfills the required effective area of 2 m2 at 1 keV on-axis, alternative design solutions, e.g., privileging the field of view or the off-axis angular resolution, are also possible. Moreover, the stringent requirement of a 5 arcsec HEW angular resolution at 1 keV entails very small profile errors and excellent surface smoothness, as well as a precise alignment of the 1000 mirror modules to avoid imaging degradation and effective area loss. Finally, the stray light issue has to be kept under control. In this paper we show the preliminary results of simulations of optical systems based on SPO for the ATHENA X-ray telescope, from pore to telescope level, carried out at INAF/OAB and DTU Space under ESA contract. We show ray-tracing results, including assessment of the misalignments of mirror modules, the impact of stray light, for different optical configurations and assuming realistic mirror imperfections. We also deal with a detailed description of diffractive effects expected in an SPO module from UV light, where the aperture diffraction prevails, to X-rays where the surface diffraction plays a major role. Finally, we perform a comparison of some predictions with the X-ray calibration tests performed at the BESSY synchrotron and suggest possible improvement of the baseline design.

9905-177, Session PS5

Development and production of a multilayer-coated x-ray reflecting stack of silicon pore optics for the ATHENA mission

Sonny Massahi, Technical Univ. of Denmark (Denmark); Finn E. Christensen, Desirée Della Monica Ferreira, DTU Space (Denmark); David Girou, Technical Univ. of Denmark (Denmark); Brian Shortt, European Space Research and Technology Ctr. (Netherlands); Maximilien J. Collon, Boris Landgraf, cosine B.V. (Netherlands); Michael Krumrey, Physikalisch-Technische Bundesanstalt (Germany)

The Advanced Telescope for High-Energy Astrophysics, ATHENA, selected as the European Space Agency's second large-mission, is based on the novel Silicon Pore Optics technology.

DTU Space has been working for several years on the development of multilayer coatings on the Silicon Pore Optics in an effort to optimize the throughput of the Athena optics. A linearly graded Ir/B4C multilayer has been deposited on the mirrors, via the direct current magnetron sputtering technique, at DTU Space. This specific multilayer has, through simulations, proven to give the highest reflectivity at 6 keV, which is a goal for the scientific objectives of the mission.

A critical aspect of the coating process concerns the use of photolithography techniques upon which we will present the most recent developments in particular related to the cleanliness of the plates.

Experiments regarding the lift-off and stacking of the mirrors have been performed and the results attained will be presented.

9905-178, Session PS5

Implementation and fabrication considerations of an optimal hybrid array for the ATHENA x-ray integral field unit instrument

Simon R. Bandler, Joseph S. Adams, Gabriele L. Betancourt-Martinez, James A. Chervenak, Meng P. Chiao, Megan E. Eckart, Audrey J. Ewin, Fred M. Finkbeiner, Richard L. Kelley, Caroline A. Kilbourne, Samuel J. Moseley, Frederick S. Porter, John E. Sadleir, Stephen J. Smith, Edward J. Wassell, Wonsik Yoon, NASA Goddard Space Flight Ctr. (United States); Roland H. den Hartog, Jan van der Kuur, Brian D. Jackson, SRON Netherlands Institute for Space Research (Netherlands); Joel N. Ullom, William B. Doriese, National Institute of Standards and Technology (United States)

Options for the design of the Athena X-IFU microcalorimeter that employ more than one type of pixel have a number of advantages but also present challenges. In this presentation, we present these advantages and challenges, how they trade off against each other from a technical perspective, and the progress made so far towards minimizing the challenges. In this paper we will discuss the technical implications of developing a hybrid array, and describe our progress to date in the development of these arrays. In particular we consider the implications of developing a hybrid array consisting of a small pixel array (SPA) at the center of a focal plane detector, where here small means that the pixel pitch is 75 to 120 microns. Surrounding the SPA is a large pixel array (LPA) where here large means a pitch of 250 to 300 microns. Both the SPA and LPA consist of close-packed X-ray microcalorimeters, where the temperature sensor is assumed to a transition-edge sensor (TES). There are a number of implications to consider when integrating SPA and LPA pixels within a hybrid array. While there will be serious impacts to a large number of instrument subsystems, including the electronics in the read-out and the signal processing, in this paper here we focus on the implications to fabrication and general testing.

In this paper our discussion of the implications will include the following topics:

(i) The TES transition temperature (Tc) of the bilayer for the SPA pixels may need to be different to the Tc for the LPA pixels, and each Tc will need to be adequately controlled.

(ii) The absorber composition desired for the SPA may well need to be different to that for the LPA, in terms of layer metals and thicknesses. We discuss the effect on the development of more complex processing steps such as the ion-milling of different absorber types.

(iii) The process needed to heat-sink the SPA is very different to that of the LPA pixels, and the two types of heat-sinking need to be integrated.

(iv) The routing of wires to all the pixels within the array and from the array to the transformer coils requires a slightly different routing algorithm.

(v) Pre-flight and in-flight calibration is more time-consuming and perhaps more challenging when there are two pixel types instead of one.

We will present recent progress we have made in demonstrating our ability to fabricate and develop hybrid arrays.

9905-179, Session PS5

Optimising the multiplex factor of the frequency domain multiplexed readout of the TES-based microcalorimeter imaging array for the X-IFU instrument on the ATHENA x-ray observatory

Jan van der Kuur, Luciano Gottardi, Hiroki Akamatsu, Roland H. den Hartog, SRON Netherlands Institute for Space Research (Netherlands); Mikko Kiviranta, VTT Technical Research Ctr. of Finland Ltd. (Finland); Brian D. Jackson, SRON Netherlands Institute for Space Research (Netherlands)

Athena is a space-based X-ray observatory intended for exploration of the hot and energetic universe.

One of the science instruments on Athena will be the X-ray Integrated Field Unit (X-IFU), which is a cryogenic X-ray spectrometer, based on a large cryogenic imaging array of Transition Edge Sensors (TES) based microcalorimeters operating at a temperature of 100mK. The imaging array consists of ±3800 pixels providing 2.5 eV spectral resolution, and covers a field of view with a diameter of of 5 arc minutes.

Multiplexed readout of the cryogenic microcalorimeter array is essential to comply with the cooling power and complexity constraints on a space craft. Frequency domain multiplexing has been under development for the readout of TES-based detectors for this purpose, not only for the X-IFU detector arrays but also for TES-based bolometer arrays for the Safari instrument of the Japanese SPICA observatory.

This paper discusses the design considerations which are applicable to optimise the multiplex factor within the boundary conditions as set by the space craft. More specifically, the interplay between the science requirements such as pixel dynamic range, pixel speed, and cross talk, and the space craft requirements such as the power dissipation budget, available bandwidth, and electromagnetic compatibility will be discussed. The status of the experiments which are aimed at demonstrating the baselined multiplex factor of 40, as well as options under study to increase the multiplex factor further, will be shown.

9905-180, Session PS5

Development of frequency domain multiplexing for the x-ray integral field unit (X-IFU) on the ATHENA

Hiroki Akamatsu, Luciano Gottardi, Jan van der Kuur, Cor P. de Vries, SRON Netherlands Institute for Space Research (Netherlands); Joseph S. Adams, Simon R. Bandler, NASA Goddard Space Flight Ctr. (United States); Marcel P. Bruijn, SRON Netherlands Institute for Space Research (Netherlands); James A. Chervenak, NASA Goddard Space Flight Ctr. (United States); Brian D. Jackson, SRON Netherlands Institute for Space Research (Netherlands); Caroline A. Kilbourne, NASA Goddard Space Flight Ctr. (United States); Mikko Kiviranta, VTT Technical Research Ctr. of Finland Ltd. (Finland); A. J. van der Linden, Roland H. den Hartog, SRON Netherlands Institute for Space Research (Netherlands); Stephen J. Smith, NASA Goddard Space Flight Ctr. (United States)

We are developing the frequency domain multiplexing (FDM) read-out of transition-edge sensor (TES) microcalorimeters for the X-ray Integral Field Unit (X-IFU) instrument on board of the future European X-Ray observatory Athena. The X-IFU instrument consists of an array of sim3840 TESs with a high quantum efficiency (>90 %) and spectral resolution $Delta E$=2.5 eV @ 7 keV ($E/DeltaEsim$2800).

FDM is currently the baseline readout system for the X-IFU instrument. In FDM, TESs are coupled to a passive LC filter and biased with alternating current (AC bias) at MHz frequencies. Each resonator should be separated beyond their detector thermal response (<50 kHz) to avoid crosstalk between neighboring resonators. To satisfy the requirement of the X-IFU, a multiplexing factor of 40 pixels/channel in a frequency range from 1 to 5MHz required.

Using high quality factor LC filters and room temperature electronics developed at SRON and low-noise two stage SQUID amplifiers provided by VTT, we have recently demonstrated good performance with the FDM readout of Mo/Au TES calorimeters with Au/Bi absorbers. We have achieved X-ray energy resolutions better than 2.8 eV at frequencies between 1.3 and 3.7 MHz in the single pixel read-out. We have also shown for the first time an X-ray energy resolution better than 3 eV in a 2 pixel FDM read-out demonstration. Recently an integrated noise equivalent power resolution of about 2.0 eV at 1.7 MHz has been demonstrated with a pixel from a new TES array.

In this paper we report on the single pixel performance of these microcalorimeters under MHz AC bias, and further results of the performance of these pixels under FDM.

9905-181, Session PS5

The impact of crosstalk in the ATHENA/X-IFU instrument on the GRB/WHIM science case

Roland H. den Hartog, Jelle de Plaa, SRON Netherlands Institute for Space Research (Netherlands); Thorsten Brand, Jörn Wilms, Friedrich-Alexander-Univ. Erlangen-Nürnberg (Germany); Stephen J. Smith, Simon R. Bandler, NASA Goddard Space Flight Ctr. (United States); Brian Jackson, Jan-Willem A. den Herder, SRON Netherlands Institute for Space Research (Netherlands); Didier Barret, Institut de Recherche en Astrophysique et Planétologie (France)

The Athena X-ray mission was selected as the second L-class mission in ESA's Cosmic Vision 2015–25 plan, with a launch foreseen in 2028, to address the theme ''Hot and Energetic Universe". One of the science cases that will be addressed by this mission is that of the missing baryons. Roughly half of the baryonic content of the Universe is suspected to be locked up in the Warm / Hot Integalactic Medium (WHIM), and detectable as OVII and OVIII absorption lines against the 0.2 - 1 keV X-ray part of spectra from distant, bright Gamma-Ray Bursts (GRBs).

One of the two instruments on board of Athena is the X-ray Integral Field Unit (X-IFU) which is based on an array of ~3800 Transition Edge Sensors (TES's) operated at a temperature of 50 mK. This science case poses an interesting challenge for this instrument, as it requires a combination of high energy resolution (better than 2.5 eV) and high countrate (several tens of counts per second per detector for GRBs as bright as 10 mCrab).

This performance on single sensor level has been demonstrated, but the operation of such detectors in an array, using multiplexed readout, brings additional challenges, both for the design of the array in which the sensors are placed and for the readout of the sensors. The readout of the

detector array will be based on Frequency Domain Multiplexing (FDM). In this system of detectors and readout, crosstalk can arise through various mechanisms: On the array, neighboring sensors can couple through thermal crosstalk. Detectors adjacent in carrier frequency may suffer from electrical crosstalk due to the finite width of the bandpass filters, and shared sources of impedance in their readout lines. The signals from the individual detectors are summed and then amplified by a pair of SQUID amplifiers before being sent to warm front-end electronics. These SQUID amplifiers exhibit a degree of non-linearity, which will give rise to higher harmonics of carriers and intermodulation products when multiple signal pulses are simultaneously present. Under high countrate conditions this is another source of crosstalk. The effect of all these crosstalk sources is that in the record of a signal pulse parasitic pulses will appear which will create a stochastic offset of the measured energy and thus a degradation of the energy resolution.

We have developed an advanced end-to-end simulator for Athena, SIXTE, with which the signals on individual detectors in an array can be simulated for various science cases. Simulated observations of WHIM absorption lines against spectra of GRBs already indicated that WHIM detections are challenging but feasible. Adding now one by one the effects of the crosstalk sources to these simulated photon streams will allow us to assess their impact on the science results, and to derive crucial information about the design of the readout chain. This will influence the choices for the wiring routing, the multiplexing factor, the number of readout chains needed, and the design and operation of the SQUID amplifiers.

9905-182, Session PS5

Gain stability with no-feedback-loop developed for the X-IFU/ATHENA readout chain

Damien Prêle, Fabrice Voisin, Cyril Beillimaz, Ctr. National de la Recherche Scientifique (France); Andrea Goldwurm, Commissariat à l'Énergie Atomique (France); Si Chen, Ctr. National de la Recherche Scientifique (France)

The focal plane of the X-ray Integral Field Unit (X-IFU) instrument of the Athena observatory is composed of about 4000 micro-calorimeters. These sensors, based on superconducting Transition Edge Sensors (TES), are readout through a frequency multiplexer and a BaseBand Feedback to linearize SQUIDs. However, the loop gain of this feedback is limited to about 10, which is not enough to fix the gain of the full readout chain. Indeed, calibration of the instrument is planned to be done at a time scale larger than 10 min and the challenging energy resolution goal of 2.5 eV at 6 keV will probably requires a gain stability better than 1/100000 over this period. A large part of this gain is provided by a low-noise amplifier in the Warm Front-End Electronic (WFEE). To reach such gain stability over tens of minutes, this non-cooled amplifier has to fight against the temperature and supply voltage variations. Moreover, mainly for noise reasons, standard large loop gain feedback can't be used. We propose a new amplifier topology using diodes as loads of a differential trans-admittance amplifier to provide a fixed voltage gain, independent to the temperature and to the biasing fluctuations. This amplifier is designed using a 350 nm SiGe BiCMOS technology and is part of an integrated circuit developed for the WFEE. Simulations already highlight stability and noise performances of such structures. Comparison with standard differential structures and feedback amplifier clearly shows the advantages of the proposed amplifier topology. Performances of this diodes load trans-admittance amplifier will be discussed in the context of the X-IFU requirements.

9905-183, Session PS5

Microcalorimeter pulse analysis by means of principle component decomposition

Cor P. de Vries, Rianne M. Schouten, Jan van der Kuur, Luciano Gottardi, Hiroki Akamatsu, SRON Netherlands Institute for Space Research (Netherlands)

The X-ray integral field unit (X-IFU) for the Athena mission consists of a microcalorimeter, transition edge sensor (TES) pixel array. Incoming photons will generate pulses which have to be analyzed in terms of the energy, in order to compute the incoming X-ray spectrum.

Usually this is done by means of optimal filtering or time-domain pulse fitting.

In this paper we use an alternate way of processing by means of principle component analysis (PCA).

PCA attempts to find the main components of an orthogonal set of functions which describe the data.

We search for those components which correspond to the energy of the photons. We apply this method to TES readout by means of Frequency Domain Multiplexing (FDM).

We show, based on simulations and real data, what components are found and to what physical parameters they correspond to. We'll discuss the usefulness of this method for microcalorimeter spectral analysis and compare with other work done in this field.

9905-184, Session PS5

Performance assessment of different pulse reconstruction algorithms for the ATHENA: an x-ray integral field unit

Philippe Peille, Institut de Recherche en Astrophysique et Planétologie (France) and Univ. Paul Sabatier (France); Maite Ceballos, Beatriz Cobo, Univ. de Cantabria (Spain); Jörn Wilms, Friedrich-Alexander-Univ. Erlangen-Nürnberg (Germany); Simon R. Bandler, Stephen J. Smith, NASA Goddard Space Flight Ctr. (United States); Thomas Dauser, Thorsten Brand, Friedrich-Alexander-Univ. Erlangen-Nürnberg (Germany); Roland H. den Hartog, Jelle de Plaa, SRON Netherlands Institute for Space Research (Netherlands); Didier Barret, Institut de Recherche en Astrophysique et Planétologie (France) and Univ. Paul Sabatier (France); Jan-Willem A. den Herder, SRON Netherlands Institute for Space Research (Netherlands); Luigi Piro, INAF - IASF Roma (Italy); Xavier Barcons, Univ. de Cantabria (Spain); Etienne Pointecouteau, Institut de Recherche en Astrophysique et Planétologie (France) and Univ. Paul Sabatier (France)

The X-ray Integral Field Unit (X-IFU) microcalorimeter, on-board Athena, with its focal plane comprising ~ 3800 Transition Edge Sensors (TESs) operating at 90 mK, will provide unprecedented spectral-imaging capability in the 0.2-12 keV energy range. It will rely on the on-board digital processing of current pulses induced by the heat deposited in the TES absorber, as to recover the energy of each individual events. Assessing the capabilities of the pulse reconstruction is required to understand the overall scientific performance of the X-IFU, notably in terms of energy resolution degradation with both increasing energies and count rates. Using synthetic data streams generated by the X-IFU End-to-End simulator, we present here a comprehensive benchmark of various pulse reconstruction techniques, ranging from standard optimal filtering to

more advanced algorithms based on differential geometry or principal component analysis. Beside deriving the spectral resolution achieved by the different algorithms, a first assessment of the computing power and ground calibration needs is presented. Finally, our study is applied to assess the performance of different TES-array configurations that are considered for the X-IFU, with a focus on their achievable count rate capability.

9905-185, Session PS5

The cryogenic anti-coincidence detector for ATHENA X-IFU: preliminary test and data analysis of the new bridges-suspended single pixel

Matteo D'Andrea, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy) and Univ. degli Studi di Roma "Tor Vergata" (Italy); Andrea Argan, INAF - IASF Roma (Italy); Simone Lotti, Claudio Macculi, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Luigi Piro, INAF - IASF Roma (Italy); Michele Biasotti, Dario Corsini, Flavio Gatti, Angiola Orlando, Univ. degli Studi di Genova (Italy); Guido Torrioli, CNR-Istituto di Fotonica e Nanotecnologie (Italy)

The ATHENA observatory is the second large-class mission in ESA Cosmic Vision 2015-2025, with a launch foreseen in 2028 towards the L2 orbit. The mission addresses the science theme "The Hot and Energetic Universe", by coupling a high-performance X-ray Telescope with two complementary focal-plane instruments. One of these is the X-ray Integral Field Unit (X-IFU): it is a TES based kilo-pixel order array able to provide spatially resolved high-resolution spectroscopy (2.5 eV at 6 keV) over a 5 arcmin FoV.

The X-IFU sensitivity is degraded by the particles background expected at L2 orbit, which is induced by primary protons of both galactic and solar origin, and by secondary electrons. To reduce the background level and enable the mission's science goals, a Cryogenic Anticoincidence (CryoAC) detector is placed < 1 mm below the TES array. It is a 4-pixel TES based detector, with wide Silicon absorbers sensed by Ir:Au TESes.

The CryoAC development schedule foresees as first step in 2016 the design, development and test of a new single pixel prototype featured by an absorber that is "bridges-suspended" with respect to a Silicon rim, the latter connected to a metallic frame representing the thermal bath of the microcalorimeter. These bridges are at present the best solution we have in mind to realize a well-defined and reproducible thermal conductance between the bath and the wide area absorber. This is necessary to speed up the detector and so to guarantee the high rejection efficiency of background particles imposed by mission requirements.

Here we will discuss the preliminary testing activity and data analysis of this detector, 1 cm^2 absorber area sensed by 65 Ir TESes. We will focus on the pulses analysis to understand how the TES network works in collecting the athermals phonons, which we use as fast anticoincidence flag. Furthermore, we will investigate both time-dynamic and threshold energy of the detector.

9905-186, Session PS5

The mechanical and EM simulations of the CryoAC DM for the ATHENA X-IFU

Dario Corsini, Michele Biasotti, Matteo De Gerone, Flavio Gatti, Istituto Nazionale di Fisica Nucleare (Italy); Luigi Piro, INAF - IASF Roma (Italy); Claudio Macculi, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Cecilia Rossi, Istituto Nazionale di Fisica Nucleare (Italy)

The Demonstration Model (DM) prototype of the X-IFU Cryogenic AntiCoincidence (CryoAC) is based on a silicon monolithic micro-bridged single pixel with an active area of about 1cm2. To design such a detector, in order to fulfil the requirements, a combination of original solutions is needed: (1) fast rise times by means of the collection of fast a-thermal primary phonons; (2) a large area/thickness aspect ratio of about 30 to 50 cm; (3) about one hundred uniformly surface-distributed small superconducting transition edge sensors (TES) with highly equalized operating characteristics; (4) properly-tuned operating temperatures and dynamic range for full signal formation at the X-IFU base temperature; (5) mechanical compatibility for the flight transfer into orbit; (6) EM and thermal compatibility with the TES microcalorimeter array.

Concerning the first four issues, we have successfully achieved good results by testing several prototypes, while we kept simulating different manufacturing solutions to address the latter.

We have started the second phase in which all these detector characteristics will be combined in a single silicon monolithic micro-bridged pixel. The full set of thermal, mechanical and EM requirements have been included in a new design. We are performing several simulations with CREO and COMSOL codes in order to set the design and fabrication processes to reach the settled requirements at the level of the DM. The peculiar structure, consisting of a silicon chip asymmetrically suspended by 4 bridges, needs to be carefully studied under mechanical stresses: the response to acceleration frequency domain spectra, shocks and time domain random displacement vibrations has been evaluated in preparation for a real vibration test campaign. We are also studying the EM compatibility of the CryoAC DM with COMSOL code simulations with particular attention to the magnetic field generated by the bias currents towards the X-IFU TES-array, which has to be kept below the ?T value. This study has set new constraints to the wiring lines, contacts and TES shapes. In this work we will show the latest advance in the design of the new detectors, showing the main results coming from various simulations.

9905-187, Session PS5

The demonstration model of the cryogenic anti-coincidence detector for ATHENA X-IFU

Michele Biasotti, Univ. degli Studi di Genova (Italy); Dario Corsini, Univ. degli Studi di Genova (Italy); Matteo De Gerone, Univ. degli Studi di Genova (Italy) and Istituto Nazionale di Fisica Nucleare (Italy); Flavio Gatti, Univ. degli Studi di Genova (Italy); Angiola Orlando, Univ. degli Studi di Genova (Italy) and Istituto Nazionale di Fisica Nucleare (Italy); Matteo D'Andrea, Claudio Macculi, Luigi Piro, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy)

The ATHENA observatory X-ray Integral Field Unit (X-IFU) is one of the two complementary focal-plane instrument for investigating "The Hot and Energetic Universe" with unprecedented spectral performance. The X-IFU sensitivity is degraded by the particles background expected at the operating orbit, which is induced by primary protons of both galactic and solar origin. In order to guarantee the X-IFU scientific goals, it is necessary to adopt a Cryogenic AntiCoincidence (CryoAC) detector placed at about 1 mm beneath the x-ray microcalorimeter array at 50 mK. The design of such a detector has required a combination of original solutions in order to fulfil the requirements: (1) fast rise-times by means of the collection of fast a-thermal primary phonons, (2) a large area/thickness aspect ratio of about 30 to 50 cm, (3) about one hundred uniformly surface distributes small superconducting transition edge sensors (TES) with highly equalized operating characteristics, (4) properly tuned operating temperatures and

dynamic range for full signal formation at the XIFU base temperature, (5) mechanical compatibility for flight transfer to the orbit, (6) EM and thermal compatibility with the TES microcalorimeter array.

In the first phase of the design we have successfully demonstrated with several prototypes the first four issues and simulated the last two ones.

We have started the second phase in which all these detector characteristics will be combined in the so-called CryoAC Demonstration Model. It is a single silicon monolithic micro-bridged pixel with an active area of about 1 cm2. The full set of thermal, mechanical and EM requirements have been included in a new design. We have performed several fabrication tests of this peculiar detector that has been fabricated with micro-machining techniques from a single wafer of silicon. The mechanical structure design is supported by simulations, including the random displacement vibrations. The EM compatibility has needed the development of TES sensor anti-inductive biasing lines. The TES operating temperature has been obtained with the technique of the gold proximization of iridium superconducting film through a proper parameter setting of the UHV film growth facility. The detector silicon microbridges are thermally qualified after each fabrication run with low temperature tests.

We report here the overview of this work of design, simulation and parameter's qualification of the silicon monolithic micro-bridges detector and a preliminary delivery test with 60 keV gamma ray.

9905-188, Session PS5

X-Ray absorption spectroscopy on test thermal filters for the ATHENA X-IFU detector

Marco Barbera, Univ. degli Studi di Palermo (Italy) and INAF - Osservatorio Astronomico di Palermo Giuseppe S. Vaiana (Italy); Luisa Sciortino, Univ. degli studi di Palermo (Italy); Ugo Lo Cicero, INAF - Osservatorio Astronomico di Palermo Giuseppe S. Vaiana (Italy); Elena Magnano, Istituto Officina dei Materiali (Italy); Igor Pí?, Elettra-Sincrotrone Trieste S.C.p.A. (Italy)

ATHENA is a large astrophysical observatory approved by the European Space Agency to address the science theme "Hot and Energetic Universe" (L2 mission with launch scheduled in 2028). One of the two instruments of ATHENA is the X-ray Integral Field Unit (X-IFU), an array of Transition Edge Sensor (TES) micro-calorimeters with spectral, imaging, and timing capabilities in the energy range 0.2÷12 keV.

The X-IFU will be cooled by a quite complex multi-stage liquid free cryostat down to nearly 50 mK. In order to allow the focused X-ray beam to reach the detector, a clear path is opened in the cryostat thermal and mechanical shields. Thin windows, transparent to X-rays, will be mounted on such openings to minimize IR radiation heat-load onto the cold detector array, and to keep the photon shot noise well below the intrinsic energy resolution of the TES micro-calorimeters (?EFWHM < 2.5 eV @ 6 keV).

In the current investigated design, five thermal filters will be mounted on the cryostat shields, each one consisting of a thin membrane of polyimide (approx. 50 nm) coated with aluminum (approx. 30 nm). The larger diameter filters being supported by a metal mesh with large open area. Despite the small thickness and the use of low Z materials, the thermal filters become quite opaque at E < 1.0 keV, and they essentially define the low energy response of the X-IFU.

Since the main characteristic of the X-IFU is the high energy resolution, a detailed calibration program of the thermal filters will need to be performed with high resolution X-ray spectroscopy to properly characterize the low energy instrument response. The thermal filters operate at different temperatures ranging from 300 K down to nearly 50 mK. For this reason, it is relevant to study what is the role of temperature, in the range 0.05-300 K, on the mechanical/optical performance of the filters (e.g. effects on the near edge absorption fine structures of the atomic elements in the filter material), to determine whether the calibration program needs to be performed at different operating temperatures.

We report the results of an X-ray Absorption Spectroscopy (XAS) measurement campaign on test filters of polyimide and aluminum performed in the energy range 175-1650 eV at the BACH beam-line of the Italian synchrotron ELETTRA. In this first campaign we have been able to explore the temperature range 130-300 K.

9905-189, Session PS5

The ATHENA X-IFU filter wheel

Enrico Bozzo, ISDC Data Ctr. for Astrophysics (Switzerland); Marco Barbera, Univ. degli Studi di Palermo (Italy) and INAF - Osservatorio Astronomico di Palermo Giuseppe S. Vaiana (Italy); Ludovic Genolet, Stéphane Paltani, Univ. de Genève (Switzerland)

The X-ray Integral Field Unit (X-IFU) instrument on-board ATHENA will be equipped with a filter wheel (FW) in order to optimize the outcomes of scientific observations.

The entire FW assembly comprises the positioning mechanism, the control electronics box and the wheel which will house a calibration source, closed and open positions, as well as filters. The latter are not fully defined yet, however, it is expected that, together with the thermal filters mounted on the cryostat shields, the X-IFU FW filters should provide: (i) protection against contamination, (ii) reduction of optical load from bright stars and other celestial sources in the field, and (iii) attenuation of the X-ray count rates for bright sources to avoid degradation of the instrument energy resolution.

In this contribution we present the status of the filter wheel mechanism and electronic design, as well as the current development plan for the filters.

9905-190, Session PS5

Conceptual design of the X-IFU instrument control unit on board the ESA ATHENA mission

Leonardo Corcione, Sebastiano Ligori, INAF - Osservatorio Astronomico di Torino (Italy); Luca Valenziano, Istituto Nazionale di Astrofisica (Italy)

Athena is the L-class mission selected in the ESA Cosmic Vision 2015-2025 programme for the science theme of the Hot and Energetic Universe.

The Athena model payload includes the X-ray Integral Field Unit (X-IFU), an advanced actively-shielded X-ray microcalorimeter spectrometer for high-spectral resolution imaging, utilizing cooled Transition Edge Sensors.

This paper describes the preliminary architecture of Instrument Control Unit (ICU), which is aimed at operating all X-IFU's subsystems, as well as at implementing the main functional interfaces of the instrument with the S/C control unit.

The ICU functions include the TC/TM management with S/C, science data formatting and transmission to S/C Mass Memory, housekeeping data handling, time distribution for synchronous operations and the management of the X-IFU components (i.e. CryoCoolers, Filter Wheel, Detector Readout Electronics Event Processor, Power Distribution Unit).

ICU functions baseline implementation for the phase-A study foresees the usage of standard and space-qualified components from the heritage of past and current space missions (e.g. Gaia, Euclid), which currently encompasses Leon2/Leon3 based CPU board and SpaceWire interfaces for

the exchange commands and data between ICU and X-IFU subsystems.

Alternative architecture, arranged around a powerful PowerPC-based CPU, is also briefly presented, in the aim at endowing the system with enhanced hardware resources and processing power capability, for the handling of control and science data processing tasks not defined yet at this stage of the mission study.

9905-191, Session PS5

Updates on the background estimates for the X-IFU instrument onboard of the ATHENA mission

Simone Lotti, Claudio Macculi, Matteo D'Andrea, Luigi Piro, Silvano Molendi, Fabio Gastaldello, Teresa Mineo, Antonino D'ai, Andrea A. Bulgarelli, Valentina Fioretti, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Christian Jacquey, Institut de Recherche en Astrophysique et Planétologie (France); Monica Laurenza, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Philippe Laurent, Commissariat à l'Énergie Atomique (France)

ATHENA is the second large mission in ESA Cosmic Vision 2015-2025, with a launch foreseen in 2028 towards the L2 orbit. The mission addresses the science theme "The Hot and Energetic Universe", by coupling a high-performance X-ray Telescope with two complementary focal-plane instruments. One of these, the X-ray Integral Field Unit (X-IFU) is a TES based kilo-pixel array, providing spatially resolved high-resolution spectroscopy (2.5 eV at 6 keV) over a 5 arcmin FoV.

The background for this kind of detectors accounts for several components: the diffuse Cosmic X-ray Background, the low energy particles (<~100 keV) focalized by the mirrors and reaching the detector from inside the field of view, and the high energy particles (> ~100 MeV) crossing the spacecraft and reaching the focal plane from every direction. In particular, these high energy particles lose energy in the materials they cross, creating secondaries along their path that can induce an additional background component.

Each one of these components is under study of a team dedicated to the background issues regarding the X-IFU, with the aim to reduce their impact on the instrumental performances. This task is particularly challenging, given the lack of data on the background of X-ray detectors in L2, the uncertainties on the particle environment to be expected in such orbit, and the reliability of the models used in the Monte Carlo background computations. As a consequence, the activities addressed by the group range from the reanalysis of the data of previous missions like XMM-Newton, to the characterization of the L2 environment by data analysis of the particle monitors onboard of satellites present in the Earth magnetotail, to the characterization of solar events and their occurrence, and to the validation of the physical models involved in the Monte Carlo simulations. All these activities will allow to develop a set of reliable simulations to predict, analyze and find effective solutions to reduce the particle background experienced by the X-IFU, ultimately satisfying the scientific requirement that enables the science of ATHENA.

While the activities are still ongoing, we present here some preliminary results already obtained by the group. The L2 environment characterization activities, and the analysis and validation of the physical processes involved in the Monte Carlo simulations are the core of an ESA activity named AREMBES (Athena Radiation Environment Models and Effects), for which the work presented here represents a starting point.

9905-192, Session PS5

TESSIM: a simulator for the ATHENA X-IFU

Jörn Wilms, Friedrich-Alexander-Univ. Erlangen-Nürnberg (Germany); Stephen J. Smith, NASA Goddard Space Flight Ctr. (United States); Philippe Peille, Institut de Recherche en Astrophysique et Planétologie (France); Maite Ceballos, Beatriz Cobo, Univ. de Cantabria (Spain); Thomas Dauser, Thorsten Brand, Friedrich-Alexander-Univ. Erlangen-Nürnberg (Germany); Roland H. den Hartog, SRON Netherlands Institute for Space Research (Netherlands); Simon R. Bandler, NASA Goddard Space Flight Ctr. (United States); Jelle de Plaa, Jan-Willem A. den Herder, SRON Netherlands Institute for Space Research (Netherlands)

We present the design of tessim, a simulator for the physics of transition edge sensors developed in the framework of the ATHENA end to end simulation effort. Designed to represent the general behavior of TES detectors and to provide input for engineering and science studies for ATHENA, tessim implements a numerical solution of the linearized equations describing these devices. The simulation includes a model for the relevant noise sources and several implementations of possible trigger algorithms. Input and output of the software are standard FITS-files which can be visualized and processed using standard X-ray astronomical tool packages. Tessim is freely available as part of the SIXTE package (http://www.sternwarte.uni-erlangen.de/research/sixte/).

9905-193, Session PS5

Background studies for ATHENA: status of the activities at IAAT

Emanuele Perinati, Sebastian Diebold, Alejandro Guzman, Andrea Santangelo, Chris Tenzer, Eberhard Karls Univ. Tübingen (Germany)

A low and reproducible background level is fundamental to guarantee succesful observations with ATHENA, and it is one of the requirements driving the design of the payload. In fact, the mass distribution at the focal plane has an impact on the sensitivity, producing secondaries that generate x-ray-like signals. Furthermore,some contamination may come from the optics, that can funnel the softer protons and ions. The optimization of the design can be pursued through simulations and laboratory tests able to reproduce the interaction of the radiation environment with mirrors, components and detectors. IAA/Tuebingen is one of the institutes that collaborate in the study for the ATHENA/WFI instrument.In this paper we present a report on the current status of the activities.

9905-194, Session PS5

Surface investigation and aluminum oxide estimation on test filters for the ATHENA X-IFU and WFI detectors

Luisa Sciortino, Univ. degli studi di Palermo (Italy); Ugo Lo Cicero, INAF - Osservatorio Astronomico di Palermo Giuseppe S. Vaiana (Italy); Elena Magnano, Istituto Officina dei Materiali (Italy); Igor Pí?, Elettra-Sincrotrone Trieste S.C.p.A. (Italy); Marco Barbera, Univ. degli Studi di Palermo (Italy) and INAF - Osservatorio Astronomico di

Palermo Giuseppe S. Vaiana (Italy)

The X-ray Integral Field Unit (X-IFU), one of the two instruments of the ATHENA mission, operates at temperature close to 50 mK. Such condition will be achieved using a sophisticated multi-stage cryostat. To allow the X-rays to reach the detector, windows are opened in the cryostat thermal and structural shields, and thin thermal filters are needed, that absorb IR radiation while being nearly transparent to X-rays. For the WFI a large area filter mounted on an external filter wheel is used to attenuate UV/VIS light to prevent optical load from bright sources as well as to protect the detector from molecular contamination.

In the current baseline design both the X-IFU thermal filters and WFI optical blocking filters are made with superposed aluminum and polyimide layers. These two materials are characterized by high transmission in X-rays, and in addition the metallic aluminum blocks the VIS/IR components mainly by reflection, while polyimide blocks the UV component by absorption. In principle, to increase the number of detectable X-ray photons, the thickness of aluminum should be the minimum value providing adequate reflectivity in the VIS/IR. However, a surface of aluminum always shows a nanometric film of native oxide that is not so efficient as metallic aluminum to block IR radiation and becomes nearly transparent to UV/VIS radiation. Generally this effect is more dramatic for thin films because the mass ratio between aluminum oxide and metallic aluminum increases.

In this work we employ X-ray Photoelectron Spectroscopy (XPS) with different incident energies measured at the BACH beamline of the Italian synchrotron ELETTRA to probe the surface (few nanometers) of two different filters consisting of 30 nm of aluminum deposited respectively on 45 nm of polyimide (sample filter investigated for the X-IFU) or 150 nm of polyimide (sample filter investigated for the WFI). We analyze XPS spectra to estimate the thickness of the native oxide that alters unfavorably the transmission of the filters, in order to determine the actual thickness of the metallic aluminum layer.

9905-195, Session PS5

Spectroscopic performance of DEPFET active pixel sensor prototypes suitable for the high count rate ATHENA WFI detector

Johannes Müller-Seidlitz, Robert Andritschke, Alexander Bähr, Norbert Meidinger, Max-Planck-Institut für extraterrestrische Physik (Germany); Rainer H. Richter, Max-Planck-Institut Halbleiterlabor (Germany); Wolfgang Treberspurg, Max-Planck-Institut für extraterrestrische Physik (Germany); Johannes F. Treis, Max-Planck-Institut Halbleiterlabor (Germany)

The wide field imager (WFI) planned for the advanced telescope for high energy astrophysics (Athena) provides two detectors with different functionalities. A wide field detector for the imaging of the large scale structures in the X-ray sky and a high count rate sensor for bright point sources up to the order of one Crab. The requirements for the high count rate capable detector are a throughput of >80% and a pile-up of less than 1% for a one Crab source.

The wide field detector is built of four wafer scale arrays of depleted p-channel field-effect transistors (DEPFET). In this sensor concept, the signal charges generated by an X-ray photon in the fully depleted silicon bulk are stored in an internal gate that is implemented underneath a transistor. The collected charges influence the transistor current proportional to their number. That allows the generated charge to be measured directly in the pixel without destruction.

While the DEPFET type used for the wide field detector shows worse spectral response for fast timings, the so-called Infinipix has been developed that mitigates this effect. The Infinipix concept allows the spatial separation of the collection and the readout of the charges. This is realized by using two DEPFETs per pixel. One DEPFET collects the charge while the other one is read out. In the next frame, the tasks of the two sub-pixels are interchanged. For the development of the Infinipix DEPFETs, three different layout variants were produced as 32 x 32 pixel arrays. They vary in the gate width and the design of the clear contacts which remove the collected charge during the measurement. In comparison to a standard DEPFET sensor, the current Infinipix layout implementations show several restrictions for the applicable operation voltages. This is an issue as the homogeneity over the sensor array area varies due to the fabrication technology. A small operation window sets different optimum parameters for individual transistors. This has to be optimized in future layouts. Nevertheless, the current implementations of the Infinipix arrays already show excellent spectroscopic results. The energy resolution expressed as FWHM at 6 keV is around 135 eV with a peak-to-valley of 3600 for the intended readout speed of 2.5 μs per row.

9905-196, Session PS5

The filter and calibration wheel for the ATHENA wide field imager

Miroslaw Rataj, Szymon Polak, Space Research Ctr. (Poland); Tomasz Palgan, Space Reasearch Ctr. (Poland); Marco Barbera, Univ. degli Studi di Palermo (Italy) and Istituto Nazionale di Astrofisica (Italy); Josef Eder, Markus Plattner, Norbert Meidinger, Max-Planck-Institut für extraterrestrische Physik (Germany)

One of the key instruments of ATHENA is the Wide Field Imager (WFI) which will provide imaging in the X-ray energy range of 0.2-15 keV over a field of view with the size of 40 arc min squared in combination with spectrally and time-resolved photon counting. The WFI detector, based on arrays of DEPFET active pixel sensors, is also sensitive to photons in the UV and VIS range. An appropriate blocking filter is thus needed for the large field of view detector as well as for the smaller high count rate capable detector of WFI.

The planned filter and calibration wheel will provide four positions, i.e. open aperture, optical blocking filter, closed position and calibration. The four positions can be individually aligned with the camera aperture. Since the camera has an extremely large detector with an aperture of 160x160 mm? and an additional small detector for fast measurements with an aperture of 15x15 mm?, the aforementioned features have to be doubled.

Apart from the size the design of the filter wheel comprises other challenges. Due to the large geometry mass saving is a major issue, the housing and integrated front baffle shall however also serve as proton shield. Launch environment becomes critical with respect to high loads in case of dynamic coupling if the frequencies cannot be moved far enough away from the eigenfrequencies of the instrument structure. FEM analysis has been performed in order to optimize the structural design.

Another major issue is the protection of the large filter during AIT as well as during launch. Due to the complexity of the camera head with its high number of cables and heat pipes, a vacuum chamber as filter wheel housing shall be avoided. It is investigated whether the Filter Wheel can be in atmosphere during launch with localized protection of the filters, mainly with respect to acoustic load. Results of acoustic simulation analysis are presented in order to demonstrate that the filter will withstand environmental loads.

To reduce complexity and mass, simple but reliable solutions are envisaged including the mechanical configuration as well as the motor drive and position control. This paper will describe the various challenges and provide trade-offs that have been performed. The baseline concept that fulfils the design requirements is presented and selected solutions are describe in detail.

9905-197, Session PS6

Ex luna scientia: lunar occultation as a paradigm for nuclear astrophysics

Richard S. Miller, The Univ. of Alabama in Huntsville (United States); David J. Lawrence, Patrick N. Peplowski, John O. Goldsten, Martin T. Ozimek, Christopher J. Scott, James C. Leary, Dave Grant, Johns Hopkins Univ. Applied Physics Lab., LLC (United States); Christopher A. Young, NASA Goddard Space Flight Ctr. (United States)

Next-generation nuclear astrophysics investigations must address a demanding set of requirements to probe the matter and energy life-cycle in our Galaxy and throughout the Cosmos. Enhanced flux sensitivity and (near) all-sky monitoring are just two of these requirements; cost effectiveness and other programmatic restrictions pose additional challenges. These competing goals can be addressed with a paradigm change, i.e. performing investigations from lunar orbit and utilizing a new detection and imaging technique.

The Moon is a unique location for experimental astrophysics that can be leveraged to obtain novel capabilities not easily achievable in near-Earth orbit. It's unique beneficial characteristics include the dense lunar regolith, lack of an appreciable lunar atmosphere and magnetosphere, and a well-characterized background environment. Although several electromagnetic regimes can utilize these features, high-sensitivity investigations in the range 0.1-10 MeV are uniquely enabled there. Use of the Moon as a scientific platform for nuclear observations also represents an opportunity for synergistic investigations spanning topical areas in astrophysics, solar physics, and planetary/lunar science.

We will report on our development of the Moon as a platform for nuclear astrophysics utilizing the Lunar Occultation Technique (LOT). Here source fluxes are temporally modulated as they are repeatedly occulted by the Moon; the modulation, as observed by a suitably configured instrument in lunar orbit, enables the detection, imaging, and characterization of both point- and extended-sources, narrow-line and broadband sources. Key benefits include maximizing the ratio of sensitive-to-total deployed mass and the operational simplicity relative to other detection schemes. A mission based on the LOT, the Lunar Occultation Explorer (LOX), will be the first to employ occultation as the principle method to characterize the intensity, variability, and spectra of detected sources.

We will present details of the LOT and discuss the dedicated time-series analysis and statistical techniques being developed and employed. An outline of the mission concept, including primary science goals and drivers, preliminary mission sensitivity estimates, and implementation trades will also be presented. Finally, we will also report on concept validation efforts, including source detection, using in-situ measurements made from lunar orbit.

Our development program is focused on realizing the first high-energy astrophysical investigations using the Moon as a scientific platform in an effort to provide unique, achievable, and cost-effective next-generation capabilities in nuclear astrophysics.

9905-198, Session PS6

GAMCOTE: a prototype for an advanced Compton telescope

Nicolas de Séréville, Vincent Tatischeff, Institut National de Physique Nucléaire et de Physique des Particules (France); Philippe Laurent, Walter Bertoli, AstroParticule et Cosmologie (France); Jean-Jacques Dormard, Bernard Genolini, Aleksandar Gostojic, Jurgen Kiener, Institut National de Physique Nucléaire et de Physique des Particules (France); Daniel Maier, AstroParticule et Cosmologie (France); Emmanuel Rauly, Ana-Sofia Torrento, Institut National de Physique Nucléaire et de Physique des Particules (France)

The answers to many key questions regarding the most violent cosmic phenomena and their implications on the general evolution of the Universe are to be found in the 0.1 - 100 MeV photon energy domain. Indeed this energy window is unique for studying matter evolution, antimatter generation and very energetic phenomena in compact stars and massive black holes.

The INTEGRAL satellite from the European Space Agency (ESA) is currently observing the sky in the 15 keV to 10 MeV band. However this mission may only last a few more years which calls for the development of the next generation gamma-ray telescopes. Progresses are slow and no experiment achieved a survey sensitivity better than the COMPTEL instrument of the CGRO mission. This situation arises from the difficulties inherent to this energy domain, where the probability of photon interaction with matter reaches a minimum while the instrumental background induced by cosmic-ray particles is very high.

One of the most promising concepts for the next generation of gamma-ray space instrument is a Compton and pair-creation telescope made of two main parts: a silicon tracker optimized for Compton scattering of cosmic gamma rays and a calorimeter that absorbs the scattered photons. Such a design also shows excellent performance for higher cosmic gamma-rays energy where the pair creation regime prevails. The ASTROGAM instrument, relying on such a design, has been proposed in response of ESA's call for a fourth Medium-size mission (M4) in the "Cosmic Vision 2010-2025" program framework. An extended mission featuring a larger scale instrument and spacecraft is currently being design for the M5 Call.

In this contribution we will present the first results of the GAMCOTE ("GAMma-ray COmpton TElescope") setup, a prototype for an advanced Compton Telescope including thick (1.5 - 2 mm) double sided silicon stripped detectors coupled to a LaBr3:Ce cristal read by a 64 multi-anode photomultiplier tube. We have developed several test benches to study each detector individually, using customized readout electronics with a new data acquisition system. We will review the detector characterization work and then discuss the performance of the telescope prototype as a Compton imager.

Experimental verification of the HERD prototype at CERN SPS

Yongwei Dong, Institute of High Energy Physics (China); Yonglin Bai, Xi'an Institute of Optics and Precision Mechanics (China); Tianwei Bao, Institute of High Energy Physics (China); Bingliang Hu, Ran Li, Yong Li, Xi'an Institute of Optics and Precision Mechanics (China); Xin Liu, Junguang Lu, Institute of High Energy Physics (China); Zheng Quan, Institute of High Energy Physics (China) and Univ. of Chinese Academy of Sciences (China); Bo Wang, Xi'an Institute of Optics and Precision Mechanics (China); Junjing Wang, Univ. of Chinese Academy of Sciences (China) and Institute of High Energy Physics (China); Le Wang, Xi'an Institute of Optics and Precision Mechanics (China); Ruijie Wang, Zhigang Wang, Bobing Wu, Ming Xu, Institute of High Energy Physics (China); Peng Yan, Xi'an Institute of Optics and Precision Mechanics (China); Li Zhang, Shuangnan Zhang, Institute of High Energy Physics (China); Piergiorgio Fusco, Istituto Nazionale di Fisica Nucleare (Italy) and Politecnico di Bari (Italy); Fabio Gargano, Istituto Nazionale di Fisica Nucleare (Italy); Francesco Loparco, Istituto Nazionale di Fisica Nucleare (Italy) and Politecnico di Bari (Italy); Mario Nicola Mazziotta, Politecnico di Bari (Italy); Filippo Ambroglini, Giovanni Ambrosi, Matteo Duranti, Domenico D. Urso, Istituto Nazionale di Fisica Nucleare (Italy); Philipp Azzarello, Xin Wu, Univ. de Genève (Switzerland); Paolo Bernardini, Giovanni Marsella, Ivan De Mitri, Antonio Surdo, Istituto Nazionale di Fisica Nucleare (Italy)

The High Energy cosmic-Radiation Detection (HERD) facility is one of several space astronomy payloads of the cosmic light house program onboard China's Space Station, which is planned for operation starting around 2020 for about 10 years. The main scientific objectives of HERD are indirect dark matter search, precise cosmic ray spectrum and composition measurements up to the knee energy, and high energy gamma-ray monitoring and survey. HERD is composed of a 3-D cubic calorimeter (CALO) surrounded by microstrip silicon trackers (STKs) from five sides except the bottom. CALO is made of about 10^4 cubes of LYSO crystals, corresponding to about 55 radiation lengths and 3 nuclear interaction lengths, respectively.

The biggest advantage over previous missions is that HERD has an effective geometrical factor of >3 m^2sr for electrons and gamma rays and >2.5 m^2sr for protons and cosmic rays, which is more than one order of magnitude higher than others. Its energy resolution of 1% for electrons and gamma-rays beyond 100 GeV, 20% for protons from 100 GeV to 1 PeV. A novel method of reading out the LYSO signals by WLS fibers and image intensified CCDs is used, which can greatly reduce the complexity of onboard electronics.

Beam test with a HERD prototype, to verify the HERD specifications and the reading out method of WLSF+ICCD, was taken at CERN SPS in November, 2015. The prototype is composed of an array of 5*5*10 LYSO crystals, which is 1/40th of the scale of HERD CALO. Each crystal is coupled with one low range fiber, one high range fiber and one trigger fiber. The three groups of WLS fibers are read out by two ICCD systems and one PMT system, respectively. A set of 4 plastic scintillator detectors are allocated in front of the prototype to generate beam trigger signals. A particular trigger mode was selected for the ICCD systems to avoid contamination to the current frame. The silicon ladder located in between is for the charge measurement and position measurement of the beam particles. Verification tests of energy resolution, linearity response, angular resolution and particle separation power were implemented by choosing 10~250 GeV electrons, 350~400 GeV protons, 50~100 GeV positrons and A/Z=2 secondary particles from Pb ions. Calibration of the calorimeter was performed everyday with 50 GeV pions. The beam rate was limited to be no more than 500 cps to adapt to the frame rate of 300 Hz for the CCD chips.

Light spot on the CCD varies with different energy deposition in the corresponding crystal, because of involvement of multiple coupling interfaces inside the ICCDs. Overlapping with nearby light spots was considered in the energy reconstruction of individual crystals. The ratio of amplitude between low range fiber and high range fiber is about 50:1. Energy information can then be derived from the high range ICCD when saturation occurs in the low range ICCD. About 8 million events were acquired during the 10 days of test campaign. Rough energy resolution without energy calibration or correction is ~5% @ 10 GeV by using the low range ICCD data. Full data analysis of the beam test is under way.

9905-200, Session PS6

PANGU: a high resolution gamma-ray space telescope

Xin Wu, Univ. de Genève (Switzerland)

PANGU (the PAir-productioN Gamma-ray Unit) is a gamma-ray telescope with wide field of view optimized for spectro-imaging, timing and polarisation studies. It will map the gamma-ray sky from 10 MeV to a few GeV with unprecedented spatial resolution. This window on the Universe is unique to detect photons emitted directly by relativistic particles, via the decay of neutral pions, or the annihilation or decay light from anti-matter and the putative light dark matter candidates. A wealth of questions can be probed among the most important themes of modern physics and astrophysics.

The PANGU instrument is a pair-conversion gamma-ray telescope based on an innovative design of a silicon strip tracker. It is light, compact and accurate. It has been submitted as a candidate to the recent ESA-CAS Call for Joint Small Science Mission. In this proposal, the telescope consists of 100 layers of silicon micro-strip detector of 40 x 40 cm2 in area, stacked to height of about 90 cm, and covered by a top anticoincidence detector. It relies on multiple scattering effects for energy measurement, reaching an energy resolution between 30-50% for 10 MeV – 1 GeV. The novel tracker will allow the first polarisation measurement and provide the best angular resolution ever obtained in the soft gamma ray and GeV band. The same mission concept, with an enlarged acceptance, is now being prepared as a proposal for the upcoming ESA M5 mission.

In this contribution, the key science objectives, the payload concept and the expected performance of PANGU will be presented.

9905-201, Session PS6

Study of the point spread function of AGILE-GRID in spinning observation mode

Fabrizio Lucarelli, Carlotta Pittori, Francesco Verrecchia, Agenzia Spaziale Italiana (Italy) and INAF - Osservatorio Astronomico di Roma (Italy); Marco Tavani, INAF - IASF Roma (Italy) and Univ. degli Studi di Roma "Tor Vergata" (Italy); Sabina Sabatini, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy)

The AGILE gamma-ray space mission is dedicated to the observation of astrophysical sources of photons with energy E > 100 MeV. The satellite has been launched in April 2007 and it has just completed its ninth year of operations.

For the first two years of nominal lifetime AGILE has been operated in Pointing mode. On Nov. 2009, the AGILE scientific operations were reconfigured and since then the satellite is operating in a "spinning observing mode", surveying a large fraction (~ 70%) of the sky every day.

In this study we evaluate the capability of the AGILE Gamma-ray Imager Detector (GRID) to reconstruct in Spinning mode the arrival direction of an incident photon, quantified through the Point Spread Function (PSF), and we compare it with the PSF evaluated on Pointing mode data. To this purpose, we estimate the PSF on in-flight data taken in Spinning mode using the aperture photometry technique.

Our results show that both the AGILE-GRID PSF in Spinning mode and the scientific performances, such as the source location accuracy, are comparable to those in Pointing mode. These results thus confirm the similarity between the AGILE-GRID PSF and the LAT instrument one, on board the Fermi Gamma-ray Space Telescope, in the 100 MeV-1 GeV energy range, already shown in a previous analysis performed on AGILE Pointing data only.

9905-202, Session PS6

Gamma ray spectrometer for future Mars mission: design concept and simulation study

Shiv Kumar Goyal, D. Banerjee, Santosh V. Vadawale, Dipak K. Panda, Arpit R. Patel, Physical Research Lab. (India); Aditya Patinge, ISRO Satellite Ctr. (India); Tinkal Ladiya, Physical Research Lab. (India)

One of the basic keys to an understanding of the formation and evolution of any planet is the knowledge of the elemental composition of its surface. Gamma spectroscopy on a Mars orbiter provides a unique opportunity to measure the elemental composition of a planet with an atmosphere thin enough to allow detection of gamma ray produced from the near surface rock and soil materials. Gamma Ray Spectrometer (GRS) flown on the 2001 Mars Odyssey Mission (Boynton et. al., 2002; 2007) provided concentration maps for the elements H, Si, Cl, K, Fe and Th for low and mid - latitudes (±52 degree) for the first time. The ~450 km spatial resolution of this instrument is too large to observe small, localized enrichment of Th and K. Hence a map of Th and K with improved spatial resolution is necessary over the entire Martial surface, especially more focused over some target areas, to understand whether a global magma ocean did exist on Mars or not.

We are developing Gamma Ray Spectrometer using HPGe (High Purity Germanium) detector for future Mars orbiter mission. The scientific objective is to map naturally occurring radioactive elements (Th, U, K) and other major elements (Fe, Mg, Cl, Al, Si, S, Mg). We plan to map the entire Martian surface with a spatial resolution of better than 250 km. HPGe detector requires a cooling to ~77 K temperature for reducing the detector background. The development of cooling mechanism of detector using Stirling type cryo - cooler has been initiated. This cryo - cooler is very compact in size and has high cooling efficiency. This instrument will also have Anti - Coincidence Shield (ACS) for background subtraction. Here ACS will be operated into both coincidence as well as anti coincidence mode.

GEANT4 simulation study has been carried out for the selection of ACS detector. In this simulation various Scintillator detectors (LaBr3:Ce, CeBr3, CsI, NaI, and BGO) with various thicknesses are used for ACS material. This simulation has also been repeated using HPGe as another option of ACS material. Performances of various options of ACS materials are compared based on the absorption efficiency, peak to Compton ratio, shielding effectiveness, overall geometry complexity and weight of the detector assembly. Effect of Martial atmosphere on the transmission of gamma rays has also been studied which reports the dependence of atmospheric attenuation factor on the energy of gamma rays. The transmission efficiency of Martial atmosphere for 1 MeV gamma energy comes out to be ~25%. This simulation also gives an idea of low energy cutoff of X - rays / Gamma ray which can be transmitted from the Martian surface to the Orbiter.

We will present the design concept of the instrument and preliminary results from the HPGe detector using in - house developed electronics. We will also present the comparative study of the GEANT4 simulations, carried out for various cases.

9905-203, Session PS6

Off-axis response of an x-/gamma-ray telescope based on Laue lenses

Enrico Virgilli, Univ. degli Studi di Ferrara (Italy); Ezio Caroli, Natalia Auricchio, John B. Stephen, INAF - IASF Bologna (Italy); Filippo Frontera, Piero Rosati, Univ. degli Studi di Ferrara (Italy)

Soft and medium energy X-ray astronomy (below 80 keV) has already benefitted of a mature technology which has allowed focusing instruments to have been already built and successfully employed. To date, only telescopes based on Laue lenses represent an appealing technique to extend focusing capabilities to the hard X-/soft gamma-ray band up to 600 keV. In this paper we show results based on Monte Carlo simulations for a Laue lens made from an ensemble of bent crystals. We compare the on-axis Point Spread Function (PSF) with that obtained for a source placed at different off-axis angles, thereby defining a lens geometry that preserves a good PSF and sensitivity throughout the Field Of View (FOV) of the instrument with the goal of extending it to ~ 5 arc min. Furthermore, experimental tests at the LARIX facility (Ferrara – Italy) have been carried out to validate our ray tracing model of the LAUE lens for off-axis sources.

9905-204, Session PS6

A compact and modular x- and gamma-ray detector with a CsI scintillator and double-readout silicon drift detectors

Riccardo Campana, INAF - IASF Bologna (Italy)

A future compact and modular X and gamma-ray spectrometer (XGS) has been designed and a series of prototypes have been developed and tested. The experiment envisages the use of CsI scintillator bars read out at both ends by single-cell 25 mm^2 Silicon Drift Detectors. Digital algorithms are used to discriminate between events absorbed in the Silicon layer (lower energy X rays) and events absorbed in the scintillator crystal (higher energy X rays and gamma-rays). The prototype characterization is shown and the modular design for future experiments with possible astrophysical applications (e.g. for the proposed THESEUS mission) are discussed.

9905-205, Session PS6

Characterization of a LaBr3 scintillator with multi-cell silicon drift detector readout

Fabio Fuschino, Riccardo Campana, INAF - IASF Bologna (Italy)

The characterization of a scintillation gamma-ray detector, composed by a 1/2" thick, 1/2" diameter LaBr3 crystal and a 7-cell exagonal Silicon Drift Detector readout is presented, together with possible medical and astrophysical applications.

9905-206, Session PS6

The advanced scintillator Compton telescope (ASCOT) balloon project

Peter F. Bloser, Tejaswita Sharma, Jason S. Legere, Christopher M. Bancroft, Mark L. McConnell, James M. Ryan, The Univ. of New Hampshire (United States)

We describe a project to develop new medium-energy gamma-ray instrumentation by constructing and flying a balloon-borne Compton telescope using advanced scintillator materials combined with silicon photomultiplier readouts. There is a need in high-energy astronomy for a medium-energy gamma-ray mission covering the energy range from approximately 0.4 - 20 MeV to follow the success of the COMPTEL instrument on CGRO. We believe that directly building on the legacy of COMPTEL, using relatively robust, low-cost, off-the-shelf technologies, is the most promising path for such a mission. Fortunately, high-performance scintillators, such as Lanthanum Bromide (LaBr3), Cerium Bromide

(CeBr3), and p-terphenyl, and compact readout devices, such as silicon photomultipliers (SiPMs), are already commercially available and capable of meeting this need. We have conducted two balloon flights of prototype instruments to test these technologies. The first, in 2011, demonstrated that a Compton telescope consisting of an liquid organic scintillator scattering layer and a LaBr3 calorimeter effectively rejects background under balloon-flight conditions, using time-of-flight (ToF) discrimination. The second, in 2014, showed that a telescope using an organic stilbene crystal scattering element and a LaBr3 calorimeter with SiPM readouts can achieve similar ToF performance. We are now constructing a much larger balloon instrument, an Advanced Scintillator Compton Telescope (ASCOT) with SiPM readout, with the goal of imaging the Crab Nebula at MeV energies in a one-day flight. We expect a ~4-sigma detection at ~1 MeV in a single transit. We present calibration results of the first detector modules, and updated simulations of the balloon instrument sensitivity. If successful, this project will demonstrate that the energy, timing, and position resolution of this technology are sufficient to achieve an order of magnitude improvement in sensitivity in the medium-energy gamma-ray band, were it to be applied to a ~1 cubic meter instrument on a long-duration balloon or Explorer platform.

9905-207, Session PS6

A concept for a soft gamma-ray concentrator using thin-film multilayer structures

Peter F. Bloser, Farzane Shirazi, Olof Echt, James Krzanowski, Jason S. Legere, Mark L. McConnell, John G. Tsavalas, Emily N. Wong, Paul H. Aliotta, The Univ. of New Hampshire (United States)

We are investigating the use of thin-film, multilayer structures to form optics capable of concentrating soft gamma rays with energies greater than 100 keV, beyond the reach of current grazing-incidence hard X-ray mirrors. Alternating layers of low- and high-density materials (e.g., polymers and metals) will channel soft gamma-ray photons via total external reflection. A suitable arrangement of curved structures will then concentrate the incident radiation to a point. Gamma-ray optics made in this way offer the potential for soft gamma-ray telescopes with focal lengths of less than 10 m, removing the need for formation flying spacecraft and opening the field up to balloon-borne instruments. Following initial investigations at Los Alamos National Laboratory, we have constructed and tested a prototype structure using spin coating combined with magnetron sputtering. We are now investigating whether it is possible to grow such flexible multi-layer structures with the required thicknesses and smoothness more quickly by using magnetron sputter and pulsed laser deposition techniques. We will present the results of our fabrication and gamma-ray channeling tests, and describe our modeling of the sensitivity of potential concentrator-based telescope designs. If successful, this technology offers the potential for transformational increases in sensitivity while dramatically improving the system-level performance of future high-energy astronomy missions through reduced mass and complexity.

9905-209, Session PS6

A new assembling technology of Laue lenses

Filippo Frontera, Enrico Virgilli, Piero Rosati, Univ. degli Studi di Ferrara (Italy); Ezio Caroli, Natalia Auricchio, John B. Stephen, INAF - IASF Bologna (Italy)

We will report on a new technology we have developed in our laboratory for assembling a Laue lens under development. The lens is made of bent crystals of Gallium Arsenide (GaAs, 220) with a focal length of 20 m for space applications. Thanks to the bent crystal the Pont Spread Function (PSF) of the lens is very thin with an angular spread at Full Width at Half Maximum (FWHM) of about 20 arcsecs for paraxial photons. In order to achieve this PSF it is crucial to fix the crystals to the lens frame in such way that the resin polimerization does not influence the initial position of the crystals. In this talk we will compare the gluing technologies adopted and presented in the past SPIE 2015 conference with a new technology that is very promising for achieving our final assembling goal.

9905-210, Session PS6

Simulation studies for compare: a discovery mission for MeV gamma-ray astronomy

Elizabeth A. Hays, NASA Goddard Space Flight Ctr. (United States); Regina Caputo, Univ. of California, Santa Cruz (United States); Andrew W. Smith, Univ. of Maryland, College Park (United States)

ComPair is gamma-ray telescope designed to detect photons in the challenging energy range from 0.2 keV to >100 MeV, where the interaction cross section is minimized and the dominant mechanism transitions from Compton scattering to pair production near 10 MeV. To measure both interactions the instrument includes a double-sided Si-strip tracker and two calorimetric layers, CZT and CsI(Tl), housed within plastic scintillator to provide rejection of charged particle events. ComPair is a wide-field instrument optimized to enhance continuum sensitivity by more than an order of magnitude and to reduce angular resolution over previous instruments in this energy range. Simulation studies of the instrument perform two primary roles, evaluating the instrument performance and exploring detailed studies of the subsystems. The spatial and energy resolution of the tracking and calorimeter elements are critical elements of the overall performance. Here we will present details of the simulated performance of the full instrument as well supporting studies of the subsystems, in particular the CZT calorimeter, for use in developing a prototype.

9905-212, Session PS6

The two-dimensional gas micro-well detectors for the advanced energetic pair telescope

Andrei Hanu, Stanley D. Hunter, Mary J. Li, Lance H. Oh, NASA Goddard Space Flight Ctr. (United States)

The Advanced Energetic Pair Telescope (AdEPT) is a 5 to 200 MeV gamma ray polarimetry mission that employs a low-density gaseous time projection chamber to achieve high polarization sensitivity and angular resolution that approaches the equivalent of the optical diffraction limit for gamma rays. To achieve this performance, AdEPT is instrumented by a large array (2 m x 2 m) of pixelized gas micro-well detectors that readout the electron-positron tracks produced when gamma rays convert in the gaseous volume. The micro-well detectors, under development at the Goddard Space Flight Center, consist of individual micro-patterned gas proportional counters than simultaneously amplify and readout the primary ionization charge falling into each well. To readout the charged, the wells are connected to X and Y electrodes on the top and bottom of the device providing two-dimensional imaging with 400 ?m position resolution. By taking advantage of silicon processing techniques, we have eliminated all outgassing of inorganic compounds and minimized the area lost due to interconnects, thus making the devices valuable for a variety of space-flight applications where large area X-ray, gamma-ray, or particle track imaging is required. In this work, we will present the initial detector design and preliminary results of the leakage current, breakdown voltage, gas gain, and energy resolution.

9905-213, Session PS6

In-depth calibration of a Laue lens prototype built at Univ. of California, Berkeley

Nicolas M. Barrière, cosine B.V. (Netherlands); Colin Wade, Univ. College Dublin (Ireland); John A. Tomsick, Space Sciences Lab. (United States); Lorraine Hanlon, Univ. College Dublin (Ireland); Steven E. Boggs, Space Sciences Lab. (United States); Peter von Ballmoos, Institut de Recherche en Astrophysique et Planétologie (France)

A Laue lens uses Bragg diffraction in the volume of a large number of small, nearly cubic crystals to concentrate soft gamma rays into a focal point. A technological demonstrator made of 48 crystals of 5 x 5 mm cross-section (12 pure Al crystals and 36 pure Fe crystals arranged into 8 partial concentric rings) was built in 2014 at UC Berkeley. This lens, designed to refocus the beam of an X-ray producing machine in the 95 - 130 keV band with a focal length of 1.5 m, was calibrated in December 2015 using a modified version of the beamline that was used to orient and glue the crystals. Here, we present the calibration method, and the results that were obtained. Finally, we take a step back and comment on the assembly process that was adopted for this prototype Laue lens, and how it could be scaled up for a full-size lens.

9905-214, Session PS6

In-depth calibration of a Laue lens prototype composed of Fe and Al mosaic crystals

Colin Wade, Univ. College Dublin (Ireland); Nicolas M. Barrière, cosine B.V. (Netherlands); John A. Tomsick, Space Sciences Lab. (United States); Lorraine Hanlon, Univ. College Dublin (Ireland); Steven E. Boggs, Space Sciences Lab. (United States); Peter Von Ballmoos, Institut de Recherche en Astrophysique et Planétologie (France)

The Laue lens uses Bragg diffraction to focus soft gamma-rays. In late 2014, the Laue lens assembly station (LLAS) at UC Berkeley was used to construct a prototype lens segment, consisting of 48 5x5 mm2 crystals - 36 Iron and 12 Aluminium. The segment is composed of 8 partial rings, each of which is aligned to diffract an energy between 90 and 130 keV. In December 2015 the prototype was tested and calibrated using a modified version of the LLAS.

The crystal mounting speed was found to be a large improvement over previous set-ups. The glue used had a 2 minute curing time instead of 5 hours as was used previously. Unfortunately the shrinkage of the glue caused significant deviations of the crystal orientation upon curing. Preliminary reflectivity measurements suggest a diffraction efficiency of between 10-20% for the lens segment.

9905-244, Session PS8

Multilayer coating of XTP telescope mirrors

Jiang Li, Runze Qi, Yang Yang, Qiushi Huang, Zhong Zhang, Tongji Univ. (China); Yuhong Bai, Changchun Institute of Optics, Fine Mechanics and Physics (China); Zhanshan Wang, Tongji Univ. (China)

We present the coating of depth-graded W/Si multilayers on the thermally slumped glass substrates for telescopes in X-ray timing and polarization mission. The coating consists of several hundred bilayers in an optimized graded power law design with stringent requirements on uniformity and interfacial roughness. We introduce the details of the planar magnetron sputtering facility including the optimization of Ar pressure and collimating geometry which allows us to make the several thousand mirror segments required for each telescope. Results are presented on the uniformity, interfacial roughness, stress, reflectivity and scatter at hard X-ray energies.

9905-245, Session PS8

X-ray mirror module analytical design from field of view requirement and stray light tolerances

Daniele Spiga, INAF - Osservatorio Astronomico di Brera (Italy)

The design of an X-ray mirror module is a critical issue. In general, the design depends on requirements such as the effective area on-axis, the angular resolution, and the field of view, meant as the angular diameter at which the effective area is half the on-axis one. The design has also to come to terms with constraints such as the maximum mass and size allocated in the spacecraft, and the mirror module design consists in fulfilling all these requirements by populating the module with decreasing diameters until the total effective area on-axis is reached without exceeding the mass limit. However, the separation between consecutive shells has to be properly chosen, to avoid an excessive obstruction off-axis that would limit the field of view. We already know, in fact, that it is possible to determine analytically a diameter population that is obstruction-free within the field of view. Even though this solution enhances the off-axis effective area, it is always optimal because it also leaves too much spacing for stray light. The optimal choice for the spacing should hence be the necessary and sufficient one to allow the required vignetting function; but, while the computation of the total vignetting from the spacing of mirrors in the module can be done by ray-tracing, the inverse problem is difficult because it should be approached by subsequent attempts. Fortunately, the geometric vignetting of a mirror shell can be analytically determined as a function of the off-axis angle and the obstruction parameter, and the expression can be solved for the mirror shell spacing in order to set the field of view at the desired value. In this paper we show how this can be done.

9905-246, Session PS8

Four-times reflection x-ray optics and its application to x-ray telescope

Yuzuru Tawara, Ikuyuki Mitsuishi, Yasunori Babazaki, Nagoya Univ. (Japan)

Effective area of the telescope for X-ray energy $E < 10$ keV including iron K emission lines has been so far limited to less than 1000 cm2 for assumed several meter focal length X-ray telescope. To increase this effective area, we propose four-reflection telescope (FXT) with the same focal length system. To prove this possibility, we performed ray tracing simulation for FXT and found that such system can have several times larger effective area than that of 2-reflection optics. As an example, the effective area of FXT with 6 m focal length can be 3100 cm2 at 6 keV. In this paper, we will discuss other telescope performances such as angular resolution, field of view, mechanical properties and application to fine spectroscopic mission using X-ray micro-calorimeter.

9905-247, Session PS8

Development of lightweight replicated Wolter x-ray optics

Suzanne E. Romaine, Ricardo Bruni, Harvard-Smithsonian Ctr. for Astrophysics (United States); Brian Choi, Christopher Jensen, ReliaCoat Technologies, LLC (United States); Brian D. Ramsey, National Space Sciences and Technology Ctr. (United States); Sanjay Sampath, Stony Brook Univ. (United States)

NASA'S future X-ray astronomy missions will require X-ray optics that have large effective area while remaining lightweight, and cost effective. Some X-ray missions, such as XMM-Newton , and the upcoming Spectrum-Röntgen-Gamma mission use an electroformed nickel replication (ENR) process to fabricate the nested grazing incidence X-ray telescope mirror shells for an array of moderate resolution, moderate effective area telescopes. We are developing a process to fabricate metal-ceramic replicated optics which will be lighter weight than current nickel replicated technology. Our technology development takes full advantage of the replication technique by fabricating large diameter mirrors with thin cross sections allowing maximum nesting and increase in collecting area. This will lead to future cost effective missions with large effective area and lightweight optics with good angular resolution.

Recent results on fabrication and testing of these optics is presented.

9905-248, Session PS8

Assemblies of segmented mirrors with interfacing ribs for high angular resolution x-ray telescopes: cold and hot slumped glass optics at work

Marta M. Civitani, Stefano Basso, Mauro Ghigo, Bianca Salmaso, Daniele Spiga, Gabriele Vecchi, Giovanni Pareschi, INAF - Osservatorio Astronomico di Brera (Italy)

The Slumped Glass Optics technology, developed at INAF/OAB since a few years, is a competitive solution for the realization of the future X-ray telescopes with a very large collecting area, as e.g. Athena, (with more than 2 m2 effective area at 1 keV and with and an angular resolution of just 5'' HEW) or the NGHXT hard X-ray missions (with just 20 arcsec HEW at 30 keV) under study in Japan. The developed technique is based on modular elements, named X-ray Optical Units (XOUs), made of several layers of thin foils of glass, previously formed by direct hot slumping in cylindrical geometry, and then stacked in a Wolter-I configuration, through interfacing ribs. The assembly method has been refined and improved and now the approach represent a valid back-up solution to the SPO assumed as a baseline for ATHENA. Moreover, last advancements in the production of thin glass substrates may allow a great simplification of this process, avoiding the pre-forming step via hot slumping. In fact, the thickness, the strength and the flexibility of these flat glass foils (with thickness lower than 0.030 mm) allow their bending up to very small radius of curvature without breaks. In this paper we provide an update of the project development, reporting on the last results achieved. In particular, we will present the results obtained on several integrated prototypes integrated with different techniques starting from flat or pre-shaped foils.

9905-249, Session PS8

Development of low-stress Iridium coatings for astronomical x-ray mirrors

Thorsten Doehring, Manfred Stollenwerk, Hochschule Aschaffenburg (Germany); Wen Mingwu, Laura Proserpio, Max-Planck-Institut für extraterrestrische Physik (Germany)

Previously used mirror technologies are not able to fulfill the challenging needs of future X-ray telescopes. Therefore the required high precision mirror manufacturing triggers new technical developments around the world. Some aspects of X-ray mirrors production are studied within the interdisciplinary project INTRAAST, a German acronym for "industry transfer of astronomical mirror technologies". The project is embedded in a cooperation of the Aschaffenburg University of Applied Sciences and the Max-Planck-Institute for Extraterrestrial Physics (MPE). One important task is the development of low-stress Iridium coatings for X-ray mirrors based on thin glass substrates. The surface figure of the glass substrates is measured before and after the coating process by optical methods and with a profilometer. By using Stoney´s formula the coating stress can be calculated from the surface curvature difference and related to the parameters of coating deposition, allowing for the optimization of the process. The sputtering parameters might have influence also on the coating density and on the micro-roughness of the mirrors, which will be monitored during the whole activity. The technical approach for the low-stress Iridium coating development, the experimental equipment, and the obtained results will be presented within this contribution.

Monte Carlo simulations of soft proton flares: testing the physics with XMM-Newton

Valentina Fioretti, Andrea A. Bulgarelli, Giuseppe Malaguti, INAF - IASF Bologna (Italy); Daniele Spiga, INAF - Osservatorio Astronomico di Brera (Italy); Andrea Tiengo, INAF - IASF Milano (Italy)

Low energy protons (< 100-200 keV) in the Van Allen belt and the outer regions can enter the field of view of X-ray focusing telescopes, interact with the Wolter-I optics, and reach the focal plane. The scattering of electrons by X-ray optics was expected before the launch of the Swift (NASA), Chandra (NASA), and XMM-Newton (ESA) X-ray telescopes. For this reason, a magnetic diverter for electrons, deflecting their path to the focal plane, is on board the three satellites. The funneling of soft protons was discovered after the damaging of the Chandra/ACIS Front-Illuminated CCDs in September 1999 after the first passages through the radiation belt. The use of special filters protects the XMM-Newton focal plane below an altitude of 70000 km, but above this limit the effect of soft protons is still present in the form of sudden flares in the count rate of the EPIC instruments that can last from hundreds of seconds to hours and can hardly be disentangled from X-ray photons, causing the loss of large amounts of observing time.

The accurate characterization of (i) the distribution of the soft proton population, (ii) the physics interaction coming into play, (iii) the effect on the focal plane are mandatory to evaluate the background and design the proton magnetic diverter on board the future X-ray focusing telescopes (e.g. Athena).

Several solutions have been proposed so far for the primary population and the physics interaction, however the difficulty in reaching low energy protons and precise angle measurements in laboratory makes the smoking gun still unclear.

Since the only real data available is the XMM-Newton spectrum of soft proton flares in orbit, we try to characterize the input proton population and the physics interaction by simulating, using the BoGEMMS framework, the proton interaction with a simplified model of the X-ray mirror module and the focal plane, and comparing the result with a real observation.

The analysis of ten orbits of observations of the EPIC/pn instrument show that the occurrence of flares in regions far outside the radiation belt largely

increases during summer, confirming the solar origin of the soft proton population. The Equator-S and ACE proton spectra detected respectively at a 70000 km altitude and at L1 are used for the proton population entering the optics and the combined multiple and Firsov scattering is used as physics interaction.

If the thick filter is used, the soft protons in the 30-70 keV energy range are the main contributors to the simulated spectrum below 10 keV. We are able to reproduce the proton vignetting observed in real data-sets, with a ? 50% decrease from the inner to the outer region, but a maximum flux of 0.01 counts cm^2 s-1 keV-1 is obtained resulting to be about 5 times lower than the EPIC/MOS detection and 100 times lower than the EPIC/pn one. Given the high variability of the flare intensity, we conclude that an average spectrum, based on the analysis of a full season of soft proton events is required to compare Monte Carlo simulations with real events.

9905-251, Session PS8

Distortion-free coating of mirror segments for high-resolution lightweight x-ray optics

Kai-Wing Chan, Univ. of Maryland, Baltimore County (United States) and NASA Goddard Space Flight Ctr. (United States); Lawrence G. Olsen, NASA Goddard Space Flight Ctr. (United States); Marton V. Sharpe, Ai Numata, SGT, Inc. (United States) and NASA Goddard Space Flight Ctr. (United States); William W. Zhang, Timo T. Saha, NASA Goddard Space Flight Ctr. (United States)

Stress-induced coating distortion poses a technical challenge for high resolution, large area, lightweight x-ray mirrors for space-based missions. High-density material such as iridium, deposited at room temperature, typically has high intrinsic stress of the order of several GPa. For telescopes requiring thin mirror segments with sub-arc-second resolution, deposition of such films can easily distort the mirrors. In this paper, we address the reduction of intrinsic stress of iridium film deposited by magnetron sputtering, by optimization of coating parameter such as the Argon pressure and by annealing. Distortion of mirror is further reduced to sub-arc-second level by the coating of a backside compensating film.

Indirect slumping of D263 glass on fused silica mould

Laura Proserpio, Peter Friedrich, Max-Planck-Institut für extraterrestrische Physik (Germany); Wen Mingwu, Max-Planck Institut fur extraterrestrische Physik (Germany); Elias Breunig, Vadim Burwitz, Max-Planck-Institut für extraterrestrische Physik (Germany); Fabio Marioni, Media Lario Technologies S.r.l. (Italy)

The Slumped Glass Optic (SGO) group of the Max Planck Institute for Extraterrestrial physics (MPE) is analyzing and progressing the indirect slumping technology for its application to X-ray telescope manufacturing. Several aspects of the technology have been studied in the past. This year we will concentrate our activities on the slumping of Schott D263 glass on a precise machined Fused Silica mould: The concave mould was produced by the Italian company Media Lario technologies with the parabola and hyperbola side of the typical Wolter I design in one single piece. Its shape quality was estimated by optical metrology to be 6 arcsec Half Energy Width (HEW) in double reflection. The application of an anti-sticking layer is under study to avoid the adhesion of the glass on the mould during the forming process at high temperatures. The mould will be used for the slumping of mirror segments of 200 mm by 100 mm, which will be integrated in optical modules using the Alignment Integration Machine (AIV) developed at MPE. The modules will be tested in X-ray in PANTER and will be employed for vibration tests. The results of these activities will be presented in the paper.

9905-253, Session PS8

Alignment of off-plane x-ray reflection gratings using optical light

James H. Tutt, Randall L. McEntaffer, Benjamin D. Donovan, Casey T. DeRoo, Ted B. Schultz, The Univ. of Iowa (United States); Ryan S. McClelland, William W. Zhang, NASA Goddard Space Flight Ctr. (United States); Stephen L. O’Dell, Jessica A. Gaskin, Jeffrey J. K. Kolodziejczak, NASA Marshall Space Flight Ctr. (United States); Ryan Allured, Peter Chiemets, Edward Hertz, Harvard-Smithsonian Ctr. for Astrophysics (United States)

The next generation of high resolution soft X-ray spectrometers will require large effective area and high resolving capability. One method of achieving this level of performance is through the use of off-plane reflection gratings. As X-rays will only reflect if they are incident onto a surface at a shallow graze angle, arrays of off-plane gratings have to be placed in the converging beam, generated by an X-ray optic, to achieve the necessary effective areas. To maintain the high resolving power of a single grating across this array and the increase in effective area due to the use of an array of gratings, the gratings have to be very precisely aligned to one another and fanned so that they match the convergence of the X-ray optic. This alignment is to ensure that the dispersed photons from each element arrive in the same line-spread function on the focal plane. The majority of our alignment tolerances are driven by the effective area requirement. To increase the technology readiness level of the gratings, they are scheduled to be flown on the OGRE suborbital rocket payload

Work has been completed at the University of Iowa to manufacture off-plane gratings and to develop a grating alignment test setup that allows for the alignment of the X-ray gratings using optical photons, at atmosphere, in a clean room environment. The alignment procedure forms a wavefront using a series of optics that reflects off the grating surface. This wavefront is then measured using a Shack-Hartmann sensor to observe its orientation relative to the sensor normal. A hexapod is then used to move the grating, and therefore allowing the grating surface to be aligned in pitch and roll. Yaw is aligned using high order diffraction of a laser from an optical grating that is imprinted in the corner of each grating element. The hexapod can be used to change the location of these dispersed orders, allowing the orientation of each grating in yaw to be constrained. The x, y and z positions for each grating are constrained through the mechanical tolerance of the alignment mount. The aligned gratings are mounted into an Invar module and a theodolite is used to measure the relative position of the module to the known position of the grating. This relative measurement is used to align gratings to an initial reference grating to reduce error stack-up.

This method for grating alignment has been used to produce a test array of 3 co-aligned gratings mounted into an invar module. This module has been tested at the Marshall Space Flight Center using the Stray-Light facility to confirm that the gratings in the module have been correctly co-aligned to each other.

This paper discusses the grating alignment process completed at the University of Iowa, the initial results from the X-ray testing of these aligned gratings in the Stray-Light Facility and the proposed path forward towards producing larger arrays of co-aligned gratings that will be used on the OGRE suborbital rocket payload.

9905-254, Session PS8

Analysis on the use of vacuum-oven for the indirect slumping of glass x-ray mirror segments

Emanuel Madarasz, Max-Planck-Institut fur extraterrestrische Physik (Germany) and Technische Univ. München (Germany); Laura Proserpio, Elias Breunig, Peter Friedrich, Max-Planck-Institut für extraterrestrische Physik (Germany)

The Max-Planck Institute for Extraterrestrial Physics (MPE) is involved in the investigation and optimization of the indirect slumping technique for the manufacturing of thin glass mirror segments to be assembled in lightweight X-ray telescopes. During the last year, we started to analyze the influence of vacuum environment on the results of this thermal forming process. The realization of slumping in vacuum offers in principle several advantages, like the absence of air between the glass and the mould and a cleaner environment free of contamination. Furthermore, the heat exchange is different with respect to a standard air-oven and this might have positive effects during the important cooling phase of the process. All these aspects will be considered in the paper, and the obtained results in the development of the MPE vacuum-slumping approach will be reviewed and presented.

9905-255, Session PS8

Development of an x-ray telescope using the carbon fiber reinforced plastic

Hisamitsu Awaki, Satoshi Sugita, Keiji Ogi, Ehime Univ. (Japan); Hironori Matsumoto, Ikuyuki Mitsuishi, Yuzuru Tawara, Nagoya Univ. (Japan)

Conventional X-ray telescopes utilize the Wolter-I optics which consist of parabolic mirrors followed by hyperbolic mirrors. X-ray telescopes on board Japanese satellites such as ASTRO-H have used many thin-foil mirrors to obtain large aperture efficiency and a large effective area. However, the mirrors are conically approximated and it is difficult to keep the shape of thin mirrors good. Therefore the angular resolution of this type of telescope has been limited. We are developing an X-ray mirror using the carbon fiber reinforced plastic (CFRP) as substrate in order to improve the angular resolution; the CFRP has a high strength-to-weight ratio and can be used to realize the quadratic surface of the Wolter-I optics.

We have fabricated Wolter-I designed monolithic CFRP mirrors and made improvements in the fabrication process. The design and the fabrication method of the mirrors were based on the Hard X-ray Telescope of the ASTRO-H. The material of the mold for the CFRP substrate was renewed from Aluminum to Super-Inver, which had lower coefficient of thermal expansion than other metals. The root-mean-square errors of shape in generatrix direction of the substrates were achieved to 1~2 ?m. The reflection surface was replicated by the epoxy-replication method with the room temperature curing, which reduced the effect of print-through. In the updated CFRP mirrors, the half-power width of the reflection image by optical measurement was 0.8 arc-minutes on average. The measurement of the X-ray characterization of the updated mirrors at ISAS X-ray beam-line is scheduled December 2015.

We are also developing more intricate-structure substrate such as four-stage X-ray optics. On parallel with the mirror fabrication, we study new assembly of the mirrors from the ASTRO-H. In the assembly of the ASTRO-H telescopes, the mirrors were held by the grooves of the alignment bars, and then the positional errors of the mirrors were limited to a few ?m by the cutting accuracy of the bars.To improve positional error from the mirror assembly, we attempt to mounting on the mirrors to each others with spacer attachments.

9905-256, Session PS8

Fabrication and efficiency testing of a new generation of off-plane gratings

Casey T. DeRoo, Randall L. McEntaffer, Jake A. McCoy, James H. Tutt, The Univ. of Iowa (United States); Gerald Lopez, David Jones, Steven Wood, Univ. of Pennsylvania (United States); Christian Laubis, Physikalisch-Technische Bundesanstalt (Germany)

Future soft X-ray spectrometers will require significant improvements in both effective area and resolving power in order to achieve their critical science goals. Off-plane gratings are one technology capable of enabling improvements in both of these spectrometer performance metrics by improving throughput into high spectral orders. Attaining this improved performance, however, requires an investment in the fabrication, development and characterization of a new generation of high performance off-plane gratings. This next generation of off-plane gratings will need to have a radially ruled groove profile matching the convergence of the X-ray telescope, a triangularly shaped facet to take advantage of the off-plane blaze effect, be optically flat so as not to aberrate the diffracted line spread function, and be fabricated over large (100 cm2) areas to increase the geometric throughput of an instrument.

Previously, off-plane gratings have been made using a holographic ruling technique followed by a directional etch to yield a blazed facet. However, this method gives little control over the groove facet angle and is incapable of realizing a high fidelity radial ruling without significant facility upgrades. Recently, a method of manufacturing off-plane gratings via a process incorporating several common microfabrication techniques has been developed. With this method, a silicon substrate is patterned via thermal nanoimprint lithography (T-NIL), an anisotropic chemical wet etch is used to create a blazed groove facet, and UV nanoimprint lithography (UV-NIL) is employed to transfer the blazed grating pattern to a flat substrate. This method has been used to yield radially ruled, blazed off-plane gratings over small (25 mm x 32 mm) formats. While this method is capable of making gratings over larger formats, patterning via T-NIL requires an imprint mold to be manufactured prior to off-plane grating fabrications. This mold is a significant investment in terms of time and cost, and must be specific to a given mission architecture at the time of manufacture.

We have begun exploring electron beam lithography (EBL) as a new means of performing the initial radial patterning of the grating grooves. The EBL-patterned substrate can then be used in the aforementioned process to yield a radially ruled, blazed off-plane reflection grating. Employing EBL as an initial patterning method offers the flexibility of producing gratings for different mission architectures and over different size formats without the upfront investment of time and cost in a grating mold required by T-NIL. Several off-plane gratings have made using this new technique have been produced, and we describe the technique in detail within.

We also report on the diffraction efficiencies of a fabricated grating tested in the Littrow configuration at the Physikalisch-Technische Bundesanstalt (PTB) soft X-ray beamline located at the BESSY II synchrotron, and compare these measured efficiencies to models of diffraction efficiency generated via PCGrate-SX software. The initial characterization of these fabricated gratings demonstrates that off-plane gratings are capable of meeting the performance requirements of future soft X-ray spectrographs.

9905-257, Session PS8

On the alignment and focusing of the Marshall grazing incidence x-ray spectrometer (MaGIXS)

Patrick R. Champey, The Univ. of Alabama in Huntsville (United States); Amy R. Winebarger, Ken Kobayashi, Sabrina Savage, Jonathan W. Cirtain, NASA Marshall

Space Flight Ctr. (United States); Peter N. Cheimets, Harvard-Smithsonian Ctr. for Astrophysics (United States); Edward Hertz, Leon Golub, Smithsonian Astrophysical Observatory (United States); Brian D. Ramsey, Jeffery E. McCracken, NASA Marshall Space Flight Ctr. (United States); Vanessa Marquez, Ryan Allured, Smithsonian Astrophysical Observatory (United States); Ralf K. Heilmann, Mark L. Schattenburg, Massachusetts Institute of Technology (United States); Alexander R. Bruccoleri, Izentis, LLC (United States)

The Marshall Grazing Incidence X-ray Spectrometer (MaGIXS) is a NASA sounding rocket instrument that is designed to observe soft X-ray emissions from 0.5 - 2.0 keV energies in the solar atmosphere. The primary science goal of this experiment is to differentiate steady, low-frequency heating events from sporadic, high-frequency heating events in an active region core. For the first time, high-temperature, low-emission plasma will be observed directly with 5 arcsecond spatial resolution and 22 mÅ spectral resolution. The novel optical design consists of a Wolter - I telescope and a 3-optic grazing-incidence spectrometer. The spectrometer utilizes a finite conjugate mirror pair and a planar, varied line spaced grating that is nanoimprinted on fused-silica. The grating design is being finalized and the grating will be fabricated by the Massachusetts Institute of Technology (MIT) and Izentis LLC. Marshall Space Flight Center (MSFC) is producing the nickel replicated telescope and spectrometer mirrors using the same facilities and techniques as those developed for the ART-XC and FOXSI mirrors. The Smithsonian Astrophysical Observatory (SAO) will mount and align the flight optics based on previous experience with similar instruments, such as the Hinode X-Ray Telescope (XRT). The telescope and spectrometer assembly will be aligned in visible light through the implementation of a centroid detector assembly (CDA) -- a device designed to align the AXAF-I nested mirrors. Focusing of the telescope and spectrometer and final alignment of the system will be achieved using the X-ray beam in the Stray Light Facility (SLF) at MSFC. We present results from an alignment sensitivity analysis performed on the spectrometer, along with ZEMAX predictions for nominal return images in the CDA. We then discuss our method for aligning and focusing MaGIXS using the CDA and the SLF.

9905-258, Session PS8

Design of a medium-size x-ray mirror module based on thin glass foils

Stefano Basso, Marta M. Civitani, Giovanni Pareschi, INAF - Osservatorio Astronomico di Brera (Italy)

The glass technology for X-ray mirror is under development and in the last years even better results have been achieved. Nustar is the first X-ray telescope based on slumped glass foils and its benefits are the low costs compare to the direct polishing of glass. With the slumping technique it is possible to maintain the glass mass to low values with respect to direct polishing, but in general the angular resolution is worst. Nustar mission is based on hot slumping of glass foils and its success pushed the development of activities based on slumping. A further technique based on glass is the cold shaping of foils. The improved capabilities of manufacturing thin glass foils pushed by the industrial application for screens open new possibilities for X-ray mirror. The increase in strength of thin tempered glasses, the reduction of thickness errors and the good roughness of flat foils are potentially great advantages. In this paper a design of a medium-size X-ray mirror module is analyzed, based on integration of glass stacks directly on a supporting structure that is part of the X-ray telescope and with the use of stiffening ribs as spacer between foils. The alignment of each stack is performed directly into the integration machine avoiding the necessity to a complex aligning of different modules. A typical module provides an effective area of 500 cm2 at 2 keV with a mass of about 50 kg and a focal length of 5 m.

9905-259, Session PS8

Design and performance of very hard x-ray and soft gamma-ray Wolter I telescopes

Desirée Della Monica Ferreira, DTU Space (Denmark); Michael J. Pivovaroff, Lawrence Livermore National Lab. (United States); Finn E. Christensen, Anders C. Jakobsen, Irfan Kuvvetli, Carl Budtz-Jørgensen, DTU Space (Denmark); Regina Soufli, Julia K. Vogel, Lawrence Livermore National Lab. (United States)

We present conceptual designs for hard X-ray/soft gamma-ray focusing telescope using depth graded multilayer coatings.

Given the latest experimental advances in the understanding of multilayer coatings and substrate technologies, we explore the performance of focusing, reflective X-ray telescopes, based on Wolter I designs, with focal lengths varying between 20 to 50 meters and energy ranges that extend from the few keVs up to 600 keV.

We begin by briefly reviewing the compelling scientific motivation for such astrophysics mission. We then discuss how factors like uncertainty in optical constants, non-uniformities and roughness of coatings, scattering and the types of figure errors that can impact performance. After describing our design and optimization process, we present the Effective Area generated from our studies.

We also include the latest results on the development of CZT detectors capable of sub-mm position resolution in three dimensions.

9905-260, Session PS8

Simulating x-ray telescopes with McXtrace

Desirée Della Monica Ferreira, DTU Space (Denmark); Erik B. Knudsen, DTU Fotonik (Denmark); Niels Joergen S. Westergaard, Finn E. Christensen, DTU Space (Denmark); Mathias Solstad, Kim Lefmann, Univ. of Copenhagen (Denmark); Brian Shortt, European Space Research and Technology Ctr. (Denmark)

We take advantage of McXtrace capabilities to simulate the performance of X-ray telescopes based on Silicon Pore Optics (SPO) technologies. We use as reference the design of the optics of the planned X-ray mission Advanced Telescope for High ENergy Astrophysics (ATHENA) which is designed as a single X-ray telescope populated with stacked SPO substrates forming mirror modules to focus X-ray photons.

McXtrace is a open source monte carlo software package for simulating x-ray optics and performing virtual X-ray experiments. It was developed with the main objective of supporting optimization of X-ray beam lines and is now used in several setups such as data analysis and experiments.

McXtrace allows for modular simulations where each pore within a SPO mirror module can be traced and simulated.

9905-261, Session PS8

Ion beam figuring of glass molds for the integration of x-ray optics

Mauro Ghigo, Marta M. Civitani, Gabriele Vecchi, Stefano Basso, Giovanni Pareschi, INAF - Osservatorio Astronomico di Brera (Italy)

The INAF-Astronomical Observatory of Brera (INAF-OAB) is studying

the technology based on the integration of thin glass foils for making segmented high-throughput good angular resolution X-ray optics. This technology represents a back-up for the Silicon Pore Optics approach presently foreseen for the ATHENA optics, aiming at achieving an angular resolution of 5 arcsec HEW. In our labs it has developed a direct hot slumping technique for the glass foils assisted by pressure. The glass optical surface during the thermal forming process is in contact with a ceramic mould and a pressure is applied in order to force the glass to copy the mould shape. After this step, the integration of the slumped glass foils is performed by means of a purpose-built machine, able to stack the foils and create the X-ray Optical Unit, the building block of the final optical module. During this phase the foils are held in position pressed against other integration moulds made in glass, glass-ceramics or Aluminum that need to have a very precise shape since they control the final optical performances of the individual glass segments. To improve the optical figure of these moulds we foresee the use of the Ion Beam Figuring, a technology that is available internally in OAB. The institute has two facilities, one for large optics up to 1.4 meters and a second one for relatively small optics, up to 350 mm. The aim of this work is to show that we can bring the optical accuracy of the present moulds from the current 5-6 arcsec HEW (achieved after classical polishing techniques) down to 2 arcsec HEW. In this paper we describe the results obtained in the correction of the integration moulds and the steps implemented to handle the thermal load.

9905-262, Session PS8

Ion beam figuring of thin glass plates: achievements and perspectives

Marta M. Civitani, Mauro Ghigo, Gabriele Vecchi, Stefano Basso, INAF - Osservatorio Astronomico di Brera (Italy)

Different hot slumping techniques have been developed in the last decade to shape thin glass plates in Wolter-I configuration and make them adapted for high angular resolution x-ray telescopes. The required high quality surface characteristic, both in terms of figure error and in micro-roughness, is not an easy task and the best results achieved so far are compatible with an HEW of few arcsec. In order to push forward the technology and make them adapted to high throughput x-ray optics with final HEW below 1 arcsec, a deterministic figuring technology like the ion beam figuring can be used to correct the low frequencies residual error on the glass plates.

In this paper we present the tests performed, giving a first assessment on a deterministic process definition. In particular, we report the results achieved on free standing samples of D263 and Eagle glasses, with particular care with respect to the removal function characterization, to the micro-roughness evolution and to the plate shape variation.

9905-263, Session PS8

Adjustable integration molds for x-ray optics with cold shaping: requirements and conceptual design

Marta M. Civitani, Stefano Basso, Giovanni Pareschi, INAF - Osservatorio Astronomico di Brera (Italy)

The cold shaping of thin substrates is a worthwhile process for the realization of x-ray optics. The technique is based on the usage of integration molds to keep the substrate in the theoretical shape while it is fixed to a structure, which will limit at the desired level the residual spring back of the plate after the release of the constrain. Since some years, this process is in use at INAF/OAB to realize Slumped Glass Optics mirror modules by means of interfacing ribs. In principle, the optical design at a given focal length of each mirror shell is different for each radius and therefore several integration molds are necessary for an assembly of plates. Depending on the optical design of the mirror module to be realized and on the desired optical performances of the system, some simplifications can be introduced in order to reduce the number of integration molds to be realized. Nevertheless the most cost-efficient solution to the problem is to realize an adjustable integration mold pair that can be shaped to the different theoretical configurations needed for the plates. This is advantageous not only in terms of number of molds and parts to be realized but also for the reduction of integration time thanks to the simplification of the process procedure. In this paper we describe the conceptual design of the system, describing its optical design, analyzing its requirements and we report on the achieved results.

9905-264, Session PS8

Design and analysis of a modular mirror assembly for segmented x-ray optics

Ryan S. McClelland, SGT, Inc. (United States); William W. Zhang, Timo T. Saha, NASA Goddard Space Flight Ctr. (United States); Peter M. Solly, SGT, Inc. (United States); Joseph A. Bonafede, SGT, Inc (United States)

Lightweight and high resolution mirrors are needed for future space-based X-ray telescopes to achieve advances in high-energy astrophysics. The Next Generation X-Ray Optics (NGXO) project at NASA's Goddard Space Flight Center is developing single-crystal silicon mirror segments to achieve better than 5 arc-seconds HPD resolution. These segments must be aligned and mounted into a stiff, stable, and strong module structure. Dozens of these modules, in turn, must be aligned and mounted into a carrier structure to create a modular x-ray mirror assembly. This paper describes the requirements for a space-flight mirror assembly, a design capable of meeting these requirements, and analysis showing the requirements can be met.

The module structures are fabricated from single-crystal silicon to match the CTE and stiffness of the mirror segments. Extensive coupon testing has been performed to characterize this stiff but brittle material. Structural analysis has been performed to demonstrate the modules are sufficiently strong for expected flight loads and that deformations from thermal gradients, gravity release, and mounting are within the error budget allocations. The modules are kinematically mounted via a system of flexures to a composite carrier structure. This interface has been optimized to minimize the module distortion and maximize the clear aperture of the mirror. The composite carrier structure has also been analyzed to demonstrate it is sufficiently strong a free of deformation. A method of module alignment into the carrier structure utilize a centroid detector assembly has been developed.

A thermal system capable of preventing unacceptable distortion of the mirror assembly has been developed and optimized for maximum performance and minimum power. Hundreds of unique mirror segments were modeled so that detailed Structural Thermal Optical Performance (STOP) analysis could be performed at the module and mirror assembly level. This paper presents the STOP results and design details driving the mirror performance. A design for a 5 arc-second HPD modular mirror assembly utilizing the NGXO single-crystal silicon mirror segments has been created and analyzed to demonstrate the system requirements can be met.

9905-265, Session PS8

Recent advances in alignment and integration of slumped glass modular x-ray mirrors at MPE using simulation and deflectometry

Elias Breunig, Peter Friedrich, Laura Proserpio, Max-

Planck-Institut für extraterrestrische Physik (Germany)

The alignment and intregration facility designed and comissioned at MPE to integrate modular x-ray mirrors based on slumped glass optics uses classical collimated beam methods as well as non contact CMM techniques and the deflectometry method to provide better insights into the alignment and integration process. Especially the effect of cure shrinkage of epoxy adhesives and similiar acting thermal distortion effects can be chracterized in-situ and with high fidelity.

The use of the deflectometry method to obtain slope data from the mirror segments during integration is also an important source for validation data for numerical simulations that have been carried out for the optimization of parameters such as mirror interface position, flexibility or adhesive type. Data from all three metrology sources can also be used to correlate to PANTER x-ray data. The design of the mirror modular structure has now arrived at a configuration that uses a flexural element to cope with the above mentioned shrink and TED effects simultanously and has als evolved to a level of sophistication where a first shaker test has been carried out.

Fot future developement especially an improvement of the thermal stability of bothe the alignment and integration facility but also the mirror module is important to further improve performance. In addition a further increase in the automation of the mirror alignment and integration process is a goal.

9905-266, Session PS8

X-ray scattering on random rough surfaces

Ping Zhao, Harvard-Smithsonian Ctr. for Astrophysics (United States)

This paper presents a new method to model X-ray scattering on random rough surfaces. An actual rough surface is (incompletely) described by its Power Spectral Density (PSD). For a given PSD, model surfaces with the same roughness as the actual surface are constructed by preserving the PSD amplitudes and assigning a random phase to each spectral component. Rays representing the incident wave are reflected from the model surface and projected onto a flat plane, which is the first order approximation of the model surface, as outgoing rays and corrected for phase delays. The projected outgoing rays are then corrected for wave densities and redistributed onto an uniform grid where the model surface is constructed. The scattering is then calculated using the Fourier Transform of the resulting distribution.

This method provides the exact solutions for scattering in all directions, without small angle approximation. It is generally applicable to any wave scatterings on random rough surfaces and is not limited to small scattering angles. Examples are given for the Chandra X-ray Observatory optics. This method is also useful for the future generation X-ray astronomy missions.

9905-267, Session PS8

Optical constants of Pt and W for current and future hard x-ray telescopes

Nicolai F. Brejnholt, Regina Soufli, Lawrence Livermore National Lab. (United States); Eric M. Gullikson, Farhad H. Salmassi, Lawrence Berkeley National Lab. (United States); Sonny Massahi, David Girou, Technical Univ. of Denmark (Denmark) and DTU Space (Denmark); Marie-Anne Descalle, Lawrence Livermore National Lab. (United States); Albert T. Macrander, Raymond P. Conley, Bing Shi, Stanislav Stoupin, Lahsen Assoufid, Argonne National Lab. (United States); Finn E. Christensen, DTU Space (Denmark) and Technical Univ. of Denmark (Denmark); Michael J. Pivovaroff, Lawrence Livermore National Lab. (United States)

Accurate knowledge of the optical constants (refractive index) of the constituent materials in any x-ray optical component (e.g: mirror, filter or grating) is crucial in order to achieve the most efficient instrument design and calibration. W and Pt are among the materials frequently used in x-ray optics, either as single-layer coatings or in multilayer interference coatings. For example, the HEFT and NuSTAR missions have employed W/Si and Pt/C multilayer optics in their x-ray telescopes. There are no experimental data available for W and Pt in the vicinity of the L absorption edges (10 – 14 keV), which is part of the operational energy range of the NuSTAR mission. Tabulated values for the refractive index of W and Pt in this region rely entirely on calculations based on independent-atom approximations, which often miss the near-edge fine structure which is present due to local atomic configurations. We are presenting the first experimentally-determined values for the optical constants of Pt and W thin films, around the L absorption edges, via transmission measurements at beamline 1-BM-C at the Advanced Photon Source synchrotron at Argonne National Laboratory. Additional transmission measurements at 0.05 – 1.3 keV (which includes the N and O absorption edges of W and Pt) were obtained at beamline 6.3.2. of the Advanced Light Source synchrotron at Lawrence Berkeley National Laboratory. The dispersive part of the refractive index was determined from the absorption data via a Kramers-Kronig transformation.

This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract No. DE-AC52-07NA27344. Funding was provided by NASA project 13-APRA13-0091.

9905-268, Session PS8

Development of manufacture of mirror glass substrate for x-ray timing and polarization observatory

Zhenbo Wei, Bing Ge, Xin Jin, Tongji Univ. (China); Na Liu, Tongji Univ (China); Yingyu Liao, Bin Ma, Zhanshan Wang, Tongji Univ. (China); Yuhong Bai, Changchun Institute of Optics, Fine Mechanics and Physics (China)

In China, X-ray timing and polarization (XTP) observatory will have a collection area of 9,000 cm2 at 2~6 keV. The observatory consists of five identical hard X-ray telescopes and ten identical soft X-ray telescopes. The angular resolution is about 1 arcminute of HPD (half-power diameter). Each telescope consists of a large number of mirror segments precisely assembled together. Our development of the minor glass substrate is presented in this manuscript. These substrates are produced by slumping commercially available thin glass sheets. Here, we report on our work of manufacturing these substrates. The optimization of the slumping process is described and optimal procedure parameters are reported. The figure error of slumped glass substrates was measured by a laser scanner and an interferometer with CGH. The measured demonstrated that the figure error is lower enough for the construction of XTP telescopes.

9905-78, Session 17

The wide-field imager instrument for ATHENA

Norbert Meidinger, Kirpal Nandra, Arne Rau, Markus Plattner, Max-Planck-Institut für extraterrestrische Physik (Germany)

The WFI (Wide Field Imager) instrument is planned to be one of two complementary focal plane cameras on ESA's next X-ray observatory Athena. It combines unprecedented survey power through its large field of view of 40 arcmin x 40 arcmin together with excellent count-rate capability (≥ 1 Crab). The energy resolution of the silicon sensor is state-of-the-art in the energy band of interest from 0.2 keV to 15 keV, e.g. the full width at half maximum of a line at 6 keV will be ≤ 150 eV until the end of the nominal mission phase. This performance is accomplished by using DEPFET active pixel sensors with a pixel size of 130 μm x 130 μm well suited to the on-axis angular resolution of 5 arcsec of the mirror system. Each DEPFET pixel is a combined detector-amplifier structure with a MOSFET integrated onto a fully depleted 450 μm thick silicon bulk. Two different types of DEPFET sensors are planned for the WFI instrument: A set of four large-area sensors with in total 1024 x 1024 pixels and a single smaller gateable DEPFET sensor matrix optimized for high count-rate observations. This high count-rate capable detector shall permit for bright point source with an intensity of 1 Crab a throughput of more than 80% and a pile-up of less than 1%.

The fast readout of the DEPFET sensor matrices is facilitated by an ASIC development, called VERITAS2. Together with the Switcher-A, another ASIC that allows for readout of the DEPFET in rolling shutter mode, these elements form the key components of the WFI detectors. The detectors are surrounded by a graded-Z shield that has in particular the purpose to avoid fluorescence lines that contribute to the instrument background. Together with ultra-thin coating of the sensor and particle identification by the detector, the particle induced background shall be minimized in order to achieve the scientific requirement of a total background value smaller than 5 x 10-3 cts/cm2/s/keV.

Each detector has its dedicated electronics for supply and data acquisition. Due to the high frame rate in combination with the large pixel array, signal correction and event filtering have to be done onboard and in real time as the raw data rate would exceed the feasible telemetry rate by far.

The data streams are merged and compressed in the Instrument Control and Power distribution Unit (ICPU). The ICPU is the data, control and power interface of the WFI to the Athena satellite that is orbiting the Lagrange point L2 in a Halo orbit.

The WFI instrument comprises in addition a filter wheel in front of the camera as well as an optical stray-light baffle.

Technical budgets have been defined for the WFI instrument in the current phase A of the Athena project. Furthermore, breadboard models will be developed to demonstrate a technical readiness level of at least 5 for the various WFI subsystems before mission adoption.

9905-79, Session 17

ATHENA wide field imager key science drivers

Arne Rau, Kirpal Nandra, Norbert Meidinger, Max-Planck-Institut für extraterrestrische Physik (Germany)

We will present the key science drivers for the Athena Wide Field Imager (WFI) and their translation into the critical instrument parameters. The WFI will be designed to provide excellent point source sensitivity and grasp for performing wide area searches for high-redshift AGN, Compton Thick AGN, and early galaxy groups. In-depth studies of the outskirst of nearby clusters of galaxies will similarly make use of the large field of view coupled and push the requirements on the instrumental background. High time resolution and throughput and low pile-up for bright Galactic compact objects will enable reverberation mapping and spin measurements.

9905-80, Session 17

Studies of prototype DEPFET sensors for the wide field imager of ATHENA

Wolfgang Treberspurg, Robert Andritschke, Alexander Bähr, Davide Bianchi, Anna Koch, Norbert Meidinger, Sabine M. Ott, Max-Planck-Institut für extraterrestrische Physik (Germany); Matteo Porro, European XFEL GmbH (Germany)

The wild field imager (WFI) camera of the advanced telescope for high energy astrophysics (ATHENA) will combine an excellent spectroscopic performance and high count rate capability with a large field of view. DEPFET active pixel sensors are best suited to accomplish these demanding requirements. Each DEPFET consists of a p-channel field effect transistor, which is placed on a fully depleted, back side illuminated silicon bulk. The focal plane detector of the WFI will be composed of four large arrays to cover the large field of view of 40x40 arcmin2 and one small array that provides a high count rate capability.

Each of the four large arrays consists of 512x512 pixels with a size of 130x130 μm2. The different rows can be individually switched on and off and are consecutively sampled with a parallel multichannel readout. To achieve a full frame time resolution below 5 ms, a readout time per row below 10 μs becomes necessary.

Charge, which is generated inside the silicon bulk is collected in a potential minimum below the transistor gate. Each collected electron modulates the channel conductivity. The DEPFET pixels can be read out in two different modes. The source follower configuration reads out the voltage step on the source nodes of the pixels, while the drain readout mode acquires the drain current of the devices. The advantage of the drain readout are fixed potentials so that no settling times are needed. On the other hand, readout in source follower mode allows a larger variation in the operating parameters of the transistors that could be caused by inhomogeneities over the sensor area. Both readout modes are available on the used VERITAS-2 readout ASIC. They have been studied and compared by the use of 64x64 pixel prototype structures. Furthermore, the effect of different timings on the spectral performance was investigated in the context of WFI specifications. A key requirement is a full width at half maximum (FWHM) of not worse than 150 eV at 6 keV until the end of the mission.

9905-81, Session 17

WFI electronics and on-board data processing

Markus Plattner, Max-Planck-Institut für extraterrestrische Physik (Germany)

The Wide Field Imager is one of the two instrument on-board the ATHENA observatory. Its main scientific objective is to perform observations of the X-ray sky in the energy range of 0.2 keV up to 15 keV with an end-of-life spectral resolution better than 150 eV (at 6 keV) and a frame rate higher than 200 Hz. The field of view will be 40 arc min squared wherefore a focal plane array with four large sensors each with a size of 512 times 512 pixels will be developed. In this presentation the WFI on-board electronics and data processing concept will be described.

DEPFET sensors are used for the detection of X-ray photons. DEPFET pixels convert incoming photons into charges which are read-out by ASICs, called VERITAS-2. These front-end ASICs convert pixel charges into analog voltages which are digitized in the WFI Detector Electronics. One of the challenges for the electronics is to process the data in real-time. The analog data stream generated by the ASICs is in the order of 2*10^8 pixels per second distributed over 32 channels which are guided to 4 Detector Electronics units, each of which processes one quadrant of the large sensor array. In order to perform event recognition, the data stream needs

to be processed. First, offset maps have to be generated by calculating each pixel's baseline level averaged over some hundreds of dark frames. Second, noise maps are calculated that provide the fluctuations for each pixel. With the use of the generated maps, offset subtraction is performed for all pixels of the frame while the common mode is corrected row-wise. Event filtering is then performed by selection of the signals with an amplitude higher than the lower event threshold but not exceeding an upper threshold. Invalid events that are e.g. due to MIPs (minimum ionizing particles) are rejected by algorithms. This pre-processing performed by the Detector Electronics significantly reduces the data and only forwards relevant science data in form of an event list. The Instrument Control Unit finally provides algorithms for loss-less data compression of the even lit such that the maximum downstream rate of approximately 75 Gbit per day is met.

The data processing electronics hardware is distributed over several WFI subsystems: DEPFET sensors and frontend ASIS are located inside the Camera Head. Data pre-processing inside the Detector Electronics will be performed in an FPGA-based frame-processor. FPGA external memory will be used to store offset and noise maps wherefore a cache memory like architecture has to be designed. Fast real-time read and write memory access combined with robustness against radiation damage (e.g. bit-flips) has to be ensured by the frame-processor design.

Newly developed hard- and software concepts of WFI electronics derived from XMM-Newton and eROSITA heritage are presented. First results of WFI breadboard laboratory electronics will be shown. Together with the results of data processing simulations, these measurement results will consolidate the WFI electronics architecture and define the technical requirements necessary for WFI hardware development.

9905-82, Session 17

Thermal analysis of the WFI on the ATHENA observatory

Maria Fürmetz, Max-Planck-Institut für extraterrestrische Physik (Germany)

The WFI (Wide-Field Imager) instrument is one of two instruments of the ATHENA (Advanced Telescope for High-ENergy Astrophysics) mission. ATHENA is the second L-class mission in ESA's Cosmic Vision plan with launch in 2028 and will address the science theme "The Hot and Energetic Universe" by measuring hot gas in clusters and groups of galaxies as well as matter flow in black holes.

A moveable mirror assembly focusses the X-ray light to the focal plane of the WFI. The instrument consists of two separate sensors, one large DEPFET array with 512x512 pixels and one small, fast DEPFET detector with 64x64 pixels and a readout time of only 1.3ms. An angular resolution of 5" will be achieved. The rather large field of view of 40'x40' in combination with rather high power consumption is challenging not only for the thermal control system.

DEPFET sensors as well as front-end electronics and electronics boxes have to be cooled, where a completely passive cooling system with radiators and heat pipes is highly favored. In order to reduce the necessary radiator area, three separate cooling chains with three different temperature levels have been foreseen. So only the DEPFET sensors are cooled down to the lowest temperature of about 180K, while the front-end electronics is supposed to be operated between 250K and 270K. The electronics boxes can be operated at room temperature, nevertheless the excess heat has to be removed.

After first estimations of heat loads and radiator areas, a more detailed model of the camera head has been used to identify gradients between the cooling interfaces and the components to be cooled. This information is used within phase A1 of the project to further optimize the design of the instrument, e.g. material selection.

9905-83, Session 18

The ATHENA x-ray integral field unit

Didier Barret, Institut de Recherche en Astrophysique et Planétologie (France); Jan-Willem A. den Herder, SRON Netherlands Institute for Space Research (Netherlands); Luigi Piro, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Thien Lam Trong, Ctr. d'Etudes Spatiales de la Biosphère (France); Xavier Barcons, Univ. de Cantabria (Spain)

The X-ray Integral Field Unit (X-IFU) on bard the Advanced Telescope for High Energy Astrophysics (Athena), ESA's second large mission of its Cosmic Vision science program, will provide spatially resolved high resolution (less than 2.5 eV up to 7 keV) spectroscopy over a field of view of 5 arc minute equivalent diameter. The X-IFU is baselined as a large format array of Transition Edge Sensors (TES) connected to a thermal bath at 50 mK. The cryogenic chain is composed of a series of mechanical coolers (Stirling, Joule Thomson, and Pulse Tube) with the last stage being a sorption Adiabatic Demagnetization Refrigerator. The readout of the TESs uses a baseband feedback loop and is based on frequency domain multiplexing, with the event reconstruction performed on-board. The X-IFU is now entering a phase A study, with the Preliminary Instrument Design due around the end of 2017. In this paper I will recall the Athena scientific objectives specific to the X-IFU and show how the derived Athena science requirements flow down into the X-IFU specifications. I will also introduce the instrument level trade-offs that are currently being performed and present a preliminary design of the instrument, as provided for the Mission Consolidation Review of the Athena mission.

The X-IFU will be provided by an international consortium led by France, The Netherlands and Italy, with ESA member state contributions from Belgium, Finland, Germany, Poland, Spain, Switzerland, with additional contributions from the United States and Japan.

9905-84, Session 18

X-IFU Instrument: technical challenges and preliminary design

Thien Lam Trong, Ctr. d'Etudes Spatiales de la Biosphère (France); Jérome André, Ctr. National d'Études Spatiales (France); Xavier Barcons, Univ. de Cantabria (Spain); Didier Barret, Institut de Recherche en Astrophysique et Planétologie (France); Ivan Charles, Commissariat à l'Énergie Atomique (France); Christophe Daniel, Emilie Gloaguen, Jeremie Hassin, Ctr. National d'Études Spatiales (France); Jan-Willem A. den Herder, SRON Netherlands Institute for Space Research (Netherlands); Michel Le Du, Irwin Maussang, Jean-Michel Mesnager, Ctr. National d'Études Spatiales (France); Francois Pajot, Institut de Recherche en Astrophysique et Planétologie (France); Johan Panh, Ctr. National d'Études Spatiales (France); Luigi Piro, INAF - IASF Roma (Italy); Alice Pradines, Ctr. National d'Études Spatiales (France); Laurent Ravera, Institut de Recherche en Astrophysique et Planétologie (France); Bruno Vella, Ctr. National d'Études Spatiales (France)

The X-ray Integral Field Unit (X-IFU) is a part of the Advanced Telescope for High Energy Astrophysics (Athena), ESA's second large mission of its Cosmic Vision science program. This instrument is developed by a large international consortium under a French leadership.

The Netherlands and Italy, with Belgium, Finland, Germany, Poland, Spain, Switzerland, are the European contributors, with the United States and Japan as international partners. The X-IFU instrument is located at the focus of a 12 meter focal length and 3 meter diameter mirror. Among its performance requirements, the spectral resolution (2.5 eV up to 7 keV) is quite challenging. The paper shall first address the technical challenges to be faced (large format array of Transition Edge Sensors cooled down to a 50 mK, the Thermal Control, EMI/EMC, micro-vivrations and read-out issues including the multiplexing process of the signal, etc.) and then shall present the preliminary design of the X-IFU instrument.

9905-85, Session 18

TES pixel parameter design of the microcalorimeter array for the x-ray integral field unit on ATHENA

Stephen J. Smith, Joseph S. Adams, Simon R. Bandler, Gabriele L. Betancourt-Martinez, James A. Chervenak, Meng P. Chiao, Aaron M. Datesman, Megan E. Eckart, Audrey J. Ewin, Fred M. Finkbeiner, Richard L. Kelley, Caroline A. Kilbourne, Frederick S. Porter, John E. Sadleir, Edward J. Wassell, Wonsik Yoon, NASA Goddard Space Flight Ctr. (United States); Douglas A. Bennett, William B. Doriese, Gene C. Hilton, Daniel S. Swetz, Joel N. Ullom, National Institute of Standards and Technology (United States); Hiroki Akamatsu, Luciano Gottardi, Roland H. den Hartog, Brian D. Jackson, Jan van der Kuur, SRON Netherlands Institute for Space Research (Netherlands); Didier Barret, Philippe Peille, Institut de Recherche en Astrophysique et Planétologie (France)

The X-ray integral field unit (X-IFU) proposed for ESA's Athena X-ray observatory will consist of ~ 4000 transition edge sensor (TES) x-ray microcalorimeters optimized for the energy range of 0.2 to 12 keV. The instrument will provide unprecedented spectral resolution of ~ 2.5 eV at energies of up to 7 keV and will accommodate photon fluxes of 1 mcrab (100 cps) for point source observations. The original baseline configuration is a uniform large pixel array (LPA) of 5" pixels that is read out using frequency domain multiplexing (FDM). However, a new configuration under study incorporates a small pixel array (SPA) of 2" pixels in the central 30"x30" portion. This hybrid array configuration would be designed to accommodate higher incident fluxes of up to 10 mcrab (1000 cps) for point source observations whilst still meeting the required energy resolution requirements. In this paper we report on the TES pixel designs that are being optimized to meet these proposed LPA and SPA requirements. In particular we describe details of how important TES parameters are chosen to meet the specific mission criteria such as energy resolution, count-rate and quantum efficiency. This includes details of key TES properties such as the small signal transition parameters, thermal design of the pixels and absorber composition. Performance trade-offs between different design options will be highlighted. The basis of the pixel parameter selection is discussed in the context of existing TES arrays that are being developed for solar and x-ray astronomy applications. These detector parameters are being used as the basis for determining the requirements for the read-out electronics, on-going studies of signal processing options for X-IFU and provide the inputs for science simulations. Although the primary readout technology for the X-IFU will utilize AC biased pixels read out with FDM, most of the pixel development to date has been focused on optimizing DC pixel performance. We describe latest results on DC biased diagnostic arrays as well as large format kilo-pixel arrays and discuss the potential differences in pixel implementation that may be required to optimize performance in an AC biased circuit.

9905-86, Session 18

The focal plane assembly for the ATHENA x-ray integral field unit instrument

Brian D. Jackson, Henk J. van Weers, Jan van der Kuur, Roland H. den Hartog, Hiroki Akamatsu, SRON Netherlands Institute for Space Research (Netherlands); Andrea Argan, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Simon R. Bandler, NASA Goddard Space Flight Ctr. (United States); Marco Barbera, Univ. degli Studi di Palermo (Italy) and INAF - Osservatorio Astronomico di Palermo Giuseppe S. Vaiana (Italy); Didier Barret, Institut de Recherche en Astrophysique et Planétologie (France); Marcel P. Bruijn, SRON Netherlands Institute for Space Research (Netherlands); James A. Chervenak, NASA Goddard Space Flight Ctr. (United States); Johannes Dercksen, SRON Netherlands Institute for Space Research (Netherlands); Flavio Gatti, Univ. degli Studi di Genova (Italy); Luciano Gottardi, Daniel Haas, Jan-Willem A. den Herder, SRON Netherlands Institute for Space Research (Netherlands); Caroline A. Kilbourne, NASA Goddard Space Flight Ctr. (United States); Mikko Kiviranta, VTT Technical Research Ctr. of Finland Ltd. (Finland); Thien Lam Trong, Ctr. d'Etudes Spatiales de la Biosphère (France); Bert-Joost van Leeuwen, SRON Netherlands Institute for Space Research (Netherlands); Claudio Macculi, Luigi Piro, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Stephen J. Smith, NASA Goddard Space Flight Ctr. (United States)

The X-ray Integral Field Unit (X-IFU) on ESA's Athena X-ray observatory will be an imaging microcalorimeter providing high spectral resolution imaging with both high count-rate capability and a large field-of-view. The X-IFU focal plane assembly (FPA) will contain the instrument's cryogenic detectors and their superconducting readout electronics, while also shielding them from their operating environment on the 2 K stage of the instrument's cryostat. This paper will describe the preliminary design concept for the focal plane assembly and identify critical technology development activities that will be required to realize this concept.

X-IFU will employ a ~ 3840-pixel TES microcalorimeter array to provide high spectral-resolution imaging over 0.2-12 keV of both bright point-sources and an extended field-of-view. This sensor array will be operated using frequency domain multiplexed SQUID readout electronics, with a two-stage SQUID amplifier chain providing low-noise readout of the TES detectors with sufficient gain to drive the cables running to the instrument's warm electronics and overcome conducted noise in this interface, while also minimizing power dissipation on the instrument's low temperature stages.

With very weak extended sources such as galaxy clusters being among the key astronomical targets to be observed by X-IFU, critical elements of the FPA design will be both active and passive elements to suppress spurious events in the detector's output signal due to the interaction of cosmic rays, or secondary particles generated by cosmic ray events, with the sensor array. This requires the use of a cryogenic anti-coincidence (Cryo-AC) detector, a second TES detector operated in close proximity to the sensor array, in order to detect cosmic rays passing through the sensor array and secondaries so that these can be flagged in off-line data processing.

The sensor array and its SQUID readout electronics are particularly sensitive to their environment, including stray-light from the thermal environment of the cryostat and spacecraft, out-of-band photons coming from sky sources, high-frequency electric fields radiated by sources such as the spacecraft's downlink antennas, conducted electrical noise in the cryo-harness between the FPA and its warm electronics, and quasi-static

magnetic fields radiated by sources such as the cryo-coolers that are used to provide the focal plane assembly's low-temperature environment. The external noise sources will be suppressed by a multi-layer shielding design to allow the required low-noise detector performance to be achieved within the expected on-ground and in-flight environment.

Finally, the focal plane assembly will be operated in a cryostat in which low-temperature cooling power is constrained by a combination of technology and spacecraft resources. As such, the assembly's thermal design is optimized to minimize the cooling power required at the lowest temperature levels, with a two-layer thermal suspension system isolating the detectors at 50 mK from the 2 K environment of the cryostat's cold stage, the design of which is further driven by strength and stiffness requirements defined to ensure survival of launch vibration loads.

9905-87, Session 18

Preliminary thermal architecture of the X-IFU instrument

Ivan Charles, Commissariat à l'Énergie Atomique (France); Christophe Daniel, Jérome André, Ctr. National d'Études Spatiales (France); Lionel Duband, Jean-Marc Duval, Commissariat à l'Énergie Atomique (France); Roland H. den Hartog, Henk J. van Weers, SRON Netherlands Institute for Space Research (Netherlands); Noriko Y. Yamasaki, Institute of Space and Astronautical Science (Japan)

The ESA Athena mission will implement 2 instruments to study the hot and energetic universe. The X-ray Integral Field Unit (X-IFU) will provide spatially resolved high resolution spectroscopy. This high energy resolution of 2.5 eV at 7 keV could be achieved thanks to TES (Transition Edge Sensor) detectors that need to be cooled to very low temperature. To obtain the required 50 mK temperature level, a careful design of the cryostat and of the cooling chain including different technologies in cascade is needed. The preliminary cryogenic architecture of the X-IFU instrument that fulfils the TES detector thermal requirements is described. In particular, the thermal design of the detector focal plane assembly (FPA), that uses three temperature stages (from 2 K to 50 mK) to limit the thermal loads on the lowest temperature stage, is described. The baseline cooling chain is based on European and Japanese mechanical coolers (Stirling, Pulse tube and Joule Thomson coolers) that precool a sub Kelvin cooler made of a 3He sorption cooler coupled with a small ADR (Adiabatic Demagnetization Refrigerator). Preliminary thermal budgets of the X-IFU cryostat are presented and discussed regarding cooling chain performances. Various cryochain options are also discussed and some preliminary thermal sensitivity analyses are presented.

9905-88, Session 18

The cryogenic anti-coincidence detector for ATHENA X-IFU: a program overview

Claudio Macculi, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Andrea Argan, INAF - IASF Roma (Italy); Matteo D'Andrea, Simone Lotti, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Luigi Piro, INAF - IASF Roma (Italy); Michele Biasotti, Univ. degli Studi di Genova (Italy); Dario Corsini, Univ. degli Studi di Genova (Italy); Flavio Gatti, Angiola Orlando, Univ. degli Studi di Genova (Italy); Guido Torrioli, CNR-Istituto di Fotonica e Nanotecnologie (Italy); Mauro Fiorini, Silvano Molendi, Michela C. Uslenghi, INAF - IASF Milano (Italy); Teresa Mineo, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Andrea A. Bulgarelli, Valentina Fioretti, INAF - IASF Bologna (Italy)

The ATHENA observatory, the second large-class ESA mission in the context of the Cosmic Vision 2015-2025, is scheduled to be launched on 2028th at L2 orbit. One of the two instruments at the focal plane is the X-IFU (X-ray Integral Field Unit): it is a TES-based kilo-pixels array able to perform simultaneous high-grade energy spectroscopy (2.5 eV at 6 keV) and imaging over the 5 arcmin FoV.

The X-IFU sensitivity is degraded by the particles background, which is induced by protons of both solar and Cosmic Rays origin, and secondary electrons. The studies performed by Geant4 simulations depict a scenario where it is mandatory the use of background reduction techniques. These combine an active anticoincidence detector and a passive electron shielding to reduce the background expected in L2 orbit down to the goal level of 5E-3 cts/cm^2/s/keV, so enabling the characterization of faint or diffuse sources (e.g. WHIM or Galaxy outskirt).

From the detector point of view, this is possible by adopting a Cryogenic AntiCoincidence (CryoAC) placed within a proper optimized environment surrounding the X-IFU TES array. The CryoAC is a 4-pixels detector made of Silicon absorbers sensed by Ir:Au TESes, and placed at a distance < 1 mm below the TES-array.

On October 2015 the X-IFU Phase A program has been kicked-off. The first model (DM1, Demonstration Model 1) of the CryoAC will be made of 1 pixel "bridges-suspended" and will address the final design of the CryoAC. The delivery to the FPA development team for integration is foreseen in 2016.

Both the background studies and the detector development work are on-going to provide confident results about the expected residual background at the TES-array level, and the single pixel design to produce a detector for testing activity on 2016.

Here we will provide an overview of the CryoAC program.

We will discuss some details on the background assessment having impacts on the CryoAC design, and we will give information on both the last single pixel characterization and on the structural issues. We will conclude with some programmatic aspects.

9905-89, Session 19

The Compton spectrometer and imager

Steven E. Boggs, Univ. of California, Berkeley (United States) and Space Sciences Lab. (United States); Jeng-Lun Chiu, Carolyn A. Kierans, Alexander W. Lowell, Clio Sleator, John A. Tomsick, Andreas Zoglauer, Cory Gerrity, Ares Hernandez, Space Sciences Lab. (United States); Mark S. Amman, Lawrence Berkeley National Lab. (United States); Pierre Jean, Peter von Ballmoos, Institut de Recherche en Astrophysique et Planétologie (France); Hsiang-Kuang Chang, Chien-Ying Yang, Chao-Hsiung Tseng, Che-Yen Chu, Sheng-Feng Chung, National Tsing Hua Univ. (Taiwan); Chih-Hsun Lin, Academia Sinica (Taiwan); Yuan-Hann Chang, National Central Univ. (Taiwan); Yu-Shao Shiao, National Applied Research Labs. (Taiwan)

The Compton Spectrometer and Imager (COSI) is a wide-field gamma-ray telescope (0.2-5 MeV) designed to probe the origins of Galactic positrons, uncover sites of nucleosynthesis in the Galaxy, and perform pioneering studies of gamma-ray polarization. COSI uses a compact Compton telescope design, resulting from a decade of development under NASA's APRA program. COSI performs groundbreaking science by combining improvements in sensitivity, spectral resolution, and sky coverage. We have built the COSI instrument and flight systems for ULDB flights. COSI will fly

on a NASA superpressure balloon from New Zealand in April 2016, the first science flight for NASA's ULDB program.

COSI is a wide-field survey telescope designed to perform imaging, spectroscopy, and polarization measurements. It employs a novel Compton telescope design utilizing a compact array of cross-strip germanium detectors (GeDs) to resolve individual gamma-ray interactions with high spectral and spatial resolution. The COSI array is housed in a common vacuum cryostat cooled by a mechanical cryocooler. An active CsI Shield encloses the cryostat on the sides and bottom. The FoV of the instrument covers 25% of the full sky at a given moment.

The COSI instrument builds upon considerable heritage from the previous Nuclear Compton Telescope (NCT) balloon instrument that underwent a successful technology demonstration flight in June 2005 from Fort Sumner, NM, a successful "first light" science flight from Fort Sumner in May 2009, and quickly turned around and delivered on time for a launch campaign from Alice Springs, Australia in June 2010, where it unfortunately suffered a launch mishap. The COSI instrument and Flight System are rebuilt under the NASA/APRA program as a ULDB payload. COSI underwent a short flight from Antarctica in 2014, terminated early due to technical difficulties with the balloon. COSI was recovered and is now flight ready for the April 2016 launch from New Zealand.

In this talk, we will present the COSI instrument and payload, preliminary results from the April 2016 flight, as well as the overall science goals of the COSI program.

9905-90, Session 19

MeV gamma-ray observation with a well-define point spread function based on electron tracking

Atsushi Takada, Toru Tanimori, Hidetoshi Kubo, Tetsuya Mizumoto, Yoshitaka Mizumura, Dai Tomono, Shinya Sonoda, Shotaro Komura, Tetsuro Kishimoto, Shohei Miyamoto, Taito Takemura, Kei Yoshikawa, Yuma Nakamasu, Yoshihiro Matsuoka, Makoto Oda, Kyoto Univ. (Japan); Kentaro Miuchi, Kobe Univ. (Japan); Shunsuke Kurosawa, Tohoku Univ. (Japan)

MeV gamma-ray astronomy at the energy range of 0.1-100 MeV is an unique window for observing nucleosynthesis, and it also provides the information on particle acceleration in active galactic nuclei or gamma-ray bursts, the strong gravity potential of black holes, the interaction of cosmic-ray and interstellar matter in the Galactic plane. However, the observation in this energy band is not advanced in comparison with other bands, because there is no imaging method having a sharp point spread function (PSF) and a powerful background rejection. In the observation of SN2014J by SPI/INTEGRAL, the signal of 847 keV from Co-56 was detected with the significance of 4.7 sigma, but the expected significance based on the count rate of SPI is ~100 sigma if we can suppress the instrumental background completely with a sharp point spread function (PSF).

For the next generation MeV gamma-ray telescope, we are developing an electron-tracking Compton camera (ETCC), which consists of a gaseous time projection chamber as an electron tracker and pixel scintillator arrays as an absorber. The track of Compton-recoil electron restricts the gamma-ray incident direction with powerful background rejection based on particle identification and Compton-scattering kinematic test. Because an ETCC detect the incident direction event by event, we can define a PSF of an ETCC as similar to usual telescopes. Moreover, we confirmed that the PSF of Compton camera strongly depends on the accuracy of Compton-recoil direction. For the future observation with the sensitivity of 1 mCrab, an ETCC will require the accuracy of Compton scattering angle (angular resolution measure: ARM) of ~2 degrees and the accuracy of Compton-recoil direction (scatter plane deviation: SPD) of ~5 degrees.

Now we are constructing a 30 cm-cubic ETCC for the second balloon experiment: Sub-MeV gamma ray Imaging Loaded-on-balloon Experiment: SMILE-II. The current ETCC has an effective area of ~1cm2 at 300 keV, a PSF of ~10 degrees (ARM and SPD are ~5 degrees and ~100 degrees, respectively) at FWHM for 662 keV, and a large field of view of ~3 sr. We will upgrade this ETCC to an effective area of several cm2 and a PSF of ~5 degrees using a CF4-based gas. Using the upgraded ETCC, our observation plan of SMILE-II is the mapping of electron-positron annihilation line and 1.8 MeV from Al-26. In this presentation, we will report current performance and our observation plan.

9905-91, Session 19

The e-ASTROGAM mission

Vincent Tatischeff, Ctr. de Sciences Nucléaires et de Sciences de la Matière (France)

e-ASTROGAM is a gamma-ray observatory to be proposed as ESA's M5 Medium-size mission by a large Collaboration comprising about 250 scientists from 18 countries. It is dedicated to the observation of the Universe with unprecedented sensitivity in the energy range 0.3 – 100 MeV, extending up to GeV energies. In this energy window, a variety of phenomena and sources await their discovery and many foundational questions can be answered. e-ASTROGAM will also feature a groundbreaking capability for measuring gamma-ray polarization, thus accessing a new observable that can provide valuable information on the source geometry and the emission processes.

e-ASTROGAM will operate as an open astronomical observatory, with a core science focused on (1) the high-energy mysteries of the Galactic center and inner Galaxy, including the supermassive black hole activity, the Fermi Bubbles, the origin of the Galactic positrons, and dark matter signatures in a new energy window; (2) nucleosynthesis and propagation of heavy elements in our Galaxy and beyond, including the life cycle of elements produced by supernovae in the Milky Way and the Local Group of galaxies; (3) activity from extreme particle accelerators, including disk-jet transitions in active galactic nuclei and the origin of the extragalactic gamma-ray background. e-ASTROGAM will be ideal for the study of high-energy sources in general, including pulsars and pulsar wind nebulae, accreting neutron stars and black holes, supernova remnants, soft gamma-ray repeaters, gamma-ray bursts, and active galactic nuclei. It will also provide important contributions to solar and terrestrial physics. e-ASTROGAM will be uniquely complementary to a variety of ground and space observatories ranging from radio, optical, X-ray and TeV energies, as well as to neutrino and gravitational wave detectors.

The e-ASTROGAM payload consists of a single instrument for the simultaneous detection of Compton and pair-producing gamma-ray events. It consists of three main detectors: (1) a silicon tracker based on the technology of double sided Si strip detectors readout by an ultra low-noise front-end electronics, (2) an imaging calorimeter made of an assembly of scintillation crystals with state-of-the-art readout, and (3) an anticoincidence system designed with segmented panels of plastic scintillators covering the payload. The e-ASTROGAM instrument inherits from predecessors such as MEGA, AGILE, and Fermi, but takes full advantages of recent progresses in silicon detectors and readout microelectronics to achieve measurement of the energy and 3D position of each interaction with an excellent spectral and spatial resolution. It is further based on an innovative design, which minimizes any passive material in the detector volume. The ideal orbit for e-ASTROGAM is an equatorial low-Earth orbit of altitude in the range 550 - 600 km, with an inclination $i < 2.5°$ and eccentricity $e < 0.01$. The foreseen launcher is Ariane 6.2.

9905-92, Session 19

The development of a low energy Compton imager for GRB polarization studies

Mark L. McConnell, Peter F. Bloser, Jason S. Legere, James M. Ryan, Sambid K. Wasti, The Univ. of New Hampshire (United States)

The Gamma Ray Polarimeter Experiment (GRAPE) is designed to investigate one of the most exotic phenomena in the universe – gamma-ray bursts (GRB). There has been intense observational and theoretical research in recent years, but research in this area has been largely focused on studies of time histories, spectra, and spatial distributions. Theoretical models show that a more complete understanding of the inner structure of GRBs, including the geometry and physical processes close to the central engine, requires the exploitation of gamma-ray polarimetry. Over the past several years, we have developed the GRAPE instrument to measure the polarization of gamma-rays from GRBs over the energy range of 50 to 500 keV. GRAPE is a large FoV instrument with a sensitive energy range covering the peak energy distribution of GRBs. The design is based on an array of independent modules, each of which consists of an array of (high-Z and low-Z) scintillator elements read out by a multi-anode PMT (MAPMT). Our eventual goal is to fly GRAPE on a long duration balloon (LDB) platform to collect data on a significant sample of GRBs. Our experience with two balloon flights (in 2011 and 2014), coupled with further design efforts focused on orbital payloads, has led to an improved polarimeter concept that represents a natural evolution of the current design. The new concept employs a large number of optically-isolated scintillator elements, each of which is designed to provide a depth-of-interaction (DOI) using two (or perhaps more) readout sensors. The resulting three-dimensional location data provides a moderate level of Compton imaging capability (1 sigma angular resolution of 10-15°). Even this level of imaging can be used to significantly reduce the instrumental background by limiting the impact of the cosmic diffuse flux, dramatically improving the polarization sensitivity. Here we shall describe this concept and the expected performance for GRB polarization measurements. We will also describe our efforts to develop a working prototype, which will be initially focused on the readout technologies (including the use of SiPMs) that will provide DOI without adversely impacting the overall instrument performance.

9905-93, Session 19

Performance study of the gamma-ray bursts polarimeter POLAR

Jianchao Sun, Bobing Wu, Tianwei Bao, Institute of High Energy Physics (China); Tadeusz Batsch, National Ctr. for Nuclear Research (Poland); Tancredi Bernasconi, Univ. de Genève (Switzerland); Junying Chai, Yongwei Dong, Institute of High Energy Physics (China); Neal Gauvin, Univ. de Genève (Switzerland); Wojtek Hajdas, Paul Scherrer Institut (Switzerland); Merlin Kole, Univ. de Genève (Switzerland); Minnan Kong, Siwei Kong, Lu Li, Jiangtao Liu, Xin Liu, Institute of High Energy Physics (China); Radoslaw Marcinkowski, Paul Scherrer Institut (Switzerland); Silvio Orsi, Martin Pohl, Nicolas Produit, Divic Rapin, Univ. de Genève (Switzerland); Aleksandra Rutczynska, Dominik K. Rybka, National Ctr. for Nuclear Research (Poland); Haoli Shi, Liming Song, Institute of High Energy Physics (China); Jacek Szabelski, National Ctr. for Nuclear Research (Poland); Ruijie Wang, Xing Wen, Institute of High Energy Physics (China); Hualin Xiao, Institute of High Energy Physics (China) and Paul Scherrer Institut (Switzerland); Hanhui Xu, Li Zhang, Laiyu Zhang, Shuang-Nan Zhang, Xiaofeng Zhang, Yongjie Zhang, Institute of High Energy Physics (China); Ania Zwolinska, National Ctr. for Nuclear Research (Poland)

The Gamma-Rays Bursts (GRBs) phenomenon is one of the most interesting topics in astrophysics. However, due to the limits of the current observation results, we know little about the GRB's prompt radiation mechanisms. The theorists predict that the polarization property of the GRB's prompt emissions may play a key role in distinguishing the emission mechanisms of GRB. Therefore, more and more polarimeters as well as precise GRB's prompt emission polarization measurement results are eagerly needed to unveil the mystery of radiation mechanism of GRB's central engine.

POLAR is a novel compact space-borne Compton polarimeter conceived for a precise measurement of hard X-ray/Gamma-ray polarization and optimized for the detection of the prompt emission of Gamma-Ray Bursts (GRB) in the energy range between 50 keV to 500 keV. The detector of POLAR consists of 25 detector modular units (DMU). Each DMU is composed of 64 low-Z plastic scintillator bars, read out by a flat-panel multi-anode photomultiplier H8500 and ASIC front-end electronics. The incoming photons undergo Compton scattering in the bars and produce a modulation pattern. Both simulations and hard X-ray synchrotron radiation experiment results have shown that the polarization degree and polarization angle can be retrieved from this pattern with the accuracy necessary for pinning down the GRB mechanisms.

As POLAR consists totally 1600 detection channels (in a 40?40 array), we studied the non-uniformity of their gains, low thresholds and pedestals which may affect the overall performance of POLAR in-orbit. In the same time, the gains, pedestals as well as some other performances of POLAR may also be affected by the environmental factors, like the temperature, vibration or shock experiences. All these performances have also been studied with dedicated tests or experiments.

With the efforts by the collaborators from China and Switzerland, POLAR has experienced the Demonstration Model (DM) phase, Engineering and Qualification Model (EQM) phase, Qualification Model (QM) phase, and now a full Flight Model (FM) of POLAR has been constructed. The FM of POLAR has passed the environmental acceptance tests (thermal cycling, vibration, shock and thermal vacuum tests) and experienced the calibration tests with radioactive sources and 100% polarized Gamma-Ray beam at ESRF after its construction. POLAR will be installed on-board the Chinese spacelab TG-2 in view of a flight expected in 2016.

The design of POLAR, performance study results, calibration results as well as the current status and progress of the project will be all presented in this paper.

9905-94, Session 19

First flight of the gamma-ray imager/polarimeter for solar flares (GRIPS) instrument

Nicole Duncan, Univ. of California, Berkeley (United States); Pascal Saint-Hilaire, Space Sciences Lab. (United States); Albert Y. Shih, NASA Goddard Space Flight Ctr. (United States); Gordon J. Hurford, Hazel M. Bain, Space Sciences Lab. (United States); Mark S. Amman, Lawrence Berkeley National Lab. (United States); Brent Mochizuki, Andreas Zoglauer, Steven E. Boggs, Robert Lin, Space Sciences Lab. (United States)

The Gamma-Ray Imager/Polarimeter for Solar flares (GRIPS) instrument is a balloon-borne telescope designed to study solar-flare particle

acceleration and transport. We describe GRIPS' first Antarctic long-duration flight in December 2015 and report preliminary calibration and science results.

Electron and ion dynamics, particle abundances and the ambient plasma conditions in solar flares can be understood by examining hard X-ray (HXR) and gamma-ray emission (20 keV to 10 MeV). Enhanced imaging, spectroscopy and polarimetry of flare emissions in this energy range are needed to study particle acceleration and transport questions. The GRIPS instrument is specifically designed to answer questions including: What causes the spatial separation between energetic electrons producing hard X-rays and energetic ions producing gamma-ray lines? How anisotropic are the relativistic electrons, and why can they dominate in the corona? How do the compositions of accelerated and ambient material vary with space and time, and why?

GRIPS' key technological improvements over the current solar state of the art at HXR/gamma-ray energies, the Reuven Ramaty High Energy Solar Spectroscopic Imager (RHESSI), include 3D position-sensitive germanium detectors, (3D-GeDs) and a single-grid modulation collimator, the Multi-Pitch Rotating Modulator (MPRM). The 3D-GeDs have spectral FWHM resolution of a few hundred keV and spatial resolution <1mm3. For photons that Compton scatter, usually >150 keV, the energy deposition sites can be tracked, providing polarization measurements as well as enhanced background reduction through Compton imaging. Each of GRIPS' detectors has 298 electrode strips read out with ASIC/FPGA electronics. In GRIPS' energy range, indirect imaging methods provide higher resolution than focusing optics or Compton imaging techniques. The MPRM grid-imaging system has a single-grid design which provides twice the throughput of a bi-grid imaging system like RHESSI. The grid is composed of 2.5cm deep tungsten-copper slats, and a quasi-continuous FWHM resolution from 12.5–162 arcsecs is achieved by varying the grid pitch between 1–13mm. This angular coverage is capable of imaging the separate magnetic loop footpoint emissions in a variety of flare sizes. In comparison, RHESSI's 35-arcsec resolution at similar energies makes the footpoints resolvable in only the largest flares.

9905-95, Session 19

First measurement of the polarisation asymmetry of a gamma-ray beam between 1.7 to 74 MeV with the HARPO high preformance TPC telescope

Philippe Gros, Lab. Leprince-Ringuet (France)

Current gamma-ray telescopes suffer from a gap in sensitivity in the energy range between 100keV and 100MeV, and no polarisation measurement has ever been done on cosmic sources above 1MeV.

Past and present electron-positron pair telescopes are limited in the lower energies by the multiple scattering of the electrons in passive tungsten converter plates.

This results in low angular resolution, so that the sensitivity to point sources drops below 1GeV.

The polarisation information, which is carried by the azimuthal angle of the conversion plane, is lost for the same reasons.

HARPO is an R&D program to characterize the operation of a gaseous detector (Time Projection Chamber or TPC) as a high angular-resolution and sensitivity telescope and polarimeter for gamma-rays from cosmic sources.

It represents a first step towards a future space instrument.

We built and characterised a 30cm cubic demonstrator [SPIE 91441M], and put it in a polarised gamma-ray beam at the NewSUBARU accelerator in Japan in November 2014.

Data were taken at different photon energies from 1.7~MeV to 74~MeV, and with different polarisation configurations.

I will describe the full experimental setup, and in particular the dedicated triggering system.

I will describe the software I developped to reconstruct the photon conversion events, especially for low energies.

Finally I will present the performances of the detector as extracted from this analysis and preliminary measurements of the polarisation asymmetry.

Our beam-test qualification of a gas TPC prototype in a gamma-ray beam could open the way to high-performance gamma-ray astronomy and polarimetry in the MeV-GeV energy range in the next future.

9905-96, Session 19

Compton-pair production gamma-ray telescope (ComPair): a wide field discovery mission for the MeV band

Julie McEnery, NASA Goddard Space Flight Ctr. (United States)

The MeV domain is one of the most underexplored windows on the Universe, mainly due to the challenging nature of the measurements. This is an energy range of transition in the Universe. Thermal sources dominate at lower energies, while non-thermal phenomena prevail at higher energies. In addition, observations at both gamma-ray and hard X-ray energies provide compelling evidence of astrophysical objects whose radiative output peaks in the MeV range. Equally crucial is the strong evidence that spectral features such as breaks, turnovers, cutoffs, and temporal behavior, which are critical discriminating factors between competing physical models, occur within this energy band. In this paper we describe a wide-aperture discovery mission concept, Compton-Pair Production Space Telescope (ComPair) and discuss the science that it will address. This mission will investigate the energy range from 200 keV to >500 MeV with good energy and angular resolution and with sensitivity approaching a factor of 20-50 better than previous instruments.

Conference 9906: Ground-based and Airborne Telescopes VI

Sunday - Friday 26–1 July 2016

Part of Proceedings of SPIE Vol. 9906 Ground-based and Airborne Telescopes VI

9906-1, Session 1

Upgrade of the HET segment control system utilizing state-of-the-art decentralized and embedded system controllers

Marco H. Häuser, Josef Richter, Univ.-Sternwarte München (Germany); Hermanus Kriel, Amanda Turbyfill, Michael H. Ward, The Univ. of Texas at Austin (United States)

Together with the ongoing major instrument upgrade of the Hobby-Eberly Telescope (HET), we present the planned upgrade of the HET Segment Control System (SCS) to SCS2. Because HET's primary mirror is segmented into 91 individual 1-meter hexagonal mirrors, SCS is essential to maintaining mirror alignment throughout an entire night of observations. SCS2 will complete tip, tilt and piston corrections of each mirror segment at a significantly higher rate than the original SCS. The new motion control hardware will further increase system reliability. The initial optical measurements of this array will be performed by the Mirror Alignment Recovery System (MARS) and the Hartman Extra Focal Instrument (HEFI). Once the segments are optically aligned, the electro-magnetic edge sensors give precise feedback of the segment's positions, relative to their adjacent segments. These sensors are part of the Segment Alignment Maintenance System (SAMS) and are responsible for providing information about positional changes, due to external influences, such as steep temperature changes and mechanical stress, and for making compensatory calculations, while tracking the telescope on sky. SCS2 will use the optical alignment systems and SAMS inputs to command corrections of each segment in a closed loop. The correction period will be roughly 30 seconds, mostly due to the measurement and averaging process of the SAMS algorithm.

The segment actuators will be controlled by the custom developed HET Segment Motion Controller (SMOCO). It is a direct descendant of University Observatory Munich's embedded, CAN-based system and instrument control toolkit. To preserve the existing HET software structure, each SMOCO will control two adjacent mirror segments. Unlike its progenitor, SMOCO is able to drive all six axes of its two segments at the same time. SCS2 will continue to allow for sub-arc-second precision in tip and tilt as well as sub-micro meter precision in piston. These estimations are based on the current performance of the segment support mechanics. SMOCO's smart motion control allows for on the fly correction of the move targets. Since SMOCO uses state-of-the-art motion control electronics and embedded decentralized controllers, we expect reduction in thermal emission as well as less maintenance time.

HET SCS2 will be built in a close collaboration of the University of Munich's Observatory (USM), which is part of the HET collaboration and the University of Texas at Austin's HET staff. The system is currently under internal design review and still needs final approval.

9906-2, Session 1

W. M. Keck Observatory primary mirror segment repair project: overview and status

Robert L. Meeks, Steven Doyle, James Higginson, John S. Hudek, William Irace, Dennis McBride, Michael L. Pollard, Kuochou Tai, Tod Von Boeckmann, Leslie Wold, Truman Wold, W. M. Keck Observatory (United States)

The W. M. Keck Observatory Segment Repair Project is repairing stress-induced fractures near the mirror support points in the primary mirror segments. The cracks are believed to result from deficiencies in the original design and implementation of the adhesive joints connecting the Invar support components to the Zerodur mirror. Stresses caused by temperature cycling over 20 years of surface drove cracks that developed at the glass-metal interfaces.

Over the last few years the extent and cause of the cracks have been studied, and new supports have been designed. The Segment Repair Project is tasked with repairing the cracks at the segment supports and returning the segments to their current in-service performance in terms of wavefront error with less than 15 nm rms degradation. Repair of the damaged glass required development of specialized tools and procedures. Maintaining the optical performance required analysis, including large scale finite element method, of the effects of modifying the supports which are bonded at different locations from the originals. Metrology procedures using a laser tracker were developed to precisely align the support assembly hardware in order to achieve the desired optical performance. Numerous tests and trials were performed on samples and a Zerodur mock-up of a segment. Repair of the first segment (the "Pathfinder") was intended to demonstrate and fine-tune the new tools and processes.

The repair process evolved into several steps: (1) transport of the segments between the summit of Maunakea and our repair facility; (2) pre-repair metrology to establish the initial condition of the assembly; (3) removal of support hardware assemblies; (4) removal of the original epoxy bonded supports; (5) grinding and re-surfacing the damaged glass areas; (6) etching to remove sub-surface damage; (7) bonding new supports; (8) re-installation of support assemblies; and (9) post-repair metrology to return the support assembly to the precise desired positions. In order to evaluate the optical performance, both before and after on-sky measurements were made, the results of which were well within the specified requirements.

Based on this success, a three-station production repair facility is being built at the Keck Headquarters in Waimea for repairing the remaining segments beginning in summer 2016. Repairs will be performed in Waimea because more space is available and it is more convenient and efficient to work there. This requires the segments be routinely transferred from the summit to Waimea for repair then back to the summit. A custom transportation system was conceptualized, designed, built and tested to safely carry the mirror segments down the rough roads from the summit.

This paper summarizes the repair process, on-sky results, transportation system, and repair facility and also provides an update on the project status and schedule for repairing all 84 mirror segments. Strategies for maintaining quality and ensuring that repairs are done consistently are also presented.

9906-3, Session 1

A new two path shaper and feedforward control architecture for the Keck telescopes

Peter M. Thompson, Systems Technology, Inc. (United States); Tomas Krasuski, Kevin Tsubota, Shui Hung Kwok, John Fumo, W. M. Keck Observatory (United States)

A new mount control architecture has been successfully implemented at the W. M. Keck Observatory as part of a project to upgrade the control systems of both telescopes. This new control architecture is providing improved tracking and reduced settling times after small repositioning moves. Two major changes were made to the control system's design: (1) new digital structural filters implemented using an FPGA, which reduce the excitation of the structural modes and allow higher velocity loop gains

while maintaining the required gain and phase margins for velocity loop stability, and (2) a two-path command shaping and feedforward system built around the position loop controller, which provides more control over the shape of the command response and reduced overshoot in response to short moves. This architecture was integrated with a new pointing model, new position encoders, and new tilt meters (all part of the control system upgrade). The improvements to settling time for short moves and improvements to tracking accuracy, especially at high tracking rates, are presented. A discussion on algorithms for streamlining the tuning of the velocity loop and feedforward filter coefficients is included.

9906-4, Session 1

MSE observatory upgrade: a revised and optimized astronomical facility

Steven E. Bauman, Greg Green, Kei Szeto, Canada-France-Hawaii Telescope (United States)

The Canada France Hawaii Telescope Corporation (CFHT) plans to repurpose its observatory on the summit of Maunakea and operate a ~10 m (effective aperture) wide field spectroscopic survey telescope, the Maunakea Spectroscopic Explorer (MSE). MSE will reuse the CFHT site and build upon the existing observatory infrastructure, facilities, processes, and expertise, while minimizing environmental impact on the summit. Central themes of the development plan are reusing and upgrading wherever possible.

The CFHT site has some of the best seeing in the northern hemisphere. MSE will upgrade the facility with a larger aperture telescope and equip it with dedicated instrumentation to better utilize the site and offer the ability to do transformative science to its users. The knowledge and experience of the current CFHT staff will contribute greatly to the engineering of this new facility.

MSE will use the same building and telescope pier as CFHT. It will be necessary to replace the current dome since a larger slit opening is needed for a larger telescope. Once the project is completed the new facility will be almost indistinguishable on the outside from the current CFHT observatory. MSE will build upon CFHT's pioneering work in remote operations, with no staff at the observatory during the night, and use modern technologies to reduce daytime maintenance work.

MSE will require structural support upgrades to the building to meet building seismic code requirements and accommodate a new larger telescope and upgraded enclosure. Additional radial bracing will be added to support the outer azimuth ring girder and lateral buckling restraint bracing will replace the current 1st, 2nd, and 3rd floor perimeter bracing. All structural modifications will be implemented from inside the building to minimize disturbances to the summit environment.

MSE will use a thermal management system which removes heat loads from the building, flushes excess heat from lower levels, and maintains the observing environment temperature. The existing building exhaust tunnels in the basement will continue to be used to remove heat loads deliberately positioned in the basement and minimize thermal loads from the building and enclosure environment. Remaining heat will be flushed from the lower levels prior to reaching the observing environment using a passive ventilation system. An active cooling system will be used to keep large structures near the ideal nighttime observing temperatures.

This paper describes the design approach for redeveloping the CFHT facility for MSE including the infrastructure and equipment considerations required to support and facilitate nighttime observations. The building will be designed so existing equipment and infrastructure can be reused wherever possible while meeting new requirements. Past experience and lessons learned will be used to create a modern, optimized, and logical layout of the facility.

9906-5, Session 1

The Hobby-Eberly Telescope wide-field upgrade

Gary J. Hill, Niv Drory, John M. Good, Hanshin Lee, Brian L. Vattiat, The Univ. of Texas at Austin (United States); Hermanus Kriel, The Univ. of Texas at Austin (United States) and Hobby-Eberly Telescope (United States); Jason Ramsey, The Univ. of Texas at Austin (United States); Randy Briant, Hobby-Eberly Telescope (United States); Linda Elliot, The Univ. of Texas at Austin (United States); James R. Fowler, Hobby-Eberly Telescope (United States); Martin Landiau, Ronnie Leck, The Univ. of Texas at Austin (United States); Stephen C. Odewahn, Hobby-Eberly Telescope (United States); David Perry, Richard Savage, The Univ. of Texas at Austin (United States); Emily Schroeder Mrozinski, Matthew Shetrone, George Damm, Hobby-Eberly Telescope (United States); Karl Gebhardt, The Univ. of Texas at Austin (United States); Jerry Martin, Hobby-Eberly Telescope (United States); Taft E. Armandroff, The Univ. of Texas at Austin (United States); Lawrence W. Ramsey, The Pennsylvania State Univ. (United States)

The Hobby-Eberly Telescope (HET) is an innovative large telescope, located in West Texas at the McDonald Observatory. The HET operates with a fixed segmented primary and has a tracker, which moves the four-mirror corrector and prime focus instrument package to track the sidereal and non-sidereal motions of objects. We have completed a major multi-year upgrade of the HET that has substantially increased the pupil size to 10 meters and the field of view to 22 arcminutes by replacing the corrector, tracker, and prime focus instrument package. The upgraded wide field HET will feed the revolutionary new integral field spectrograph called VIRUS, in support of the Hobby-Eberly Telescope Dark Energy Experiment (HETDEX), a new low resolution spectrograph (LRS2), an upgraded high resolution spectrograph (HRS2), and later the Habitable Zone Planet Finder (HPF). The upgrade is being commissioned and this paper discusses the commissioning process and performance of the new HET.

9906-6, Session 2

Chinese Large Aperture Optic-IR ground-based telescope: planning for next decade *(Invited Paper)*

Dingqiang Su, Nanjing Univ. (China); Ming Liang, National Optical Astronomy Observatory (United States); Xiangyan Yuan, Hua Bai, Bozhong Gu, Xiangqun Cui, Nanjing Institute of Astronomical Optics & Technology (China)

The twelve meters optical telescope has put forwarded in China recently. It is considered as a general purpose optical telescope with three parts: wide field prime focus for imaging and spectroscopic survey, Nasmyth focus for high resolution observations of many instruments, and coude focus for interferometry and extremely accurate instruments. In above three parts there are important innovations or the better design results than other telescopes. The optical systems, structure, fan-shaped segmented primary mirror, and the innovations, design results are presented in this invited talk.

9906-7, Session 2

Mayall telescope control system modernization: design, implementation, and performance

David Sprayberry, Patrick Dunlop, Matthew Evatt, Larry Reddell, National Optical Astronomy Observatory (United States); Shelby Gott, John Donaldson, Robert J. Stupak, Robert Marshall, Behzad Abareshi, Deanna Stover, National Optical Astronomy Observatory (United States); Michael Warner, Rolando E. Cantarutti, National Optical Astronomy Observatory (Chile); Ronald G. Probst, National Optical Astronomy Observatory (United States)

The Dark Energy Spectroscopic Instrument (DESI) is under construction to measure the expansion history of the Universe using the Baryon Acoustic Oscillation technique. The spectra of 40 million galaxies over 14000 sq. deg. will be measured during the life of the experiment. A new prime focus corrector for the KPNO Mayall telescope will deliver light to 5000 fiber optic positioners. The fibers in turn feed ten broad-band spectrographs. Motivated both by a desire to improve the Mayall's pointing and tracking performance prior to the start of the DESI installation and by a need to improve the maintainability of the Telescope Control System, we recently completed a major modernization of that system. The changes to the Mayall drew heavily from the servo designs and implementation developed for its sister telescope, the CTIO Blanco 4-meter, as described by Warner, et al (2012), SPIE 8451-29. Reusing as much of their work as possible enabled our project to be completed in less than one year. We describe here the things we did differently from the Blanco upgrade, either because of mechanical challenges specific to the Mayall, or because of the different higher-level software environment that has evolved at the Mayall over the years. We also present results from the as-built performance of the new servo and pointing systems, showing the dramatic improvements from the old system to the new.

9906-8, Session 3

The Large Millimeter Telescope (LMT): project status, early science, and operational performance *(Invited Paper)*

David H. Hughes, Instituto Nacional de Astrofísica, Óptica y Electrónica (Mexico); F. Peter Schloerb, Univ. of Massachusetts Amherst (United States); Alberto Carramiñana, Miguel Chávez Dagostino, Instituto Nacional de Astrofísica, Óptica y Electrónica (Mexico); Min S. Yun, Grant W. Wilson, Gopal Narayanan, Neal Erickson, Univ. of Massachusetts Amherst (United States); Arak Olmos Tapia, Instituto Nacional de Astrofísica, Óptica y Electrónica (Mexico); David R. Smith, MERLAB, P.C. (United States); Kamal Souccar, Univ. of Massachusetts Amherst (United States); David M. Gale, José Luis Hernández Rebollar, César E. Cuevas-Arteaga, Alfredo Montaña, Daniel Ferrusca Rodriguez, Milagros Zeballos, David Sánchez-Argüelles, Instituto Nacional de Astrofísica, Óptica y Electrónica (Mexico)

The Large Millimeter Telescope (LMT) Alfonso Serrano is a bi-national (Mexico & USA) telescope facility operated by the Instituto Nacional de Astrofisica, Optica y Electronica (INAOE) and the University of Massachusetts. The LMT is designed as a 50-m diameter single-dish millimeter-wavelength telescope that is optimized to conduct scientific observations at frequencies between ~70 and 350 GHz. The LMT is constructed on the summit of Sierra Negra at an altitude of 4600m in the Mexican state of Puebla. The site offers excellent mm-wavelength atmospheric transparency all-year round, and the opportunity to conduct submillimeter wavelength observations during the winter months. Following first-light observations in mid-2011, the LMT began regular scientific operations in 2014 with a shared-risk Early Science observing program using the inner 32-m diameter of the primary reflector with an active surface control system. The LMT has already performed successful VLBI observations at 3mm with the High Sensitivity Array and also at 1.3mm as part of the Event Horizon Telescope. The LMT will enter full scientific operations as a 50-m diameter telescope in early 2017, making it the world´s largest single-dish telescope operating at 1.1mm. I will describe the current status of the telescope project, including the early scientific results, as well the instrumentation development program, the plan to improve the overall performance of the telescope, and the on-going transition towards the formation of the LMT Observatory to support the scientific community in their use of the LMT to study the formation and evolution of structure at all cosmic epochs.

9906-9, Session 3

Atmospheric seeing measurement from bright star trails with frame transfer CCDs

Bin Ma, National Astronomical Observatories (China); Zhaohui Shang, Tianjin Normal Univ. (China); Yi Hu, National Astronomical Observatories (China)

We present a new application of frame transfer Charge-Coupled Device (CCD) on measuring atmospheric seeing.If a telescope is equipped with a shutterless, frame transfer CCD camera, a bright star will generate a trail during the frame transfer phase. Because the transfer is very fast, the trail is a series of short exposures (~ 1 ms) of the target star. Therefore the centroid is jittery due to atmospheric turbulence, and the amplitude can be utilized to derive astronomical seeing. We present the preliminary results from STA1600FT CCD on Antarctic Survey Telescopes (AST3) tested in China and Antarctica.

Atmospheric seeing is one of the key site parameters for the optical/IR observatories, because it limits the spatial resolution of large aperture telescopes. The best median seeing of ground-base site was 0".27, which was measured at Dome C, Antarctica. Dome A is expected to have similar or even better seeing for its extremely low boundary layer, however, there has not been direct seeing measurement during polar night yet. Because it is unattended all the year except a 20-day expedition, the widely used seeing measurement instruments, such as DIMM (Differential Image Motion Monitor), MASS (Multi-Aperture Scintillation Sensor), are hard to be operated at Dome A automatically. This new method enables us to estimate seeing with an existing telescope and CCD camera.
AST3 is an array of three 50/68 cm modified Schmidt telescopes, and equipped with 10560 x 10560 STA1600FT CCD cameras. The cameras have no shutter,instead they work in frame transfer mode to terminate the exposure. During the frame transfer, the pixels where a star is located keep collecting photons of the star, but the charges are transferred to the adjacentpixels every time when vertical shift occurs. Finally this generates a bright trail along the readout direction for a bright star, and the horizontal positions of the trail varies randomly due to atmospheric turbulence.We show the random motion in the trail, estimate seeing, and compare it with the results from simultaneous DIMMobservations when AST3-2 was tested in Mohe, China.The trend oftrail seeing agrees well with DIMM seeing, while more careful calibration is still necessary because of AST3's larger aperture than the Fried parameter r0. In addition, benefitting from its ~3x1.5 square degree wide field-of-view, AST3 is able to capture multi bright stars simultaneously, whose separations can be from sub-arcmin to degrees. Their trails offer an excellent opportunity to investigate turbulences with angular distance much larger than the isoplanatic angle, which is usually on the order of several arcsecs.

9906-10, Session 3

Sutherland site characterization and prospects of an AO system for SALT

Laure Catala, Univ. of Cape Town (South Africa) and South African Astronomical Observatory (South Africa); Steven M. Crawford, David A. H. Buckley, South African Astronomical Observatory (South Africa)

As part of future plans to improve the performances and increase the competitivity of the Southern African Large Telescope (SALT), we have been looking at possible ways of implementing an adaptive optics (AO) system as part of the second generation of instruments. In this framework, we conducted a 5 year long atmospheric turbulence characterization at the Sutherland site, measured the overall effects of the telescope structure on optical performance, and carried out detailed simulations of the performance of an AO system on SALT.

This study produced realistic and up-to-date seeing values, atmospheric turbulence profiles as well as specific site characteristic and patterns that were used to feed AO simulations. We found a median seeing seeing value of 1.49". And it appears that the 2 main contributors to the turbulence are the ground layer turbulence below 100 m and around 300 m, and to a lower extent the wind shear layer around 3 km. Also the winter months show worse seeing conditions than average, this is due to predominant East, South-easterly winds associated with degraded seeing conditions.

Moreover, as part of the overall study, we tested dome seeing measurements with the Berkley Visible Imaging Tube (BVIT) instrument on SALT as well as analyzing the overall performance of the image quality for SALT. BVIT is a visible photon counting detector designed for high time resolution astronomy, with 25 ns time precision. Using the SALT segmented primary mirror in burst mode as an Hartmann mask and the fast imaging capabilities of BVIT we created the equivalent of a Shack-Hartmann wavefront sensor that we used for seeing measurements.

Our SALT AO simulations were based on the results from the site characterization along with SALT design specificities, including its prime focus tracker leading to pupil size and shape variations. We used the software PAOLA to determine the optimum general parameters of an AO system on SALT in the case of natural guide star (NGS), taking into account performances and sky coverage. We then use those system parameters to look at the possible improvement in spectroscopic performances for different conditions of seeing, wavelength, slit/fiber size and NGS magnitude and off-axis angle.

We present here, the results from the Sutherland site characterization and our BVIT experiment project as well as the SALT AO simulations and their consequences in the prospect of the future design of an AO system on SALT.

9906-11, Session 4

Design solutions for dome and main structure (mount) of giant telescopes

Armando Bilbao, Gaizka Murga, Alberto Vizcargüenaga, IDOM Ingenieria y Consultoria S.A. (Spain)

During the last recent years, designs for several giant telescopes ranging from 20 to 40m in diameter are being developed: European Extremely Large Telescope (E-ELT), Giant Magellan Telescope (GMT) and Thirty Meter Telescope (TMT).

It is evident that simple direct up-scaling of solutions that were more or less successful in the 8 to 10m class telescopes can not lead to viable designs for the future giant telescopes. New solutions are required to provide adequate load sharing, to cope with the large-scale derived deflections and to provide the required compliance, or to respond to structure-mechanism control interaction issues, among others.

From IDOM experience in the development of the Dome and Main Structure of the European Extremely Large Telescope and our participation in some other giant telescopes, this paper reviews several design approaches for the main mechanisms and key structural parts of enclosures and mounts/main structures for giant telescopes, analyzing pros and cons of the different alternatives and outlining the preferred design schemes.

The assessment is carried out mainly from a technical and performance-based angle but it also considers specific logistical issues for the assembly of these large telescopes in remote and space-limited areas, together with cost and schedule related issues.

9906-12, Session 4

Holographic beam mapping of the CHIME pathfinder array

Philippe Berger, Univ. of Toronto (Canada)

The Canadian Hyrodgen Intensity Mapping Experiment (CHIME) is a new transit interferometer currently being deployed at the Dominion Radio Astrophysical Observatory (DRAO) in Penticton, British Columbia. We have built and deployed the CHIME Pathfinder, a smaller, 2-cylinder test-bed which has been instrumented with 128 dual polarisation dipole antennas and a custom correlator and is currently surveying the Northern hemisphere in 1024 frequency bands between 400-800 MHz. In this paper, we describe the holography instrument and technique we are employing to characterize the radiation pattern for each of the Pathfinder's 256 inputs.

CHIME's frequency band is chosen to correspond to the redshifted 21 cm line emission of neutral hydrogen (HI) at redshifts 0.8–2.5. It's angular resolution is designed for intensity mapping of the large scale distribution of HI across this largely unexplored redshift range and targeted to measure the Baryon Acoustic Oscillation scale. The results will provide constraints on the time evolution of dark energy, including the moment it begins to dominate the energy density of the universe. To do so, we must contend with astrophysical foregrounds, notably the synchrotron emission of the Milky Way, which are some five orders of magnitude brighter than the HI signal. Detailed characterisation of the polarised telescope beam is crucial to the foreground cleaning process, preventing the bleeding of angular structure in to the frequency direction or "mode mixing" and leakage of polarised signal into total intensity.

The John A. Galt telescope is an equatorial mounted 26 meter diameter parabolic telescope also located at the DRAO. We have equipped it with a separate 400-800 MHz instrument which is fed into the CHIME Pathfinder correlator, allowing cross-correlation of its signal with the rest of the array. By tracking point sources with the 26m as they slice through the CHIME beam, we map the polarised beams of the CHIME pathfinder, a technique known as holography. This allows for high signal-to-noise measurements of all 256 beams in both amplitude and phase. We report the status of the holography instrument and initial results of this effort.

9906-13, Session 4

A survey of enclosure suspension and rotation systems for 3-15m telescopes

Bruce C. Bigelow, GMTO Corp. (United States); Nathan P. Loewen, Emile van Vuuren, Sightline Engineering Ltd. (Canada); William S. Burgett, GMTO Corp. (United States)

The enclosure suspension and rotation systems for the next generation of Extremely Large Telescopes (ELTs) will carry structures that are 2-3 times larger in diameter, and 5-10 times heavier than those for the last generation of 6-10m optical/infrared telescopes. The enclosure rotation and suspension systems can present single-point failure modes for an observatory, so the requirements on reliability, availability, and

maintainability increase with increasing telescope size (and cost). We report here on a survey of several optical, infrared, and sub-millimeter telescope enclosures, considering the key design features of the suspension and rotation systems, including wheel and track geometry, details of the wheel/track interface, number of wheels per bogie, average load per wheel, rotation drive method, etc. We outline some of the key decisions and design choices to make during the development of enclosure suspension and rotation systems, and a logical process for defining those systems based on the architecture of the enclosure.

9906-14, Session 4

Performance of cable isolators in the transport of large optical assemblies

John M. Good, Gary J. Hill, Richard Savage, Emily Schroeder Mrozinski, Hermanus Kriel, Hanshin Lee, The Univ. of Texas at Austin (United States); Scott D. Benjamin, Robert M. Stone, Eric Frater, The Univ. of Arizona (United States)

Following a 7-year, multi-million dollar effort to fabricate a 730 kg, 4 element Wide Field Corrector (WFC) for the Hobby-Eberly Telescope (HET) Wide Field Upgrade (WFU), it needed to be transported 820 km to its destination at the McDonald Observatory in West Texas. Alignment tolerances for individual mirrors in the assembly were in the 5 um range. Due to the size and mass and ultimate destination of the payload, the only option available for transport was via roadway on a flat-bed trailer. While the route was primarily interstate highway, it presented a great variety of vibrational inputs due to poor paving conditions, and mountain roadways. Consideration also had be given to avoiding high ambient temperatures. Early in the design of the corrector assembly it was assumed that cable isolators would be the key element to isolate the payload from vibrational inputs, however, few documented references were available to provide the assurances required for transporting a load so key to the success of the telescope program. Tests were designed to simulate the load conditions and inputs and outputs to the test load were measured for verification of the isolator performance. This was followed up with monitoring of vibration throughput during the actual shipment of the WFC. Upon arrival at the destination, the alignment of the assembly was checked and found to have no appreciable change in the alignment. Data and lessons learned are presented on the performance of air-ride trailers as well as the performance of cable isolators.

9906-15, Session 5

SRT as a receiver in bistatic radar space debris observations

Tonino Pisanu, Giuseppe Valente, Enrico Urru, Francesco Gaudiomonte, Andrea Melis, Raimondo Concu, Giampaolo Serra, INAF - Osservatorio Astronomico di Cagliari (Italy)

The Sardinia Radio Telescope (SRT) is a fully steerable antenna with a Gregorian optical configuration, equipped with a 64 meters diameter shaped primary mirror with a focal length to diameter ratio (f/D) of 0.33. The antenna is managed by INAF (National Institute for Astrophisics) and by ASI (Italian Space Agency) with the aim of using it for radio astronomical and for spatial observations. The time allocated to ASI is used to perform space debris observations and deep space down link data reception. The antenna has three focal positions, one in the primary, one for the Gregorian and two in the Beam Waveguide. In the primary focus, the SRT has a cryogenic cooled dual band L-P receiver designed to perform radio astronomical observations. Recently we have been involved in performing some space debris radar observation at P band in a bistatic configuration, receiving the echo diffused from few well known space debris illuminated with an Italian Air Force transmitter located in Sardinia. In this first tests we made different observation of space debris in parking mode which means by pointing the transmitter and the receiver in the same space region where we know the transit of a catalogued space debris. The transmitting antenna was switched on at 410 MHz in a CW (continuous wave) mode for few seconds during which the SRT was pointed in the same direction to receive with the P band receiver the small diffused signal. The radar transmitter has a 4kW emitting power and a small aperture antenna, with a beam of about 30°, much wider than the 0.8° HPBW of the SRT at the same frequency. During the CW transmission of the radar, due to the 30 km short line of sight distance between the SRT and the transmitter, we were able to receive not only the diffuse signal by the space debris, but also the direct powerful signal emitted by the antenna transmitter, pointed in the sky direction. In this way, while waiting for the diffused signal from the debris, we were also sure that the transmitter started to emit and was well working. As a back end we used a spectrum analyzer, with a Labview© control software, centered at a frequency of 410 MHz and with a very narrow frequency span and low resolution bandwidth, in order to be able to visualize the Doppler frequency shifted by the space debris. We performed different observing campaigns during which we were able to receive the echoes of debris of different RCS (Radar Cross Sections) from which we could measure the frequency Doppler shift and so the velocity of the debris. Due to the low flexibility and programmability of the SA, we decided to develop a new back end specifically designed for space debris observations, based on the ROACH (Reconfigurable Open Architecture and Computing Hardware, FPGA-based) and a GPU-based PC. In this article we will show the results of this preliminary SRT space debris observations and back end development.

9906-16, Session 5

On preparing UKIRT to observe satellites and orbital debris

Richard L. Kendrick, Matthew Bold, Lockheed Martin Space Systems Co. (United States)

For 35 years the United Kingdom Infrared Telescope has provided exquisite infrared astronomical data from the summit of Mauna Kea on the big island of Hawaii. The observatory operates an assortment of instruments that allow the collection of photometric, spectroscopic and polarimetric measurements of astronomical objects across a wavelength band of 1 to 25 microns. This covers the Y,Z,J,H,K,L,M,N and Q bands of IR astronomy. In addition R band photometry can be acquired via the telescope guider.

In 2013 the process of developing an Orbital Debris and Satellite observation capability for the United Kingdom Infrared Telescope was initiated. This process involved the modification of various operational aspects of the observatory. For example a system for converting orbital object two line elements into telescopes pointing position with rates was necessary. Data pipeline modifications were also necessary to account for the differences between typical astronomical data and the orbital debris and satellite data. There was also a shift in observing philosophy for orbital debris and satellite observations. Whereas a typical night in an astronomical observatory can involve the observation of 10's or 100's of objects, a night of orbital debris and satellite observations might only involve the observation of one object and various calibration standards.

After a year of implementing modifications the observatory became capable of providing deep space observations of orbital debris and satellites in a queue based format. The telescope has been operating with this capability for the past 2.5 years and has generated terabytes of observational data of orbital debris and satellites that are in the GEO belt distributed across the Pacific Ocean.

This paper will discuss the steps that were required to implement a GEO belt object observing capability at the UKIRT observatory. Representative photometric and spectroscopic data will be presented for a variety of orbiting objects.

9906-87, Session PS1

Network management plan for SKA

Rodrigo A. Olguin, Juande Santander-Vela, SKA Organisation (United Kingdom)

The SKA Observatory will be the largest astronomy facility in the world. It will be composed of the SKA1-Mid telescope in South Africa, and SKA1-Low in Australia, with the General HQ in UK, and local headquarters in the host countries. The SKA1-Mid is formed by an array of 190 dishes, and the SKA1-Low is an aperture array with 512 stations of 131072 antennas in total. Both arrays will contain a massive number of components that need to be connected to a shared data network to allow the operation of SKA. To ensure the interoperability of the different elements in SKA a Network Management Plan is key. In this contribution we present an outline of this plan, and the challenges that it will try to overcome.

9906-88, Session PS1

Prefocal station mechanical design concept study for the E-ELT

Paul D. Jolley, Christoph Frank, Steffan A. Lewis, Enrico Marchetti, Enzo T. Brunetto, European Southern Observatory (Germany)

The E-ELT will host one Prefocal Station on each of its two Nasmyth platforms. The main functional requirements of these units are to provide a focal plane to any of three Nasmyth focal stations & one Coudé focus, optical sensing to support telescope low order optimisation and seeing limited image quality, and optical sensing to support characterising and phasing of M1 and other telescope subsystems. The Prefocal Stations will also provide a reference for aligning the Nasmyth instruments. The Prefocal Station User Requirements are being used to derive the Prefocal Station Technical Requirements Specification that will form the basis for the detailed design, development and production of the system. This specification process includes high-level architectural decisions and technical performance budget allocations. The concept mechanical design studies reported here have been performed in order to validate key system specifications and their associated technical budgets. The main subsystems of the Prefocal Station A are described in the breakdown below:

Sensor arms: The current baseline requires the use of 3 sensor arms for the telescope wavefront sensors. This requires the use of three independent arms, capable of moving within the patrol area. They carry the necessary optics and cameras to carry out the telescope wavefront sensors functions.

Cable wrap: Due to the limited space and mass constraints a proof of concept design of the cable wrap has also been developed. This needs to feed the three independent sensor arms with their necessary cables and cooling. In this concept there is a main wrap that carries all the necessary cables and cooling using a classical loop design onto the unit. The cables are then split into the necessary three groups and are passed through separate secondary wraps. These secondary wraps act in the same plane as each other. The main wrap then provides 540° of rotation.

M6N fold mechanism: The M6N fold mechanism needs to feed light into either of the two lateral science ports with minimal vignetting of the patrol area for the TWS. It is deployable in and out of the beam to allow a straight through science focus. The concept design has considered the accurate positioning of the fold mirror to meet the focal plane position error budgets, its Eigen frequencies, its mass and minimising its vignetting profile to provide sufficient field past it for the TWS.

M6C Coudé flat: The Coudé flat mechanism is a small deployable flat used to feed science light to the Coudé focal train. As with the larger M6N fold mechanism, its vignetting profile is minimised.

Supporting structure: This is a large steel framework (5m x 4.75m x 10m) that carries all the above sub-units. It has conflicting requirements for stiffness vs mass (which is quite challenging – especially when considering earthquake loads). It provides the interface to the Nasmyth platform.

Phasing Station: Provides optical sensing to characterise M1 and support mirror segment phasing and to correct high order figure errors such as scalloping.

Auxiliary equipment: Safe working platforms and ladders for maintenance, access, and covers.

9906-90, Session PS1

1.2m astronomical telescope for space-to-ground quantum communication experiment

Bo Qi, Institute of Optics and Electronics (China)

Quantum Key Distribution (QKD), the fastest growing and most technologically sophisticated quantum communication technology, has become the pioneer in the future practical quantum communications because of its unconditional security guaranteed by basic principles of quantum mechanics. Chinese Academy of Sciences has plans to launch quantum science experiment satellite in the near future, a series of quantum communication experiments can be done through this satellite. The success of the experiment depends on the continuous tracking and pointing between the optical ground station(OGS) and onboard communication terminal. This paper describes the equipment and features of the 1.2m astronomical telescope which will perform experiments with quantum experiment satellite of China. The optical ground station uses 1.2m gimbaled telescope to collect the photons, the strategy of the system is slightly developed to meet the need of tracking LEO satellite?which has coarse and fine loop, and it can control a transmitting and receiving laser beam within a few micro radians jitter. This telescope with multiple functions will play an important role in space-to-ground quantum communication.

9906-91, Session PS1

Mauna Kea Spectroscopic Explorer design development from feasibility concept to baseline design

Kei Szeto, Canada-France-Hawaii Telescope (United States); Hau Bai, Nanjing Institute of Astronomical Optics & Technology (China); Steven E. Bauman, Canada-France-Hawaii Telescope (United States); David Crampton, NRC - Herzberg Astronomy & Astrophysics (Canada); Nicolas Flagey, Pascal Fouqua, Canada-France-Hawaii Telescope (United States); Peter R. Gillingham, Australian Astronomical Observatory (Australia); Xuefei Gong, Nanjing Institute of Astronomical Optics & Technology (China); Kevin K. Y. Ho, Canada-France-Hawaii Telescope (United States); Alan W. McConnachie, NRC - Herzberg Astronomy & Astrophysics (Canada); Shan B. Mignot, Observatoire de Paris à Meudon (France); Richard Murowinski, Derrick Salmon, Canada-France-Hawaii Telescope (United States); Paolo Spanò, INAF - Osservatorio Astrofisico di Arcetri (Italy); Chao Zhai, Univ. of Science and Technology of China (China); Kai Zhang, Nanjing Institute of Astronomical Optics & Technology (China)

The Maunakea Spectroscopic Explorer (MSE) is designed to be the largest non-ELT optical/NIR astronomical telescope, and will be a fully dedicated facility for multi-object spectroscopy over a broad range of spectral resolutions. The MSE design has progressed from feasibility concept into its current baseline design where the system configuration of main systems such as telescope, enclosure, summit facilities and instrument are fully defined. This paper will describe the engineering development of the main systems, and discuss the trade studies to determine the optimal telescope and multiplexing designs and how their findings are incorporated in the current baseline design.

9906-92, Session PS1

The DAG project, a 4m-class telescope: the rotating enclosure performances

Gianpietro Marchiori, Francesco Rampini, Simone De Lorenzi, Cristiana Manfrin, Enrico Marcuzzi, EIE Group s.r.l. (Italy); Cahity Yesilyaprak, Onur Keskin, Sinan Kaan Yerli, Atatürk Üniv. (Turkey); Cristina Battistel, EIE Group s.r.l. (Italy)

DAG (Dogu Anadolu Gözlemevi, Eastern Anatolia Observatory) is a project fully funded by Turkish Ministry of Development and the Atatürk University of Astrophysics Research Telescope - ATASAM.

DAG will be a 4m class optical and infrared telescope and will be installed at an altitude of 3170m asl on the Erzurum Plateau, near the town of Erzurum, Eastern Anatolia, Turkey.

EIE GROUP - Venice, Italy was awarded the contract for the construction of the DAG D, last October 2015.

The design of the Rotating Enclosure fits in the TBO Program which aims at developing a Dome /Telescope systemic optimization process for both performances and competitive costs, based on previous project commitments like NTT, VLT, VST and VISTA.

The Enclosure will provide wind and other environmental conditions protections for the Telescope. The main characteristics of the Enclosure are: a light structure and a specific cladding system, a modular windscreen with fixed permeability and a ventilation door system, to allow the air flushing and temperature control during the Telescope observation.

9906-93, Session PS1

DEdicated MONitor of EXotransits and Transients (DEMONEXT): a low-cost robotic and automated telescope for followup of exoplanetary transits and other transient events

Steven Villanueva Jr., The Ohio State Univ. (United States); Jason D. Eastman, Harvard-Smithsonian Ctr. for Astrophysics (United States); B. Scott Gaudi, Richard W. Pogge, The Ohio State Univ. (United States); Keivan G. Stassun, Vanderbilt Univ. (United States); Mark Trueblood, Patrica Trueblood, Winer Observatory (United States)

We present the design and development of the rebuilt and recommissioned 20'' DEMONEX telescope, now known as DEMONEXT, an automated and robotic telescope jointly funded by The Ohio State University and Vanderbilt University. The telescope is a PlaneWave CDK20 f/6.8 Corrected Dall-Kirkham Astrograph telescope on a Mathis Instruments MI-750/1000 Fork Mount located at Winer Observatory in Sonoita, AZ. The new DEMONEXT has a Hendrick electronic focuser, FLI CFW-3-10 filter wheel, and a 2048x2048 pixel FLI Proline CCD3041 camera with a pixel scale of 0.89'' per pixel and a 30.5' Field-of-View. The telescope's automation, controls, and scheduling are implemented in Python, including a facility to add new targets in real time for rapid follow-up of time-critical targets. DEMONEXT will be used for the confirmation and detailed investigation of newly discovery planet candidates from the KELT survey telescope, exploration of planet atmosphere transmission studies, and monitoring of select eclipsing binary star systems as benchmarks for models of stellar evolution. DEMONEXT will enable rapid confirmation imaging of supernovae, flare stars, active galaxy tidal disruption events, and other transients discovered by the ASAS-SN survey telescopes. DEMONEXT will also provide follow-up observations of single-planet transits discovered by the upcoming TESS mission, and to investigate long-period eclipsing systems discovered by GAIA.

9906-94, Session PS1

The University of Tokyo Atacama Observatory 6.5m Telescope: enclosure design and wind analysis

Masahiro Konishi, Shigeyuki Sako, The Univ. of Tokyo (Japan); Takanori Uchida, Kyushu Univ. (Japan); Ryou Araya, Environmental GIS Lab., Co. (Japan); Koui Kim, Fukushima College (Japan); Yuzuru Yoshii, Mamoru Doi, Kotaro Kohno, Takashi Miyata, Kentaro Motohara, Masuo Tanaka, Takeo Minezaki, Tomoki Morokuma, Yoichi Tamura, Toshihiko Tanabé, Natsuko Kato, Takafumi Kamizuka, Hidenori Takahashi, Tsutomu Aoki, Takao Soyano, Ken'ichi Tarusawa, The Univ. of Tokyo (Japan)

We present preliminary results from our wind studies on the enclosure design for the University of Tokyo Atacama Observatory (TAO) 6.5-m telescope now being constructed at the summit of Co. Chajnantor in northern Chile (5,640-m altitude).

A detailed design of the enclosure for the TAO 6.5-m telescope is currently underway, where as a part of studies we perform unsteady computational fluid dynamics (CFD) calculations and wind tunnel experiments in order to investigate how the wind flow, which rises from the plateau at 5,000-m altitude, is disturbed topographically and blows through the summit facilities.

First, we construct a three-dimensional solid model of the whole of Co. Chajnantor (5 km on a side and a height of 800 m) by using a state-of-the-art technology in Geographic Information System (GIS).

A CFD calculation with about 20 million grid points adaptively refined (more finely spaced near the ground) reveals the wind speed to be accelerated at the summit by a factor of 1.2--1.3 compared to that at the plateau, which is in good agreement with the result of the wind tunnel experiment.

We use the resulting wind pressure (3850 N/m^2 at wind speed of 85 m/s expected at a maximum) in structural analysis of the summit facilities.

We also investigate how the wind flows around the summit facilities and make sure that there is a sufficient space between the enclosure and the adjacent operation building so that the wind flow obstructed at the operation building does not affect the flow to the enclosure.

We then use the disturbed and accelerated wind speed profile to analyze the wind flow and the distribution of air temperature around and inside the telescope enclosure in detail.

In the basic design reported in 2012, we allocated the maximum number of the ventilation windows in the enclosure: 13 windows at a level of the observing floor (hereafter VW1), 12 at a level of the telescope primary mirror (VW2), and 12 at a level of the secondary mirror (VW3).

By changing the number of windows VW3, we examine the importance of the windows VW3.

Several configuration of CFD calculations with about 90 million grid

points (finest resolution of about 15 cm inside the enclosure) represent little difference in the wind speed distribution or the distribution of air temperature.

We find that any air turbulence rising from the ground is drifted through the windows VW1 and therefore would have little influence on imaging performance of the telescope.

These facts are unchanged with changing the enclosure rotation (azimuth) angle against the prevailing wind direction, i.e. the west.

After considering operation procedures and construction costs, we decide to locate 13 windows VW1 (at a level of the observing floor), 12 VW2 (the primary mirror), and 2 VW3 (the secondary mirror).

9906-95, Session PS1

Analysis of the three-mirror systems for survey telescopes

Alexey V. Bakholdin, Galina E. Romanova, Kseniia D. Butylkina, ITMO Univ. (Russian Federation)

Survey telescopes, which are the systems with angular field up to a few degrees, are applied in several areas, not only for the astronomy, but for the weather observing, and asteroid and comet detection (ACD). Systems with relatively small diameters (up to 1,5 m) are of great interest both as ground-based and space instruments. For the best functionality telescope schemes should have small sizes, have sufficient characteristics for sky survey. It is also preferable that the systems can be manufactured by the most simple methods and facilities.

As a rule such survey systems are fast (up to F/3 ... F/1.5 and faster). Therefore, the most part of survey telescopes are reflective systems with additional lens correctors. Lens elements in these instruments can lead to some difficulties because the possibility of manufacturing of large size lens corrector of the optimal glass sort does not always exist. So from that point of view mirror systems can give some advantages. Mirror systems are also of interest due to the wide spectrum range used for operation. However, the design of the mirror system that can give both sufficient f-number and large angular field is the complicated and complex task, first of all because of difficulty during the choosing the initial principal scheme.

For the sky survey the three- and four–mirror systems can be used. The decreasing of the number of the mirrors can decrease the cost of the project, make the mechanical construction simpler, etc. To provide the wide field it's necessary to correct four aberrations (spherical aberration, coma, astigmatism and field-curvature) and the minimum number of the mirrors is three. But in the case of the three mirror systems the range of parameters, which lead to realizable systems taking into account the constructional and stray light limitations, becomes much narrower.

Using the expressions based on the third-order aberration theory the several system of survey telescopes were chosen which can provide the needed characteristics. The examples of the schemes are given, including their optical characteristics and the baffles configuration.

9906-39, Session PS2

A primary mirror metrology system for GMT

Andrew P. Rakich, GMTO Corp. (United States)

The Giant Magellan Telescope (GMT) will consist of seven 8.4 m aperture "unit telescopes" arranged as a phased, radially symmetrical array, on a common mount. First light with a subset of four unit telescopes is currently scheduled for 2022. Installation and testing of the first M1/M2 segment pair will begin in 2021.

The project is currently considering an important aspect of the assembly, integration and verification (AIV) of the unit telescopes; a dedicated system to characterize the on-sky performance of the M1 segments, independently of the M2 subsystem. A primary mirror metrology system is proposed. The main purpose of this system will be to characterize the deflections and deformations of the M1 segment with respect to the axis of an instrument interface, as a function of gravity and temperature.

The metrology system will incorporate a small prime focus corrector, the largest optical element of which will be of the order of 150 mm diameter. The corrector can provide a small field (0.5 to 1 arc minute diameter) corrected to ~ 0.1 arc-second 80% encircled energy spot sizes. At the focal plane a linear stage will be utilized to position either a suitable imaging detector or a Shack Hartman wavefront sensor.

The prime focus camera design presented here incorporates four spherical elements of standard optical glass. The design has the advantage of being tilt insensitive; tilts of up to 0.5 degrees about the coma neutral point, near the focal plane, produce no significant aberration. On the other hand, lateral translations of 50 microns lead to an easily measureable aberration signal. These properties enable the system to determine the optical axis of the M1 segments, with respect to the corrector, to well with 50 microns in de-centre.

A 3-D metrology system (as presented in another paper in this conference) will be employed to centre the corrector with respect to the axis of a suitable instrument interface. An expected accuracy of this centering expected to be at worst 50 microns.

With the desired location of the M1 segment optical axis thus determined, and after acquiring a suitable stellar target, the system utilizing either a detector, and/or Shack Hartmann wavefront sensor, will be employed to correct the M1 segment for tilt and position. At the same time, the Shack Hartmann wavefront sensor can measure segment deformations. This exercise will be repeated at a number of Alt/Az position, and over some range of thermal conditions, enabling the production of accurate pointing models and collimation/deformation look-up tables.

The advantages of having a well-characterized M1 subsystem in advance of utilizing the M2 subsystem, have been discussed in part by Blanco (2012). A primary advantage is that with an accurate pointing model for the M1 segments already established in this way, co-linearity of the M1 and M2 segment axes can be established to a high accuracy, just by correcting both pointing and coma with M2. Other advantages include the thorough early workout of various telescope subsystems, and on a system of considerably less complexity than the final telescope/instrument configuration.

9906-40, Session PS2

GMT azimuth bogie wheel-rail interface wear study

Jose Teran, M3 Engineering & Technology Corp. (United States); Cory Lindh, Chris Morgan, Uni-Systems Engineering (United States); Eric Manuel, M3 Engineering & Technology Corp. (United States); Bruce C. Bigelow, William S. Burgett, GMTO Corp. (United States)

Performance of a rotating enclosure azimuth bogie system is vital for the operation of an observatory and as such, all components are subject to wear. The bogie design and rail interface merit a high level of scrutiny for achieving a proper balance between capital costs, maintenance costs, and the risk for downtime during planned and unplanned maintenance or replacement procedures.

To properly assess tradeoffs between various wheel-rail and roller-track interfaces, M3 Engineering & Technology Corp. (M3) and Uni-Systems Engineering (UNI) performed a comprehensive comparison study of multiple bogie wheel and rail interface alternatives, thereby allowing Giant Magellan Telescope (GMT) to make an informed decision with regards to the available options.

The paper provides information of various azimuth bogie design options studied in regards to the performance of GMT rotating enclosure. The

azimuth bogie design and rail interface merit a high level of scrutiny for achieving a proper balance between capital costs, maintenance costs, and the risk for downtime during planned and unplanned maintenance or replacement procedures.

Of particular importance is the interface between the azimuth wheels and rail, as usage frequency is high, the full weight of the rotating enclosure must be transferred through small patches of contact, and replacement of the rail would pose a greater logistical challenge than the replacement of smaller components such as bearings and gearmotors.

Regardless of the magnitude of loading, wear is an inevitable outcome of rolling and sliding contact between bodies. Even if contact stresses are, in theory, limited to the elastic regime – a highly conservative approach rarely implemented by the railway or crane industries – plastic deformation is invariably observed in rail cross sections due to microscopic asperities on the wheel and rail surfaces. Consequently, wear still occurs. From this vantage point, the design objective is not to eliminate wear from the system but, rather, to address it in an intentional manner and ensure that the anticipated wear rate meets design objectives.

9906-96, Session PS2

Real-time alignment and co-phasing of multi-aperture systems using phase diversity

Sebastien Vievard, ONERA (France) and Thales Alenia Space (France); Frédéric Cassaing, Aurélie Bonnefois, Laurent M. Mugnier, Jospeh Montri, ONERA (France)

Multiple aperture systems (segmented mirrors or telescope arrays) are now an established solution to build large telescopes on ground or in space. However the alignment of the sub-apertures remains a difficult task, dominated by the difficulty of phase measurements with optical quadratic detectors. The alignment procedure is held in two steps: a coarse phasing to correct strong instrumental perturbations (after a space deployment for example) followed by a fine phasing. The perturbations to correct in such systems are the relative orientation of sub-apertures (tip/tilt aberration) and the optical path differences between sub-apertures (piston aberration).

Focal-plane wavefront sensing is an elegant solution to measure the segment misalignments. Since the focal (and/or near focal) image(s) of any source taken by a 2D camera shows distortions when the system is not perfectly aligned, the system misalignments can be retrieved by solving the inverse non-linear problem. The main interests of this technique are that this wavefront sensor is included in the main imaging detector, simplifying the hardware and does not introduce a differential path between wavefront sensor and science camera. In addition, the focal image intrinsically contains information resulting from the interferometric (or not) superposition of all the sub-aperture beams, allowing measurements even on discontinuous sub-apertures. The phase retrieval technique, based on the sole focal-plane image, is generally not sufficient to solve for all ambiguities. The phase diversity technique, typically based on a focal and a slightly defocused image, removes all ambiguities and operates even on unknown extended sources.

We show here that a phase-diversity sensor can fully and efficiently align a multiple-aperture system, both for the coarse and fine phasing modes, with low computing cost algorithms. We describe the required algorithms, quantify their performance by numerical simulations and experimentally demonstrate their capability.

For the coarse phasing mode, we introduce ELASTIC (Estimation of Large Amplitude Subaperture Tip-tilt from Image Close-by data), a new series of algorithms enabling for the first time (to the best of our knowledge) a full-field tip/tilt non-iterative estimation from only a pair of diversity images and a simple on-the-fly data-processing. All the segments can be co-aligned after two successive closed-loop sequences. First, an ELASTIC variant based on exact wide-field tip/tilt estimation puts the focal spots in a reference position, and then a second variant based on a local linearization is used to superimpose the spots. The correction of large-amplitude piston can be then performed with classical techniques such as channelled spectrum or 1D scan. An additional advantage of the ELASTIC algorithm is to maintain tip/tilt control while the pistons are changed.

For the fine phasing mode, several versions of fast phase diversity for piston/tip/tilt measurements are currently investigated and compared [Mocoeur et al. Optics Letter (2009) and Denolle et al. Proc. SPIE 8713 (2013)].

The experimental validation of these algorithms is performed on a dedicated testbed at ONERA, including an unresolved source, a segmented mirror with 19 piston/tip/tilt active segments, and a phase diversity sensor.

The experimental and numerical results we will present quantify the performances of this novel, automatic and fast way to align the segments of a multi-aperture system.

9906-97, Session PS2

OVMS-plus at the LBT: disturbance compensation simplified

Michael Böhm, Univ. Stuttgart (Germany); Jörg-Uwe Pott, José Luis Borelli, Max-Planck-Institut für Astronomie (Germany); Elwood C. Downey, Denis Defrère, Philip Hinz, The Univ. of Arizona (United States); John Hill, Univ. of Arizona (United States); Kellee R. Summers, Albert Conrad, Univ. of Arizona (United States) and Large Binocular Telescope Observatory (United States); Martin Kürster, Thomas Herbst, Max-Planck-Institut für Astronomie (Germany); Oliver Sawodny, Univ. Stuttgart (Germany)

The optical vibration measurement system (OVMS) at the LBT [1] was commissioned in 2013 and since then accelerometer values are continuously measured and archived at all 6 mirrors of the telescope. The values are digitized and distributed via multicast to various clients. However, the original design left the calculation of OPD, TIP and TILT disturbance values to each instrument's control loop. In hindsight, this does not seem reasonable. To increase synergy between using and testing OVMS with different instruments, we now implemented a centralized calculation of OPD, tip and tilt, as these calculations do not rely on instrument specific parameters. We use a broadband filter published in [2] to estimate the OPD and the TIP and TILT values for each mirror. With these values, instrument specific gains and coordinate transformations can now be used to transform the tip and tilt into focal plane centroid shifts. These shifts, together with accelerometer values, are then distributed via multicast.

Additionally, we use a delay compensation algorithm to compensate for the measurement delay of 3ms and for potential additional delay occurring in the compensation loops of the instruments. The respective algorithm is based on an extension of the original broadband filter and will be sketched in the paper, but is described in more detail in a publication currently under review.

The new architecture simplifies the use of the OVMS for the users and makes the mirror motions easily available for anyone. This greatly enhances the functionality of the OVMS and enables instrument engineers and scientists to focus on other challenges they are facing with their instruments. At the same time they can rely on a quality estimate of the disturbance which can be used for feedforward disturbance compensation in the respective instruments.

Eventually, OVMS-plus will be an observatory facility provided and maintained by LBTO. LBTI is now the first user of the OVMS-plus and we will present on sky measurements illustrating the performance of the new disturbance estimation and compensation.

9906-98, Session PS2

Introduction to the SKA low correlator and beam-former system

Grant A. Hampson, John D. Bunton, Commonwealth Scientific and Industrial Research Organisation (Australia); Andre Gunst, ASTRON (Netherlands); Peter Baillie, Auckland Univ. of Technology (New Zealand)

The SKA organisation is building a low frequency (50-350?MHz) aperture array to be located in remote Western Australia. The array consists of 512-stations, each consisting of 256-dual polarisation log-periodic antennas. The stations are distributed over a distance 80?km, with the greatest density of stations located in the central core. The input bandwidth is processed in a two stage polyphase filterbank, with the first stage channeliser producing 384 x 781?kHz narrow band channels. Each station beamforms the antennas together to form a single dual polarisation beam with a bandwidth 300?MHz (additional beams can also be traded for bandwidth.) The second stage polyphase filterbank is located in a system called the Correlator and BeamFormer (CBF) [1] which is the topic of this paper.

The CBF processes the 512-stations to produce visibilities for imaging, as well as two pulsar outputs; search and timing. The CBF is capable of dividing the 512-stations into 16 independent subarrays - each with independent frequency resolution, integration time, and beams (with the caveat that each station only belongs to one subarray.) The CBF system requires 30?Tera-bits-per-second of data communications (inputs, cross-connects, outputs) combined with approximately 1?Peta-multiply-accumulates-per-second. The CBF system uses power efficient FPGAs to handle to the very high communication and processing rates. All FPGAs are optically connected to allow for arbitrary interconnections [2, 3]. Each FPGA, optical transceivers and memories are liquid cooled for higher efficiency and reliability.

The signal processing is divided into two types of processing; one at the station level and the other on the array of stations. The station based processing involves a second stage critically sampled filterbank which provides the necessary spectral line zoom modes going down to a frequency resolution of 226?Hz. There are also two other filterbanks for the pulsar processing; the pulsar search filterbank is also critically sampled at approximately 16?kHz, however the pulsar timing filterbank is oversampled so that after the narrowband beamforming it can be re-synthesised back to the original frequency resolution of 781?kHz. The station based processing also includes a delay correction (divided into coarse and fine adjustments) as well as RFI detection and excision.

The array based processing contains two core functions - correlation to generate visibilities and tied array beamforming for pulsar search and timing. A majority of the computations are contained in these two functions. The correlator always forms visibilities on 226?Hz channels and through post integration of frequency channels can form wider bandwidth channels, with the standard mode being 64k channels each of 4.5kHz. The beamformer processing is more than the standard multiply accumulate algorithm; for pulsar timing accurate off boresight beams require polarisation correction before beamforming for each look direction. However for pulsar search this is more relaxed and post beamforming polarisation correction is allowed. RFI excised station data is ignored in the correlator and beamformers.

In this paper the CBF system will be described on several different levels; from Matlab models to signal processing firmware, from FPGA to packaging/cooling, from the firmware framework to the peripheral interface firmware, and finally from the monitor and control software to how the CBF fits into the larger SKA Low instrument.

9906-99, Session PS2

Large aperture millimeter/submillimeter telescope: which is more cost-effective, aperture synthesis telescope versus large single dish telescope?

Satoru Iguchi, Masao Saito, National Astronomical Observatory of Japan (Japan)

The Atacama Large Millimeter/submillimeter Array (ALMA) was built in a global partnership of ESO, NSF and NINS, and has been operated at an altitude of about 5000m for 5 years. The array consists of 66 antennas with high surface accuracy and high pointing accuracy with an operating wavelength range of 0.3 to 3 mm, which will be extended up to 8.5 mm in the future. For realizing high fidelity of imaging with mosaicing observations, the ALMA is designed to combine a homogeneous array of 50 12 m antennas (12 m Array) and the Morita Array - Atacama Compact Array (ACA) (4 12-m antenna and 12 7-m antennas) in order to cover all spatial frequency Fourier components of the brightness distribution of observed sources. The ALMA successfully realized a huge millimeter/submillimeter aperture equivalent to a 91-m diameter antenna.

The Green Bank Telescope (GBT) was built in 2000 and is the world’s largest, fully-steerable telescope with a diameter of 100 m in the wavelength range of 3 mm to 30 cm. The Large Millimeter Telescope (LMT) was built in 2011 and started early science operations as a 32-m diameter telescope in 2013 in the wavelength range of 1.3 to 4 mm. After the surface of the telescope is completed and adjusted, the LMT will be the world´s largest, steerable millimeter-wavelength telescope with a diameter of 50 m in the wavelength range of 0.85 to 4 mm. The Cerro Chajnantor Atacama Telescope (CCAT) is a proposed 25-m diameter telescope and will be the world’s largest, submillimeter-wavelength telescope.

The Aperture Synthesis Telescope can achieve a huge aperture with more than 100-m diameter with the advent of JVLA, ALMA and SKA, but it still has some scientific weak points due to technological limitations: for instance, small “field of view.” On the other hand, while the Single-dish Telescope can achieve a wide “field of view” with a multi-pixel radio camera and a multi-beam heterodyne receiver, it also has a disadvantage of requiring a huge aperture to achieve high sensitivities, due to several technological limitations.

We aim to identify what technological development items need to be addressed from scientific requirements based on several science use cases (e.g. wider field of view, higher sensitivity, higher angular resolution and wider bandwidth), by investigating advantages and disadvantages of both the Aperture Synthesis Telescope and the Large Single-dish Telescope, including comparative analysis of their cost effectiveness. These study results will be presented as a proposal of the design of antenna structure for a future telescope project at millimeter and submillimeter wavelengths.

9906-100, Session PS2

New co-phasing and AO strategies for an extremely large telescope dedicated to extremely high contrast: the Colossus project

Gilberto Moretto, Ctr. de Recherche Astronomique de Lyon (France); Jeffrey R. Kuhn, Institute for Astronomy (United States); Éric M. Thiébaut, Michel Tallon, Maud P. Langlois, Ctr. de Recherche Astronomique de Lyon (France); Svetlana V. Berdyugina, Kiepenheuer-Institut für Sonnenphysik (Germany)

Detecting an exoplanetary life signal is extremely challenging with current technology because it requires a sensitive telescope and instrument that can measure the planet's reflected optical and infrared light, while distinguishing this from the star's scattered light and the terrestrial thermal noise background. This requires highly accurate adaptive optics, a coronagraph system, and a specially designed and aligned giant telescope. We present here new strategies for building such a telescope with large circular segments using adaptive optics correction independently for each of these segments prior to cophasing the segments. The foreseen cophasing technique uses focal plane images that allow piston measurements and correction between all the segments. In this context we propose to derive the segment phase error using the inverse approach knowing the segment positions and the single aperture Airy function. Preliminaries AO simulations and on-bench cophasing results are presented here.

SPEED: The Segmented Pupil Experiment for Exoplanet Detection: design advances and progress overview

Patrice Martinez, Observatoire de la Côte d'Azur (France); Olivier Preis, Carole Gouvret, Lab. J.L. Lagrange (France); Julien Dejonghe, Observatoire de la Côte d'Azur (France); Mathilde Beaulieu, Pierre Janin-Potiron, Lab. J.L. Lagrange (France); Alain Spang, Observatoire de la Côte d'Azur (France); Lyu Abe, Lab. J.L. Lagrange (France); Frantz Martinache, Observatoire de la Côte d'Azur (France); Yan Fantéï-Caujolle, Lab. J.L. Lagrange (France); Aurélie Marcotto, Marcel Carbillet, Observatoire de la Côte d'Azur (France)

Direct imaging of exoplanets ideally down to Earth-like planet is one of the most exciting but challenging area in modern astronomy. In this context, segmented telescopes appears as the next leap forward for both ground- and space-based observatories for increasing significantly the exoplanet detection paradigm.

However, along with the unavoidable run for spatial resolution and photon sensitivity comes a catch that leads to telescope architectures that by design are far from optimal for the exoplanet search problem.

Inevitably, various problems and brand new critical issues such as pupil discontinuities, missing segments, stellar resolution, Fresnel effects, etc., make high-contrast imaging more demanding with the next generation of observatories (E-ELT, TMT, AFTA-WFIRST, LUVOIR, etc.).

The SPEED testbed is designed to enable a wide range of studies of these asymmetric and unfriendly apertures related issues. The upmost objectives of the SPEED bench are (1) to develop in-depth expertise in instrumental design and control of contrast considering Fresnel/Talbot effects; (2) to improve high-contrast imaging observing mode toward very small inner-working angle; (3) to develop new co-phasing sensors at the telescope or at the instrument level to serve as a primary co-phasing sensor or for a fine-tuning and/or temporal stability control purposes.

This communication reports on the progress in the development of the SPEED facility. We describe the testbed optical and opto-mechanical design performance. More specifically, we discuss as-build optics surface errors, multi-deformable mirrors architecture regarding Fresnel effects, coronagraph design, and advance in the development of a new co-phasing sensor. Finally, first light results are presented.

9906-102, Session PS2

Improving E-ELT M1 prototype hard position actuators with active damping

Babak Sedghi, Martin Dimmler, Michael Müller, European Southern Observatory (Germany)

During the advanced design phase of the European Extremely Large Telescope (E-ELT) several critical components have been prototyped. In particular, a representative section of the E-ELT primary mirror has been assembled. It is equipped with complete prototype segment subunits including prototype edge sensors and position actuators. One purpose is to test various control strategies and evaluate the achievable performance. One of the segment subunits is equipped with three prototype 'hard' actuators, i.e. typically piezo actuators being passively stiff. To improve such type of position actuators various active damping techniques were implemented and tested. In this paper an active damping strategy based on positive position feedback is introduced. The theoretical and implementation test results are presented. This also includes results related to vibration transmission.

9906-103, Session PS2

SPEED (Segmented Pupil Experiment for Exoplanet Detection) design optimization via Fresnel propagation analysis

Mathilde Beaulieu, Lyu Abe, Patrice Martinez, Carole Gouvret, Farrokh Vakili, Lab. J.L. Lagrange (France)

Future extremely large telescope will open a unique niche in the detection and characterization of faint exoplanet close to their sun. However this kind of large telescope requires segmented primary mirror (~ 800 segments to achieve diameters of ~ 40 m) that creates gaps between each mirror segments. Those discontinuities, combined with the secondary mirror obstruction and spiders are a major concern for high-contrast imaging that future instrument will have to deal with. A promising technique is the wavefront shaping which consists in the combination of a coronagraph and two deformable mirrors (DM). Located in non-conjugated planes, these mirrors can correct for both phase and amplitude aberrations, and be controlled to create dark zones at the focal plane. Algorithm and laboratory demonstrations have been made since in the past 20 years, but mainly in the continuous surface case.

SPEED (Segmented Pupil Experiment for Exoplanet Detection) is an experiment, started at Lagrange laboratory, Observatoire de la Cote D'Azur, in early 2013 to test high contrast capabilities with segmented pupils at very small separations (~ 1 ?/D) in H-band. The science driver for this project is the observation of planets around M-star. SPEED will combine a coronagraph and adaptive optics (2 deformable mirrors) to create high contrast regions (dark holes) at small separation. The SPEED coronagraph will be a PIAACMC (Phase Induced Amplitude Apodization Complex Mask Coronagraph) combining two out-of-pupil apodized optics and a complex focal mask that provide very high contrast at very small separation (1 ?/D or less). We have developed simulation tools to study the achievable

contrast with “unfriendly” pupils, but also to optimize the optical layout (optics locations, sizes…). An end-to-end simulation has been developed that includes the Fresnel propagation between each SPEED optic.
This paper presents updated results of these simulations for the setup optimization part. The DM optimum location is a key point for the layout optimization. We study the best solutions in different configurations: in collimated beams (when the first DM is at the pupil plane and the second DM is out of the pupil plane and when the two DMs are out of pupil plane), and in converging beam (first DM at pupil plane, second DM in converging beam). The simulations are currently done with perfect coronagraph and ideal DMs in order to study the mirror distance impact and assess the ultimate effects of Fresnel propagation on contrast performances. We show that the best contrast performance, whether the first DM is located out of the pupil plane or not, is always achieved for a constant separation (rather large in our case) between the two DMs, the latter being only determined by the dark zone parameters.

9906-105, Session PS2

Segment handling system prototype progress for Thirty Meter Telescope

Satoru Sofuku, Yutaka Ezaki, Noboru Kawaguchi, Toshitaka Nakaoji, Yusuke Saruta, Masaki Haruna, Lyon Kim, Mitsubishi Electric Corp. (Japan)

SHS (Segment Handling System) is the subsystem permanently implemented on TMT’s telescope structure that enables fast, efficient, semi-automatic exchange of M1 segments. TMT plans challenging segment exchange (10 segments per 10 hours a day). To achieve these, MELCO develops innovative SHS by accommodating FA (Factory Automation) technology such as force control system and machine vision system into the system. Force control system used for install operation, achieves soft handling by detecting force exerted to mirror segment and automatically compensating the position error between handling segments and primary mirror. Machine vision system used for removal operation, achieves semi-automatic positioning between SHS and mirror segments to be handled. Prototype experience proves soft (extraneous force ~100N) and fast (~3 minutes) segment handling. The SHS will provide upcoming segmented large telescopes for cost-efficient, effortless, and safe segment exchange operation.

9906-106, Session PS2

Force control technology of segment mirror exchange robot for Thirty Meter Telescope

Masaki Haruna, Lyon Kim, Kazuhiko Fukushima, Satoru Sofuku, Toshitaka Nakaoji, Junji Takaki, Yusuke Saruta, Noboru Kawaguchi, Yasushi Horiuchi, Yutaka Ezaki, Mitsubishi Electric Corp. (Japan)

SHS (Segment Handling System) is the subsystem permanently implemented (installed to) on TMT’s (telescope) structure that enables fast, efficient, semi-automatic exchange of M1 segments. TMT plans challenging segment exchange (10 segments per 10 hours a day). To achieve these, MELCO develops innovative SHS by accommodating FA (Factory Automation) technology such as force control system and machine vision system into the system.

Our developed force control technology makes it possible for SLF (Segment Handling and Fixture) to achieve safe and reliable mirror segment exchange of which mechanical interfaces are designed under the back side of the segment where machine vision system hardly measure the relative position. Owing to both well-studied design of the interface between the mirror segment/the jack of the telescope and the force control algorithm, the difficulty of the decoupling between the translational and rotational forces could be solved and enabled SLF to exchange the segment with acceptable performance. The effectiveness of our developed technology was verified through the experiments using the almost full scale prototype SLF that segment exchange could be completed within 180sec which was required from the system budget of SHS under all the assumed situations which included various relative position and attitude errors between SLF and the segments, and inclination of the segment from 0deg to 14.5deg.

This presentation focused on the concrete technology of SLF force control would contribute to deeper understanding of the MELCO’s SHS.

9906-107, Session PS2

Accelerometer-based online reconstruction of fast telescope vibrations from delayed measurements

Alexander Keck, Univ. Stuttgart (Germany); Jörg-Uwe Pott, Max-Planck-Institut für Astronomie (Germany); Oliver Sawodny, Univ. Stuttgart (Germany)

The imaging quality of ground-based telescopes is largely affected by telescope vibrations induced by wind, ground-vibrations or vibrations of technical equipment on site. A feedforward vibration cancellation system can be used to cancel fast wind-induced telescope vibrations out of the optical imaging system. This feedforward loop unburdens the adaptive optical system of the telescope. The disturbance feedforward system is based on accelerometer-measurements of the telescope vibrations, a position reconstruction algorithm to reconstruct the vibrational displacement based on the measured acceleration and a piezo-driven compensation mirror used to cancel the vibrations out of the optical path. Crucial is the position reconstructor’s ability to provide the compensation mirror with an accurate online estimate of the vibrational displacement. In this case, the vibrational disturbances will be canceled entirely. The authors have developed and presented a sophisticated position reconstruction algorithm based on adaptive resonators. Ultimately, the proposed disturbance feedforward control system permits observing faint stars with sufficient imaging contrasts on both the wavefront sensor and the main observational camera while disturbances caused by mechanical vibrations of the telescope structure are compensated for by a disturbance feedforward system.

Network data transmission protocols like UDP are typically used to transmit the acceleration measurement signals from the sensors to the control system computer. This data transmission introduces a non-negligible time delay into the measurement chain. However, any effective feedforward compensation setup can only function well if a delay-free estimate of the disturbance signal is provided. The consequences of a measurement time delay for vibrational feedforward compensation systems are discussed and illustrated. Three delay-compensating extensions of the developed position reconstructor are presented and analyzed. These modified position reconstructors have the same advantageous properties as original the adaptive resonator reconstructor, for example strong attenuation of both low-frequency drift and high-frequency noise. In addition, the measurement delay is compensated for in a predictive way. The reconstructed position signal is thus free of delay and can be used for disturbance feedforward compensation.

9906-108, Session PS2

The Square Kilometre Array mid-digital receiver concept

Gie Han Tan, SKA Organisation (United Kingdom) and European Southern Observatory (Germany); Krzysztof

Caputa, NRC - Herzberg Astronomy & Astrophysics (Canada); Stéphane Gauffre, Ctr. de Recherche Paul-Pascal (France); Thushara K. Gunaratne, Zoran Ljusic, NRC - Herzberg Astronomy & Astrophysics (Canada); Adriaan Peens-Hough, SKA South Africa (South Africa); Benjamin Quertier, Ctr. de Recherche Paul-Pascal (France)

The Square Kilometre Array (SKA) project is a global science and engineering project aiming at designing and constructing the next-generation radio telescope operating in the metre and centimetre wavelengths regions. The first phase of construction of the telescope (SKA1), which represents roughly 10% of the full SKA (SKA2), is currently well advanced with its design and expected to be operational early next decade. The SKA radio telescopes will be co-hosted in two locations with central array sites in Australia, SKA1-Low (50 – 350 MHz), and South Africa, SKA1-Mid (350 MHz – 13.8 GHz with an option for > 20 GHz).

This paper will address the use of state-of-the-art analogue-to-digital converters (ADC) and subsequent digital signal processing in the broadband receivers deployed in the SKA1-Mid radio telescope. The most recent developments in ADC technology has resulted in the availability of very fast and high resolution converters that are ideally suited for the SKA1-Mid telescope and enable direct digitization, after ample amplification by very low noise amplifiers, at RF signal frequencies as high as 13.8 GHz.

This novel concept for radio telescopes avoids the need for frequency conversion in the analogue front end. Except for broadband, anti-aliasing, filtering in the RF chain all bandpass filtering and frequency conversion will be performed in the digital domain. This direct digitization concept avoids the need for local oscillator signals, introducing the risk of unwanted spurs, and gives increased flexibility in catering the different back-ends dedicated to different types of astronomical science.

SKA1_Mid foresees in a total of five receiver bands, Band 1 (350 – 1050 MHz), Band 2 (950 – 1760 MHz), Band 3 (1650 – 3050 MHz), Band 4 (2800 – 5180 MHz) and Band 5 (4.6 – 13.8 GHz). For each of these bands the digitizers have to cope with different RF scenarios and appropriate ADC resolution and sampling frequencies are selected.

After digitization of the RF band various steps of signal processing, including digital down-conversion and filtering, are performed at the antenna before central correlation or beam-forming.

9906-109, Session PS2

Blind and reference channel-based time interleaved ADC calibration schemes: a comparison

Rosario F. Cimmino, Consorzio Nazionale Interuniversitario per i Transporti e la Logistica (Italy); Francesco Centurelli, Pietro Monsurro, Sapienza Univ. di Roma (Italy); Francesco Romano, EExSKA (Italy); Alessandro Trifiletti, Sapienza Univ. di Roma (Italy)

Time-interleaved (TI) ADCs are used to improve the sampling frequency of the ADCs by operating more than one in parallel. Time-interleaving, however, produces nonlinear terms due to the aliasing of the signals, and these distortion terms can only be eliminated if all the channels have the same offset and frequency response (gain, timing and bandwidth). All mismatches produce distortions, even if they are linear in nature, like these.

Blind calibration techniques exploit the properties of the input signal, or of time-interleaved systems, to estimate the calibration parameters required to maximize linearity. For instance, if the signal is from DC to a certain fraction of the Nyquist band, it is shown that aliasing in a 2-channel TI-ADC will create around the Nyquist frequency. Other techniques exploit the property that the signal and its derivative are orthogonal (bandwidth and timing errors can be approximated as a derivative).

Reference-based techniques, on the other hand, use a reference channel to obtain a reference signal: they exploit the property that if all the channels have the same offset and frequency response, no aliasing occurs. Calibration forces the offsets and frequency responses of all the channels to be the same as the reference channel, thus eliminating aliasing.

For a number of channels higher than 4, an additional reference channel implies a small overhead cost to the system, requires a thorough redesign of the whole system, and cannot be applied to OTS TI-ADCs. For 2 and to a lesser extent 4 channels, however, the overhead is large and blind calibration techniques may be preferred.

This paper compares both types of techniques for 2- and 4- channel TI-ADCs in terms of accuracy and convergence speed. Convergence speed is important because time-varying errors can be more easily tracked with a fast algorithm, which achieves thus a higher linearity during the tracking. Computational complexity is also considered, using the both LMS and RLS versions of the adaptive filters (which introduce a further trade-off between complexity, convergence speed, and steady-state linearity).

There are many blind and reference-based techniques in the literature, differing in terms of complexity, accuracy, speed. Comparison is performed among several of them, using the same testbed to assure the replicability of the results. The sources of mismatch investigated in this paper are offset, gain, timing and bandwidth.

9906-111, Session PS2

The Gemini Observatory protected silver coating: ten years in operation

Thomas Schneider, Gemini Observatory (United States); Tomislav Vucina Parga, Claudio Araya, Cristian Moreno, Gemini Observatory (Chile); Clayton Ah Hee, Gemini Observatory (United States)

Since 2004 the Gemini telescopes have used a protected 4-layer silver coating on their 8-meter diameter primary mirror and other smaller optics. Protected silver was chosen for the twin telescopes due to its high reflectivity and low emissivity properties. For over 10 years the protected 4-layer silver coating at Gemini has met the science requirements for reflectivity of 88% between 0.3-0.7 ?m and 84% between 0.7-1.1 ?m. Initial requirements also stipulated that the coating should last at least two years, which have been met and exceeded. All mirrors have at least met the durability requirement, with most outlasting it significantly. Provided is a ten year retrospective on the progress in the use and maintenance of 4-layer silver coatings on large astronomical optics.

9906-113, Session PS2

E-ELT project: more than 10 years of design, engineering and management preparation for the biggest telescope ever

Gianpietro Marchiori, Francesco Rampini, Simone De Lorenzi, Leonardo Ghedin, Stefano Mian, Cristiana Manfrin, Cristina Battistel, Enrico Marcuzzi, EIE Group s.r.l. (Italy)

The European Extremely Large Telescope by ESO (European Southern Observatory) is at present the most sophisticated technology challenge ever conceived before. For more than 10 years, upon specific contracts with ESO, EIE GROUP has developed research and analysis activities with the aim of finding all possible solutions to meet the over 1000 main requirements envisaged by the Dome and Telescope Main Structure. The technologies defined, will allow remarkable improvements for the

future extremely large Telescopes and Domes, as it happened with those adopted for the four VLTs. The hub of all processes is the innovative System Engineering Approach, which has allowed to combine together scientific, functional, operational, safety and maintenance parameters, though maintaining costs and lead time within the frame envisaged by these projects. Wind and seismic extreme parameters and the relevant rules, have imposed non-conventional solutions. All manufacturing and pre-assembly processes, the Packing and Transport ones, and Erection on site have been analyzed in detail and verified in order to guarantee the overall performances.

9906-114, Session PS2

Design and study of the mask exchange system based on Delta parallel mechanism

Feifan Zhang, Jianping Wang, Hongfei Zhou, Zengxiang Zhou, Jiaru Chu, Univ. of Science and Technology of China (China)

Mask exchange system is the main part of Multi-Object Broadband Imaging Echellette (MOBIE) on the Thirty Meter Telescope (TMT). The robot is one of the key parts in the mask exchange process. In view of the facts that the scheme the on-board robot is hard to meet the requirements of TMT and the traditional industrial robot is difficult to use in the Mask Exchange System (MEX). The delta parallel mechanism has much advantages such as good dynamic performance, high speed and could integrate a vision recognition system to identify the masks. The design for MEX based on off-board Delta parallel mechanism was proposed in the paper.

The stiffness models of MEX based on Delta parallel mechanism with different structure parameters in SolidWorks were analyzed to obtain relationship between different parameters and stiffness. Workspace of different Delta robots were calculated in MATLAB to gain relationship between parameters and workspace. These provide guidance for the design of Delta parallel mechanism which could use in different MEX schemes. By the requirements of MOBIE and preliminary schemes, the parameters of Delta parallel mechanism were determined and 3D models was established. Then, the kinematics analysis of Delta robot model was carried out to obtain the relationship between the driving arm and the position of the center point of the moving platform. On this basis, the MEX model was imported into MOBIE model to study schemes and obtained the routings. MATLAB and ADAMS software were used to perform simulation analysis and optimize the route to acquire the kinematics parameters. According to research above, advantages and disadvantages of various schemes were analyzed and compared. Through these studies, the basis and guidance for Delta parallel mechanism were provided in the MEX system design. The whole research process shown in the paper provided a reference for this specific project.

9906-115, Session PS2

Concepts for testing starshades on the ground

Stefan R. Martin, Stuart Shaklan, Mark Colavita, Eric J. Cady, Bertrand P. Mennesson, Jet Propulsion Lab. (United States)

Starshades are external occulters that would be used in conjunction with a space telescope and are being considered for future missions which will search for and characterize nearby exoplanets. Testing starshade technology on the ground is not straightforward because of the spatial scales involved. To reach small inner working angles (IWAs) the physics of diffraction dictates starshade size, so that for an IWA of 100 mas for example, something like a 30 m class starshade is needed. The corresponding separation of starshade and telescope would be of order 40 Mm. Such scales are obviously impossible on the ground, but can anything be done to test our understanding of starshades without going into space, and can any useful astronomy be done with ground-based starshades? We discuss concepts for testing meter class starshades using modest aperture telescopes such as the 2.1 m McMath solar telescope and applying the technology to larger telescopes with an adaptive optics system such as the 8.1 m Gemini telescopes. Larger telescopes which will enable larger but still subscale starshades are nearing construction. Realizable starshade geometries employing fixed ground-based assets are considered. We review some possible astronomical targets and consider the effects of atmospheric seeing on contrast. Finally we consider whether such starshades can be used to test current models of diffraction for small deformations of the shade.

This work was conducted at the Jet Propulsion Laboratory, California Institute of Technology, under contract with the National Aeronautics and Space Administration.

9906-116, Session PS3

Design of the high precision thermostat for birefringent filter

Jiaben Lin, Yuanyong Deng, Juan Guo, Zhen Zeng, National Astronomical Observatories (China)

A high precision thermostat design was presented to improve the temperature stability of the birefringent filter for the solar telescope in Huairou Solar Observatory. As the first step, three types of temperature sensors were investigated, PT, NTC thermistor and Wheatstone bridge. To grab the small temperature variations from these sensors, a complicated weak signal detection circuits with a 24 bits AD was designed; Then, high efficiency thermal insulation layers and a peripheral constant temperature layer were designed and set up to minimum thermal exchange; Finally, an ARM 7 processor was used as the central processing unit and the intelligent PI heating algorithm was realized. Two sets of thermostats had been put into use for more than two years, the temperature stability is better than 0.01??

9906-117, Session PS3

The Single Mirror Small Size Telescope (SST-1M) of the Cherenkov Telescope Array

Enrico Junior Schioppa, CERN (Switzerland)

The Small Size Telescope with Single Mirror (SST-1M) is one of the proposed types of Small Size Telescopes (SST) for the Cherenkov Telescope Array (CTA). The CTA south array will be composed of about 100 telescopes, out of which about 70 are of SST class, which are optimized for the detection of gamma rays in the energy range from 3TeV to 300TeV.

The SST-1M implements a Davies-Cotton optics with a 4m dish diameter providing a field of view of 9 degrees. The Cherenkov light produced in atmospheric showers is focused onto a 88cm wide hexagonal camera, composed of 1296 custom designed large area hexagonal silicon photomultipliers and a fully digital readout and trigger system. The SST-1M camera has been designed to provide high performance in a robust as well as compact and lightweight design.

In this contribution, we review the different steps that led to the realization of the first telescope prototype and its innovative camera.

9906-118, Session PS3

Cryogenic performances of high-efficiency germanium immersion grating

Yuki Sarugaku, The Univ. of Tokyo (Japan); Yuji Ikeda, Photocoding (Japan) and Kyoto-Sangyo Univ. (Japan); Sayumi Kaji, Kyoto Sangyo Univ. (Japan); Naoto Kobayashi, The Univ. of Tokyo (Japan); Takashi Sukegawa, Canon Inc. (Japan); Takayuki Arasaki, Sohei Kondo, Kenshi Nakanishi, Kyoto Sangyo Univ. (Japan); Chikako Yasui, The Univ. of Tokyo (Japan); Hideyo Kawakita, Kyoto Sangyo Univ. (Japan)

We present optical performances of a high-efficiency Germanium immersion grating under a cryogenic condition. Immersion grating is a diffraction grating of which the grooved surface is immersed in a medium with high refractive index (n). This optical device can offer n times higher spectral resolution than a classical reflective grating with the same clear aperture, thus it enables us to realize compact spectrographs keeping the spectral resolution. This new device will play important roles for infrared astronomy in the next generation.

We have been developing immersion gratings made of a variety of infrared crystals. Recently, we succeeded in fabricating a CdZnTe immersion grating with the theoretically predicted diffraction efficiency by machining process using an ultrahigh-precision five-axis processing machine developed by Canon Inc. (Ikeda et al. 2015). This achievement has a great impact because the direct cutting technique is applicable for any kind of infrared crystals, while the etching method, which was succeeded by a group of University of Texas, is used for fabricating a single crystal Si immersion grating.

Using the same technique, Canon Inc. completed a practical Ge-immersion grating with both a reflection coating on the grating surface and the an AR coating on the entrance surface. As an application, we are developing a long-NIR (2-5 um) high-resolution (R=80,000) spectrograph, VINROUGE, which will be the first IR spectrograph with a Ge-immersion grating. Thanks to the high refractive index of Ge, the instrument size is very compact (600 mm x 600 mm x 500 mm) for the spectral resolution (see Arasaki et al. in this conference). The Ge-immersion grating has a blaze angle of 75 degree and a diffraction surface area of 104 mm x 31 mm. Although the high optical performance is confirmed at room temperature (diffraction efficiency > 70%), it is necessary to verify it under the cryogenic condition. We built an in-house equipment to measure the light diffracted by the immersion grating at 4-4.5 um under variable cryogenic condition (20-80 K). This system employs a quantum cascade tunable laser in a single mode with a band width of < 6.8e-6 um, as the light source. The spatially-cleaned and expanded collimated beam enters and diffracted back by the immersion grating in the perfect Littrow configuration, being focused on a two-dimensional PbSe detector. TE or TM modes can be selected by a rotating half-wave plate. Both the immersion grating and a reference mirror are mechanically switchable under the cryogenic condition without changing the light path. We report the diffraction efficiency determined by using the system and robustnesses of the coatings on the Ge-immersion grating against thermal cycles.

9906-119, Session PS3

Optical designs for the Maunakea Spectroscopic Explorer Telescope

Will Saunders, Peter R. Gillingham, Australian Astronomical Observatory (Australia)

We present two optical designs for the proposed Maunakea Spectroscopic Explorer (MSE) telescope. The AOmega is twice as large as for existing wide-field spectroscopic designs (DESI, PFS), and the desired wavelength range is also larger (0.36-1.8 microns). The wide field corrector (WFC) for both designs includes a Compensating Lateral ADC which allows atmospheric dispersion correction without additional elements. A 12.3m F/2.97 Cassegrain design derived from VISTA gives 1.4 degree field-of-view with just three silica lenses. The largest lens is spherical with aperture diameter 1.26m, the other two are ~1.1m with a concave asphere. This design is pupil-centric, unvignetted and remarkably compact. An 11m F/1.97 Prime Focus design with 1.52 degree field is also presented. The WFC consists of five elements, three large and strongly powered silica lenses, and two thin and weakly powered light flint elements. The largest element is 1.21m aperture diameter, all other elements are <1m. All lenses have a concave asphere, one very strong but a pure conic. Blanks are available for all lenses. The ADC action involves moving the hexapod and just one individual lens, and a simple and robust single-actuator mechanism for this is also presented. The ADC action also allows a small change in plate-scale, which halves the image motions caused by differential refraction. A modest amount of vignetting at L1 allows the design to be effectively pupil-centric. Both designs give d80 < 0.35”-0.45” depending on zenith distance. The prime focus design has been adopted by MSE as the baseline design.

9906-120, Session PS3

SALT segmented primary mirror: experience with alignment control with inductive edge sensors

Hitesh Gajjar, John W. Menzies, Chris Coetzee, Ockert Strydom, Jonathan Love, Keith R. J. Browne, South African Astronomical Observatory (South Africa)

The Southern African Large Telescope (SALT) is a 10-m class 91-segment fixed altitude telescope located at Sutherland, South Africa. The segment alignment is maintained by inductively coupled sensors mounted on Sitall brackets beneath the segments. An extensive period of testing in environmental chambers and on the telescope has been conducted to establish the stability of the sensors and their response to temperature and humidity variations in the telescope chamber. We present some of the test results, including a demonstration of the ability of the sensors to maintain the alignment of a subset of the array over a period of 20 days.

We also present the initial results following the commissioning of the full edge sensing system on the telescope, technical challenges and lessons learned.

9906-121, Session PS4

Liverpool Telescope 2

Chris M. Copperwheat, Iain A. Steele, Robert M. Barnsley, Stuart D. Bates, Michael F. Bode, Neil R. Clay, Chris A. Collins, Liverpool John Moores Univ. (United Kingdom); Johan H. Knapen, Instituto de Astrofísica de Canarias (Spain); Jonathan M. Marchant, Christopher J. Mottram, Robert J. Smith, Liverpool John Moores Univ. (United Kingdom)

In this talk we will provide a progress report on Liverpool Telescope 2 (LT2): a new, fully robotic optical/infrared telescope planned to be commissioned at the Observatorio del Roque de los Muchachos (ORM) on the Canary island of La Palma in the early years of the next decade. Robotic telescopes are powerful tools for the study of the time variable sky. The 2-metre Liverpool Telescope, sited at the ORM, is one of the world’s leading time domain facilities, and LT2 will build on the success of this telescope with a larger aperture, novel instrument complement and an even more rapid response time for highly variable and fast-fading

transients. It is an exciting period for time domain astronomy: we are on the brink of a new era which will brought about by the next generation of discovery facilities such as LSST, SKA, SVOM and CTA. These facilities will survey vast regions of the sky and detect unprecedented numbers of transients and time variable phenomena across the electromagnetic spectrum. Facilities like Advanced LIGO / Virgo and IceCube will are also beginning to open non-electromagnetic windows on the transient universe for the first time. A key problem is a lack of follow-up facilities for classification and exploitation of these new discoveries. LT2 is designed to meet this need: a modern, large aperture and reactive robotic telescope to maximally exploit the discovery space of the new time domain era.

9906-122, Session PS4

LSST AOS software architecture

Sandrine J. Thomas, Srinivasan Chandrasekharan, Paul J. Lotz, Bo Xin, Charles F. Claver, George Z. Angeli, Jacques Sebag, LSST (United States); Gregory P. Dubois-Felsmann, California Institute of Technology (United States)

The Large Synoptic Survey Telescope (LSST) is an 8-meter class wide-field telescope now in construction on Cerro Pachon, Chile. This ground-based telescope is designed to conduct a decade-long time domain survey of the optical sky. In order to achieve the LSST scientific goals, the telescope requires delivering a robust good image quality over the 3.5 degrees field of view. As many telescopes, LSST will use an Active Optics System (AOS) to correct in real time the system aberrations mostly introduced by gravity and temperature gradients. The LSST AOS uses a combination of 4 curvature wavefront sensors (CWS) located on the outside of the LSST field of view. The information coming from the 4 CWSs are combined to calculate the appropriate corrections to be sent to the 3 different mirrors. The AOS software is composed of a wavefront sensor estimation pipeline (WEP) and an active optics control system (AOCS). The WEP estimates the wavefront residual error from the CWS images. The AOCS determines the correction to be sent both the M1/M3 and M2 mirrors every 30 seconds. In this paper, we describe the design and implementation of the AOS. More particularly, we will focus on the software architecture as well as the AOS interaction with the different subsystems within LSST.

9906-123, Session PS4

A new telescope design suitable for massive spectroscopy

Luca Pasquini, Bernard-Alexis Delabre, Tim de Zeeuw, European Southern Observatory (Germany)

In the framework of a thought experiment, we present a novel concept for a five- mirror telescope design, especially suitable for massively multiplexed spectroscopy. The concept provides a large field of view (FOV) in a convenient, gravity-invariant focal plane that can be adapted to a large range of telescope diameters. As a specific example we present a design for an 8m diameter telescope with a 1.5 degree diameter FOV and a relay system that allows simultaneous spectroscopy with 10000 mini-integral field units over a square degree, or, alternatively a 5x4 arc-minutes giant integral-field-unit, by using 240 MUSE-type spectrographs. The importance is stressed of simultaneously developing telescope and instrument.

9906-124, Session PS4

ASTRI camera electronics

Giuseppe Sottile, Osvaldo Catalano, Giovanni La Rosa, Milvia Capalbi, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Carmelo Gargano, Salvatore Giarrusso, Domenico Impiombato, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Francesco Russo, Pierluca Sangiorgi, Alberto Segreto, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Giovanni Bonanno, Salvatore Garozzo, Davide Marano, Giuseppe Romeo, INAF - Osservatorio Astrofisico di Catania (Italy); Luca Stringhetti, INAF - IASF Milano (Italy); Renato Gimenes, Univ. de São Paulo (Brazil)

ASTRI SST-2M is a Cherenkov Telescope prototype developed by INAF and proposed as one of the Small Size Telescope (SST) options for the Cherenkov Telescope Array (CTA) observatory. It is based on a dual mirror optic system, an innovative solution for Cherenkov light imaging. The focal plane of the ASTRI camera is composed of silicon photo-multipliers (SiPMs), a recently developed technology for light detection that exhibits very fast response and an excellent single photoelectron resolution. The ASTRI camera electronics is specifically designed to catch the fast pulses produced by the SiPM sensors.

To optimize the overall camera design, the ASTRI Camera Electronics is divided into two main systems: the Front End Electronics (FEE) and the Back End Electronics (BEE).

Each one of the 37 photon detection modules (PDMs), constituting the camera focal plane, hosts its own FEE. In each PDM, the FEE is composed of a front end readout ASIC directly interfaced to the SiPM sensors, an ADC to convert the event pulses and a FPGA that implements all the required logic for the generation of a local trigger and the transmission of the data produced to the BEE.

The BEE is hosted on a separate common board. The BEE is based on a FPGA with a System on Chip (SoC) running an operating system that manages the configuration of all the 37 PDMs. The BEE receives commands from a camera controller and sends data packets to a camera server, both connected through a LAN.

In this contribution we present the general architecture of the ASTRI camera electronics with special emphasis to some innovative solution.

9906-126, Session PS4

LSST primary/tertiary monolithic mirror

Jacques Sebag, William J. Gressler, Ming Liang, Douglas Neill, Constanza Araujo Hauck, John Andrew, Chuck Gessner, Gary A. Poczulp, LSST (United States); Michael T. Tuell, Hubert M. Martin, Steve C. West, The Univ. of Arizona (United States); George Z. Angeli, Myung Kyu Cho, Bo Xin, LSST (United States)

At the core of the Large Synoptic Survey Telescope (LSST) three-mirror optical design is the primary/tertiary (M1M3) mirror that combines these two large mirrors onto one monolithic substrate. The M1M3 mirror was spin cast and polished at the Steward Observatory Mirror Lab at the University of Arizona (SOML). Final acceptance of the mirror occurred during the year 2015 and the mirror is now in storage while the mirror cell assembly is being fabricated. The M1M3 mirror will be tested at SOML after integration with its mirror cell before being shipped to Chile.

This paper details the results from the mirror final acceptance. All critical parameters were measured with sufficient accuracy to demonstrate compliance with the specifications. For each mirror M1 and M3, the vertex radius of curvature, conic constant, and position of the optical axis with respect to the mechanical axis of the blank were demonstrated to be within the specifications including the relative position of M3 optical axis relative to M1 optical axis. The residual surface errors for each mirror were also measured and analyzed by SOML and LSST to verify the impact on the final image quality of the telescope.

After final acceptance, the mirror surface was protected with a thin coating

of polyethylene to protect the mirror as it was prepared for removal of its polishing cell for delivery. Formal delivery happened toward the middle of May 2015 when the LSST Project took responsibility for the mirror in its shipping container and moved it to a secure facility for storage. The mirror is expected to remain in storage for approximately two years until the operational M1M3 mirror cell assembly is fabricated, at which time the M1M3 mirror and mirror cell can be integrated and tested before being shipped to Chile

9906-127, Session PS4

An afocal three-mirror optical system for 3D laser receiver and imaging detection

Xin Wang, Jinlong Wan, Shouwang Jiang, Rong Shu, Shanghai Institute of Technical Physics of the Chinese Academy of Sciences (China)

We present a novel 3D laser imaging optical receiver comprised by a coaxial three-reflective aspherical afocal telescope, an off-axis TMA camera and a lens laser collector, able to realize the altitude measurement and array spatial detection. The afocal design is to permit a very narrow filter to work at a high efficiency in the parallel ray beam and avoid the background spectral influence except for laser wavelength. Different from the coaxial R-C reflective plus lens corrector system, all reflective configuration shows very small distortion, more compact and easier to manufacture especially as larger and larger pupil size is in a great demand for the high spatial resolution. The distortion is optimized to be less than 5 micrometer in order to obtain the high image position. Several methods of measurement for interior orientation elements are studied, and the simulated analysis for measuring accuracy of principle point, principle focal length and distortion are achieved. The tolerance analysis for engineering application is done to give the detailed requirement on manufacture and alignment. An opto-mechanical stray light analysis is simulated to eliminate the straight ghost beams outside of FOV which graze the secondary mirror, then go across the inner hole of primary mirror, and finally arrive at the detector. A shutter with some laminas is designed which is connected with secondary mirror's structure, and the direct stray light is blocked completely. A lab prototype will be built in the next year.

9906-128, Session PS4

Effects of glycol on first surface aluminum coatings

David Sprayberry, Patrick Dunlop, Matthew Evatt, Larry Reddell, Ronald G. Probst, National Optical Astronomy Observatory (United States)

The Dark Energy Spectroscopic Instrument (DESI) is under construction to measure the expansion history of the Universe using the Baryon Acoustic Oscillation technique. The spectra of 40 million galaxies over 14000 sq deg will be measured during the life of the experiment. A new prime focus corrector for the KPNO Mayall telescope will deliver light to 5000 fiber optic positioners. The fibers in turn feed ten broad-band spectrographs. The DESI Prime Focus Assembly will require liquid cooling to maintain its average temperature within ±1°C of ambient, so as not to disrupt the seeing. Because of concerns about fluid deposition onto optical surfaces from possible leaks in the cooling system, we are conducting systematic tests of the effects of candidate coolants on aluminized mirrors. Ethylene glycol is used extensively throughout the KPNO Mayall 4 meter facility, making it a good candidate coolant. Ethylene glycol is placed on test mirrors with first surface aluminum coatings for varying lengths of time. Various cleaning methods are then used to remove it. A spectrophotometer is used to analyze the condition of the coating before and after each experiment. The findings within this report reflect glycol as being a very volatile reactive solution when it comes in contact with first surface aluminum coatings. The effect seen is that of dissolving the aluminum coating. The results coincide with reports from other facilities that have experienced glycol leaks in cooling systems above first surface aluminum coatings.

9906-129, Session PS4

Optical design of the 25m CCAT sub-mm wave telescope

German Cortes-Medellin, Univ. de Antioquia (Colombia) and Cornell Univ. (United States); Stephen C. Parshley, Cornell Univ. (United States)

CCAT is a 25m-class sub-millimeter wave telescope designed to operate from 350-2100 microns (850-150 GHz), covering multiple telluric windows available at the unique site, 5612m above sea level, on Cerro Chajnantor overseeing the Atacama plateau in Northern Chile. CCAT will work in synergy with ALMA using a wide-field camera (among other instruments), opening the door for large scale survey missions to find targets that could be followed up with the very fine resolution of the ALMA array.

Affordability constraints created the need to slim down the very appealing but expensive 1˚ field of view in favor of a smaller FoV (1/3˚) but with the same scientific potential. Numerous optical designs were investigated that include an f/8 Nasmyth and quasi-Nasmyth as well as f/6 Gregorian designs. We will present the details of the final optical design including diffraction limited performance of these possibilities at the available focal locations, and the impact on scientific instrumentation.

9906-130, Session PS4

An all-silica three-element wide-field corrector design for GMT

Will Saunders, Peter R. Gillingham, Australian Astronomical Observatory (Australia); Sean Lin, Andrew P. Rakich, GMTO Corp. (United States)

We present a proposed design for a Wide-Field Corrector and Atmospheric Dispersion Compensator for GMT. It allows a 20' field of view with 3 fused silica lenses with diameter <1.55m, including just one low-precison asphere. For a 10' field, a smaller L3 without an aspheric surface suffices, giving somehat better monochromatic images than the uncorrected Gregorian focus as well as atmospheric dispersion correction. The polychromatic image quality is d80<0.05" at zenith and d80<0.20" for ZD<60 degrees, while the monochromatic image quality is d80<0.05" everywhere. The ADC action is achieved by tilt and translation of L1 and L2, via simple mechanisms each using a single encoded actuator. There is also a small motion of the M2 hexapod, automatically generated by the AGWS system. The design allows better UV and NIR throughput than can be achieved with the baseline Risley prism design, and blanks are known to be available in the required sizes and homogeneities. The main issues preventing the design being adopted at this time are that (a) the M2 motions are unbudgetted and it is not yet clear if they can be accommodated, and (b) the ADC action moves the exit pupil, which decreases throughput and allows off-axis stray light to enter the instruments. The exit pupil can be kept fixed by also translating and tilting L3, but this is complicated by space constraints and by L3 being below the instrument rotator. Mechanisms for achieving the required L3 motions are presented.

9906-131, Session PS4

Holographic telescope

Jefferson E. Odhner, Odhner Holographics (United States)

A telescope is designed, manufactured, and demonstrated that uses an achromatic configuration of diffractive optical elements. The color spread normally associated with holographic lenses is compensated for with a second sandwiched diffractive optical element that exactly cancels out the chromatic aberration of the first element. This technique is used to make the primary and objective optics. The advantage of this is that large aperture optics can be made that weigh significantly less than conventional optics. Various F/#'s were experimented with. The resulting lightweight telescope would be suitable for UAV (unmanned aerial vehicle) applications. The telescope was modeled in Zemax® (ray tracing software) and the modeled results are compared to experimental results.

9906-132, Session PS4

The design of an adaptive optics telescope: the case of DAG

Laurent Jolissaint, HEIG-VD (Switzerland); Onur Keskin, Isik Üniv. (Turkey); Sinan Kaan Yerli, Middle East Technical Univ. (Turkey); Cahity Yesilyaprak, Atatürk Üniv. (Turkey); Lorenzo Zago, HEIG-VD (Switzerland)

Turkey is taking a lift in astronomical science by preparing a new 4-m telescope for infrared observation at high angular resolution, with adaptive optics. First light is scheduled for 2019. The telescope image quality specification is set such that once the AO system is running, the telescope and other pseudo-static aberrations should be significantely smaller than the average residual optical turbulence. In other words, the observations must be limited by residual turbulence, not the telescope. Following this objective, we have systematically chosen, at each step, solutions that should offer the maximum stability of the AO instrumentation (only Nasmyth with no rotation of the instruments), the easiest access to the AO system (optical laboratory-like environement) and stringent requirements on the telescope active optics low order and high order wavefront residuals. This paper is a review of this design process.

9906-17, Session 6

Final design of the Large Synoptic Survey Telescope *(Invited Paper)*

Steven Kahn, SLAC National Accelerator Lab. (United States) and LSST (United States)

The Large Synoptic Survey Telescope (LSST) is a large-aperture, wide-field, ground-based telescope, designed to perform a time-domain imaging survey of the entire southern hemisphere of sky in six optical colors. The development and construction of LSST involves a public/private partnership with funding from the National Science Foundation, the Department of Energy Office of Science, and various private sources. Within the past two years, the Project team passed a series of final technical and management reviews conducted by both federal agencies, and is now fully approved for construction. The expected science performance of the final design remains consistent with the advertised performance that led to the New Worlds New Horizons decadal survey endorsement of LSST as the top-ranked new large facility in ground-based astronomy. The optical design incorporates 3-mirror wide field optical system; an 8.4 meter primary, 3.4 meter secondary, and 5 meter tertiary mirror that feed three refractive elements and a 64 cm 3.2 gigapixel focal plane camera. The data management system is designed to reduce, transport, alert, and archive the 15 terabytes of data produced nightly, and will serve raw and catalog data accumulating at an average of 7 petabytes per year. Additional access portals and tools developed with the LSST will extend the scientific reach of the survey to education and public outreach efforts of students and other non-professionals. LSST has completed key performance demonstrations and procurements for many critical systems including the telescope mount assembly, the summit facility, the dome assembly, the imaging sensors, the secondary mirror optical fabrication, the camera refractive optics, and the camera and secondary mirror hexapod system. Software data challenges and data releases designed to test software and algorithms to significant pre-construction levels have continued and have supported harvesting existing data sets for additional science. Construction on the summit is well-underway, and fabrication of all of the major subsytems is in process, leading to LSST "first light" in 2020, and the onset of the ten-year survey in 2022.

9906-18, Session 6

Final design of the LSST hexapods and rotator

Douglas Neill, LSST (United States); Ryan C. Sneed, Scott Kidney, Moog CSA Engineering (United States); Constanza Araujo Hauck, William J. Gressler, Paul J. Lotz, Dave Mills, Jacques Sebag, LSST (United States); Thomas A. Sebring, Xoptx LLC (United States); Michael Warner, Oliver Wiecha, LSST (United States)

The Large Synoptic Survey Telescope (LSST) is a large (8.4 meter) wide-field (3.5 degree) survey telescope, which will be located on the Cerro Pachón summit in Chile. Both the Secondary Mirror (M2) Cell Assembly and Camera utilize hexapods to facilitate optical positioning relative to the Primary/Tertiary (M1M3) Mirror. A rotator resides between the Camera and its hexapod to facilitate tracking. The final design of the hexapods and rotator has been completed by Moog CSA, who are also providing the fabrication, integration and testing. Geometric considerations preclude the use of a conventional hexapod arrangement for the M2 Hexapod. To produce a more structural efficient configuration the camera hexapod and camera rotator will be produced as a single unit. The requirements of the M2 Hexapod and Camera Hexapod are very similar; consequently to facilitate maintainability both hexapods will utilize identical actuators. The open loop operation of the optical system requires very low hysteresis. This requires that the hexapod actuators use flexures rather than more traditional end joints. Operation of the LSST requires high natural frequencies, consequently, to reduce the mass relative to the stiffness, a unique THK rail and carriage system is utilized rather than the more traditional slew bearing. This system utilized two concentric tracks and 18 carriages. To ensure safe and reliable operation the hexapod and rotators will undergo extensive testing.

9906-19, Session 6

LSST telescope and site status

William J. Gressler, National Optical Astronomy Observatory (United States)

The Large Synoptic Survey Telescope (LSST) Project received its construction authorization from the National Science Foundation in August 2014. The Telescope and Site (T&S) group has made considerable progress towards completion in subsystems required to support the scope of the LSST science mission. The LSST goal is to conduct a wide, fast, deep survey via a 3-mirror wide field of view optical design, a 3.2-Gpixel camera, and an automated data processing system. The summit facility is currently under construction on Cerro Pachón in Chile, with major vendor subsystem deliveries and integration planned over the next several years.

This paper summarizes the status of the T&S group, tasked with design, analysis, and construction of the summit and base facilities and infrastructure necessary to control the survey, capture the light, and calibrate the data. All major telescope work package procurements have been awarded to vendors and are in varying stages of design and fabrication maturity and completion. The unique M1M3 primary/tertiary mirror polishing effort is completed and the mirror now resides in storage

waiting future testing. Significant progress has been achieved on all the major telescope subsystems including the summit facility, telescope mount assembly, dome, hexapod and rotator systems, coating plant, base facility, and the calibration telescope. In parallel, in-house efforts including the software needed to control the observatory such as the scheduler and the active optics control, have also seen substantial advancement. The progress and status of these subsystems and future LSST plans during this construction phase are presented.

9906-20, Session 6

LSST mirror system status: from design to fabrication and integration plan

Constanza Araujo Hauck, Jacques Sebag, Ming Liang, Douglas Neil, Sandrine J. Thomas, William J. Gressler, LSST (United States)

Currently in Construction phase since 2014, the Large Synoptic Survey Telescope (LSST) is a large (8.4 meter) wide-field (3.5 degrees) survey telescope, which will be located on the Cerro Pachón summit in Chile. The reflective telescope uses an 8.4 m f/1.06 concave primary, an annular 3.4 m secondary and a 5.2 m concave tertiary. The primary and tertiary mirror aspheric surfaces are located on one monolithic borosilicate substrate, the so-called M1M3 mirror. This unique design offers significant advantages in the reduction of degrees of freedom, improved structural stiffness for the otherwise annular surfaces and provides a very compact design. The secondary mirror is a 100mm thick meniscus convex asphere. The three-mirror system feeds a three element refractive corrector to produce a 3.5 degrees diameter field of view over a 64-cm flat focal surface.

This paper describes the current status of the mirror system components and provides an overview of the upcoming milestones. The future activities, including the mirror coating specifications, the system tests and the integration plan are presented.

9906-21, Session 6

Large Synoptic Survey Telescope mount final design

Shawn P. Callahan, National Optical Astronomy Observatory (United States); Alfredo Orden Martinez, Manuel Perezagua Aguado, Luis Garcia-Marchena, GHESA Ingeniería y Tecnología, S.A. (Spain); Ismael Ismael Ruiz de Argandoña, IK4 Tekniker (Spain); Marco Venturini, Phase Motion Control S.r.L. (Italy); Francisco M. Romero, Ricardo Rodríguez, José Carlos González Gonzále, Asturfeito S.A. (Spain); Sandrine J. Thomas, Chuck Gessner, Michael Warner, Jeffrey D. Barr, Paul J. Lotz, German Schumacher, Oliver Wiecha, George Z. Angeli, John Andrew, Charles F. Claver, William J. Gressler, Bill Schoening, Jacques Sebag, Victor L. Krabbendam, Douglas Neill, Edward A. Hileman, Gary Muller, Constanza Araujo Hauck, LSST (United States)

This paper describes the status and details of the large synoptic survey telescope mount assembly (TMA).

On June 9th, 2014 the contract for the design and build of the large synoptic survey telescope mount assembly (TMA) was awarded to GHESA Ingeniería y Tecnología, S.A. and Asturfeito, S.A.

The design successfully passed the preliminary design review on October 2, 2015 and is currently being detailed for the final design review. This paper describes the detailed design, analytical model results, preparations being taken to complete the fabrication, and the transportation and installation plans to install the mount on Cerro Pachón in Chile.

The telescope mount assembly is designed to provide a low-hysteresis high resonant frequency structure to meet the demanding pointing repeatability requirements required for this telescope.

The TMA is supported on a 19-m diameter steel reinforced concrete pier designed by Arcadis Chile S.A. The azimuth structure is in turn supported on six custom SKF axial and eight radial hydrostatic bearings optimized to provide stiffness. The elevation structure is supported on two trunnions mounted with two pairs of custom SKF radial bearings and two pairs of axial bearings. The oil supply system has been designed by HYDX hydraulic solutions.

The azimuth assembly is driven by sixteen dual-gap linear motors designed by Phase Motion Control. The elevation assembly uses two drive arcs driven by a total of six dual gap motors. The azimuth and both elevation drive arcs are encoded by the latest generation Heidenhain tape encoders.

The top end assembly is attached to the elevation structure by a spider design composed of sixteen truss elements. This rigid assembly supports a removable spindle that supports the 4000 kg LSST camera and the large 5500 kg secondary mirror (M2) assemblies.

The TMA design also supplies all cooling plumbing, refrigerant lines, power, and communication services throughout the TMA. All services are connected to the TMA inside the pier and are routed to the azimuth structure through a motorized may-pole type cable wrap with enhancements based on GHESA's know-how from previous projects. Services are routed to the elevation structure through two passive cable wraps, one on each side of the elevation axis, located over the Azimuth Platforms.

A third motorized cable wrap has been designed by IK4 Tekniker to route all services and utilities to the camera through the camera rotator and hexapod.

The TMA also incorporate light baffles to work in unison with the dome shutter and wind screen.

The latest detailed schedule for the TMA is included to show the milestones for the installation at fabrication facilities at Asturfeito in northern Spain and then on top of Cerro Pachón, Chile. A detailed integration plan is provided showing the planned integration of the telescope in the dome. We are planning for a safe design by using a hazard analysis process and best practice safety standards

This large project is the culmination of work by many people and the authors would like to thank everyone that has contributed to the success of this project.

9906-22, Session 7

The LSST Dome final design

Joseph DeVries, Douglas Neill, Jeffrey Barr, LSST (United States); Gianpietro Marchiori, Simone De Lorenzi, EIE Group s.r.l. (Italy)

The Large Synoptic Survey Telescope (LSST) is a large (8.4 meter) wide-field (3.5 degree) survey telescope, which will be located on the Cerro Pachón summit in Chile. As a result of the Telescope wide field of view, the optical system is unusually susceptible to stray light. In addition, limiting the effect of wind on the Telescope from the environment is important. The rotating enclosure system (Dome) includes a moving wind screen and light baffle system. All of the Dome vents include hinged light baffles, which provide exceptional Dome flushing, stray light attenuation, and allow for vent maintenance access from inside the Dome. The wind screen also functions as a light screen, and helps define a clear optical aperture for the Telescope. Since the Dome must operate continuously without rotational travel limits to accommodate the Telescope cadence and travel, the Azimuth drives are located on the fixed lower enclosure to accommodate glycol water cooling without the need for a utility cable wrap. An air duct system aligns when the Dome is in its parked position, and this provides

air cooling for temperature conditioning of the Dome during the daytime. A bridge crane and a series of ladders, stairs and platforms provide for the inspection, maintenance and repair of all of the Dome mechanical systems. The contract to build the Dome was awarded to European Industrial Engineering in Mestre, Italy in May 2015. In this paper, we present the final design of this telescope and site sub-system.

9906-23, Session 7

The LSST calibration hardware system design and development

Patrick J. Ingraham, Charles F. Claver, LSST (United States); Christopher W. Stubbs, Harvard Univ. (United States); Robert H. Lupton, Princeton Univ. (United States); John Andrew, Constanza Araujo Hauck, Jeffrey D. Barr, Kairn Brannon, LSST (United States); Michael Coughlin, Harvard Univ. (United States); Merlin Fisher-Lavine, Brookhaven National Lab. (United States) and Princeton Univ. (United States); Ming Liang, Sandrine J. Thomas, Jacques Sebag, LSST (United States)

The Large Synoptic Survey Telescope (LSST) is currently under construction and upon completion will perform precision photometry over the visible sky at a 3-day cadence. The relative photometric design specifications of LSST for bright unresolved point sources are 5 mmag in the bvri filters and 7.5 mmag in the uzy filters. Furthermore, the accuracies must be achievable in non-photometric observing conditions. Meeting these requirements poses a significant challenge and necessitates the calibration of systematic errors, such as atmospheric transmission, that evolve both temporally and spatially over the course of a ~2-3 LSST pointings. Similar to other surveys, calibration measurements and corrections must be determined for static effects such as vignetting and system properties that may evolve over longer timescales, such as optical throughput. This paper describes multiple hardware systems that LSST is developing to measure and compensate for numerous sources of systematic errors.

To compensate for the effects of atmospheric transmission and its temporal and spatial variability, LSST will utilize a robotic 1.2-meter diameter auxiliary telescope dedicated to obtaining spectra of main-sequence stars in the immediate vicinity of where LSST is pointed. This paper describes the auxiliary telescope, its enclosure and the spectrograph that has been specifically optimized to characterize the atmospheric transmission properties at high cadence in coordination with the main telescope.

Characterization of numerous optical properties of LSST is accomplished using two independent systems. The first system is a custom-made collimated beam projector that projects a field of sources on to user-defined discrete sections of the telescope optics. This device enables the ability to characterize the spatial dependence of the telescope and instrument transmission function, monitor of filter throughput evolution and assist in the characterization of ghosting effects. The second system is a flat-field screen that will be illuminated by both a white-light and a tunable monochromatic illumination system. These systems will produce data to measure the high-frequency variations in the global transmission function. This paper describes both of these hardware systems and the suite of measurements they are expected perform. Lastly, this paper details numerous smaller pieces of hardware that will conduct environmental monitoring such as a DIMM and GPS precipitable water vapor measuring system.

9906-24, Session 7

LSST summit facility construction progress report: reacting to field conditions and design refinements

Jeffrey D. Barr, William J. Gressler, Jacques Sebag, Jaime Seriche, Eduardo Serrano, LSST (United States)

The civil work and buildings for Summit Facility of the Large Synoptic Survey Telescope (LSST) are among the first major elements that need to be designed, bid and constructed to support the subsequent, sequential integration of the dome, telescope, instruments and supporting systems. As the contracts for those other major subsystems move forward there is inevitable and beneficial evolution in their designs, which can result in significant modifications to the early development of the facility and infrastructure.

The contract for construction of the LSST Summit Facility was initiated in January, 2015. Since then, now roughly halfway through construction, there have been some necessary modifications to the facility design resulting from unanticipated field conditions as well as the evolution of interfaces to other major elements of the LSST project – principally the telescope mount, the dome and mirror handling and coating facilities. The modifications related to field conditions have included specifying and testing alternative methods of excavation and contending with the lack of competent rock substrate where it was predicted to be. Changes resulting from interface evolution have included alternate anchor bolting methods for the telescope and dome as well as increases in mass, dimensions, and heat loads of major project components. While these and other changes that have been required are somewhat specific to the LSST project, they also exemplify an inherent challenge in the design and construction of facilities and infrastructure for ground-based astronomical observatories.

Responding to these changing interfaces, and to field conditions as they are encountered, presents challenges during the leading edge of the observatory construction project which require sensible and resourceful solutions to avoid potential schedule, budget and operational problems downstream.

9906-25, Session 7

Final design of the LSST primary/tertiary mirror cell assembly

Douglas Neill, Gary Muller, Edward A. Hileman, Constanza Araujo Hauck, Joseph DeVries, William J. Gressler, Dave Mills, Jacques Sebag, Oliver Wiecha, Paul J. Lotz, LSST (United States)

The Large Synoptic Survey Telescope (LSST) primary/tertiary (M1M3) mirror cell assembly supports both on-telescope operations and off-telescope mirror coating. This assembly consists of the cast borosilicate M1M3 monolith mirror, the mirror support systems, the thermal control system, a stray light baffle ring, a laser tracker interface and the supporting steel structure. During observing the M1M3 mirror is actively supported by pneumatic figure control actuators and positioned by a hexapod. When the active system is not operating the mirror is supported by a separate passive wire rope isolator system. The center of the mirror cell supports a laser tracker which measures the relative position of the camera and secondary mirror for alignment by their hexapods. The mirror cell structure height of 2 meters provides ample internal clearance for installation and maintenance of mirror support and thermal control systems. The mirror cell also functions as the bottom of the vacuum chamber during coating. The M1M3 mirror has been completed and is in storage. The mirror cell structure is presently under construction by CAID Industries. The figure control actuators, hexapod and thermal control system are under developed and will be integrated into the mirror cell assembly by LSST personnel. The

entire integrated M1M3 mirror cell assembly will the tested at the Steward Observatory Mirror Lab.

9906-26, Session 8

The University of Tokyo Atacama Observatory 6.5m telescope: project overview and current status *(Invited Paper)*

Yuzuru Yoshii, Mamoru Doi, Kotaro Kohno, Takashi Miyata, Kentaro Motohara, Kimiaki Kawara, Masuo Tanaka, Takeo Minezaki, Shigeyuki Sako, Tomoki Morokuma, Yoichi Tamura, Toshihiko Tanabe, Hidenori Takahashi, Masahiro Konishi, Takafumi Kamizuka, Natsuko Kato, Tsutomu Aoki, Takao Soyano, Ken'ichi Tarusawa, The Univ. of Tokyo (Japan); Toshihiro Handa, Kagoshima Univ. (Japan); Shintaro Koshida, Subaru Telescope (United States); Leonardo Bronfman, Maria T Ruiz, Mario Hamuy, Rene A. Mendez, Guido Garay, Univ. de Chile (Chile)

The University of Tokyo Atacama Observatory Project is to construct a 6.5m infrared telescope at the summit of Co. Chajnantor (5640m altitude) in northern Chile, promoted by the Institute of Astronomy, University of Tokyo. Thanks to the dry climate (PWV~0.5mm) and the high altitude, it will achieve excellent performance in the NIR to MIR wavelengths.

The telescope has two Nasmyth foci where the facility instruments are installed and two folded-Cassegrain foci for carry-in instruments. All these four foci can be switched by rotating a tertiary mirror. The final focal ratio is 12.2 and the telescope foci have large field-of-view of 25 arcmin in diameter.

We adopted the 6.5-m F/1.25 light-weighted borosillicate honeycomb primary mirror and its support system that are developed by Steward Observatory Richard F. Caris Mirror Lab.

The dome enclosure has the shape of carousel, and large ventilation windows with shutters control the wind to flush heat inside the dome. The building with control room, aluminizing chamber and maintenance facilities is located at the side of the dome.

Two cameras, SWIMS for spectroscopy and imaging in the near-infrared and MIMIZUKU in the mid-infrared, are being developed as the first-generation facility instruments. The operation of the telescope will be remotely carried out from a base facility at San Pedro de Atacama, 50km away from the summit.

The construction of the telescope is now underway. Fabrication of the telescope mount has almost finished, and the pre-assembly has been carried out in Japan. The primary, secondary, and tertiary mirrors and their cells have been also fabricated, as well as their cells and support systems. Fabrication of structures of dome enclosure is now underway, and their preassembly in Japan will be carried out in 2016. Construction of the base facility at San Pedro de Atacama has been already completed in 2014, and operated for the activities in Atacama. Both of the two instruments, SWIMS and MIMIZUKU, are at their final stages of development. They are now planned to be transported to the Subaru telescope at Hawaii for the test observations in 2016, and after adjustments, will be transported to Chile. The telescope is now scheduled to see the first light at the end of FY2017.

9906-27, Session 8

San Pedro Martir Telescope: Mexican design endeavour

Gengis Toledo-Ramirez, Noe Reyes-Elias, Jorge A. Uribe, César Martinez, Xóchitl Caballero, Aldo Lopez, Luis del Llano, Carlos Tovar, Eduardo Macias, Ctr. de Ingenieria y Desarrollo (Mexico); Antonio Estrada, Ctr. de Ingenieria y Desarrollo (Mexico); José Segura, Ctr. de Ingenieria y Desarrollo (Mexico); William H. Lee, Univ. Nacional Autónoma de México (Mexico); Alberto Carramiñana, Instituto Nacional de Astrofísica, Óptica, y Electrónica (Mexico); Michael G. Richer, Jesús Gonzalez-Hernandez, Beatriz Sanchez, Univ. Nacional Autónoma de México (Mexico); Diana Lucero, Ctr. de Ingenieria y Desarrollo (Mexico); Fabian Rosales Ortega, Instituto Nacional de Astrofísica, Óptica, y Electrónica (Mexico); Vicente Bringas-Rico, Ctr. de Ingenieria y Desarrollo (Mexico)

The Telescope of San Pedro Martir (TSPM) is a new ground-based optical telescope project, with a 6.5 meters honeycomb primary mirror, to be built in the National Astronomical Observatory (OAN) located in Baja California, Mexico. The OAN, with an altitude of 2830 meters above sea level, is within the five best places for astronomical observation in the world. It is located 1830 m higher than the atmospheric inversion layer with 57% of photometric nights, 80% of spectroscopic nights and, a sky brightness up to 22 mag/arcsec2 .

The TSPM will be suitable for general science projects intended to improve the knowledge of the universe, as established on the Official Mexican Development Plan for Science and Technology 2014-2018. The telescope is mainly supported by two Mexican institutions, the National Autonomous University of Mexico and the National Institute of Astrophysics Optics and Electronics. It is developed by Mexican scientists from the Center for Engineering and Industrial Development. This development is supported by a Mexican-American scientific cooperation, throught a partnership with the Arizona Steward Observatory, and the Harvard-Smithsonian Astrophysical Observatory. M3 Engineering will be encharged of enclosure and building design.

The TSPM will be designed to allow flexibility and upgradeability in order to maximize resources. It will be based in the optical and mechanical design of the MMT and Magellan telescopes. The TSPM primary mirror and its cell will be provided by the Arizona Mirror Lab. The telescope will be optimized from the near ultraviolet to the near infrared wavelength range (0.35-2.5 μm), but will allow up to 26μm. The TSPM will feature a f/5 Cassegrain optical arrangement and four bent arrangements. Additionally, f/5 and f/11 Nasmyth optical arrangements are also considered.

The concept will allow the use of existing instruments like MMIRS and MEGACAM. Available experience from currently working ground-based telescopes will be integrated with up-to-date technology specially for control and information management systems.

Its mount is the well known azimuth-elevation configuration. The telescope total mass is estimated in about 230 metric tones, with a total azimuth load of 190 metric tones including around 110 metric tones as the total elevation load. A tracking error lower than 0.03 arcsec RMS is expected under steady wind up to 24 Km/hr. A pointing accuracy between 10 and 2 arcsec is planned. The TSPM is in its design phase. It is the first large optical ground-based telescope to be designed and developed primary by Mexican scientist and engineers. This endeavor will result in the improvement of the scientific and technical capabilities of Mexico including: complex scientific instruments development, systems engineering and project management for large engineering projects. In this paper, which aims to gather the attention of the community for further discussions, we present the engineering preliminary design, the basic architecture and challenging technical endeavors of the TSPM project.

9906-28, Session 8

ALMA: from early science into full operations

William R. F. Dent, ALMA (Chile)

ALMA is a $1b-class facility for mm and sub-mm astronomy now operating at 5000m altitude in the north of Chile. The 66 antennas and two correlators provide an order of magnitude improvement in both sensitivity and resolution over previous instruments. Astronomy at these wavelengths ranges from gas and dust in galaxies at the highest redshifts in the early universe through to comets and moons in our solar system; these topics are reflected by the wide range of PI proposals now being received by the observatory. The mm and sub-mm wavelength atmospheric windows available at the ALMA site offer the ability to peer into regions where planets, stars and galaxies form, unhindered by obscuration from dust.

ALMA is now moving from Early Science and Commissioning (where restricted capabilities were available to the user) through to full operations and PI science (providing external users with almost all capabilities). The fraction of available time used for testing, commissioning, antenna integration, and other observatory tasks has decreased from >30% down to approaching 10%. During the last year, typical PI science programs used 36-45 12m-diameter antennas and up to 12 7m-diameter antennas. Over 1500 applications were received for the current round (Cycle 3), and we show the breakdown of PI proposals in terms of science, array configuration and observing band. Seven bands ranging from 90 to 900GHz, and multiple array configurations with baselines from approximately 20m to 10km are now being used. The facility aims to be flexible, allowing rapid change of observing frequency depending on the weather conditions, in particular the precipitable water vapour and the phase stability. PI observing is currently classed either as 'standard', where the observing and data reduction is routine and automatic, or 'non-standard', where the observing method is still being refined, and data reduction is not pipelined and can require manual intervention. Standard observing is up to band 7 (380GHz) and baselines to 2km. Non-standard observing currently includes the longer baselines and higher frequencies. Efforts are being made to broaden the coverage of the standard capabilities.

This paper describes the real, on-sky performance of the system, and compare this with the original specifications. This includes observatory-wide aspects such as number of usable antennas, bands, and 'teething problems' experienced during the early observing Cycles. Also we describe the technical performance (such as receiver and system temperatures), the site performance (PWV and phase stability), and the sensitivity of the final images. We also show some of the results from measurements using the extended capabilities during recent campaigns. These include high frequencies (up to 900GHz), long baselines (up to 16km), solar observing, VLBI and polarisation. These push the limit of both the system and the site.

Finally we show some of the exciting new science coming from ALMA. These include images with resolutions down to 20 milliarcseconds, and sensitivities down to 10 microJansky. Both of these are unprecedented in sub-mm astronomy.

9906-29, Session 8

The Greenland Telescope (GLT): antenna retrofit status and future plans

Philippe Raffin, Ming-Tang Chen, Paul T. P. Ho, Makoto Inoue, Satoki Matsushita, Institute of Astronomy and Astrophysics - Academia Sinica (Taiwan); Raymond Blundell, Timothy J. Norton, Smithsonian Astrophysical Observatory (United States)

Since the ALMA North America Prototype Antenna was awarded to the Smithsonian Astrophysical Observatory (SAO) in 2011, the project partners – the Academia Sinica Institute of Astronomy & Astrophysics (ASIAA) and SAO, have been working towards retrofitting the antenna for cold weather operation prior to shipping to Greenland for millimeter and submillimeter VLBI and submillimeter single dish observations. At the Montreal conference in 2014 we reported on antenna recommissioning tests made at the ALMA test Facility in New Mexico, subsequent antenna disassembly, and major retrofitting tasks required to enable antenna operation possible in the extreme arctic environment of the Greenland site.

A project risk review, which was held at ASIAA in Taipei in April 2015, endorsed plans to deploy the antenna to Thule Air Base (TAB) for VLBI operation at 230 GHz prior to installing the telescope at Summit Station for higher frequency VLBI and submillimeter operation. Here we report on progress made towards antenna refurbishment, including design studies, the fabrication of critical components, testing, and readiness for deployment to Thule.

Current plans call for shipping the bulk of the antenna components and subsystems from the U.S. Navy Base at Norfolk, Virginia to TAB during summer, 2016, and for the pre-assembly and testing of major antenna systems before that date. We have secured a site close to the naval dockyard to store, assemble and test all but the main dish; and many of the critical components required to assemble the antenna up to the elevation axis are beginning to arrive.

During early 2016, the antenna pedestal will be assembled, including the new support cone and the azimuth bearing, to the yoke, cabin, and invar cone and elevation bearings. Following assembly and alignment, the antenna will be disassembled into a few large sub-assemblies, of transportable size, with as much cabling, electronics, and insulation as possible left in place. The receiver cabin HVAC will also be assembled and tested.

While much of the antenna base will be assembled at the Norfolk site, the assembly of some critical elements, such as the entire dish, including back up structure and reflector, will only take place at TAB. The GLT team has already been trained on backup structure assembly procedures at Vertex, the prime contractor for this antenna, and the reflector panels can only be assembled once the dish is mounted on top of the antenna mount

Working with the US National Science Foundation, we have identified a site for antenna deployment at TAB; and negotiations are ongoing with Base Command to enable assembly to proceed as soon as the antenna components arrive in Greenland in July 2016. The assembly is expected to last until early spring of 2017, as the reflector panels need to be assembled at the coldest temperature at Thule, during the winter months, in order to maintain good figure for eventual operation at Isi station at the peak of the ice sheet. Antenna and telescope commissioning should proceed through summer and fall 2017, and early science tests are expected to start during the winter.

9906-30, Session 8

The 6.5-m MMT Telescope: status and plans for the future

Grant Williams, Ricardo Ortiz, William Goble, J. Duane Gibson, MMT Observatory (United States)

The MMT Observatory, a joint venture of the Smithsonian Institution and the University of Arizona, operates the 6.5-m MMT telescope on the summit of Mount Hopkins approximately 45 miles south of Tucson, AZ. The upgraded telescope has been in routine operation for nearly fifteen years and, as such, is a very reliable and productive general purpose astronomical instrument. The telescope can be configured with one of three secondary mirrors that feed more than ten instruments at the Cassegrain focus. The f/9 secondary is used primarily with legacy instruments from the original Multiple Mirror Telescope. The f/5 secondary, together with a multi-element corrector, provides excellent image quality over a wide field-of-view for a more modern set instruments. The deformable f/15 secondary, the first of its kind, provides adaptive optics that enables high spatial resolution studies. Nightly observations are scheduled both classically and in a queue mode. In this paper we provide an overview of the the telescope, its current capabilities, and its performance. We will review the existing suite of instruments and their different modes of operation. We will describe some of the general operations challenges and strategies for the Observatory. Finally, we will discuss plans for the near-term (five years) future including technical upgrades, new instrumentation and routine queue operation of MMIRS and Binospec.

9906-133, Session PS5

Ground-based atmospheric water vapor monitoring system with spectroscopy of radiations at 20-30 GHz and 50-60 GHz bands

Takeo Nagasaki, Osamu Tajima, High Energy Accelerator Research Organization, KEK (Japan); Kentaro Araki, Hiroshi Ishimoto, Meteorological Research Institute (Japan)

There is a big demand for preventing meteorological disasters such as local heavy rainfalls and significant tornadic storms. We propose a novel ground-based measurement system for atmospheric water vapor based on the observation of radiation spectra at 20 – 30 GHz and 50 – 60 GHz band. Time trends of the water vapor estimates a thermodynamic environment in the atmosphere and cloud micro physics. Short-term forecasting and now casting of severe storms are determined by them. There have been some commercial systems [1] [2]. However, their noise temperatures are 10 times higher than intensity of the atmospheric radiation (~ 20 K in the case of Japanese winter). Maintenance of low physical temperature for instruments drastically improves its noise level because the exiting commercial system are operated at ambient condition. Therefore, our cold receiver system identifies a rapid increase of water vapor before clouds generation. At the frequencies between 20 and 30 GHz, our system measures water vapor as a broad absorption peak at 22 GHz and cloud liquid water. Another 50 - 60 GHz band provides supplement information from an Oxygen radiation which contains vertical profiles of physical temperature of molecules in the atmosphere.

We designed our system as simple as possible to deploy the system on top of high buildings, mountains, and on a deck of ship. Our system has a simple transport optical system which has main mirror and wire grid to separate the radiation signal into lower and higher frequency band. For the construction of the compact receiver system, novel technologies which developed for CMB (cosmic microwave background radiation) observation are applied. In particular, a technology to operate a cryocooler on a rotating system [3] and a radio-transparent thermal insulator [4] are key seeds, e.g., cooling and protection of dew condensation in the optical path. At 20 GHz band, the input atmosphere signal is amplified by a HEMT, spectrum shape is simply measured by using a signal analyzer. The 60 GHz receiver is ambient heterodyne receiver and down-convert to 20 GHz because of radiation from Oxygen is high, it is same order as the radiation of ambient. Cold blackbody calibration source of 50 K is implemented inside of the cryostat. The calibration signal is also transported to each receivers via the wire grid. Our system is designed to be less than one cubic meter and low electrical consumption.

We developed a prototype multi-band band receiver. The receiver noise temperature is about 70 K (350 K) at 20 GHz (60 GHz) band which was confirmed by based on Y-factor measurements with 77 K cooled blackbody. We also demonstrated the monitoring of the atmospheric water vapor and radiations from oxygen molecules along to determine in the zenith. We confirmed opacity by our system is consistent with the result of the balloon-borne observations. In this conference, we will present overview of our system including status of development, and results of long-term monitoring.

GroundBIRD: observation of CMB polarization with fast scan modulation and MKIDs

Shugo Oguri, High Energy Accelerator Research Organization, KEK (Japan); Jihoon Choi, Korea Univ. (Korea, Republic of); Thushara R. M. Damayanthi, RIKEN (Japan); Makoto Hattori, Tohoku Univ. (Japan); Masashi Hazumi, High Energy Accelerator Research Organization, KEK (Japan); Hikaru Ishitsuka, The Graduate Univ. for Advanced Studies (Japan); Hiroki Kutsuma, Tohoku Univ. (Japan); Satoru Mima, RIKEN (Japan); Makoto Minowa, The Univ. of Tokyo (Japan); Makoto Nagai, Univ. of Tsukuba (Japan); Taketo Nagasaki, High Energy Accelerator Research Organization, KEK (Japan); Chiko Otani, RIKEN (Japan); Yutaro Sekimoto, National Astronomical Observatory of Japan (Japan); Osamu Tajima, High Energy Accelerator Research Organization, KEK (Japan); Nozomu Tomita, The Univ. of Tokyo (Japan); Eunil Won, Korea Univ. (Korea, Republic of); Tomohisa Uchida, Mitsuhiro Yoshida, High Energy Accelerator Research Organization, KEK (Japan)

Cosmic microwave background radiation (CMB) is an important source of information about the origin of our universe. In particular, large angular scale odd-parity patterns in the CMB polarization, primordial B-modes, are strong evidence for the inflationary universe. GroundBIRD aims to detect them from the ground with novel techniques: high-speed rotation scan system, cold optics, and microwave kinetic inductance detectors (MKIDs). We plan to start observation at Canary Islands in 2017.

The high-speed rotation scan is realized by the operation of the cryocooler on a rotating table. We developed a series of two rotary joints for high-pressure helium gas and electricity lines, which enable connection of helium gas and power supply between the cryocooler on the table and the compressor on the ground. We already achieved cold condition of 0.23 K with a hold time of more than 24 hours under a condition of continuous rotation at 20 rpm. Scan strategy of most ground-based experiments is periodic left–right motion along the azimuth direction. The scan frequency is limited by the mechanical specifications. On the other hand, our rotation scan results in continuous high-speed pointing motion without any deceleration. It allows us a significant expansion of multipole range at 6 < l < 300 while mitigating the effect of 1/f noise.

We hold two mirrors in the cryostat at below 4K. This condition mitigates a radiation noise from the mirror surfaces. The diameter of the aperture window is 30 cm. In shielding from thermal radiation from the aperture, a combination of metal mesh filters (QMC Instruments Ltd.) and radio-transform multi-layer insulations (RT-MLI) is applied. The RT-MLI is a novel thermal radiation blocker. They consist of a set of stacked formed-polystyrene layers. The layers are transparent to radio waves but block infrared radiation. No thermal link is necessary for RT-MLI and the performance of cooling does not vary with the aperture size. This is because its cooling mechanism is radiative cooling similar to conventional MLI. We achieved to maintain the mirrors at 3.4 K on the optical configuration. We also achieved 0.21 K temperature for Helium sorption cooler and demonstrated to operate a MKIDs in the same condition.

MKID is chosen for the focal plane detector array of GroundBIRD. The fast time response (order of 100 us) of MKID is well-matched with our high-speed scan. MKID has another advantage on its scalability because of frequency-division multiplexing readout. The number of readout cables can be kept small, the thermal conduction along the cables is maintained to be small. We plan to observe at 220 GHz (109 pixels) for an understanding of dust emission as well as at 145 GHz (330 pixels) for CMB. We will briefly present about focal plane development, i.e., design and simulation of horn coupled MKIDs, fabrication of them, and their tests.

9906-136, Session PS5

Science-based requirement and operations development for the Maunakea Spectroscopic Explorer

Alan W. McConnachie, Canada-France-Hawaii Telescope (United States) and NRC - Herzberg Astronomy & Astrophysics (Canada)

The Maunakea Spectroscopic Explorer (MSE) is designed to be the largest non-ELT optical/NIR astronomical telescope that will be a fully dedicated facility for multi-object spectroscopy over a broad range of spectral resolutions. We have developed the top level requirements, system architecture and operational concept with close reference to a suite of science reference observations (SROs). The SROs are themselves the result of a detailed re-examination of the science drivers for such a facility in the context of the range of astronomical capabilities anticipated to be available to the international community in the 2025+ era. Here, we discuss this process, the flowdown into technical requirements, and the ongoing science-based development of MSE, with particular reference to the operational concept for the facility.

9906-137, Session PS6

Thai National Telescope beam simulator testbed development status

Christophe Buisset, Apirat Prasit, National Astronomical Research Institute of Thailand (Thailand); Thierry Lépine, Institut d'Optique Graduate School (France) and Lab. Hubert Curien (France); Saran Poshyachinda, National Astronomical Research Institute of Thailand (Thailand)

The Thai National Telescope (TNT) (latitude 18.573725o N, longitude 98.482194o E, altitude 2457 m) is a Ritchey-Chretien Telescope with a primary mirror diameter ?M1 = 2.4 m, a focal ratio f/10 and a central obscuration Obsc = 0.3. The TNT is the main instrument of the Thai National Observatory (TNO) which is located near the summit of the Doi Inthanon, situated in the Chiang Mai Province of Thailand at altitude 2,457 meters. The median seeing on this site is approximately 0.9" and is remarkably stable on most nights, rarely exceeding 2".

The TNO is located in a tropical region and the observing season with quasi-continuous clear sky conditions from November to April. During this observing season, the observing time is mainly dedicated to the astronomical observations to take profit as much as possible of the clear sky conditions. The nights dedicated to the optical activities are then limited to 2 half-nights per month to characterize and improve the performance of the TNT. We thus decided to develop an optical setup to simulate in laboratory conditions the geometry of the TNT output beam and carefully prepare the test to be performed in real conditions.

The setup comprises the sources, 1 collimator, 1 focusing optics and 1 detector. The sources consist of both LED monochromatic sources and of 1 stabilized tungsten source. These sources cover the full visible and near infrared domains, from ? ≈ 400 nm to ? ≈ 1 ?m that is the typical wavelength range currently used by the TNT instruments. The light emitted by the source is injected inside mono-mode or multi-mode fibers of various core diameters that simulate the star image provided by the TNT on various seeing conditions.

The fiber core is placed at the focal plane of 1 Cassegrain telescope of diameter ? = 200mm, focal ratio F/12 and central obstruction Obsc = 0.3 that collimates the light toward an identical Cassegrain telescope (focusing optics). This telescope focuses the light toward the instrument to be tested. Each telescope is mounted on 1 mount with 4 degree of freedom (2 rotations and 2 translations) that was fully designed and manufactured at NARIT. The setup is fully achromatic, and the focal ratio and the central obscuration are similar to the TNT.

The first application of this setup will be the preparation of the TNT optical alignment. This alignment will consist of measuring the TNT output wavefront over the FOV, calculating the in-field variation of the astigmatism coefficients, assessing and correcting the lateral shift between the mirrors M1 and M2. The TNT beam simulator setup will be used to prepare this activity by adjusting the parameters of the wavefront measurement setup in laboratory conditions and by measuring the on-axis and in-field variations of the beam simulator output WFE. The second application of this setup will be the development and the test of the future instruments for the TNT such as a focal reducer or a spectrograph.

In this paper, we present the setup optical and mechanical design, we describe the optical alignment method, we present the performance and we discuss the future configurations of the setup that will be used to test the future TNT optical instruments.

9906-138, Session PS6

The Cherenkov Telescope array on-site integral sensitivity: observing the Crab

Valentina Fioretti, Andrea A. Bulgarelli, INAF - IASF Bologna (Italy); Fabian Schussler, CEA-IRFU (France); Gernot Maier, Deutsches Elektronen-Synchrotron (Germany)

The Cherenkov Telescope Array (CTA) is the future large observatory in the very high energy (VHE) domain. Operating from 20 GeV to 300 TeV, it will be composed of tens of Imaging Air Cherenkov Telescopes (IACTs) displaced in a large area of a few square kilometers in both the southern and northern hemispheres.

Thanks to the wide energy coverage and the tremendous boost in effective area (10 times better than the current IACTs), for the first time a VHE observatory will be able to detect transient phenomena in short exposures. The CTA/DATA On-Site Analysis (OSA) is the work package devoted to the development of ad-hoc pipelines and algorithms to be used at the CTA site for the reconstruction, data quality monitoring, science monitoring and real-time science alerting during observations.

The minimum exposure required to issue a science alert is not a general requirement of the observatory but is a function of the astrophysical object under study, because the ability to detect a given source is determined by the integral sensitivity which, in addition to the CTA Monte Carlo simulations, providing the energy-dependent instrument response (e.g. the effective area and the background rate), requires the spectral distribution of the science target.

The OSA integral sensitivity is computed here for the most studied source at Gamma-rays, the Crab Nebula, for a set of exposures ranging from 1000 seconds to 50 hours, using the full CTA Southern array. The reason for the Crab nebula selection as the first example of OSA integral sensitivity is twofold: (i) its spectral energy distribution, spanning from radio to gamma-rays, covers the entire CTA energy range, so that the cross-correlation of different IACTs and other instruments (e.g. Fermi and AGILE) is needed to model its emission; (ii) it represents, at the time of writing, the standard candle in VHE and it is often used as unit for the IACTs sensitivity.

The effect of different Crab Nebula emission models on the CTA integral sensitivity is evaluated, with the aim of emphasizing the need for representative spectra of the CTA science targets in the evaluation of the OSA use cases. Using the most complete model as input to the OSA integral sensitivity, we obtain a significant detection of the Crab nebula (about 10% of flux at 5 sigma) even for a 1000 second exposure, for a minimum energy less than 10 TeV.

9906-139, Session PS6

Modal vibration testing of the DVA-1 radio telescope

Peter W. G. Byrnes, Gordon Lacy, NRC - Herzberg Institute of Astrophysics (Canada)

The Dish Verification Antenna 1 (DVA-1) is a 15m aperture offset Gregorian radio telescope featuring a rim-supported single piece molded composite primary reflector on an altitude-azimuth pedestal mount. The DVA-1 was completed at the Dominion Radio Astrophysical Observatory (DRAO) in 2014 and has since been used for a variety of engineering tests and observations with excellent performance and results.

Vibration measurements of the DVA-1 telescope were conducted over three days in October 2014 by NSI Herzberg engineers. The purpose of these tests was to measure the first several natural frequencies of the DVA-1 telescope.

Seismic accelerometers were mounted on the antenna structure at specific locations chosen with regard to the analytically predicted mode shapes. Vibratory disturbances were induced by several means: natural wind, step-release of a suspended mass, and impulse hammer impacts. Normal modes were clearly identified by all three methods. Additionally, transfer functions between the azimuth bearing and receiver platform were also obtained. This paper describes the experimental approach, and summarizes some interesting results.

The measured values of the first three natural frequencies were 2.6-2.8Hz, 4.0Hz, and 6.3Hz, agreeing well with available analytical predictions. The range of values associated with the first mode is due to the varying geometery of the altitude drive over its range of motion. Step-release tests were performed at a range of zenith angles, and unexpectedly high damping of the first vibration mode was observed over a narrow range of angles. The likely cause of this phenomenon was determined to be slight mechanical backlash in a single joint located between the dish rim and its support structure, which undergoes a load reversal at that particular zenith angle. This joint has since been adjusted and follow-up vibration measurements are planned to verify that the observed effect has been rectified. The paper will also report these results and any conclusions drawn.

9906-140, Session PS6

A position sensing device for measuring the self-weight load induced displacements of the SRT subreflector

Enrico Urru, Tonino Pisanu, Franco Buffa, Sergio Poppi, Giampaolo Serra, Pasqualino Marongiu, Marco Buttu, Andrea Saba, Pierluigi Ortu, Mauro Pili, INAF - Osservatorio Astronomico di Cagliari (Italy)

The Sardinia Radio Telescope (SRT) metrology team is working on the design and test of the devices needed to maintain as high as possible the antenna efficiency and the pointing performances in the safe weather conditions. The SRT is a fully steerable antenna with a Gregorian optical configuration, equipped with a 64 meters diameter active primary mirror (M1) with a focal length to diameter ratio (f/D) of 0.33 and an elliptical shape secondary mirror (M2) of about 8 meters with an f/D of about 2.35. Moreover thanks to a six degree of freedom system (hexapod) the M2 position can be adjust to guarantee the best possible alignment. The optical configuration of the antenna should be maintained with an alignment accuracy of few tenths of millimeter in order to guarantee the optimal antenna efficiency. The SRT homology configuration has been designed to operate up to 22 GHz frequency with a total RMS surface error of about 600 ?m and repeatable pointing errors of about 5 arcmin, without any measurement or correction for deformations affecting the antenna structure. At higher frequencies (SRT has been designed to operate up to 100 GHz), at which gravitational loads and thermal effects become critical for the antenna performances, accurate devices to check, for instance, the M1 and M2 optical alignment are needed.

Here we present a system consisting of a commercial optical position sensing device (PSD) that, coupled with a laser diode, is able to measure the secondary mirror displacement with respect to the telescope optical axis. We will describe the mechanical assembly realized to align the laser diode and to operate the PSD on board the antenna. The PSD has been integrated in M2, modifying the central flange of the subreflector in order to host two devices. The first device, the PSD, allows us to evaluate the shifts on the X-Y plane orthogonal to the antenna optical axis and the tilts of M2 around the X and Y axis, the second device will be soon installed, in order to measure the displacements along the Z optical axis. The laser diode has been installed in a very stable mount, by using a mechanical system that allows a rapid alignment of the laser with respect to the PSD window. The preliminary tests were performed during night time, when the thermal deformation are not critical, firstly aligning the laser on the PSD with the antenna at the zenith and then moving the antenna in elevation in small steps (from 5° to 90°) reading the corresponding M2 deflections by its ideal position. By varying the antenna elevation and acquiring the PSD data, it is possible to evaluate the overall gravitational effects. Our aim is to check the PSD response in operative measurement conditions, then to optimize the antenna pointing capabilities updating the current M2 lookup table. The results of the measurement campaigns will be shown.

9906-141, Session PS6

Characterization of the mechanical properties of the SOFIA secondary mirror mechanism in a multi-stage approach

Benjamin Greiner, Yannick Lammen, Andreas Reinacher, Alfred Krabbe, Jörg Wagner, Univ. Stuttgart (Germany)

The Stratospheric Observatory for Infrared Astronomy (SOFIA) uses its compact and highly integrated Secondary Mirror Mechanism (SMM) to perform chopping, a technique to determine and subtract infrared background radiation from the signal of the astronomical target. The SMM tilts the secondary mirror in a square wave pattern in order to switch between different portions of the sky. The actuation of this square wave chopping also excites various eigenmodes of the tilt chop mechanism. Specifically, a previously unknown mode at a frequency of 300 Hz disturbs and limits the performance of the chopping controller. In order to determine the nature of the excited eigenmodes and to be able to investigate possible countermeasures various test campaigns as well as finite element model analyzes have been performed. As the flight hardware of the SMM on the operational observatory is not generally available for experimental tests, a test bench with mechanical parts identical to the flight hardware has been designed and manufactured, which allows experimental characterization of the structure without taking time away from science operations. The structural dynamics of the test bench model were characterized in several design stages. Additionally in 2014, during SOFIA's heavy maintenance down time, the SMM flight hardware was removed from the telescope for separate inspection and maintenance. This allowed for a modal test campaign directly using the flight hardware while a dummy aluminum mirror was mounted instead of the original silicon carbide mirror with its sensitive optical surface. All tests employed accelerometers placed on the mechanism and the structure was excited with an impact hammer. Additionally, signals from internal position sensors and from the voltage induced by the motion of the electromagnetic actuators of the mechanism were acquired. A detailed finite element model of the SMM has been created, where model parameters were initially derived from design specifications and drawings. These parameters were updated using eigenfrequencies, mode shapes, and damping parameters derived from the test campaigns. This paper reports on the test campaigns and results of the experimental characterization of the various test bench design stages and of the flight hardware. It presents the identification of

mechanical properties from those tests and the correlation of test bench to flight hardware. Further correlation of the rather coarse mode shape vectors of test data to mode shapes derived from finite element models allows for the identification of those vibration modes which are excited during observatory operation and thus limit the chopping performance. By examining the detailed mode shapes derived by finite element modal analysis we identify those parts of the mirror which contribute primarily to the excited mode, even though they could not be equipped with sensors due to their small size or limited accessibility. The results of this characterization serve as basis for improvements for the current SMM as well as for a next generation advanced chopper.

9906-142, Session PS6

The absolute calibration strategy of the ASTRI SST-2M telescope proposed for the Cherenkov Telescope Array and its external ground-based illumination system

Alberto Segreto, Maria Concetta Maccarone, Osvaldo Catalano, Benedetto Biondo, Carmelo Gargano, Giovanni La Rosa, Francesco Russo, Giuseppe Sottile, Mauro Fiorini, Salvatore Incorvaia, Giorgio Toso, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy)

ASTRI is the end-to-end prototype for the CTA small-size class of telescopes in a dual-mirror configuration (SST-2M) proposed by the Italian National Institute of Astrophysics (INAF) in the framework of the Cherenkov Telescope Array. ASTRI SST-2M has been installed at the Serra La Nave Astrophysical Observatory on Mount Etna (Sicily) and its Performance Verification Phase started in autumn 2015. For the relative pixel calibration and gain monitoring, the ASTRI SST-2M camera is equipped with an internal illumination device, while an external, portable, illumination system, placed at a few km distance from the telescope, will be used for the absolute end-to-end calibration of the telescope spectral response. Moreover analysis of signals induced in the camera pixels by the night sky background (diffuse emission and reference stars) will be used to monitor the long term evolution of the telescope calibration. We present an overview of the ASTRI SST-2M absolute calibration strategy and the external illuminating device that will be used for its spectral calibration.

9906-143, Session PS6

System performance testing of the DVA1 radio telescope

Lewis B. G. Knee, NRC - Herzberg Astronomy & Astrophysics (Canada); Lynn A. Baker, Cornell Univ. (United States); Gary J. Hovey, NRC - Herzberg Astronomy & Astrophysics (Canada); Gordon Lacy, Timothy Robishaw, NRC - Herzberg Astronomy & Astrophysics (Canada); Michael Kesteven, CSIRO Astronomy and Space Science (Australia)

DVA1 (Dish Verification Antenna 1) is an innovative rim-supported single-piece composite-material dish radio telescope developed by the National Research Council of Canada and the US SKA Technology Development Program. It has a feed-high offset Gregorian optical arrangement with a primary surface effective diameter of 15 metres and has been designed for efficient operation to a frequency of at least 10 GHz.

DVA1 has been undergoing mechanical and astronomical system tests since 2014 at the Dominion Radio Astrophysical Observatory (DRAO), with a focus on single-dish performance measurements. Ku band holography measurements of commercial broadcast satellites have been used to measure the effective surface accuracy of the dual-reflector antenna system and to characterize surface stability against thermal, insolation, and wind variations. The measured Ruze efficiency is ~ 0.8 at 10 GHz, indicating good efficiency up to about 20 GHz.

The surface is very stable (~ 10% variation in surface RMS) over the range of environmental conditions able to be tested at the DRAO site.

Astronomical measurements using DVA1 were made in L band using a prototype front end developed for the MeerKAT array by EMSS Antennas in South Africa. Key performance metrics measured in L band include the aperture efficiency, sensitivity (Aeff/Tsys), and tipping curves. The clean shaped optics of the offset Gregorian design, careful attention to feed design, and the high sensitivity of the L band receiver yield a system with high aperture efficiency (~ 0.8), excellent sensitivity (~ 9 m^2/K), and very low spillover contribution to the system temperature. Observations of the 21 cm atomic hydrogen lines towards a number of sources demonstrate the low stray radiation pickup of the antenna.

Testing is ongoing, with a current focus on measuring the polarimetric performance of the antenna on polarized continuum sources and Zeeman observations of 21 cm line sources.

9906-144, Session PS6

Mirror coating and cleaning methodology to maintain the optical performance of the GTC telescope

Manuela Abril-Abril, Agustín Nuñez-Castaín, Luis Alberto Rodríguez-García, Antonio Cabrera-Lavers, GRANTECAN S.A. (Spain)

This paper presents a strategy to optimize GTC telescope optical performance in terms of reflectivity and scattering by means of a suitable combination of mirror coating, CO2 and in-situ cleaning. The analysis is based on repetitive measurements made with an accurate reflecto-scatterometer plus an evolutional model for dust effects over mirror surfaces. The fact that GTC primary mirror is segmented implies specific difficulties to determine the total improvement in image quality compared with a monolithic mirror. Factors such as frequent presence of calima (Saharian dust), optical improvement due to segments recoating and the effects of mirror orientation were also studied. According to our experience, a monthly period of CO2 cleaning was established, except during episodes calima, when a shorter weekly period is much more appropriate. Trends of the main optical parameters (reflectivity at different wavelengths and total integrated scattering) were recorded and analyzed to identify causes for the variation of the mirrors performance. The data also reveals an evolution of the yearly weather conditions. Results presented include the time evolution of the reflectivity and the improvement due to the presented practices for mirror maintenance. An additional degradation of optical parameters appears due to environmental factors. In this sense, lack of cleaning in presence of calima and/or high humidity reduces the effectiveness of the cleaning method. The total reflectivity results from combination of three optical surfaces, hence thresholds were set for individual components and used to select the mirrors to replace and clean. Historical data about total reflectivity is correlated against optical OSIRIS zeropoints evolution and a non-linear relation was established. This relation is applicable for the periods where real measurements are not feasible. Furthermore, an innovative reflectivity measurement method for a segmented mirror is proposed based on zeropoint measurement of unstacked primary. This new method will allow more frequent control of the individual segments relative reflectivity. This will easily disentangle the impact of the different environmental factors from maintenance practices. In that way, their effects over the total instrument throughput will be quantified. Maintenance of telescope optical quality and observing time availability compete for resources, and a suitable trade-off between these should be achieved in order to increase the overall productivity. Finally, to preserve optimal performance

operational limits for environmental conditions, like density of dust, were established.

In summary, a method for measuring optical quality of large segmented telescope has been designed and suitable data processing tools developed. Periodical measurements were recorded for over six years and results analyzed. These data allows us to propose suitable environmental thresholds, optimal mirror cleaning and components replacement rate. All these achievements improve the overall system and observing performance. Likewise they are a valuable baseline for the future large-aperture segmented-mirror telescopes.

9906-145, Session PS6

Antenna pattern characterization of the low-frequency receptor of LOFAR by means of an UAV-mounted artificial test source

Pietro Bolli, INAF - Osservatorio Astronomico di Arcetri (Italy); Fabio Paonessa, IEIIT Torino (Italy); Giuseppe Pupillo, INAF - Istituto di Radioastronomia (Italy); Giuseppe Virone, IEIIT Torino (Italy); Michel Arts, ASTRON (Netherlands); Andrea Lingua, Politecnico di Torino (Italy); Jader Monari, INAF - Istituto di Radioastronomia (Italy); Stefan J. Wijnholds, ASTRON (Netherlands)

In a few years time, the Square Kilometre Array (SKA) will become the most powerful radio telescope on Earth, surpassing the sensitivity of existing instruments by an order of magnitude and able to produce images with extremely high dynamic range. The calibration of SKA is of fundamental importance to successfully achieving the expected performance and it poses significant challenges from different points of view. In particular, instrumental calibration involves accurate electromagnetic (EM) characterization of the array in the real operating conditions. At low frequencies, this is more difficult due to the strong mutual coupling with the environment and due to the fact that it is practically impossible to measure the system in anechoic chambers.

In this perspective, we developed an original system consisting of a radio frequency transmitter mounted on an Unmanned Aerial Vehicle (UAV) for the characterization and calibration of Low-Frequency Aperture Arrays (LFAAs). This artificial source has proved to be a reliable and accurate system for characterizing embedded element patterns and array patterns of the Medicina Array Demonstrator [1] and in the context of the aperture array verification systems of SKA [2]. Recently, interest arose for using this system in the Low Frequency Array (LOFAR), an operational aperture array telescope that is also a pathfinder of the low-frequency element of SKA phase 1. LOFAR consists of about 50 stations spread all over Europe. Each station is composed of two subarrays, each with a different type of dual-polarized receptors: the Low Band Antenna (LBA) and the High Band Antenna covering respectively the frequency range between 10 and 80 MHz and between 120 and 240 MHz.

In this contribution, we show several experimental results obtained by measuring the antenna patterns of the LBA. This activity has been performed to achieve a certain degree of confidence before measuring the embedded element patterns of a complete LOFAR station. In these measurements, the UAV system was used at such low frequencies (below 100 MHz) for the first time. The frequency range of the LBA made this campaign challenging since the antenna on the UAV is not matched (even if it is quite large) below 60 MHz. Therefore, a careful characterization of the test source gain has been performed in order to measure the absolute gain of the LBA. The experimental results, which include both the co-polar and the cross-polar patterns at different frequencies, are in excellent agreement with full-wave EM simulations.

9906-146, Session PS6

Re-aluminising the South African Astronomical Observatory's 74-inch primary mirror

Lisa A. Crause, John W. Stoffels, Brendt Christian, Wilhelmina de Water, Timothy Fransman, Denville Gibbons, Willie P. Koorts, Nelson Machete, Ramotholo R. Sefako, Sinethemba Taaibos, South African Astronomical Observatory (South Africa)

Telescope mirrors are subject to relatively harsh environments and thus require periodic re-aluminisation to maintain their reflectivity. The mirrors also need to be carefully replaced and/or re-aligned to avoid having coating-related throughput gains reduced by subsequent optical misalignment and image quality degradation. The SAAO's Sutherland field station suffers from two environmental challenges: dust and frequent bouts of high humidity when the south-east wind drives moisture rich air up over the observing plateau, often rapidly forming thick orographic cloud. Dust settling on the mirrors thus ends up adhering to the upward-facing optical surfaces and this sticky layer is not removed by CO2 cleaning. The 74-inch primary mirror was unsuccessfully re-aluminised in April 2015. Certain parts of the mirror proved difficult to clean and the resulting coating included rough, hazy white patches where those problem areas had been. Dreading that the patches might indicate that the optical surface had been etched, we used cotton wool soaked with ferric chloride to strip the coating in a couple of small areas. To our immense relief, we confirmed that the problem was restricted to the coating. The aluminising equipment for the 74-inch dates from 1959 and an inspection of the aluminising lab situated beneath the telescope triggered an extensive overhaul of the system. The vacuum tank was thoroughly cleaned and the severely degraded o-ring was replaced. The tungsten filaments in the tank were replaced and all of their connections checked and tightened as required. A new vacuum gauge was installed and the roughing and diffusion pumps were serviced. One of the two diffusion pumps had developed multiple leaks which were traced and repaired. That pump also needed oil and a new o-ring. Given all that had been wrong with the hardware at the time, the quality of the April coating was actually quite impressive! The spruced up aluminising system was put through its paces in mid-November 2015 using a few small mirrors that had been appropriately stripped, cleaned and prepared. This trial-run was successful and so we proceeded to redo the 74-inch primary in late November, using the same de-ionised water, potassium hydroxide, sodium lauryl sulphate, cotton wool, safety gear and cleaning techniques employed by the mirror coating team at the neighbouring Southern African Large Telescope (SALT). The new coating looks superb and an on-sky image quality assessment using bright defocused stars confirmed that the primary required no tip/tilt adjustment. We used SALT's Ocean Optics reflectometer to quantify the improvement in reflectivity. Measurements made on different parts of the dirty primary ranged between 20 and 70%, while the new coating uniformly exceeded 90% at the reference wavelength of 320 nm. The resulting increase in telescope throughput will also be evaluated quantitatively, using spectroscopic domeflats and spectro-photometric standard star observations obtained with our recently upgraded Cassegrain spectrograph (SpUpNIC) before and after the re-aluminising. Our next task will be to re-aluminise the 74-inch secondary and then optically re-align the telescope using the new 74-inch alignment procedure and associated hardware developed in early 2015.

9906-147, Session PS6

Characterization of friction in the 3.6 m Devasthal optical telescope

Tripurari S. Kumar, Aryabhatta Research Institute of Observational Sciences (India); Christian Bastin, AMOS Ltd. (Belgium); Brijesh Kumar, Aryabhatta Research Institute of Observational Sciences (India)

In this paper, we present friction characterization of the 3.6 m Devasthal optical telescope installed in the year 2015 at Aryabhatta Research Institute of Observational Sciences (ARIES), Nainital. The telescope azimuth axis is supported on a hydrostatic bearing while the altitude and rotator axes are supported on hydrodynamic bearings. Both altitude and azimuth axes are driven directly by high power brushless D.C (BLDC) motors and the rotator is driven by BLDC motor via a gearbox. This system is designed by Advanced Mechanical and Optical Systems (AMOS), Belgium and tuned to achieve tracking accuracy better than 0.1 arcsec RMS. Friction poses control related problems at such low speeds hence it is important to periodically characterize the behaviour at each axes. Compensation is necessary if the friction behaviour changes over the time and starts dominating the overall system response. For identifying friction each axis of telescope is rotated at different constant speeds and speed versus torque maps are generated. The LuGre model for friction is employed and nonlinear optimization is performed in Matlab to identify the four static parameters of friction. The behaviour of friction for each axis is presented and the results are discussed.

9906-148, Session PS6

Collimating the Gemini telescopes using a peripheral wavefront sensor

Thomas Schneider, Gemini Observatory (United States); Thomas Hayward, Gemini Observatory (Chile); Andrew Stephens, Katherine C. Roth, Gemini Observatory (United States)

We have developed an improved technique to collimate the Gemini telescopes using the Peripheral Wavefront Sensors (PWFS) to measure focal plane offset and tilt. For several years prior to 2014, observers at Gemini North noticed a variation in the focus Zernike term of about +/-30 µm when guiding with the PWFS. This variation was originally attributed to a tilt of the PWFS rotary table, and plans were made to shim the table. Further testing, however, revealed that it was actually due to an incorrect tilt of the secondary mirror (M2), causing the curved focal plane to be both offset and slightly tilted relative to the PWFS axis. Gemini's normal tuning technique adjusts the M2 offset to remove coma. Due to the coma insensitive Ritchey-Chrétien design of the telescopes there is no Seidel comatic field pattern typical of an aligned telescope. Instead a constant comatic field pattern occurs from either tilt or decenter of M2, and patterns arising from tilt can be eliminated with the appropriate decenter. For the Gemini telescopes, a zero-coma condition alone does not guarantee proper telescope collimation. The new technique measures PWFS focus variation around the periphery of the imaging field, 6 arcminutes off-axis, by programming the telescope pointing to move in a circle while PWFS tracks a guide star, completing a full circle in about 20 minutes. The measured focus variation is then used to infer the focal plane offset and corresponding M2 tilt, and the tilt and decenter offset are then adjusted to zero both focus variation and coma and achieve true collimation. The technique permits correction of the erroneous M2 tilt to <~ 30 arcseconds, corresponding to a wavefront error <~ 3 µm, limited by short-period variations of the focus.

9906-149, Session PS6

Simulation of the wavefront sensing of the active primary mirror system for the 2.1-m telescope of the SPMO

Jose A. Araiza-Duran, Instituto Nacional de Astrofísica, Óptica y Electrónica (Mexico) and Univ. Nacional Autónoma de México (Mexico); Esteban Luna, Univ. Nacional Autónoma de México (Mexico); Alejandro Cornejo-Rodríguez, Instituto Nacional de Astrofísica, Óptica y Electrónica (Mexico)

In this work we present a simulation of the wave-front sensing of the active primary mirror system for the 2.1-m telescope of the San Pedro Mártir's Observatory (SPMO) by Non-Linear Curvature Wave-front Sensing (nl-CWFS). The active cell from the SPMO have a passive support system intended to allow us to induce and correct deformations of azimuthal frequency 2 and 3, such as astigmatism and comma, according to their Zernike expansions. The purpose of the active system is to control the pressure in each of the 18 actuators (air bags) so that the load carried and the desired deformation and position of the mirror are kept to their desired values. For that, measuring the wave-front produced by the active primary mirror is an important task to do, so that the best performance of the active cell can be assured. The nl-CWFS method is derived from the curvature wave-front sensing (CWFS) concept but using a non-linear phase retrieval wave-front reconstruction procedure. This technique offers a method that can be performed without having to include extra equipment to the telescope delivering high precision measurement. Different wave-front techniques have been employed on this telescope's active cell and now the nl-CWFS is going to be simulated, waiting for a future work with experimental images. The active cell is going to be tested by changing its actuators values. In each active cell state, defocused images from either focal plane are simulated and the wave-front reconstruction is performed by using the Gerchberg-Saxton (GS) phase diversity algorithm. The GS algorithm is an iterative phase retrieval scheme which requires a pair of light distributions in defocus pupil planes. The wave-front is propagated via Fourier Transform (Fresnel propagation) from one pupil plane to another and the phase information at the resulting propagated plane is preserved while the known pupil plane amplitude is used to apply constrains to the next wave-front propagation. The algorithm begins with an estimate of the first light distribution, with a phase that usually is taken to be zero or any random value. The wave-front is iteratively propagated between the defocused planes until the phase extracted between propagations converges. The telescope simulations are performed by ZEMAX and MATLAB working together. In ZEMAX the model of the 2.1-m telescope of the SPMO is used to obtain the information of the Zernike Polynomials in a specific position in the detector while the defocus images are created by moving the secondary mirror up and down. The MATLAB code simulates the effect of the active cell in the primary mirror and introduced to the ZEMAX file, then the routine will extract the Zernike Polynomials generated to simulate the defocus pupil images. The wave-front reconstruction algorithm is discussed, the system's configuration used in each simulation, the detector properties, and error obtain from the measurement are mentioned. Our main interest is to study the measure the wave-front of the telescope, the sensitivity of the method, considerations that have to be taken into account related with seeing conditions, and considerations from sampling conditions.

9906-150, Session PS6

Addressing chronic operational issues at the W. M. Keck Observatory

Thomas Nordin, Richard Matsuda, W. M. Keck Observatory (United States)

The W. M. Keck Observatory (WMKO) has a good track record at addressing large critical faults which impact observing. Our performance tracking and correcting chronic minor faults has been mixed, yet this class of problems has a significant negative impact on scientific productivity and staff effectiveness. We have taken steps to address this shortcoming. We describe the creation of a program to identify, categorize and rank these chronic operational issues, track them over time, and develop management options for their resolution. The success of the program at identifying these chronic operational issues and the advantages of dedicating observatory resources to this endeavor are presented.

9906-151, Session PS6

Point-diffraction interferometer for radio telescopes

Taishi Okumura, Hiroaki Imada, Makoto Nagai, Tom Nitta, Naomasa Nakai, Nario Kuno, Univ. of Tsukuba (Japan)

We propose a novel wavefront sensor in radio bands with a point diffraction interferometer (PDI) which is one of the wavefront sensors. A small object to work as a point source divides an incident wave into a reference wave and a test wave. Wavefront errors can be estimated with interferograms of the two waves.

Millerd et al. (2004) and Imada et al. (2015) discussed PDIs using a polarizing point-diffraction beam splitter (PPBS). The PPBS has a polarizing pinhole at its center, while the other region than the pinhole has a different polarizing property from that of the pinhole. The beams passing through the pinhole and the other region are orthogonally polarized, and work as the reference beam and the test beam, respectively, since only the latter carries wavefront errors from the upper stream. Millerd et al. (2004) demonstrated a PDI with the PPBS at a focal plane and a phase mask attached to a detector array at a pupil plane. It is assumed that amplitude and phase changes are very little in a small region. Interferograms are collected with each unit cell comprised with four pixels in the phase mask that provide four discrete phase shifts. Imada et al. (2015) proposed another system using both of the reflected and transmitted beams split by the PPBS. A Savart plate is put on each beam path, while one of the paths has a quarter-wave plate. The Savart plate makes a phase difference of pi radians and quarter-wave plate introduces pi/4 shift, then interferograms with four different phase shifts are obtained simultaneously. Since the reflected and transmitted beams are utilized, this method needs an ordinary camera instead of the pixelated unit cells seen in Millerd's method and can achieve higher precision and efficiency, though the optical system become more complicated.

In this work, we propose a new PDI method with a certain kind of detector array which enables an optical system to be free of sophisticated optical elements (e.g., the phase mask or quarter-wave plate). An optical system proposed here has one lens and PPBS only, and needs either the transmitted or reflected beam. The reference and test beam can be split via polarizations and guided to a superconducting delay circuit with slot antennas. The circuit modulates the phase of the reference wave by 0, pi/2, pi, and 3pi/2 radians; we can take four interferograms of the reference and test beams with different phase shifts, simultaneously. It is shown that a complex Fourier transform can be obtained with the interferograms at the plane of the detector.

Let us consider a case where the PPBS is set at a pupil plane and the detector array at a focal plane. In this case, a complex Fourier transform of the electric field at the pupil plane can be obtained at the focal plane. We can measure wavefront errors due to the optical system of an operating telescope if we install a detector array proposed and a PPBS without any other modifications.

9906-152, Session PS6

Temporal characterization of Zernike decomposition of atmospheric turbulence

Adam Snyder, Kavli Institute for Particle Astrophysics & Cosmology (United States) and SLAC National Accelerator Lab. (United States) and Stanford Univ. (United States); Srikar Srinath, Univ. of California, Santa Cruz (United States); Bruce A. Macintosh, Kavli Institute for Particle Astrophysics & Cosmology (United States); Aaron J. Roodman, SLAC National Accelerator Lab. (United States) and Kavli Institute for Particle Astrophysics & Cosmology (United States)

Atmospheric turbulence limits the performance of ground-based surveys such as the future Large Synoptic Survey Telescope (LSST). LSST uses an active optics system to adjust the alignment of the secondary mirror and camera and the optical figure of both the secondary and the primary/tertiary mirrors to restore the optics towards its optimal setting in response. The operation of this system depends critically on the covariance matrix for the measurements, in this case coefficients of Zernike polynomials describing the pupil-plane wavefront, which encapsulates the amount of noise present in the control system. While currently, LSST estimates the covariance matrix from Kolmogorov atmospheric turbulence simulations, ideally this should be supported by data. Using pseudo-open loop phase maps, reconstructed from deformable mirror commands obtained from the Gemini Planet Imager Adaptive Optics telemetry, estimates are made for the variation in wavefront, as a function of the spatial and temporal frequencies. This analysis is done by performing Zernike polynomial fits to the instantaneous phase maps, and calculating the resulting temporal power spectra for each Zernike coefficient. The time averaged covariances, over 60 second observations, are calculated and compared to the results of the Kolmogorov atmosphere simulations currently used by LSST. Longer time-series exposures allow for a characterization of how the wavefront variation due to atmospheric turbulence average over different time-scales, through study of the Zernike variances as a function of averaging time. Noticeable deviations from the Kolmogorov simulations have been observed in the scale of the Zernike coefficient variances, and the spatial and temporal spectral density power exponents.

9906-153, Session PS6

A new telescope control system for the Telescopio Nazionale Galileo II: azimut and elevation axes

Adriano Ghedina, Manuel Gonzalez, Héctor Pérez Ventura, Luis Riverol, Fundación Galileo Galilei - INAF (Spain)

TNG is a 4m class active optics telescope at the observatory of Roque de Los Muchachos. In the framework of keeping optimum performances during observation and continuous reliability the telescope control system (TCS) of the TNG is going through a deep upgrade after nearly 20 years of service. The original glass encoders and bulb lamp heads are substituted with modern steel scale drums and scanning units. The obsolete electronic racks and computers for the control loops are replaced with modern and compact commercial drivers with a net improvement in the tracking error RMS. In order to minimize the impact on the number of nights lost during the mechanical and electronic changes in the TCS the new TCS is developed and tested in parallel to the existing one and three steps will be taken to achieve the full upgrade. We describe here the second step that affected the main axes of the telescope, AZ and EL.

9906-154, Session PS6

The first Aluminum coating of the 3700 mm primary mirror of the Devasthal Optical Telescope

Krishna Reddy Bheemireddy, Maheswar Gopinathan, Jayshreekar Pant, Amitesh Omar, Brijesh Kumar, Wahab Uddin, Aryabhatta Research Institute of Observational Sciences (India); Nirmal Kumar, Indian Institute of Astrophysics (India)

The modern day very large telescope mirrors are a marvel of engineering and glass making, having a very precise curved shape and surfaces polished to within a few wavelengths of light. These large mirror surfaces are covered with a thin layer of highly reflecting material (normally aluminium/silver), ensures approximately 90% of the photons from stars impinging on the mirror to be registered by the sensitive telescope instruments. The optical telescope mirror coatings used in the observatories get damaged and tarnished over time due to oxidation, humidity, dust, impact of charged particles from space etc. In order to maintain the accuracy of observations these mirrors must be recoated frequently. For this purpose the Coating plant to do the aluminium coating on primary mirror of the 3.6m Devasthal Optical Telescope is installed by HHV, india and commissioned in the extension building of the telescope. The coating unit consists of a vacuum chamber fabricated out of stainless steel, with 2 halves, torrispherical dished ends welded with flanges, top lid sits on the bottom chamber separated by two viton O-rings. Motor controlled wiffle tree assembly is in the bottom chamber for rotating the mirror while coating process. Magnetron sputtering technique (one of the PVD methods) is used for the coating. Sputtering is a plasma-assisted technique that creates a vapor from the source target through bombardment with accelerated gaseous ions (typically Argon). To do this the coating chamber is evacuated with the help of rotary, roots and cryo pumps to get vacuum of 10^-6 mbar level before coating and ion beam cleaning. A washing unit is also installed for cleaning of the primary mirror. Initially the primary mirror of the 3.6m Devasthal Optical Telescope is uncoated polished zerodur glass blank supplied by LZOS/AMOS. The primary mirror is cleaned very carefully with the help of diluted acidic, basic solutions and distilled water. The primary mirror is handled with the help of 10 ton cranes and mirror handling tool to place it on wiffle tree of the washing unit as well as the coating chamber. We did proper rehearsal with dummy mirror prior to the actual mirror. Ion beam cleaning of the primary mirror is done for 35 minutes at vacuum level of 10^-2 mbar using rotary and roots pumps for good adhesion of the coating. Magnetron sputtering is done at a vacuum of 10^-3 mbar for the aluminium deposition for 100 minutes with the waffle tree speed of 2 RPM. Argon gas is used in the ion beam cleaning and the magnetron sputtering. Reflectivity and its uniformity, coating thickness and its uniformity measurements have been done in our optics lab and in HHV. We got the reflectivity of the samples is around 85-88%. The thickness of the samples is 102nm +/-3nm which is supposed to be 100nm+/-5nm over the wavelength range from 400-1000nm. For this test we have used the samples of size 75X25X1.5 mm by placing on a holder with the seperation of around 150 mm. Initially sputtering is run for 75 minutes with 5kW power of magnetron, later the sputtering is done for 100 minutes with the same power to achieve the proper optical density. The coating thickness of the samples is measured with optical profiler, stylus profiler and the reflectivity is measured by VW-experimental set up in optics lab and also with Perkin elmer spectrophotometer. Scotch tape pull test is done to verify adhesivity of the coating. We present here a brief description of the coating plant, Mirror cleaning and coating procedures and the testing results of the samples.

9906-155, Session PS6

Temperature characterization of the CITIROC front-end chip of the ASTRI SST-2M Cherenkov camera

Domenico Impiombato, Salvatore Giarrusso, Teresa Mineo, Osvaldo Catalano, Carmelo Gargano, Giovanni La Rosa, Francesco Russo, Giuseppe Sottile, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Giovanni Bonanno, Salvatore Garozzo, Davide Marano, Giuseppe Romeo, INAF - Osservatorio Astrofisico di Catania (Italy)

The Cherenkov Imaging Telescope Integrated Read Out Chip, CITIROC, is the chip adopted as front-end for the focal plane camera of the Cherenkov telescope ASTRI SST-2M, proposed as small size telescope for the CTA observatory.

The telescope, operating in the energy range from a few TeV up to 100 TeV, is characterized by innovative technological solutions. The optical system is arranged in a dual-mirror configuration and the focal plane camera consists of a matrix of multi-pixel silicon photo-multipliers. Among others, one of the most important project issue consists in the thermal characterization of the entire camera.

While the ASTRI SST-2 M prototype camera is thermo controlled in a narrow temperature range, in the new generation Mini-Array cameras the thermal control could be relaxed with a considerable gain in terms of power consumption, cost and simplicity. So, a study of the temperature dependence of the camera components is needed. The present work addresses this issue showing the results of the measurements carried out to study the behavior of CITIROC as a function of the temperature. We investigated the pedestal stability, the linearity of the charge output signal, the gain and the trigger uniformity in the temperature range 15-30 °C. Our results show, for the above-mentioned characteristics, that the measured differences varying the temperature, are at the level of a few percent.

9906-156, Session PS6

Delivery, installation, on-sky verification of Hobby Eberly Telescope wide-field corrector

Hanshin Lee, Gary J. Hill, John M. Good, Brian L. Vattiat, The Univ. of Texas at Austin (United States); Matthew Shertrone, Hobby-Eberly Telescope (United States); Hermanus Kriel, The Univ. of Texas at Austin (United States) and Hobby-Eberly Telescope (United States); Jerry Martin, Emily Schroeder Mrozinski, Hobby-Eberly Telescope (United States); Chang Jin Oh, College of Optical Sciences, The Univ. of Arizona (United States); Eric Frater, Bryan K. Smith, James H. Burge, The Univ. of Arizona (United States)

The Hobby-Eberly Telescope (HET), located in West Texas at the McDonald Observatory, operates with a fixed segmented primary (M1) and has a tracker, which moves the prime-focus corrector and instrument package to track the sidereal and non-sidereal motions of objects. We have completed a major multi-year upgrade of the HET that has substantially increased the pupil size to 10 meters and the field of view to 22 arcminutes by deploying the new Wide Field Corrector (WFC), new tracker system, and new Prime Focus Instrument Package (PFIP). The focus of this paper is on the delivery, installation, and on-sky verification of the WFC, of which fabrication was sub-contracted to the College of Optical Sciences at the University of Arizona. We details the transportation from Tucson to the HET, on-site ground verification test results, post-installation static

alignment among the WFC, PFIP, and M1, and on-sky verification of alignment and image quality via deploying multiple wavefront sensors across 22 arcminutes field of view. The new wide field HET will feed the revolutionary new integral field spectrograph called VIRUS, in support of the Hobby-Eberly Telescope Dark Energy Experiment (HETDEX), a new low resolution spectrograph (LRS2), an upgraded high resolution spectrograph (HRS2), and later the Habitable Zone Planet Finder (HPF).

9906-157, Session PS6

Progress on the 1.8m Solar Telescope: the CLST

Changhui Rao, Naiting Gu, Lei Zhu, Cheng Li, Jinglong Huang, Yuntao Chen, Yangyi Liu, Benxi Yao, Zhiyong Wang, Xuedong Cao, Ming Zhang, Hong Liu, Yongjian Wan, Hao Xian, Wenli Ma, Institute of Optics and Electronics (China)

In order to study some special solar activities, such as the emergence, evolution and disappearance progress of the sunspot and magnetic flux, and the key role of magnetic field, a new 1.8-meter size high-resolution solar telescope —the CLST will be built in the Institute of Optics and Electronics(IOE), Chinese Academy of Science(CAS). The CLST has a classic Gregorian configuration, alt-azimuth mount, retractable dome. A 1.8m primary mirror with honeycomb sandwiches structure made by using ULE material will reduce about 70% of weight. Thermal controlling system will also be equipped for the CLST, which including Heat-Stop, primary mirror, tube truss, mount and the other optics elements. An experimental system for validating thermal controlling of primary mirror and Heat-Stop has been built, and the temperature tracking results will be illustrated in this paper. Currently, we have finished the detailed design of the CLST, and some important components also have been manufactured and finished. According to our scheduler, the CLST will be finished in 2017. In this paper, we describe some important progresses and the latest status of the CLST project during these two years. Certainly, the future plan will also be described in our oral report.

9906-158, Session PS6

Sky pointing direction reconstruction resolution studies for a precision pointing device for the large-size telescopes of the Cherenkov Telescope Array

Robert M. Wagner, Gerrit Spengler, Stockholm Univ. (Sweden)

The performance of an optical camera system is characterized with respect to its suitability to serve as a sky pointing direction monitoring device for the 23-m diameter Large-Size Telescopes (LST) of the future Cherenkov Telescope Array (CTA). Test data sets of sky pictures taken with a sensitive commercial CCD camera (Allied Vision Technologies BigEye B-132G) in combination with a commercial wide-field lens (Walimex Pro 85mm f/1.4) are analyzed with the astrometry.net software package. The accuracy of the image center sky coordinate reconstruction is studied under varying conditions for test data set taking and compared with science requirements imposed for CTA and LST. Conclusions with respect to the performance and limitations of the investigated experimental setup to serve as a precision monitoring device for the LST telescopes of the planned CTA observatory are drawn.

9906-159, Session PS6

The Stratospheric Observatory for Infrared Astronomy (SOFIA) at full operational capability: status and performance

Pasquale Temi, NASA Ames Research Ctr. (United States)

The Stratospheric Observatory for Infrared Astronomy (SOFIA) has completed major development activities, and it has transitioned into full operational status. With the completion of three observing cycles and the acquisition of a large engineering data set we are able to make a comprehensive assessment of the observatory performance and capabilities. This paper describe the current status of the observatory with an emphasis on its mission performance. We focus on certain areas such as image stabilization, pointing, and tracking which pose specific challenges to the Observatory.

9906-160, Session PS6

Experimental studies on near-field holographic antenna measurement

Yingxi Zuo, Linfen Xu, Hongye An, Jixian Sun, Zheng Lou, Ji Yang, Xuguo Zhang, Zhenqiang Li, Dengrong Lu, Xinghai Pang, Yang Li, Purple Mountain Observatory (China)

Dome A 5m Terahertz Explorer (DATE5) is a proposed telescope to be deployed at Dome A, Antarctica. According to the conceptual design of DATE5 antenna, error budget allocated to the reflector panels setting is no more than 5 microns rms, which is very challenging for on-site surface measurement. Near-field radio holography may be the best way for DATE5 surface measurement for panel adjustments to meet the accuracy requirement.

A near-field radio holography system operating in the 3-mm waveband have been developed as a prototype for DATE5. The dual-channel receiver frontend unit is mounted in the vicinity of the primary focus of an antenna under test, with a signal horn illuminating the reflector and a reference horn, mounted back to the signal horn, pointing to a near-field transmitter. The local oscillator is also mounted in the frontend unit.

Experimental measurements at 92 GHz have been made on a 1.45-m test antenna which is a single-piece parabolic dish made from CFRP sandwich. The transmitter is located 63 m away from the antenna on a tower, with an observing elevation around 19 degrees. The experiments show that, during the night time at which the ambient temperature doesn't vary rapidly, a 75-minute repeatability (repeating measurement 3 times) of ~2.3 microns rms has been achieved, with an aperture spatial resolution of 46 mm. In order to measure a known surface change we attached a piece of aluminum foil with a thickness of 43~47 microns to the reflector. By making difference between the holographic measurements before and after the foil attached we obtained a surface change of approximately 45 microns at the foil position, which met with the foil thickness. Random errors of the experiment system, such as the pointing error, the amplitude and phase variations of the correlation receiver, have been evaluated and their contributions to the derived surface error have been simulated, indicating that the relatively poor pointing accuracy of the test antenna pedestal is the major contribution to the repeatability, and better repeatability will be expected if the pointing accuracy improves.

During the holographic data processing, we need to fit and remove 6 phase terms (constant, 2 linear gradients in the horizontal and vertical directions, 3 focus translations) from the aperture field. These terms account for a phase offset, an antenna pointing error and a small vector displacement of the signal horn relative to the nominal position. After long-time repeated measurements we have observed regular variations of the

fitted terms, that we believe to be correlated with the ambient temperature and sunshine direction. This implies that if the temperature distribution of the antenna structure are measured simultaneously, we can by this means obtain the relation of the structure temperature distribution to the variation of pointing and optimum signal horn position. This is very helpful for a telescope to improve the pointing accuracy and aperture efficiency, and also for verifying the related finite element analysis.

9906-161, Session PS6

Mechanical analysis and measurement of wheel-rail contact system in large aperture radio telescope

Zhiping Chen, Hangzhou Dianzi Univ. (China); Deqing Kong, National Astronomical Observatories (China); Chunguang Li, Nanjie Zhu, Hangzhou Dianzi Univ. (China); Hu-li Shi, National Astronomical Observatories (China)

The azimuth rotating part of a large aperture radio telescope usually apply one wheel-rail system; therefore, the impact of wheel-rail pointing errors and the problem of wheel-rail wear are very important to the antenna's point accuracy. This paper first discusses the wheel-rail rolling contact theory and some specific features in large aperture radio telescope. Then builds one 3D model of wheel-rail contact system according to the parameters of 50m antenna in China, and analyzes it by one whole body in MSC.Patran/Nastran. Next we use the multi-body dynamic method to build the model of wheel-rail and simulate it in RecurDyn software. We compare the two results and find that the coupling of rigid-body and soft-body is more important to the contact deformation. And also the results point out the crevice's influence on the mechanical properties of wheel-rail contact system. Finally by some experiments and measurements of 50m antenna, we present some useful measurements for large aperture radio telescope and the testing results show that the multi-body dynamic method is more suitable to the mechanical analysis of wheel-rail contact system.

9906-163, Session PS6

The Huntsman Telephoto Array: low surface brightness imaging with COTS optics

Anthony J. Horton, Australian Astronomical Observatory (Australia); Lee R. Spitler, Macquarie Univ. (Australia); Steve Lee, Australian Astronomical Observatory (Australia)

The Huntsman Telephoto Array is a dedicated imaging telescope assembled from an array of commercial off the shelf (COTS) optics. The primary science goal is the study of the signatures of galaxy formation through low surface brightness imaging. Simulations of galaxy formation predict an abundance of structures such as streams, shells, tails and dwarf satellites however they generally have very low surface brightness which makes them difficult to observe at distances much beyond the Local Group, where resolved star counts become impractical and integrated starlight imaging must be used. The ultimate sensitivity of low surface brightness imaging such as this is typically limited by systematic errors rather than photon statistics, e.g. scattered light and internal reflections, sky subtraction and flat fielding errors. There is evidence that small telescopes can have an advantage over large professional telescope in terms of lower instrumental systematics, and the competitiveness of small COTS optics for low surface brightness imaging has been demonstrated by the Dragonfly Telephoto Array. Dragonfly is based on an array of 10 Canon 400mm f/2.8 telephoto camera lenses and has achieved impressive results, such as the discovery of a new class of 'Ultra-Diffuse Galaxies' in the Coma cluster. Huntsman provides a similar observing facility for the southern skies while also serving as a testbed for long duration side-by-side comparisons of COTS optical equipment. While the majority of the observing time will be dedicated to the primary programme of low surface brightness imaging in g' and r' bands we anticipate narrowband imaging during bright time and Huntsman will also contribute to the optical follow up of gravitational wave detections from the LIGO/Virgo consortium.

In its initial configuration the Huntsman Telephoto Array incorporates an array of 5 Canon 400 mm f/2.8 telephoto lenses equipped with SBIG STF-8300M CCD cameras with a field of view of 2.6 x 2.0 degree and one 11 inch Celestron Rowe-Ackerman Schmidt Astrograph (RASA) with FLI Microline ML11002 camera with a field of view of 3.3 x 2.2 degrees. The system has an overall collecting area of 0.12m^2 and etendue of 0.76m^2 deg^2 and we plan upgrades this year which will increase the collecting area by a further 50% and double the etendue. The telescope is very cost effective due to maximal use of COTS components. The optics, CCD cameras, telescope mount, telescope dome, dome control system and other electronics are all standard commercial items. The only custom components are support structures for the optics, camera mounting adaptors and optical bandpass filters. Total hardware costs for the project have been approximately AUD $200,000. The Huntsman is currently undergoing commissioning at Siding Spring Observatory in Australia.

9906-164, Session PS6

The Blanco Telescope and its instruments: a status report

Timothy M. C. Abbott, Alistair R. Walker, Sean D. Points, David J. James, Brooke Gregory, Roberto Tighe, Esteban Parkes, Rolando E. Cantarutti, Michael Warner, Omar Estay, Manuel Martínez, Edison Bustos, Marco A. Bonati, Andrés Montané, Freddy Muñoz Arancibia, Patricio Schurter, Cerro Tololo Inter-American Observatory (Chile)

In recent years the V. M. Blanco 4-m telescope at Cerro Tololo Inter-American Observatory (CTIO) has been renovated for use as a platform for a completely new suite of instruments: DECam, a 520-megapixel optical imager, COSMOS, a multi-object optical imaging spectrograph, and ARCoIRIS, a near-infrared imaging spectrograph. This has had considerable impact, both internally to CTIO and for its wider community of observers. In this paper, we report on the performance of the renovated facility, ongoing improvements, lessons learned during the deployment of the new instruments, how practical operations have adapted to them, unexpected phenomena and subsequent responses. We conclude by discussing the role for the Blanco telescope in the era of LSST and the new generation of extremely large telescopes.

9906-165, Session PS6

The 3,6 m Indo-Belgian Devasthal Optical Telescope: performance results on site

Nathalie Ninane, Christian Bastin, Carlo Flebus, AMOS Ltd. (Belgium); Brijesh Kumar, Aryabhatta Research Institute of Observational Sciences (India)

AMOS SA has been awarded the contract for the design, manufacturing, assembly, tests and on site installation (Devasthal, Nainital in central Himalayan region) of the 3.6 m Indo-Belgian Devasthal Optical Telescope (IDOT).

The telescope has Ritchey-Chrétien optical configuration with one axial and two side Cassegrain ports. The meniscus primary mirror is active and it is supported by pneumatic actuators. The azimuth axis system is equipped with hydrostatic bearing.

After successful factory acceptance at AMOS SA, the telescope has been dismounted, packed, transported, and re-mounted on site. This paper provides the final performances (i.e. image quality, pointing and tracking) measured during sky tests at Devasthal Observatory.

9906-166, Session PS6

Alignment procedure for the South African Astronomical Observatory's 74-inch (1.9-m) telescope

John A. Booth, Large Telescope Consulting Engineering (United States); Lisa A. Crause, South African Astronomical Observatory (South Africa); David R. Doss, McDonald Observatory (United States); Egan Loubser, James E. O'Connor, Craig Sass, Amanda A. Sickafoose, Hannah L. Worters, South African Astronomical Observatory (South Africa)

A great deal of effort has gone into improving the performance and reliability of the SAAO's 74-inch telescope during the past year. This includes replacing the telescope encoders, refining the pointing model, water-proofing the dome and shutter, replacing the old fibre infrastructure and increasing the telescope throughput – the latter by re-aluminising the primary and correctly aligning the mirrors. The re-aluminising is described in AS103-149 and here we present the procedure developed to ensure the optimal alignment of the telescope mirrors. This technique is based on the process used to align the 107-inch Harlan J. Smith Telescope at McDonald Observatory in West Texas, adapted to suit the SAAO 74-inch. Being an optically slow telescope (F/18 at the Cassegrain focus), the alignment of the 74-inch is insensitive to translation, only tip/tilt adjustment of the two mirrors is required. The equipment list includes a Taylor Hobson Micro Alignment Telescope (AT) and a custom-built mount employing high precision adjusters to provide the necessary X-Y and tip/tilt adjustment of the AT. This mount securely attaches the AT to the Cassegrain port on the 74-inch instrument rotator, allowing the AT to be rotated back and forth on the telescope's tail-piece while pointing up at the secondary mirror through the Cassegrain hole. A set of crosswires is arbitrarily set up atop the central baffle in the primary mirror, and a piece of graph paper is secured in front of the secondary mirror. With the AT focused on the crosswire, the tail-piece of the telescope is rotated back and forth through 180 degrees and the crosswire adjusted (iteratively) until the crosswire no longer describes an arc in the AT as the tail-piece rotates. This process is repeated with the graph paper and so the crosswire and graph paper become the near and far references that mark the rotation axis of the instrument rotator. We define this rotation axis to be the optical axis of the telescope, since the instruments attach to the tail-piece and this is what counts. Once that axis is defined by the two points in space (viewable individually at the appropriate AT focus settings), the AT has to be translated and adjusted in tip/tilt to place it on the optical axis of the telescope. A custom-made pinhole, illuminated by a bright LED, is centred on the AT axis and this bright pip gets reflected back towards the AT by the secondary mirror. Viewing the return spot in the AT allows the secondary to be adjusted in tip/tilt to bring it into auto-collimation with the AT. With the secondary thus aligned, the AT, crosswire and graph paper can be removed and an eyepiece (or wavefront camera) installed at the Cassegrain port. Comatic star images indicate the need to tip/tilt the primary mirror to align it to the secondary. Tuning out a brightness gradient seen in an out-of-focus image of a bright star may also be used as feedback when adjusting the tip/tilt of the primary mirror to null coma.

9906-167, Session PS6

HET wide-field upgrade tracker system performance

John M. Good, Niv Drory, James R. Fowler, Gary J. Hill, Martin Landriau, The Univ. of Texas at Austin (United States)

To enable the Hobby-Eberly Telescope Dark Energy Experiment (HETDEX), a major upgrade to the HET spherical aberration corrector and tracker was implemented to increase the pupil size from 9.2 to 10 meters and the field of view from 4 to 22 arcminutes. The new Tracker, is comprised of 13 servo-controlled axes, weighs 20 tons, and is required to position the corrector to acquire and track targets within the specified +/-9.5um de-center, +/-15um de-focus, and +/-4.4 arc-sec tip/tilt. Following preliminary testing of the Wide Field Upgrade (WFU) Tracker, the Wide Field Corrector (WFC) was installed in July of 2015. This paper describes the physical characteristics of the 115 ton telescope system, metrology techniques utilized, as well as the mount modeling approach and implementation for achieving this requirement, prior to the installation of the corrector. It then follows up with subsequent pointing, acquisition, and tracking tests which were performed after corrector installation, to verify system mechanical, control, and software performance.

9906-168, Session PS6

Verification of alignment status and image quality of KMTNet 1.6m wide-field optical telescopes

Sang-Mok Cha, Korea Astronomy and Space Science Institute (Korea, Republic of) and Kyung Hee Univ. (Korea, Republic of); Chung-Uk Lee, Korea Astronomy and Space Science Institute (Korea, Republic of) and Univ. of Science & Technology (Korea, Republic of); Yongseok Lee, Korea Astronomy and Space Science Institute (Korea, Republic of) and Kyung Hee Univ. (Korea, Republic of); Seung-Lee Kim, Korea Astronomy and Space Science Institute (Korea, Republic of) and Univ. of Science & Technology (Korea, Republic of); Chang Jin Oh, The Univ. of Arizona (United States); Ho Jin, Kyung Hee Univ. (Korea, Republic of)

Korea Astronomy and Space Science Institute(KASI) have initiated KMTNet program to discover Earth-mass exoplanets in the habitable zone by analyzing a perturbation signal of micro-lensed light curves. To perform the science KMTNet deployed three identical 1.6-m wide field telescopes equipped with 18k ? 18k Mosaic CCD camera covering 2?2deg? FOV in the Southern hemisphere. Since the planetary signal is so weak to be distinguished from the amplified noisy light curves, it is critical to maintain the performance of the three telescopes as best and consistent alignment status. To accommodate highly demanding periodic verification of the alignment status of the telescopes, an interferometric wavefront test using a CGH has been implemented. This paper presents overview of the telescopes, flow down of error budget, actual alignment process and results from the alignment verification by system wavefront test. Also the measured on-sky image quality has been evaluated and reviewed along with the telescope alignment status.

9906-169, Session PS6

Supernova and optical transient observations using the three wide-field telescope array of the KMTNet

Dae-Sik Moon, Univ. of Toronto (Canada); Sang-Chul Kim, Jae-Joon Lee, Mina Pak, Hong Soo Park, Chung-Uk Lee, Seung-Lee Kim, Byeong-Gon Park, Dong-Jin Kim, Sang-Mok Cha, Yongseok Lee, Korea Astronomy and Space Science Institute (Korea, Republic of)

The Korean Microlensing Telescope Network (KMTNet) is a network of three new 1.6-m, wide-field telescopes spread over three different sites in Chile, South Africa and Australia. Each telescope is equipped with a wide-field, i.e., 2 degree by 2 degree, CCD camera of 18K by 18K detector pixels of four mosaic CCDs from E2V. The pixel sampling of the CCD camera is 0.4" and BVRI and H-alpha filters are available. These make the KMTNet facility an ideal and unique facility for discovering and monitoring supernovae and other optical transients by providing continuous 24-hour sky coverage of the 4 square degree wide field. The KMTNet supernova program (KSP), which we report here, is a program that uses approximately 20% of the entire KMTNet observing time in 2015-2019 for observations of supernovae alongside other optical transients and related sources. The program is exclusively focused on discovering early supernovae and peculiar ones by conducting high-cadence, multi-color monitoring observations - we typically visit a smaller number of nearby galaxies several times per night using three different filters of B, V and I, aiming primarily at detecting early supernovae within a few hours from the explosion and obtaining their useful color information for detailed photometric analyses. We use a combination of publicly-available algorithms and our own programs for the data processing and analyses. These comprise routines for image re-projection, source detection, image combination and subtraction, false alarm, automatic photometry and light curve extraction, etc. Our early results include the detection of a highly eccentric optical transient that shows a previously-unidentified light curve to the best of our knowledge, a candidate for early supernova potentially detected within only several minutes from the explosion, various types of variable stars of long and short periods, numerous low surface brightness dwarf galaxies and tidal streams.

9906-170, Session PS6

Comparison of LSST and DECam wavefront recovery algorithms

Bo Xin, LSST (United States); Aaron J. Roodman, SLAC National Accelerator Lab. (United States) and Kavli Institute for Particle Astrophysics & Cosmology (United States); George Z. Angeli, Charles F. Claver, LSST (United States)

We make a detailed quantitative comparison of the wavefront recovery algorithms developed for DECam and LSST. Samples used in this study includes images of out of focus stars collected by the Dark Energy Camera at the Blanco 4-meter and artificial donuts simulated from a Kolmogorov model of the atmosphere and an optical model of LSST. Both samples are analyzed with the forward wavefront retrieval algorithm developed for DECam and the transport of intensity algorithm developed for LSST. Quantitative comparison of results between the two implemented algorithms is made, and the relative strengths and weaknesses of each algorithms is discussed.

9906-171, Session PS6

Long-term performance of the VLT UT active optics system

Christian Stephan, European Southern Observatory (Chile); Stéphane Guisard, European Southern Observatory (Germany); Pierre Bourget, European Southern Observatory (Chile)

For telescopes with large and thin solid meniscus mirrors, like the Very Large Telescopes (VLT) unit telescopes (UT), it is compulsory to use an effective and reliable active optics system in order to guarantee the optimal optical performance. The actual performance of a telescope depends strongly on the avoidance of wavefront aberrations. The main error sources, ordered according to the average frequency of their band-pass, are optical design and manufacturing, structural deformations, support errors, local air and the free atmosphere. By definition, active optics corrects only slowly varying errors generated by the telescope itself and, partially, by air effects near the telescope. The frequency limit for the active optics system is 0.03 Hz. Systems that deal with higher frequency aberrations are called adaptive optics systems and are not considered in this paper. The VLT active optics system runs in closed loop operation, using a Shack-Hartmann sensor for wavefront analysis and performing the corrections on the primary and secondary mirror. Movements of the secondary mirror correct defocus and decentering coma, while all other wavefront errors are corrected by changing the shape of the primary mirror, using differential force changes. The active optics system of the VLT is now continuously in operation since 1998. In order to evaluate the long-term performance of the system, an extended timeseries data analysis of the available telemetry data for all unit telescopes was performed. The dependence of the system performance on external (e.g. seeing, wind speed and ambient temperature) and internal parameters (e.g. performance of Shack-Hartmann wavefront analyzer, the used algorithms for wavefront reconstruction and telescope altitude position) is analyzed in order to give a detailed performance estimate for the different unit telescopes. To assed the basic performance of the system, the residual RMS wavefront error is used as performance indicator. The RMS error is the expected error after application of the forces that correct the last fitting. Assuming the force application to be perfect then this corresponds directly to the optical performance of the system. The results presented in this paper demonstrate that the VLT UT active optics system works very stable and reliable with no performance degradation over time.

9906-172, Session PS6

Telescope performance at the Large Binocular Telescope

John M. Hill, Barry Rothberg, Julian C. Christou, Large Binocular Telescope Observatory (United States)

The Large Binocular Telescope Observatory is a collaboration between institutions in Arizona, Germany, Italy, Indiana, Minnesota, Ohio and Virginia. The telescope uses two 8.4-m diameter primary mirrors mounted side-by-side on the same AZ-EL mount to produce a collecting area equivalent to an 11.8-meter aperture. Adaptive optics loops are routinely closed with natural stars on both sides for sided and combined beam observations. Rayleigh laser guide stars provide GLAO seeing improvement. With the telescope now in operation for 10 years, we report on various statistics of telescope performance and seeing-limited image quality. Performance of the adaptive optics systems and instruments are discussed elsewhere. Statistics of telescope performance are reported in the areas of off-axis guiding, active optics, and open-loop mount tracking. Delivered image quality is reported as measured by the DIMM and several guide cameras as a function of other parameters such as temperature, wind velocity and wind direction. The performance of the honeycomb mirror ventilation

system is also discussed as it impacts local seeing and collimation. Projects to improve image quality and dome seeing are underway.

9906-31, Session 9

The E-ELT program status *(Invited Paper)*

Roberto Tamai, Michele Cirasuolo, Juan Carlos González, Bertrand Koehler, Mauro Tuti, European Southern Observatory (Germany)

The European Extremely Large Telescope (E-ELT) is a 39m optical/infrared telescope to be located on Cerro Armazones about 25 km away from the current ESO VLT Observatory at Cerro Paranal, Chile. After initial conceptual studies in collaboration with the community and preliminary design studies performed with industrial partners, the Programme was formally approved in 2012 with the requirement that major spending should be initiated only when the funding level would reach 90% of the total cost to completion. This was expected to be reached soon when Brazil would formally join ESO as a new Member State. However, the accession procedure of Brazil taking more time than originally anticipated, ESO Council decided in December 2014 to give the green-light for the construction of a first phase (Phase 1) that could defer the development of some components while preserving the future science capabilities and synergy with other project such as the James Web Space Telescope. This ‘green light' marked the start of an intense effort on many fronts, within ESO and inside the member states astronomical community, to launch the required construction activities.

This paper will first recall the main scientific objectives of the E-ELT and describe the interaction with the scientific community and ESO's committees that recently led to the signature of the agreements with consortia of astronomical institutes for the development of the first set of three instruments. An overview of the management organization will be provided, highlighting the challenges inherent to such large telescope projects but also related to the phased approach imposed by the funding situation.

The overall status of the project will then be described focusing on the major achievements obtained since early 2015.

These include the completion of the 24km road and the top platform at Cerro Armazones which is the result of a contract signed with the Chilean company ICAFAL back in late 2013 and completed in fall 2015.

Another significant achievement, in early summer 2015, was the signature of two industrial contracts for the production of the highly fragile thin shells of the 2.5m diameter M4 adaptive mirror as well as the final design and construction of the complete M4 Unit. Those are the first contracts to deliver hardware that will eventually equip the telescope.

The managerial and system engineering processes put in place to support the launch and the follow-up of such construction contracts will be briefly described.

Later in 2015, the joined effort by ESO and the scientific community in ESO member states led to the signature of the agreements for the design and construction of the first set of instruments: a precision wide-field, high-resolution (Adaptive Optics) imager (MICADO), an integral field spectrograph (HARMONI) and a thermal-infrared imager and spectrometer (METIS) as well as a multi-conjugate adaptive optics module using 6 laser guide stars (MAORY).

In addition, the article will report on the result of currently on-going activities such as the call for tender for the most important contract in the E-ELT Programme and in ESO history, namely for the Dome and the Main Structure and the procurement of the opto-mechanics.

The main processes and tools put in place to manage and control the Programme complexity will be briefly presented as well as its master schedule.

9906-32, Session 9

E-ELT assembly, integration, and technical commissioning plans

Peter Gray, Emanuela Ciattaglia, F. Gago, S. Guisard, Juan Marrero, Robert Ridings, Andrew Wright, European Southern Observatory (Germany)

EELT AIV is the activity of assembly, integration and technical commissioning of EELT sub-systems to deliver an operational telescope and the first light instrument technically capable of the top-level requirements and ready to start science commissioning leading to operations. The AIV phase covers all technical activities on Armazones from the moment the sub-systems and components are delivered or accepted on-site (by the sub-system EELT project manager). AIV includes final system tests of the completed telescope (known as “Technical Commissioning”) and the installation, alignment and telescope integration of the science instruments. The AIV phase ends with the handover of the completed telescope with installed instruments to the start of Science Commissioning. Responsibility then passes to the Commissioning team, however the technical resources for debugging and tuning the telescope and instrument will come from a combination of the AIV team working together with the Paranal operations staff. AIV is the major technical challenge of EELT. The scale and complexity of the telescope involves challenging logistical and scheduling i.e. 798 mirror segments, staged delivery over 4 years, 5,000 edge sensor pairs, 2,376 position actuators. More than ten major sub-systems e.g.M2-3-4-5, PFS & instruments will be integrated and tested in parallel. Finally, the technical commissioning phase will be a significant challenge. EELT is a highly complex active telescope system. During early testing nothing will be straightforward and there will be many system-level problems to overcome.It will take the “best of the best” people to troubleshoot, debug, tune, and turn over as an operational facility.

9906-33, Session 9

Overview of key technologies for TMT telescope structure

Yutaka Ezaki, Noboru Kawaguchi, Junji Takaki, Atsushi Kato, Tomoya Hattori, Toshitaka Nakaoji, Yusuke Saruta, Satoru Sofuku, Masaki Tabata, Yoshihiro Hosokawa, Mitsubishi Electric Corp. (Japan)

Mitsubishi Electric Corporation has been in charge of many telescopes such as Subaru 8.2 meter optical telescope and ALMA 16 radio telescopes.

In the TMT project, Mitsubishi Electric Corporation is advancing the detailed design of the following systems.

- Telescope structure that exceeds 50 meter in width, height and 2,000 ton in weight
- Telescope drive control systems
- Segment exchange system

For these systems, technical requirements below are specified, to which technical challenges are needed.

- The telescope structure that is light-weight but has small gravitational deformation of the primary mirror cell during elevation angle change
- The telescope structure with seismic isolation system that withstand large earthquake of 1000 thousand year return period
- Drive control of massive telescope structure that realizes high tracking accuracy and short move performance
- Segment exchange system that enables 10 segment exchanges per day.

To satisfy these technical requirements, Mitsubishi Electric Corporation has conducted the detail design and the technology developments. In this paper, the major key technologies that are planned to be applied in the detailed design phase are introduced.

9906-34, Session 9

Production metrology design and calibration for TMT primary mirror fabrication used at multiple manufacturing sites

Ulrich Mueller, Integrated Optical Systems (United States)

The TMT telescope is being built by several partnering countries. Each of them produces a share of the 492 mirror segments consisting of 82 different segment types. In order to produce consistent results at each site the metrology has to be cross calibrated and the segment surface data has to be traceable from raw glass blank through grinding, polishing and hexing into a segment.

An automated metrology instrument called 2-D profilometer (2DP) was designed. Each site uses a copy of this instrument for roundel fabrication, post hexing metrology and alignment of the hex segment in the telescopes SSA assemblies. The error budget for this design will be presented and compared to actual test results.

The 2DP uses 61 surface probes mounted in a carbon fiber panel (CFRP) to measure the surface shape of the mirrors. The panel is attached to a rotary actuator that positions it at any desired angle on the part to be measured. It can be lowered from the rotary axis to the mirror surface using 3 steel wires. During measurement when the CFRP touches the mirror surface with three balls. In order to reduce the weight deformation of the surface and minimize hertzian contact stress under the contact points the CFRP is counterweighted at the three contact points. The surface probes are arranged in a spiral manner such that each probe evaluates the same amount of surface area. The system capability to measure the surface at multiple angles. This leads to dense surface data. In order to align the data with the segment coordinate system cameras measure the position of backside fiducials on the part.

The fiducials are applied at each segment backside to report surface data orientation throughout the manufacturing and assembly process. The fiducials are applied using a carbon fiber fixture that uses replaceable sandblast masks. The location of the fiducials were calibrated using a coordinate measurement machine (CMM) calibration using an optical probe.

Two 1.5diameter Reference Spheres were built with the median radius of the primary mirror segments. There surface were evaluated for radius and figure at their respective polishing sites. These spheres are the metrology null at the Japan, USA and India manufacturing site. The 2DP is nulled on the sphere prior to each measurement. Both spheres and their mounts were shipped to the Coherent, Richmond site for cross calibration. After the 2DP instruments were completed the repeatability and reproducibility was evaluated using repeat measurements on the reference spheres. The two reference spheres were compared using each 2DP to verify the optical and CMM data provided by the manufacturer. In addition a self-calibration scheme proposed by Jerry Nelson was used measure the non-axisymmetric terms of the surface figure. The angles used during this calibration are selected based on the sensitivity of the non-axisymmetric terms vs the angle. This fast process can be used intermittently during manufacturing to verify that the instrument is still working well.

9906-35, Session 9

GMT site, enclosure, and facilities design and development overview and update

Jose Teran, M3 Engineering & Technology Corp. (United States); William S. Burgett, GMTO Corp. (United States); Eric Grigel, M3 Engineering & Technology Corp. (United States); Bruce C. Bigelow, Eduardo Donoso, GMTO Corp. (United States); Fransisco Figueroa, GMTO Corp. (Chile)

The Giant Magellan Telescope (GMT) will have a 25.4-meter diameter effective aperture, and is one of three currently planned next generation extremely large telescopes (ELTs). The GMT will be located at the summit of Cerro Campanas at the Las Campanas Observatory (LCO) in Chile, one of the world's best observing sites.

This paper provides an overview of the site master plan comprising site infrastructure, enclosure, and facilities, and outlines the analysis of alternatives trade studies that will lead to the final design. Also presented is an update of the site infrastructure development and pre-construction activities currently underway that will be completed prior to the beginning of enclosure construction near the end of 2016.

9906-36, Session 10

Primary mirror control for large segmented telescopes: combining high performance with robustness

Gert Witvoet, TNO (Netherlands); Niek Doelman, TNO (Netherlands) and Leiden Observatory (Netherlands); Remco den Breeje, TNO (Netherlands)

The desire for improved resolution has led to the design of increasingly larger telescopes, such as the Thirty Meter Telescope (TMT) and the European Extremely Large Telescope (E-ELT). Their enormous sizes require them to use a segmented primary mirror concept. Each individual mirror segment must then be actively controlled, e.g. in rigid-body piston, tip and tilt motions, in order to create the desired mirror surface shape, even in the presence of disturbances. To this end each segment needs to be equipped with three dedicated single-DOF actuators. These piston-tip-tilt actuators should combine extremely high accuracy with a relatively large stroke (to compensate for the rotation with respect to the gravitational field), while being exposed to non-stationary structural vibrations and wind loads.

In the E-ELT case there will be a total of 2394 piston-tip-tilt actuators, each of them actively controlled. Each actuator will experience a different structural dynamical response, which could even change with the orientation of the telescope, since the actuator—segment assemblies on e.g. the edge of the primary mirror will behave differently from the ones in the center. The same holds for the disturbances; wind forces and frame vibrations on the edge will be different than in the center. When using classical control strategies, this imposes a dilemma. Designing one robust controller for all actuators will inevitably sacrifice performance, while designing 2394 different controllers for all possible disturbances will be extremely cumbersome or even infeasible.

To overcome this classical trade-off between robustness and performance, TNO has developed and tested an automated control strategy for mirror segment actuators. The goal of this development was to create one single reliable algorithm which can be applied to all actuators (thus being robust to variations in dynamics), automatically tunes itself to obtain optimal performance, and tracks the disturbances over time, thereby maintaining its optimality. The basis is a very robust (but low-performant) linear feedback loop, which is automatically identified within a few seconds. The identified closed-loop system is then used both in a real-time estimation of the disturbances, and for the conditioning of an additional adaptive controller. This automated controller converges to optimal performance in less than 10 minutes from the start, and keeps track of changing disturbances. The algorithm has been successfully demonstrated on a segment actuator prototype for the E-ELT, converging to sub-nanometer accuracy, which surpasses earlier results with classic linear controller design. Moreover, the stability and reliability of the algorithm has been demonstrated over multiple days. These tests illustrate the feasibility of such an approach on a segmented telescope like the E-ELT, where in principle all 2394 actuators can be automatically tuned to an optimal

performance within just a couple of minutes after the press on a single button, and kept optimal even when the wind forces or frame vibrations change over time.

9906-37, Session 11

Overview and status of the Giant Magellan Telescope Project *(Invited Paper)*

Patrick J. McCarthy, James L. Fanson, Rebecca A. Bernstein, GMTO Corp. (United States)

We will report on the status of the Giant Magellan Telescope (GMT) Project. The GMT is a 25m telescope built around seven 8.4m honeycomb primary mirrors and a segmented secondary mirror system. The telescope is designed to address forefront questions in astrophysics, cosmology and the study of exoplanets. Adaptive optics is integral to the system through the use of adaptive secondary mirrors that share heritage with a number of 8m class telescopes. The GMT will be located at Las Campanas Observatory in Chile. The site has been thoroughly characterized following an extensive site testing campaign and has excellent seeing and weather.

The GMT project has moved to the construction phase following a series of reviews in 2014. Production of the primary mirror segments is progressing with segments 1-4 under contract and long-lead time materials procured for segments 5 and 6. Core infrastructure at the GMT site is nearing completion as power, water, roads and staff housing are under development. Designs for the telescope, enclosure and key subsystems are proceeding from preliminary through final design phases in anticipation of the release of major fabrication contracts in 2016. Several subsystems are undergoing prototype development to reduce risk. Primary mirror supports, positional actuators and thermal control systems have been prototyped and are undergoing testing. A subscale prototype adaptive secondary mirror segment that includes the final electronics and incorporates the geometry of the GMT segmented secondary mirrors is under development. The telescope phasing system has been tested using a segmented pupil on the Baade 6.5m telescope at Las Campanas and meets our capture range and sensitivity requirements.

As one of the three Extremely Large Telescopes under development the GMT is an important part of the next generation of astronomical observatories. Since the 2014 SPIE meeting the GMT project has undergone considerable growth and is now poised to start major construction. We will report on the status of the project as of the first quarter of 2016.

9906-38, Session 11

The GMT active optics system: design and simulated end-to-end performance

Brian McLeod, Harvard-Smithsonian Ctr. for Astrophysics (United States); Antonin H. Bouchez, GMTO Corp. (United States); Daniel Catropa, Harvard-Smithsonian Ctr. for Astrophysics (United States); Rodolphe Conan, Alan Conder, Benjamin Irarrazaval, GMTO Corp. (United States); Derek Kopon, Kenneth McCracken, Stuart McMuldroch, William A. Podgorski, Harvard-Smithsonian Ctr. for Astrophysics (United States); Fernando Quirós-Pacheco, GMTO Corp. (United States)

The alignment and figure control of the seven 8.5-m primary and seven 1-m secondary mirror segments of the Giant Magellan Telescope will be controlled by the active optics system. We consider the performance of the telescope under the influence of perturbations including wind-shake, vibration, atmospheric turbulence, and gravity- and thermal-induced distortions of the structure and optics. The measurements driving the control system are made using a set of four off-axis Shack-Hartmann sensors that comprise the Acquisition Guiding and Wavefront-sensing System. We present end-to-end simulations including the perturbations, optical propagation, sensors, and the control algorithms.

9906-41, Session 11

Designing the primary mirror support for the E-ELT

Jan Nijenhuis, TNO (Netherlands)

During the period 2009-2010 prototypes for the primary mirror support of the E-ELT have been developed. These have been tested elaborately by ESO. Design improvement were found to be necessary, especially in the field of manufacturability and maintainability. Furthermore, the technical performance had to improve in specific areas as well. This has evolved into a new specifications which have resulted in a new design for the segment support structure. The design rules that have led to the prototype design have been maintained but the implementation has been much improved. Also considerable improvement has been obtained with respect to the dynamic behavior. Accessibility and visibility on all parts and subsystems has changed such that everything is clearly visible now. Despite the increased performance no mass increase has been recorded meaning that more efficient use has been made of the material.

The active means to influence the segment shape by use of the warping harness has been completely redesigned. Cooperation between the TNO team and TMT has led to a design that has much in common but is also optimized for the specific performance requirements of the individual telescopes. A very important quality that has been achieved is simplicity. Hence a minimum amount of components is used. Reliability and safety were other aspects that have been greatly improved compared to the prototypes.

9906-42, Session 11

Thirty Meter Telescope project status *(Invited Paper)*

Fengchuan Li, Gary H. Sanders, Thirty Meter Telescope (United States) and California Institute of Technology (United States)

The Thirty Meter Telescope (TMT) is an extremely large optical-infrared telescope with diffraction-limited performance that will shape the landscape of astronomy for the next 50 years from its vantage point in the northern hemisphere on Mauna Kea, Hawaii, USA. The TMT International Observatory is a public-private-international partnership that unites the scientific, instrumental and industrial communities of India, Canada, China, Japan and the USA for this endeavor with all partners contributing to the design, development, and scientific use of the observatory. This paper will describe progress made since the construction phase started in April, 2014: challenges and opportunities on the telescope site, communications and management of a truly global collaboration, requirements flow down and interface definition, telescope and instrument performance, hardware and software development, education and public outreach.

9906-112, Session 11

A 3D metrology system for the Giant Magellan Telescope

Andrew P. Rakich, Lee R. Dettmann, Wylie N. Rosenthal, Chris Alongi, GMTO Corp. (United States)

The Giant Magellan Telescope (GMT) will consist of seven 8.4 m aperture telescopes mounted as a radially symmetrical phased array in a common mount. Each primary and conjugated secondary mirror segment will optically feed a common instrument interface. During telescope operation, it is expected that the alignment of the optical components will deflect due to nonrepeatable variations in thermal environment and gravity induced structural flexure of the mount. In order to reposition the optical components due to these influences, a metrology system incorporating a large number of absolute distance measuring interferometers is being developed for the GMT. The system would be required to align optical components of the telescope to the instrument interface to within the capture range of the active optics wavefront sensing systems. Combinations of multiple interferometric measurement paths would provide information to the telescope actuator control system to maintain the rigid body orientation between the primary and secondary mirror segments, as well as between the central primary mirror segment and the reference instrument interface. The interferometers and targets would be mounted directly to the optical components to minimize differential deflection between the optical surface and the metrology network. Since the interferometers measure the absolute distance to an optical target, the system could be shuttered or powered off while telescope science data is being acquired and collimation is maintained using information from the wavefront sensing systems. Initial investigations of the Absolute Multiline™ system by Etalon AG show that a metrology network based on this product should be capable of meeting all of the requirements. This system uses a large number of optical fibers to illuminate individual distance measuring interferometers. The individual components that would be mounted to the optical elements are passive and relatively inexpensive. A series of measurements using this product have been made to evaluate the performance of the system in conditions that are similar to the environment at the telescope site. A subscale geometry test has also been performed and results are compared to displacements measured with laser tracker and coordinate measurement machine, (CMM). A conceptual design of the system is presented and expected performance based on simulations is discussed.

Very high energy gamma-ray astronomy with the Cherenkov Telescope Array

(Invited Paper)

Werner Hofmann, CTA Consortium (Germany) and Max-Planck-Institut für Kernphysik (Germany)

Very high energy gamma-ray astronomy – with energies in the teraelectronvolt domain– has made rapid strides in the last decade, driven mainly by the atmospheric Cherenkov technique, where gamma-ray induced particle cascades in the atmosphere are imaged with large telescopes. The first VHE source was discovered in 1989; currently the number of known sources is approaching 200, tracing cosmic particle accelerators.

The Cherenkov Telescope Array (CTA) is a next-generation observatory for very high energy (VHE) gamma-ray astronomy, supported by a worldwide community. With one array of imaging atmospheric Cherenkov telescopes each in the northern and southern hemispheres, CTA will provide full-sky coverage, enhance flux sensitivity by one order of magnitude compared to current instruments, and cover a four-decade energy range.

The presentation will aim at covering the science drivers, function, design characteristics, and status of CTA.

9906-44, Session 12

The ASTRI SST-2M prototype for the Cherenkov Telescope Array: opto-mechanical performance

Rodolfo Canestrari, INAF - Osservatorio Astronomico di Brera (Italy); Enrico Giro, INAF - Osservatorio Astronomico di Padova (Italy); Salvatore Scuderi, INAF - Osservatorio Astrofisico di Catania (Italy); Gino Tosti, Elisa Antolini, Univ. degli Studi di Perugia (Italy); Giorgia Sironi, Claudio Tanci, Dino Fugazza, INAF - Osservatorio Astronomico di Brera (Italy); Federico Russo, INAF - Osservatorio Astrofisico di Torino (Italy); Daniele Gardiol, INAF - Osservatorio Astronomico di Torino (Italy); Carlos Eduardo Fermino, USP (Brazil); Luca Stringhetti, INAF - IASF Milano (Italy); Giovanni Pareschi, INAF - Osservatorio Astronomico di Brera (Italy)

ASTRI SST-2M is an end-to-end telescope prototype developed by the Italian National Institute of Astrophysics (INAF) in the framework of the Cherenkov Telescope Array (CTA). The CTA observatory, with a combination of large-, medium-, and small-size telescopes (LST, MST and SST, respectively), will represent the next generation of imaging atmospheric Cherenkov telescopes. It will explore the very high-energy domain from a few tens of GeV up to few hundreds of TeV.

The ASTRI SST-2M telescope structure and mirrors have been installed at the INAF observing station at Serra La Nave, on Mt. Etna (Sicily, Italy) in September 2014. Its performance verification phase began in autumn 2015. Part of the scheduled activities foresees the study and characterization of the optical and opto-mechanical performance of the telescope prototype.

In this contribution we report the results achieved in terms of kinematic model verification, Point Spread Function on the full field of view, and its stability with respect to telescope elevation, the pointing models and effective area.

9906-45, Session 12

FACT: status and experience from four years of operation of the first G-APD Cherenkov Telescope

Adrian Biland, ETH Zürich (Switzerland)

Imaging Atmospheric Cherenkov Telescopes (IACT) are measuring the dim and short flashes of Cherenkov light emitted by extended air showers induced by energetic particles entering the atmosphere. To be able to catch such signals, due to the high background of ambient light even during dark nights, IACT cameras need very sensitive photosensors and fast readout electronics. To be able to statistically distinguish between air showers induced by charged particles and gamma-rays, respectively, the cameras need more than 1000 individual pixels. The current IACT arrays H.E.S.S., MAGIC and VERITAS have proven that the high energy sky is far more diverse than expected, and the next generation CTA is currently in the prototyping phase. So far, all IACTs used Photo Multiplier Tubes (PMT) as photo sensors. When the first generation of Geiger-mode operated Avalanche Photo Diodes (G-APD), nowadays usually called Silicon Photo Multipliers (SiPM), became commercially available, the question raised if these novel devices are a viable alternative to PMTs

under the harsh operation conditions intrinsic to IACTs. The First G-APD Cherenkov Collaboration (FACT) was formed by ETH Zurich and the Universities Geneva, Dortmund and Wuerzburg in 2008, with the intention to develop and install a G-APD based camera in a refurbished 9.5m^2 HEGRA telescope on the Canary island La Palma. In October 2011, the camera having 1440 Pixels, consisting each of a light guide, a G-APD chip with 3600 individual cells and a fast readout electronics operating at 2 Gigasamples per second was installed. Few hours after installation, the camera successfully recorded the first self-triggered Cherenkov images. These first events had been measured under strong moonlight condition that would have damaged standard PMTs if directly exposed to such bright light under full voltage. This already showed one advantage of SiPM.

Within short time, stable operation of was reached, and FACT is taken data almost every night without any major problem encountered so far. To reduce operation cost and load on the members of the small collaboration, FACT is operated since Summer 2012 from remote without the need of a data-taking crew onsite every night. In case of an emergency, it is agreed that the crew of the nearby MAGIC telescopes can be asked for help. Due to the excellent reliability if FACT, the task of operation changed gradually from remote operation to remote system monitoring, and fully robotic operation is envisaged.

The success of FACT convinced the community, and several SiPM based projects for CTA exist now. In addition to investigating the viability of SiPM, FACT is regularly monitoring the high-energy emission of several bright extra-galactic sources and alerting the community in case of bright flaring activities. This observations also allow to gain long term experience about the performance of SiPM. Despite regular operation under bright moonlight conditions and therefore collecting far more photons per sensor than under dark night observations, no indication of any ageing or any other SiPM related problem was encountered so far.

9906-46, Session 13

Construction status of the Daniel K. Inouye Solar Telescope *(Invited Paper)*

Joseph P. McMullin, Thomas R. Rimmele, Mark Warner, Valentin Martinez Pillet, National Solar Observatory (United States); Roberto Casini, National Ctr. for Atmospheric Research (United States); Steven J. Berukoff, Simon C. Craig, David F. Elmore, Andrew Ferayorni, Robert P. Hubbard, Bret D. Goodrich, David Harrington, Steve L. Hegwer, Paul Jeffers, Erik M. Johansson, National Solar Observatory (United States); Jeffrey R. Kuhn, Haosheng Lin, Univ. of Hawai'i (United States); Heather K. Marshall, National Solar Observatory (United States); Mihalis Mathioudakis, Queen's Univ. Belfast (United Kingdom); William R. McBride II, William McVeigh, National Solar Observatory (United States); Wolfgang Schmidt, Kiepenheuer-Institut für Sonnenphysik (Germany); Steve Shimko, Stacey R. Sueoka, Alexandra Tritschler, Timothy R. Williams, Friedrich Wöger, National Solar Observatory (United States)

We provide an update on the construction status of the Daniel K. Inouye Solar Telescope (renamed from the ATST, Advanced Technology Solar Telescope, in December 2013). This 4-m diameter facility is designed to enable detection and spatial/temporal resolution of the predicted, fundamental astrophysical processes driving solar magnetism at their intrinsic scales throughout the solar atmosphere. These data will drive key research on solar magnetism and its influence on solar winds, flares, coronal mass ejections and solar irradiance variability. The facility is developed to support a broad wavelength range (0.35 to 28 microns) and will employ state-of-the-art adaptive optics systems to provide diffraction limited imaging, resolving features approximately 20 km on the Sun. At the start of operations, there will be five instruments initially deployed: Visible Broadband Imager (VBI; National Solar Observatory), Visible SpectroPolarimeter (ViSP; NCAR High Altitude Observatory), Visible Tunable Filter (VTF (a Fabry-Perot tunable spectropolarimeter); Kiepenheuer Institute for Solarphysics), Diffraction Limited NIR Spectropolarimeter (DL-NIRSP; University of Hawaii, Institute for Astronomy) and the Cryogenic NIR Spectropolarimeter (Cryo-NIRSP; University of Hawaii, Institute for Astronomy).

As of mid-2016, the project construction is in its 4th year of site construction and 7th year overall.

Major milestones in the off-site development include the conclusion of the polishing of the M1 mirror by University of Arizona, College of Optical Sciences, the delivery of the Top End Optical Assembly (L3), the acceptance of the Deformable Mirror System (Xinetics); all optical systems have been contracted and are either accepted or in fabrication.

The Enclosure and Telescope Mount Assembly passed through their factory acceptance in 2014 and 2015, respectively. The enclosure site construction is currently concluding while the Telescope Mount Assembly site erection is underway. The facility buildings (Utility and Support and Operations) have been completed with ongoing work on the thermal systems to support the challenging imaging requirements needed for the solar research. The instrument systems have mostly completed their critical design reviews and are in fabrication.

Finally, we present the plans for the integration and commissioning leading to a start of operations in late 2019 as well as the ongoing risk management.

9906-48, Session 13

Integration of functional safety systems on the Daniel K. Inouye Solar Telescope

Timothy R. Williams, Robert P. Hubbard, National Solar Observatory (United States)

The Daniel K. Inouye Solar Telescope (DKIST) was envisioned from an early stage to incorporate a functional safety system to ensure the safety of personnel and equipment within the facility. Early hazard analysis by a dedicated hazard analysis team showed the need for a functional safety system. The design used a distributed approach in which each major subsystem contains a PLC-based safety controller. This PLC-based system complies with the latest international standards for functional safety. During the design phase, the hazard analysis team continued to analyze the design as it was refined. The use of a programmable controller also allows for flexibility to incorporate changes in the design of subsystems without negatively impacting safety.

Various subsystems were built by different contractors and project partners but had to function as a piece of the overall control system. Using distributed controllers allows project contractors and partners to build components as standalone subsystems that then need to be integrated into the overall functional safety system. Recently factory testing was concluded on the major subsystems of the facility. Final integration of these subsystems is currently underway on the site. Building on lessons learned in early factory tests, changes to the interface between subsystems were made to improve the speed and ease of integration of the entire system. New safety functions were need as revealed by continuous hazard analysis of the design and requirements.

Because of the distributed design, each subsystem can be brought online as it is delivered and assembled rather than waiting until the entire facility is finished. This enhances safety during the risky period of integration and testing. The DKIST has implemented a functional safety system that has allowed construction of subsystems in geographically diverse locations but that function cohesively once they are integrated into the facility currently under construction.

9906-49, Session 13

DKIST telescope mount factory testing overview and lessons learned

Paul Jeffers, National Solar Observatory (United States); Todd Trieloff, Ingersoll Machines Tools, Inc. (United States); Hans J. Kärcher, Steffen Seubert, MT Mechatronics GmbH (Germany); William R. McBride II, National Solar Observatory (United States)

The Daniel K Inouye Solar Telescope (DKIST) will be the largest solar telescope in the world, and will be able to provide the sharpest views ever taken of the solar surface. The telescope has a 4m aperture primary mirror, however due to the off axis nature of the optical layout, the telescope mount has proportions similar to an 8 metre class telescope.

The Telescope Mount Assembly (TMA) includes both the telescope mount and the 16m diameter laboratory table or Coudé Rotator. The Coudé Rotator supports the full instrument suite of up to 40 tonnes and has full rotation capabilities similar to the Mount Azimuth axis. The TMA has been going through the design, fabrication and assembly process since 2009 with Ingersoll Machine Tool's and this culminated with the Factory Acceptance Testing (FAT).

The preparation for the FAT started not long after the Final Design Review was complete and planning continued through the assembly stages. The official Factory Acceptance testing of the Coudé Rotator was conducted during May/Jun 2014 and the Mount in Jan through Apr 2015.

This paper provides an overview and discussion of the testing that was carried out. The depth and extent of testing will be described with discussion on what we would do differently next time. Also details of the preparation / process that lead into the testing will be presented.

Most importantly the results will be summarized and lessons learned during the testing provided as well as discussion on how this influences the planned site assembly and extent of re-test post assembly.

9906-50, Session 13

New Solar Telescope and its science instruments

Wenda Cao, Philip R. Goode, Big Bear Solar Observatory (United States) and New Jersey Institute of Technology (United States)

The 1.6-meter clear aperture, off-axis New Solar Telescope (NST) is the first facility class solar telescope built in the U.S. for a generation and is largest aperture, highest resolution solar telescope in the world. NST will dominate U.S. ground-based solar observations until the end of this decade when the 4-m DKIST comes online. Since its commissioning in 2009, the NST has regularly provided high resolution data covering the spectral range from 0.4 to 5.0 ?m to photometrically and polarimetrically probe the solar atmosphere from the deepest photosphere to the base of the corona, from the smallest scales to largest scales, and from the quietest to most active Sun. This presentation reports the up-to-date progress on the NST and its next generation instruments including the AO systems (AO-308 & MCAO), the Broad-band Filter Imager (BFI), the Near-InfraRed Imaging Spectro-polarimeter (NIRIS), the Visible Imaging Spectrometer (VIS), and the Cryogenic Infrared Spectrograph (CYRA).

9906-196, Session 13

Active thermal control for the 1.8-m primary mirror of the solar telescope CLST

Yangyi Liu, Naiting Gu, Cheng Li, Yuntao Cheng, Benxi Yao, Zhiyong Wang, Changhui Rao, Institute of Optics and Electronics (China)

The primary mirror of solar telescope is heated by the solar radiation and introduce harmful mirror seeing degrading the imaging quality. In essence, the mirror seeing is produced by the air convection temperature difference between heated primary mirror surface and ambient air. For the 1.8-m Chinese Large Solar Telescope (CLST), the quantitative relationship between the mirror seeing effect, wind velocity and temperature difference between primary mirror surface and ambient air under different convection type is established. The analytical results show that the maximum temperature rise is within 1 kelvin under the condition that the corresponding image degradation induced by the mirror seeing effect is less than 0.05 arc seconds, which is the maximum optical tolerance for mirror seeing effect based on the optical tolerance distribution for the CLST. To meet this thermal requirement, an active thermal control system and its control strategy design based on the concept of "temperature compensation" for the CLST primary mirror is proposed. The thermal control system includes two subsystems: one is the cooling subsystem and the other is the heating subsystem. On the one hand, when the primary mirror surface temperature is higher than the ambient air, the cooling subsystem works and cools the primary mirror surface. On the other hand, when the primary mirror surface temperature is lower than the ambient air, the heating subsystem works and heats the primary mirror surface. Therefore, the temperature difference induced by the variable solar irradiance and fluctuating ambient air temperature is rapidly eliminated under the collaborative work of above two subsystems. The corresponding numerical simulation validates the thermal control system. Furthermore, the outfield experiment has also been carried out to validate its effectiveness. Based on the experimental system, the thermal control system is able to control the temperature difference between primary mirror surface and ambient air within 1 Kelvin during one day's continuous solar irradiance. In the meanwhile, the average and maximum temperature difference between primary mirror surface and ambient air are less than 0.3 and 0.7 Kelvins respectively. It completely meets the proposed thermal requirement. The relevant thermal control design has already been used in the CLST.

9906-52, Session 14

Investigation of effects on figure of W. M. Keck Observatory primary mirror segments due to installation of new supports

Graham Cranston, Simpson Gumpertz & Heger Inc. (United States); Dennis McBride, W. M. Keck Observatory (United States); Andrew T. Sarawit, Frank W. Kan, Simpson Gumpertz & Heger Inc. (United States)

The W. M. Keck Observatory Segment Repair Project includes replacement of the original axial and radial supports with new designs, and installation of the new supports in different positions. In this paper, we present finite element analyses of a primary mirror segment including whiffletree mirror support system to determine the effect of the modified supports on the mirror figure. Displacements of the front surface are calculated for a number of operational and assembly fit-up cases, and differential displacements between the old and new support system are found. Zernike coefficients are calculated for front surface displacements and differential

displacements. Stresses on the glass surface at the radial pad bond locations are also determined. We find the residual deformations of the mirror front surface with the new supports to be similar to those with the old supports, differing only in the immediate vicinity of the inserts, and the impact on the imaging quality of the Keck telescopes to be negligible.

9906-53, Session 14

Concept design for seismic upgrade of Keck telescopes

Frank W. Kan, Simpson Gumpertz & Heger Inc. (United States); Sam Park, W. M. Keck Observatory (United States); Andrew T. Sarawit, Graham Cranston, Simpson Gumpertz & Heger Inc. (United States)

On 15 October 2006 a large earthquake damaged both telescopes at W. M. Keck Observatory resulting in weeks of observing downtime. A significant portion of the downtime was attributed to recovery efforts repairing damage to telescope bearing journals, radial pad support structures, and encoder subsystems. The study uses the finite element models of the telescopes we developed in 2012 and which were reported 2014 SPIE Ground-Based and Airborne Telescope Conference. In this paper, we discuss the conceptual design for the seismic upgrade of the twin Keck Telescopes, and the approach we took to develop the concept. The paper covers the design requirements and constraints for the seismic upgrade, the evaluation method used to check the safety of sensitive components, and the trade-off study used to compare different options and to select the best design. Various design options such as base isolating the structure, strengthening seismic restraints, adding dampers, adding break-away mechanisms, and combinations of these design options are considered in this study. Nonlinear time history analyses are performed to evaluate the performance of the design concepts.

9906-54, Session 14

Mauna Kea Spectroscopic Explorer: the status and progress of a major site redevelopment project

Richard Murowinski, Alan W. McConnachie, NRC - Herzberg Astronomy & Astrophysics (Canada); Douglas Simons, Kei Szeto, Canada-France-Hawaii Telescope (United States)

The Maunakea Spectroscopic Explorer (MSE) project is a collaboration designing the largest non-ELT optical/NIR astronomical telescope. MSE is unique as a major astronomical facility being the only redevelopment of an existing site, that of CFHT, with a newly expanded partnership. The project office is hosted at the Canada France Hawaii Telescope in Waimea HI, and includes new partners from Australia, China, India and Spain. The project is being developed by an international collaboration with design team membership distributed across three continents. In addition to a report on the progress and organization of design work, this paper will describe the challenges of redeveloping a major astronomical site. We will discuss the Project Office and engineering work from the aspects of meeting the Science requirements while satisfying the unique conditions imposed by redevelopment on Maunakea.

9906-55, Session 14

The large arrays- from ALMA to SKA and CTA: meeting the specifications for successful productions

Gianpietro Marchiori, Francesco Rampini, Simone De Lorenzi, Andrea Busatta, EIE Group s.r.l. (Italy)

2015 sees the completion of the ALMA European Antennas Warranty Period: more than 10 years of System Engineering.

25 (12m diameter) out of the 66 antennas constituting the ALMA Array, have been delivered by AEM consortium composed by Thales Alenia Space France, Thales Alenia Space Italy , European Industrial Engineering (EIE GROUP), and MT Mechatronics.

Other two big astronomical instruments arrays are now passing from the conceptual phase to prototyping and production ones:

SKA (Square Kilometer Array), for which EIE is developing the Dishes and the CTA (Cherenkov Telescope Array) for which EIE is realizing the ASTRI prototypes.

This paper offers a synthesis about the lessons learnt during the development of the ALMA Antennas, presenting all major factors which have been involved, from selection and qualification processes, to management and contractual, engineering and design, prototyping and tests up to the production and installation on site processes.

It is only through well detailed training and focused plans during each phase that success in terms of performances, budget and schedule can be obtained.

The complex phase of requirement definition can lead to the entire project failure if led by inexpert hands.

Inappropriate engineering specifications can result in unsustainable production costs.

Inadequate bidding documentation can lead to inadequate suppliers and products as well as to difficult contractual paths.

Wrong evaluations on the prototyping processes can distort the entire series production phase with unplanned operational and maintenance costs.

This paper is a sort of vademecum by EIE, in more than 25 years experience in the relations with the most important International scientific organizations. A real support for managers and project managers in the astronomical field.

9906-56, Session 14

QUIJOTE-CMB experiment: current status of telescopes and instrumentation

Maria Rosario Ángeles Pérez-de-Taoro, Marta Aguiar-González, Juan Cózar-Castellano, Ricardo T. Génova-Santos, María F. Gómez, Roger J. Hoyland, Alba E. Peláez-Santos, Frédéric Poidevin, Denis Tramonte, Rafael Rebolo-López, Jose Alberto Rubiño-Martín, Vicente Sánchez-de-la-Rosa, Afrodisio Vega-Moreno, Teodora Aleida Viera-Curbelo, Riccardo Vignaga, Instituto de Astrofísica de Canarias (Spain); Enrique Martinez-Gonzalez, Eduardo Artal, Fransisco Casas, David Ortiz, Juan L. Cano-de-Diego, Luisa de la Fuente, Enrique Villa, Univ. de Cantabria (Spain); Lucio Piccirillo, The Univ. of Manchester (United Kingdom)

The QUIJOTE (Q-U-I JOint TEnerife) experiment is an international collaboration led by the Instituto de Astrofísica de Canarias (IAC), with the

participation of The University of Cantabria, The University of Manchester and The University of Cambridge. The installation is located at the Teide Observatory in Tenerife (Canary Islands, Spain).

The main scientific objective of the QUIJOTE Experiment is the characterization of the polarization of the extragalactic emission and the Cosmic Microwave Background (CMB) in the frequency range of 10 – 40 GHz. The instrumentation has been designed with the sensitivity to detect the signature of primordial gravitational-waves generated during the inflationary epoch, if the tensor-to-scalar ratio is larger than r = 0,05.

The whole QUIJOTE project installation consist in a sliding dome building, containing two telescopes of 2,5m and three microwave cryogenic instruments.

The first telescope QT1 and the first instrument MFI (Multi Frequency Instrument) are both operating in the band from 10 to 20 GHz, since November 2012, when the commissioning phase started.

The MFI is a multi-channel instrument with four independent polarimeters to observe at 11, 13, 17 and 19GHz. Its first light occur in November 2012 and scientific routine operation started by May 2013. Nowadays, the instrument works 24 hours per day and 13.330,3h of data have been accumulated, with an observing efficiency (accounting for bad weather and technical maintenance time losses) of about 50%. The main science driver for the MFI is the characterization of the Galactic emission.

The second telescope QT2 and the second instrument TGI (Thirty GHz Instrument) starts working on early 2016, covering the range of 26 to 36 GHz. The second QUIJOTE telescope (QT2) is a replica of QT1, with some improvements in order to amplify capabilities to operate up to 200GHz in the future. This second telescope has been installed and tested at the observatory during 2014, after that, control software has been adapted and commissioned along 2015.

The TGI was conceived to observe exclusively in the 26–36GHz frequency band. The instrument has 30 receivers chains based on a fixed polarizer combined with two phase switches of 90º and 180º working at room temperature and in the direct correlation of the microwave signals. The TGI will be installed in the QT2 focus in January 2016.

Another third instrument, the FGI (Forty GHz Instrument), will join the experiment to complete the sky survey in the frequency range from 37 to 47 GHz. The FGI is based on the same polarimeter concept as the TGI, in fact, the FGI polarimeters will be integrated in the same cryostat than the TGI chains, since the chains are modular in both instruments and the FGI polarimeters fit within the same footprint than the TGI ones. The FGI is composed of 30 polarimetric chains, as well as the TGI, although in this case they are working at 41GHz with 10GHz bandwidth.

Some prototypes of the FGI receivers were built and tested at La Universidad de Cantabria, trying to reduce size, weight and costs, and finally all the elements are being manufactured. Up to day, most of the commercial components have been acquired and fabrication of main subsystem have started. Chains will start to be assembled during the firsts months of 2016 and observing test could be done with some FGI polarimeters by May 2016.

9906-57, Session 15

The Astronomical Telescope of the University of Stuttgart: setup, commissioning, and first results

Karsten Schindler, NASA Ames Research Ctr. (United States) and Deutsches SOFIA Institut (Germany); Jürgen Wolf, NASA Ames Research Ctr. (United States); Giovanni Dal Lago, Gianluca Carotta, Alessio Galliazzo, Officina Stellare SRL (Italy); Alfred Krabbe, Deutsches SOFIA Institut (Germany)

We report about the conceptual design, setup and commissioning of the University of Stuttgart's new 0.6 m telescope, located in the foothills of California's Sierra Nevada. The telescope is operated fully remotely via internet connection since September 2013. Based on extensive optical measurements and a detailed structural analysis, the design of the optical tube assembly has been reiterated considerably. As a result, a Mark II instrument was delivered and setup in May 2015.

The fully-reflective Ritchey-Chrétien telescope features a dual truss structure made of carbon fiber reinforced plastic (CFRP) tubes with titanium alloy joints. The back plane, central frame and front ring are made of a carbon and glass fiber reinforced plastic laminate (CFRP-GFRP-CFRP). Both mirror substrates are manufactured from the ultra-low-expansion glass ceramics CLEARCERAM-Z HS. The primary mirror has a conically shaped backside to reduce its weight. For focusing, the secondary mirror cell can be moved along the optical axis via a linear actuator. The primary mirror is protected by four cover flaps that can be opened via software command. The optical tube assembly is held by a German equatorial mount with a precision encoder system. We will describe the characteristics of the telescope system and summarize our results from on-sky testing such as the achieved optical quality, focus stability and pointing and tracking accuracy.

The main instrument is a fast EMCCD camera with a back-illuminated, frame-transfer sensor, combined with a 10-position filter wheel containing a Sloan filter set. A piggy-back mounted 130mm f/6 refractor and a wide field imager with a commercial 135 mm photo lens complement the setup.

The telescope serves as a training platform for aerospace engineering students in basic astronomy and in remote control of complex systems, and is used from Germany for lectures and courses. M.Sc. and Ph.D. students use it as a research instrument for their engineering and astronomy projects. For SOFIA, it acts as a test platform to evaluate new software and hardware before their integration on the observatory. In some cases, the telescope will also be used to support SOFIA missions by providing preparatory or parallel measurements of a target (astrometry, photometry) or to conduct follow-up observations. The characteristics of the camera also make it an ideal instrument to observe stellar occultations. We will present a selection of use cases and provide an outlook on future plans.

9906-58, Session 15

The Evryscope: design and performance of the first full-sky gigapixel-scale telescope

Nicholas M. Law, Octavi Fors, Jeffrey Ratzloff, Philip Wulfken, The Univ. of North Carolina at Chapel Hill (United States)

The Evryscope is a new type of telescope which covers the entire accessible sky in each exposure. Its 8000-square-degree field-of-view 691 MPix telescope is sensitive to exoplanet transits and other short timescale events not discernible from existing large-sky-area astronomical surveys. The telescope, which places 27 separate individual telescopes into a common mount which tracks the entire accessible sky with only one moving part, is building 1%-precision, many-year-length, high- cadence light curves for every accessible object brighter than ~16th magnitude. The camera readout times are short enough to provide near-continuous observing, with a 97% survey time efficiency. The Evryscope has the largest survey grasp of any current ground-based survey, and is the only existing survey within an order of magnitude of LSST's étendue. We deployed the Evryscope, funded by NSF/ATI, at CTIO in late May 2015. We will present the telescope design, performance, and the first results from the system.

The Evryscope is producing a night-by-night two-minute cadence record of all Southern sky events down to at least 16th magnitude, enabling searches for rapid-timescale variability phenomena ranging from exoplanet transits to gamma-ray-bursts. The system's enormous field of view allows us to simultaneously monitor very large numbers of targets that would otherwise require individual targeting by dedicated telescopes. The Evryscope is sensitive to transiting exoplanets around white dwarfs,

M-dwarfs, and the nearest and brightest stars, and is the first to be able to rapidly monitor most of the sky for nearby-star microlensing events. The Evryscope obtains precise and high-cadence eclipse timing for all Southern eclipsing binaries brighter than 16th magnitude, simultaneously monitors a host of compact-object pulsation and accretion phenomena, and is searching for young stars by their photometric activity. When relatively rare transients events occur, such as gamma-ray bursts (GRBs), nearby supernovae, or even gravitational wave detections from the Advanced LIGO/Virgo network, the telescope will return minute-by-minute light curves and upper limits without needing pointing towards the event as it occurs. By co-adding images, the system will reach V?18 in one-hour integrations, enabling the monitoring of faint objects. Finally, by recording all data, the Evryscope will be able to provide pre-event imaging at two-minute cadence for bright transients and variable objects, enabling the first high-cadence searches for optical variability before, during and after rapid events detected at other wavelengths.

The system has already produced hundreds of thousands of images and over 20TB of data, is meeting our image quality goals, and is achieving at least 5 mmag photometric precision in light curves. We will also present our plans for further development: a Polar Evryscope which takes advantage of the continuous winter darkness in the Arctic and Antarctic to achieve much higher detection efficiency for long-period exoplanets; a world-wide network of telescopes which could cover most of the entire sky continuously 24 hours-a-day; and larger-aperture systems which would be capable of rapidly detecting faint extragalactic events.

9906-59, Session 16

Progress of Antarctic survey telescopes

Xiangyan Yuan, Shihai Yang, Bozhong Gu, Fujjia Du, Xiaoyan Li, Zhengyang Li, Haikun Wen, Haiping Lu, Nanjing Institute of Astronomical Optics & Technology (China)

The Antarctic Survey Telescope-AST3 consists of three optical telescopes with 680mm primary mirror and 8 square degree field of view, mainly for observations of supernovas and extrasolar planets searching from Antarctic Dome A, where is very likely to be the best astronomical site on earth for astronomical observations according to site testing works jointly by CCAA and UNSW. The second AST3 was mounted on Dome A in Jan. 2015, but the observation had to be stopped due to the frost on the entrance window since May. Anti-frost methods including new electronic control for window ITO heating and active air blowing were designed for the coming maintenance. The anticipated automatic observations will be started from March 2016. The third AST3 is optimized mainly for K band with focal plane outside the main optical tube aiming a better tube seeing and diffraction limited imaging in K band. Now the telescope is under development in NIAOT and the K-band camera is under development in AAO.

9906-60, Session 16

Prototyping and environmental experiments of an aluminum panel for the Dome A 5m terahertz explorer (DATE5)

Zheng Lou, Yuan Qian, Purple Mountain Observatory (China); Yuan Lu, Huan Zhang, China Electronics Technology Group Corp. (China); Yingxi Zuo, Hairen Wang, Jingquan Cheng, Ji Yang, Purple Mountain Observatory (China)

Dome A 5m Terahertz Explorer (DATE5) is a proposed telescope to be deployed at Dome A, Antarctica to explore the excellent terahertz observation condition unique to the site. One of the key challenges of the telescope is to realize and maintain the required 10 micron rms overall reflector surface accuracy under the extreme site conditions and unmanned operating mode. Aluminum panels on carbon fiber backup structures is one of the candidate options for the 5 meter main reflector. For aluminum panels, three major technical risks were identified: 1) the large CTE of aluminum causes significant panel deformation due to the large seasonal soak temperature change; 2) internal stress may cause additional surface deformation when operating under a cold environment; 3) reflector panels working at Dome A run high risks of icing (which degrades antenna efficiency and increases noise) and automatic active de-icing mechanisms has to be implemented on the panels. In order to verify the feasibility of the aluminum panels for DATE5 and identify possible technical risks, a prototype panel was fabricated and went through rigorous tests. The manufacture error at the room temperature is 3.2 micron rms, which meets the budget. The panel surface is then measured at various ambient temperatures down to -60oC in a climate chamber using photogrammetric techniques. The additional surface error at the low temperatures is found to be mainly contributed by defocusing error, and the dependence of the panel focal length on temperature is well predictable. No additional surface error caused by internal stress has been observed. Next, the icing condition of the panel is analyzed and a prototype de-icing system based on polyimide film heaters was installed on the panel. The performance of the de-icing system was tested in a climate chamber as well as in the field experiments to simulate a variety of operating environments. The experiments indicate that the power required for de-icing the entire main reflector is less than 1kW and the temperature field produced by the de-icing system has trivial effect on the surface accuracy of the panel. This study indicates that aluminum panels have the potential to meet the reflector surface error budget under the harsh environment of Dome A.

9906-250, Session 16

Nonlinear transient survival level seismic finite element analysis of Magellan 6.5 meter telescopes

Matt Griebel, Christine Buleri, Andrew Baylor, Quartus Engineering Inc. (United States); Steve Gunnels, Paragon Engineering (United States); Povilas Palunas, Charlie Hull, Mark M. Phillips, Las Campanas Observatory (Chile)

The Magellan Telescopes are a set of twin 6.5 meter ground based optical/near-IR telescopes operated by the Carnegie Institution for Science at the Las Campanas Observatory (LCO) in Chile. The primary mirrors are f/1.25 paraboloids made of borosilicate glass and a honeycomb structure. The secondary mirror provides both f/11 and f/5 focal lengths with two Nasmyth, three auxiliary, and a Cassegrain port on the optical support structure (OSS).

The telescopes have been in operation since 2000 and have experienced several small earthquakes with no damage. Measurement of in situ response of the telescopes to seismic events showed significant dynamic amplification, however, the response of the telescopes to a survival level earthquake, including component level forces, displacements, accelerations, and stresses were unknown. The telescopes are supported with hydrostatic bearings that can lift up under high seismic loading, thus causing a nonlinear response. For this reason, the typical response spectrum analysis performed to analyze a survival level seismic earthquake is not sufficient in determining the true response of the structure. Therefore, a nonlinear transient finite element analysis (FEA) of the telescope structure was performed to assess high risk areas and develop acceleration responses for future instrument design. Several configurations were considered combining different installed components and altitude pointing directions. A description of the models, methodology, and results are presented.

9906-173, Session PS7

Pre-construction results of giant steerable science mirror for TMT

Fei Yang, Hongchao Zhao, Qichang An, Peng Guo, Haibo Jiang, Linchu Han, Changchun Institute of Optics, Fine Mechanics and Physics (China)

The results of the prototype will provide more technical support to the preliminary design of GSSM and give more confidence to CIOMP and TMT.

9906-174, Session PS7

Site assembly and testing of the second QUIJOTE telescope

Rubén Sanquirce, Iñaki Sainz, Esther Fernandez Santos, Borja Etxeita, Gaizka Murga, IDOM Ingenieria y Consultoria S.A. (Spain); Vicente Sánchez-de-la-Rosa, Jose Alberto Rubiño-Martín, Maria Rosario Angeles Perez-de-Taoro, Teodora Aleida Viera-Curbelo, María F. Gómez, Marta Aguiar-González, Instituto de Astrofísica de Canarias (Spain)

The QUIJOTE (Q-U-I JOint TEnerife) experiment is a scientific collaboration, led by the Instituto de Astrofísica de Canarias (IAC), with the aim of measuring the polarization of the Cosmic Microwave Background (CMB) in the frequency range 10-40 GHz and at large angular scales (around 1º). The project is composed of 2 telescopes and 3 instruments, located in Teide Observatory (Tenerife, Spain). Idom´s contribution for this project is divided in two phases.

Phase I consisted on the design, assembly and factory testing of the first telescope (2008), the integration and functional tests for the 5 polarimeters of the first instrument (2009), and the design and construction supervision of the building which protects both telescopes (2009), including the installation and commissioning of the mechanism for domes apertures.

Phase II comprised the design, factory assembly & testing, transport and final commissioning on site of the second telescope, which finished in January 2015. The optical design of both telescopes should allow them to reach up to 200 GHz. The required opto-mechanical performance was checked under nominal conditions, reaching a pointing and tracking accuracy lower than 5 arcsec in both axes, 8 times better than specified. Particular inspections and tests were carried out for critical systems, as the rotary joint that transmits fluid, power and signal to the rotary elements, or for the safety system to ensure personnel and hardware protection under emergency conditions.

This paper contains a comprehensive description of the power electronics and acquisition/control design required for safely operation under nominal and emergency conditions, as well as a detailed description of the factory and observatory tests required for the final acceptance of the telescope

9906-175, Session PS8

Astronomical site survey in large Shangri-La area in western China

Yu Liu, Tengfei Song, Xuefei Zhang, Shunqing Liu, Zhenyu Jin, Zhong Liu, Yunnan Observatories (China); Haisheng Ji, Purple Mountain Observatory (China)

During the last 5 years, based on the close collaboration among Chinese astronomical society and the scientists from IfA, NSO, HAO and other institutes, we have successfully developed standard instruments for site survey and applied them to candidate sites distributed in the large Shangri-La area located at the eastern edge of Tibetan plateau. Clear evidence, including the key parameters of seeing factor, sky brightness and water vapor content, has indicated that a few potential sites in the large Shangri-La areas in western China should obtain the excellent astronomical conditions for our purpose to develop large telescopes including solar coronagraph. We introduce the fresh site survey results in this report.

9906-176, Session PS8

The astronomical site selection in the Beni Mellal-Khenifra region

El Arbi Siher, Zineb Ihsane, Univ. Sultan Moulay Slimane (Morocco)

We use satellite data to conduct a preliminary study on three selected sites in the Beni Mellal-Khenifra region (Morocco). Data refer climatology, cloudy cover, aerosol index and aerosol optical depth. The sites are Tassemit (32?18'33" N, 6?15'28" W, 2248 m), Ghnine (32?12'45" N, 6?21'28"W, 2358 m) and Tazerkounet (32?09'56"N, 6?29'14"W, 1702 m). These sites are easily accessible and not far from the university center of Beni Mellal (Sultan Moulay Sliman University)

9906-177, Session PS8

The University of Tokyo Atacama Observatory 6.5m Telescope: design of mirror coating system and its performances

Hidenori Takahashi, Yuzuru Yoshii, Mamoru Doi, Kotaro Kohno, Takashi Miyata, Kentaro Motohara, Masuo Tanaka, Takeo Minezaki, Tomoki Morokuma, Shigeyuki Sako, Yoichi Tamura, Toshihiko Tanabe, Takafumi Kamizuka, Masahiro Konishi, Natsuko M. Kato, Tsutomu Aoki, Takao Soyano, Ken'ichi Tarusawa, The Univ. of Tokyo (Japan)

We present the mirror coating facility dedicated to a 6.5m infrared-optimized telescope that will be constructed in the University of Tokyo Atacama Observatory (TAO) on the summit of Co. Chajnantor in Atacama. The mirrors have honeycombed structure made from borosilicate for lightweighting and for temperature control. Since it is very delicate, the mirrors must be treated tenderly. Accordingly the coating system will be installed in the support building close to the telescope enclosure.

The reflectivity is over 95% in the infrared wavelength with < 1% in-uniformity. The uniformity of thickness of reflecting film is 10nm (RMS) over the whole mirror. In order to achieve these requests, a conventional evaporation system with a metal pre-wetted filament array is adopted.

The coating chamber is divided into three sections. The upper high vacuum portion of the coating chamber is mounted permanently to the ceiling of the support building. The lower part of chamber is on the movable lifting cart. The primary mirror cell (PMC) is sandwiched between upper and lower chambers for mirror coating process, that is, it makes up a center section of vacuum chamber. To protect the mirror support system and the actuators and to isolate the clean upper portion of the chamber from the dirty lower portion for mirror coating, an inflatable O-ring is adopted.

Since the mirrors must be handled very delicately, the mirror is in the state of looking up and the mirror coating process is performed. That is, evaporators (filaments) are set on above mirror. Therefore the filament with the special shape to prevent drips of the fusion aluminum is requested. Tungsten is used as filament core material. The filament like a spring coil is formed by twisting three tungsten wires. And it is

covered with tungsten net for containing more amount of aluminum and for preventing melted aluminum drip onto the mirrors. The laboratory experiment showed that the thickness of film is 120nm as same as design. Ideal spray pattern will be realized by adjusted filament array configuration and mask pattern.

Old coating film on the mirror has to be removed and the mirror surface should be cleaned up before evaporation. The fixed multi-ring mechanism is adopted for washing system. There are other ideas in this system, for example, many angle controllable spout and center liquid buffer tank. As a result, uniform and stable injection of solvent is achieved. Additionally by air blow system add to cleaning system, uneven residual liquid on the mirror surface is removed. Sodium hydroxide is used to dissolve old aluminum layer as a solvent.

The process of PMC removing from telescope, mirror cleaning, and mirror coating are carried out on same floor level. The PMC is transported by special cart that moves from under telescope to cleaning and coating areas across the bridge connecting telescope enclosure and support building. Since it is necessary to lift up and to lower on each area, the cart has elevator function. The specifications are up to 60ton in lifting load and 1750mm in stroke. It has individual controlled 4 jacking-up motors. Furthermore it has safety braking function on telescope, cleaning, and evaporation positions.

9906-178, Session PS8

Optical turbulence profiles with meteorological data at Aklim site

Kamilia Mraini, Abdelhadi Jabiri, Aziza Bounhir, Zouhair Benkhaldoun, Univ. Cadi Ayyad (Morocco); Aziz Ziad, Univ. de Nice-Sophia Antipolis (France); Mohamed Sabil, Univ. Cadi Ayyad (Morocco)

The stellar image quality is one of the important criteria used for the selection of the best astronomical sites. However, the turbulence in Earth's atmosphere can seriously limit the resolution of ground based astronomical observation. The study of atmospheric physics shows the importance of some parameters of atmospheric turbulence, such as the structure constant of refractive index fluctuation CN2 , wich characterize the strength of turbulence in the different layers. In the context of this paper we present, first, an example of a CN2 estimated from the National Center for Environmental Prediction/National Center for Atmospheric Research NCEP/NCAR Reanalysis and also from the weather station located at 2m above ground level in Aklim site. Secondly, we will compare it with the profile measured by the Multi-Aperture Scintillation Sensor (MASS), above Aklim Moroccan site (lat.= 30°07'38" N, long.= 8°18'31"W).

9906-179, Session PS8

The 1.56m astronomical telescope retrofitting in the western suburb of Shanghai

Zhendong Chen, Shanghai Astronomical Observatory (China)

The 1.56m astronomical telescope built in 1980s was designed for astrometric observation. With the expansion of the urban areas, the light pollution has been getting increasingly serious, so that the telescope is no longer suitable for its original scientific objectives. To avoid its getting useless and take advantage of its mirror power, we decide to retrofit the telescope to make it capable of doing a very different job, satellite laser ranging, collaborating with the adjacent International Laser Ranging Station of Shanghai.

To achieve the goal, the telescope must be able to track artificial satellites with the accuracy as high as a few arcseconds and the speed as high as 1 to 2 degrees per second, hundreds of times higher than its original tracking speed of diurnal motion. In addition, tracking a star just need moving the right ascension axis, while tracking a satellite must move both axes.

We installed two incremental grating encoders on both axes with 2 readheads each to compensate for the effect of bearing wander and eliminate odd error harmonics, including eccentricity. We removed a worm gear to reduce the transmission ration from 12500 to 625 and installed two 5kw servo motors. We installed new instrumentation for laser ranging, in the first phase just as a co-receiver of the adjacent 60cm laser ranging telescope, and developed new software.

After entering commissioning phase, a serious problem arose. The RA axis jittered severely while tracking at high speed. After analysis, we believed the problem was caused by the hydrostatic bearings of the RA axis. We tried to lower the oil pressure to reduce the oil film thickness, in order to increase friction i.e. damping, and the problem improved. This method however did not completely solve the problem, because the oil pressure was unstable and the film thickness is also affected by the viscosity changing with temperature.

Therefore, we tried many other methods. An oil pressure controller was installed to stabilize the oil pressure. We used a new oil with low water absorption and a viscosity that does not vary unacceptably over the common temperature. We re-adjusted the balance of the telescope mount under the condition of worm gear detached, because unbalanced torque may cause the oil pad bearing unstable.

Unfortunately, after all the attempts, the problem was not improved significantly. Now we are considering to restore the RA axis transmission rate back to 12500 from 625, in order to prevent it from jittering at the expense of speed and noise and so forth.

9906-180, Session PS8

A new test environment for the SOFIA secondary mirror assembly to reduce the required time for inflight testing

Yannick Lammen, Deutsches SOFIA Institut (United States); Andreas Reinacher, Benjamin Greiner, Deutsches SOFIA Institut (Germany); Rick Brewster, NASA Ames Research Ctr. (United States); Alfred Krabbe, Deutsches SOFIA Institut (Germany)

The Stratospheric Observatory For Infrared Astronomy (SOFIA) reached its full operational capability in 2014 and takes off from the NASA Armstrong Flight Research Center to explore the universe about four times a week. Maximizing the program's scientific output naturally leaves very little flight time for engineering tasks such as implementation and testing of improved software and hardware. Consequently it is very important to have a comparable test environment and infrastructure to perform troubleshooting, verifications and improvements on ground without interfering with science missions. SOFIA's Secondary Mirror Mechanism (SMM) is one of the most complex systems of the observatory. Since it is the only actively controlled element in the optical path its improvement offers great potential for influencing the whole observatory's performance. A primary goal has been to identify and characterize a 300Hz structural resonance frequency that limits the SMM's performance. In 2013 a first simple laboratory mockup of the mechanism was built to perform basic controller tests in the lower frequency band of up to 50Hz. This was a first step to relocate required engineering tests from the active observatory into the laboratory. However, to test and include accurate filters and damping methods as well as to evaluate hardware modifications, a more precise mockup is required that represents the system characteristic over a much larger frequency range. Therefore the mockup has been improved in several steps to a full test environment, representing the system dynamics with high accuracy. This new ground equipment allows moving almost the entire secondary mirror test activities away from the observatory.

As fast actuator in the optical path, the SMM also plays a major role in SOFIA's pointing stabilization concept. To increase the steering bandwidth, hardware changes are required that ultimately need to be evaluated using the telescope optics. To minimize the impact on science time, the laboratory test setup will be expanded in the near future with an optical measurement system so that it can be used for the vast majority of the testing.

This contribution describes the current laboratory test environment for the SOFIA Secondary Mirror Mechanism including its previous design steps. Moreover, an outlook is presented about the expansion with an optical measurement setup including a fast camera feedback and a fast steering mirror to induce simulated in-flight image disturbances. By using a camera very similar to SOFIA's focal plane guider camera, this optical test setup will also allow for investigation of the potential for image motion compensation for SOFIA with a SMM of increased bandwidth.

9906-181, Session PS8

Statistics of meteorological and 225 GHz opacity data for early science 2014-ES3 period of the Large Millimeter Telescope

Daniel Ferrusca Rodriguez, Jesús Contreras R., Milagros Zeballos, Instituto Nacional de Astrofísica, Óptica y Electrónica (Mexico)

The Large Millimeter Telescope (LMT) located in Sierra Negra Puebla, Mexico has started its early science programs since 2013, to achieve its exceptional performance a large effort has been put into the alignment and control of the antenna, calibration, readout and pipeline of the scientific receivers, as well as on the meteorological monitoring instrumentation. In this paper we present statistical data taken with our weather station and 225 GHz radiometer for the first full season of eight months (2014-ES3) of the LMT. The weather and opacity data provide important information to astronomers to allocate scientific observations and calibrate data, and plays an important role to technical staff to schedule maintaining operations at the telescope.

9906-182, Session PS8

Telescope site survey at the US Naval Observatory, Flagstaff station

Michael DiVittorio, U.S. Naval Observatory (United States)

The US Naval Observatory (USNO) anticipates the installation of a new telescope (2m-4m class) at the Naval Observatory Flagstaff Station (NOFS). In support of this project NOFS personnel will conduct a site survey on NOFS property and at a few nearby locations on government land. The survey will include seeing measurements using differential image motion monitors (DIMM) and sky brightness measurements using all-sky cameras. In addition, analysis of integrated precipitable water (IPW) measurements made by a near-by National Oceanic and Atmospheric Administration (NOAA) station will be discussed with respect to site thermal infrared capability. NOFS history and status, measurement methodologies, and preliminary results will be presented.

9906-184, Session PS8

Collecting various sustainability metrics of observatory operations on Mauna Kea

Blaise C. Kuo Tiong, Steven E. Bauman, Canada-France-Hawaii Telescope (United States); Romilly Benedict, Honoka'a High School (United States); John Wesley Draughn, Quinn Probasco, Univ. of Wisconsin-Madison (United States)

Situated on Maunakea, the Canada France Hawaii Telescope has a variety of operations components at the summit and in a headquarters facility in Kamuela, HI. The observatory operates a fleet to shuttle between facilities and also maintains two computer server rooms at their two locations. Both building facilities have specific consumption levels in energy, water use and waste generated. Other facets such as employee air travel for meeting and conferences such as SPIE also have measurable profiles. By collecting metrics in these categories, the collective impact of CFHT and other observatories operations on the Maunakea Astronomy Precinct can be estimated. An audit of carbon emissions in these aspects as well as specific efficiency metrics such as data center Power Use Efficiency gives a general scale of environmental and social alterations. Measurables can be gathered in use phases as well as throughout the lifecycle, especially in energy intensive categories. Applications of the audit would be for such things as crafting sustainability strategies.

While many observatories are located at remote or uninhabited sites, the observatories in the Maunakea Astronomy Precinct benefit from a solid infrastructure on the Big Island of Hawaii. To keep astronomy sustainable in this environment requires presenting a clear picture of impact to the various stakeholders made up of government, businesses, local population and collaboration groups. Current assessments can establish a baseline for future proposals as well as highlight present best efforts to interested stakeholders. Within CFHT, some best efforts with a projected positive impact are the use of renewable energy system, remote automation and designing for the environment.

Beyond applications for a sustainability strategy, a few items such as new telescope construction, engineering for an observatory site reuse, a master lease renewal and an environmental impact statement can benefit from metrics on impact. The master lease for the reserve in which the Astronomy Precinct is situated expires in 2033 and thus work for supporting documents is taking shape now. New and reuse facilities are anticipated to take shape in the meantime.

Having switched to remote observing in January of 2011, CFHT already has a system in place that gathers facility metrics at the summit and has now archived a few year's worth of operations data. This along with other systems that have tracked fleet use, and data center statistics can be assessed for resource intensity by using carbon emissions as a common measurement.

Work for the study was done in collaboration with the University of Wisconsin at Madison through the Sustainable Systems Engineering Program.

9906-186, Session PS8

Atmospheric phase characteristics of the ALMA long baseline

Satoki Matsushita, Academia Sinica (Taiwan); Yoshiharu Asaki, National Astronomical Observatory of Japan, Chile Observatory (Chile) and Joint ALMA Observatory (Chile); Edward B. Fomalont, National Radio Astronomy Observatory (United States) and Joint ALMA Observatory (Chile); Denis Barkats, Harvard-Smithsonian Ctr. for Astrophysics (United States); Stuartt A. Corder, National Radio Astronomy Observatory (United States); Richard E. Hills, Cavendish Lab. (United Kingdom); Ryohei Kawabe, National Astronomical Observatory of Japan (Japan); Luke T. Maud, Leiden Observatory (Netherlands); Koh-Ichiro Morita, National Astronomical Observatory of Japan, Chile Observatory (Chile) and

Joint ALMA Observatory (Chile); Bojan Nikolic, Cavendish Lab. (United Kingdom); Remo P. J. Tilanus, Leiden Observatory (Netherlands); Catherine Vlahakis, National Radio Astronomy Observatory (United States)

Atacama Large Millimeter/submillimeter Array (ALMA) is the world's largest mm/submm interferometer. Along with science observations, ALMA has performed several long baseline campaigns in the last 5 years to characterize and optimize its long baseline capabilities. To achieve full long baseline capability of ALMA, it is important to understand the characteristics of atmospheric phase fluctuation at long baselines, since it is believe to be the main cause of mm/submm image degradation. We present here, for the first time, detailed properties of atmospheric phase fluctuation at mm/submm wavelength from baselines up to 15 km in length. Atmospheric phase fluctuation increases as a function of baseline length with a power-law slope close to 0.6, and many of the data display a shallower slope (0.2 - 0.3) at baseline length greater than about 1 km. Some of the data, on the other hand, show a single slope up to the maximum baseline length of around 15 km. The phase correction method based on water vapor radiometers (WVRs) works well, especially for cases with precipitable water vapor (PWV) greater than 1 mm (i.e., when the amount of water vapor in the atmosphere is significant), typically yielding a 50% decrease or more in the degree of phase fluctuation. However, significant amount of atmospheric phase fluctuation still remains after WVR phase correction; about 200 micron in root-mean-square (rms) excess path length (rms phase fluctuation in unit of path length) even at PWV less than 1 mm. This result suggests the existence of other non-water-vapor sources of phase fluctuation, and emphasizes the need for additional phase correction methods, such as the fast switching. The fast switching phase correction method has been simulated using observations of single sources, and result suggests that it works best with short cycle time; the phase coherence linearly improves with the cycle time.

9906-187, Session PS8

Development of the optical laser system for testing and checking equipment for transmitting and receiving terminals of the space optical communication line

Dmitryi I. Dmitriev, Arkadyi D. Tsvetkov, NII OEP (Russian Federation); Alexey V. Arminen, Galina E. Romanova, ITMO Univ. (Russian Federation)

Development of the high-speed and reliable space laser communication systems is of current interest for the space instrumentation. Thus, it is necessary to test working characteristics of the terminals in laboratory conditions. The task in that case is to create the high precision optical system, with minimum self errors, and to provide absence of external influence to the laser beam structure during measurements. One of these effects is the influence of the refraction index inhomogeneity inside the medium of propagation to the measurement parameters.

The goal of the work is to develop the control and verification equipment (CVE) intended for the laboratory testing of the space optical communication line (SOCL) and to define the statistical characteristics of the laser beam during its propagation through the air space of the imitative optical track. This is necessary to determine the ability of performing of precision angular measurements in presence of the atmosphere. CVE should test:

1. The form and the width on the half maximum of the directivity diagram of the SOCL beams.

2. Coincidence of the axes of the detector and the transmitter of the SOCL.

3. The coinciding process of SOCL axis with the CVE beam axis during the entering to the communication and during the tracking (with the given angular movement velocity CVE)

4. The working-off process for the beam capture and tracking system of the SOCL during the imitations of the SOCL mounting platform vibrations, and also the background illuminations by the illuminated surface of the Earth and the solar disk.

CVE consists of two channels. The first, transmitting channel forms the beam that imitates the radiation of the distant correspondent which is directed to the tested module SOCL. The receiving channel forms a far-field distribution of the received radiation and compares it with the reference distribution. With various conditions of the tested module (imitations of the vibrations of the mounting platform, correspondent movements, background illumination, modulation amplitude variations of the radiation) the work of the capture and tracking system can be controlled by the coincidence of the axes of the directivity diagram for the tested module and reference beam.

To check out of the CVE system the model was created. The main algorithms of the adjustment and self-test were tested. The statistical characteristics of the laser beam with the wavelength of 1,06 microns and the diameter of 50, 100, 200 mm passed through the 40-m air layer in enclosed laboratory conditions (the dispersion of the half-width of the far-field distribution and roaming of its center of gravity) were measured.

With the results obtained the conclusions of the ability of the complex tests of the SOCL apparatus in the laboratory conditions were made.

9906-188, Session PS8

The Calern atmospheric turbulence station

Julien Chabé, Observatoire de la Côte d'Azur (France); Aziz Ziad, Yan Fantéï-Caujolle, Éric Aristidi, Lab. J.L. Lagrange (France); Catherine Renaud, Observatoire de la Côte d'Azur (France); Flavien Blary, Mohammed Marjani, Lab. J.L. Lagrange (France)

The Observatoire de la Côte d'Azur and the J.L. Lagrange Laboratory have a long and confirmed expertise in Atmospheric Optics. This expertise allowed this team to participate in the selection of the major sites of all the greatest projects of existing telescopes in particular of the 8-10 meter class: GranTeCan in the Canary Islands, the European VLT and Southern Gemini in Chile, Keck, Northern Gemini & Subaru in Hawaii. With a unique set of instruments to probe the atmospheric turbulence, the Lagrange Laboratory was involved in the site selection of the future Extremely Large Telescopes (ELT) as the 40m European E-ELT and the 30m American TMT. Our team was also in charge of the qualification of the site of Dome C in Antarctica whose potential is Astronomy is considerable.

In the continuity of this long tradition, the Calern Observatory now benefits of a station of atmospheric turbulence measurement (CATS: Calern Atmospheric Turbulence Station). This station is a response to real needs in support of other projects that will give additional dynamic to the Calern Observatory. This is mainly to improve the link budget of Laser Telemetry from MeO station and generally free space optical links. It is also supporting projects to equip MeO and C2PU telescopes with Adaptive Optics systems in the context of a real synergy between researchers and engineers from different laboratories and institutes.

The CATS station is equipped with a set of complementary instruments for monitoring atmospheric turbulence parameters. These new-generation instruments are autonomous within original techniques for measuring optical turbulence since the first meters above the ground to the borders of the atmosphere. One of the CATS instruments is the PML (Profiler of Moon Limb) measuring the vertical distribution of turbulence using lunar and solar edges. The second instrument, called G-DIMM for Generalized DIMM, is dedicated to provide wavefront parameters at ground level (seeing, outer scale, time coherence and isoplanatic angle). In order to avoid the surface layer, the G-DIMM instrument is installed on a platform at 4m above the ground (PML insensitive to this layer can remain on the ground). To protect our instruments from bad weather conditions (rain,

snow, wind) that occur on the Calern site, GDIMM and PML are sheltered under domes that close automatically. These instruments are installed near the MeO telescope.

The CATS station is also a support for our training activities as part of our Masters IMAG2E and OPTICS, through the organization of on-sky practical works. We are also considering the organization of international summer schools and workshops on the techniques of Atmospheric Optics and Site-Testing in Astronomy around the CATS station.

9906-189, Session PS8

Oukaimeden Observatory: ground meteorology

Mohammed Sabil, Zouhair Benkhaldoun, Abdelfettah Habib, Mohammed Lazrek, Abdelhadi Jabiri, Youssef El Azhari, Univ. Cadi Ayyad (Morocco)

In this paper we present the results of the ground meteorological properties obtained analyzing a long time series of data taken at one of the most important astronomical observatories in the world: Oukaimeden Observatory in High-Atlas of Morocco.

These data were obtained from January 2011 to December 2014 making use of automatic weather stations (AWSs) equipped with standard meteorological sensors providing the air temperature, relative humidity, barometric pressure, wind speed, and wind direction

9906-190, Session PS9

Support optimization of the ring primary mirror of a 2m solar telescope

Dehua Yang, Nanjing Univ. of Aeronautics and Astronautics (China)

A special 2-m Ring Solar Telescope (2-m RST) is to be built by YNAO. Its distinct primary mirror is shaped in a ring with an outer diameter of 2.02 m and a ring width of 0.35 m. Careful calculation and optimization of the mirror support pattern have been carried out first of all to define optimum blank parameters in view of performance balance of support design, fabrication and cost. This paper is to review the special consideration and optimization of the support design for the unique ring mirror. Schott zerodur is the prevailing candidate for the primary mirror blank. Diverse support patterns with various blank thicknesses have been discussed by extensive calculation of axial support pattern of the mirror. We reached an optimum design of 36 axial supports for a blank thickness of 0.15 m with surface error of ~5 nm RMS. Afterwards, lateral support scheme was figured out for the mirror with settled parameters. A classical push-and-pull scheme was used. Seeing the relative flexibility of the ring mirror, special consideration was taken to unusually set the acting direction of the support forces not in the mirror gravity plane, but along the gravity of the local virtual slices of the mirror blank. Nine couples of the lateral push-pull force are considered. When pointing to horizon, the mirror surface exhibits RMS error of ~5 nm with three additional small force couples used to compensate for the predominant astigmatism introduced by lateral supports. Finally, error estimation has been performed to evaluate the surface degradation with introduced errors in support force and support position, respectively, for both axial and lateral supports. Monte Carlo approach was applied using unit seeds for amplitude and position of support force. The comprehensive optimization and calculation suggests the support systems design meet the technic requirements of the ring mirror of the 2-m RST.

9906-191, Session PS9

DKIST facility management system integration

Charles White, LeEllen Phelps, National Solar Observatory (United States)

The Daniel K. Inouye Solar Telescope (DKIST) Observatory is under construction at Haleakala, Maui, Hawaii. When complete, the DKIST will be the largest solar telescope in the world. The Facility Management System (FMS) controls the Facility Thermal System (FTS) including the Carousel Cooling System, the Telescope Chamber Environmental Control System, and the Temperature Monitoring System. It will also integrate the Power Energy Management System, and several service systems such as HVAC, the Domestic Water Distribution System, and the Vacuum System. All of these subsystems must operate in coordination to provide the best possible observing conditions and overall building management. In doing so, the FMS must actively react to varying weather conditions and observational requirements. In addition, the impact of the facility must not interfere with neighboring installations while operating in a very environmentally and culturally sensitive area. The FMS system will be comprised of five Programmable Automation Controllers (PACs). I present the current standing, challenges, and plan to integrate all of the FMS subsystems.

9906-192, Session PS9

Daniel K. Inouye Solar Telescope optical alignment plan

Predrag Sekulic, Chen Liang, Kerry L. Gonzales, Robert P. Hubbard, Simon C. Craig, Association of Universities for Research in Astronomy, Inc. (United States)

The Daniel K. Inouye Solar Telescope (DKIST) is a 4-meter solar telescope under construction at Haleakala, Hawaii. The challenge of the DKIST optical alignment is the off-axis Gregorian configuration based on an altitude-azimuth mount, the independently-rotating Coudé platform and the large number of relay mirrors. This paper describes the optical alignment plan of the complete telescope, including the primary 4.24-m diameter off-axis secondary mirror, the secondary 620 mm diameter off-axis mirror, the transfer optics and the Coudé optics feeding the wavefront correction system and the science instruments. A number of accurate metrology instruments will be used to align the telescope and to reach the performances, including a laser tracker for initial positioning, a theodolite for accurate tilt alignment, a Coordinate Measurement Machine (CMM) arm for local alignment in the Coudé room, and a Shack-Hartmann wavefront sensor to characterize the aberrations by measuring selected target stars. The wavefront will be characterized at the primary focus, the Gregorian focus, the intermediate focus and at the telescope focal plane. The laser tracker will serve also to measure the mirrors positions as function of altitude angle due to the Telescope Mount Assembly (TMA) structure deflection. This paper describes also the method that will be used to compute the compensating mirrors shift and tilt needed to correct the residual aberrations and position of the focal plane.

9906-194, Session PS9

The COSMO coronagraph optical design and stray light analysis

Dennis J. Gallagher, National Ctr. for Atmospheric Research (United States); Zhen Wu, Nanjing Institute of Astronomical Optics & Technology (China); Brandon Larson, National Ctr. for Atmospheric Research (United

States); Peter G. Nelson, Sierra Scientific Solutions, LLC (United States); Phillip H. Oakley, Scott Sewell, Steven Tomczyk, National Ctr. for Atmospheric Research (United States)

The COronal Solar Magnetism Observatory Large Coronagraph (COSMO-LC) is a 1.5 meter Lyot coronagraph dedicated to measuring magnetic fields and plasma conditions in the corona and chromosphere of the Sun. The COSMO-LC is designed to measure weak magnetic fields (1 gauss) in the solar corona by observing the polarization of coronal emissions lines from 530-1100nm using a filtergraph instrument. COSMO-LC will have a 1 degree field of view to observe the full solar corona out to 1 solar radii beyond the limb of the sun with a spatial resolution of 2 arc-seconds per pixel (4k X 4k detector). The large Etendue of the system presents challenges to the design of the optical system and the narrow band birefringent filter. The LC employs a 1.5 meter refractive objective lens and an all refractive optical system. The birefringent filter was designed using high index Lithium Niobate crystals. The most critical part of the coronagraph is the objective lens that is exposed to direct sunlight several million times brighter than the corona. The objective lens (O1) must scatter as little light as possible, on order a few parts per million. This is accomplished through choice of the glass and specification of the surface polish. In this paper we discuss the optical design of the COSMO-LC and the detailed design of the O1 and other elements that keep stray light to a minimum. The result is an instrument with stray light below 5 millionths the brightness of the sun 50 arcseconds from the sun. The COSMO-LC has just had a Preliminary Design Review and the post PDR design will be presented.

9906-195, Session PS9

Pointing a solar telescope

Patrick T. Wallace, STFC Rutherford Appleton Lab. (United Kingdom)

As far as pointing is concerned, a solar telescope is merely an ordinary astronomical telescope but with enhancements for observing solar and coronal features. The paper discusses the additional coordinate systems that need to be supported, shows how to generate the required solar ephemerides (both orbital and physical), and sets out a suitable application programming interface for the telescope control system to use when making solar observations.

9906-197, Session PS10

The upgraded telescope control system performance for the Canada-France-Hawaii Telescope

Windell H. Jones-Palma, Canada-France-Hawaii Telescope (United States); Brandon C. Metz, Jet Propulsion Lab. (United States); Kevin K. Y. Ho, Jim Thomas, Canada-France-Hawaii Telescope (United States)

The Canada-France-Hawaii Telescope (CFHT) completed the first phase of its TCS upgrade in early 2015. Prior to this effort, the previous version of CFHT's TCS was largely unmodified since it began operation in 1979 and had begun to exhibit reliability and maintainability issues entering its third decade of operation. The first phase consisted of replacing the custom built servo control hardware built by the Canadian Marconi Company with an off-the-shelf Delta Tau Systems Power PMAC and replacing the absolute and incremental encoders with modern equivalents. Adapting the motion control algorithms used within the Power PMAC for real-time control of the telescope on the sky posed unique challenges. This work will briefly summarize the design for the upgraded TCS at CFHT, describe the solutions that adapted the traditional use of the Power PMAC for use at CFHT, and discuss the improved performance of CFHT's new TCS in terms of decreased time to target and decreased tracking error.

9906-198, Session PS10

Time synchronization diagnosis and enhancements at GTC telescope

Tim Daniel Gaggstatter, Agustín Núnez Castain, Jordi Molgó Sendra, Francisco Ramos Landaeta, GRANTECAN S.A. (Spain)

GTC, among the largest ground based optical infrared telescopes, has been now fully operative for 7 years. Besides major upgrades, maintenance activity still finds glitches that are difficult to isolate as these don't affect daily operations but appear erratically only under some circumstances. Sometimes, hidden problems are more relevant than expected, as is the case of a recently discovered issue with Time Service, that just shows up eventually during Leap Second adjustment. It is surprising that errors are still found in the system that have been under inspection since day one. This becomes even more strange when this errors lay inside one of the backbone services of a large telescope: Time Synchronization.

On every telescope it is crucial to maintain a perfect time reference as a Swiss watch. One does not only need a high precision pointing, to aim stars accurately but as time goes by the earth and some celestial objects with proper motion change its relative position, so tracking is required that means targeting at different directions on every precise moment. Furthermore, mechanical and optical effects are considered with a pointing model and optomechanics close loops, as well as atmospheric turbulence are compensated with guiding and even adaptative optics. But this target-earth-telescope synchronization, is not the single requirement for having a perfect time source, there are other reasons that makes Time Service extremely important in modern distributed environments: the synchronization of different subsystems of telescope control platform in real-time.

Talking about Time, often known as 4th dimension, is conceptually easy, as long as it moves forward in a linear way as in our daily experience. But when it behaves otherwise, jumping into the future or into the past, it can be mindbreaking, becoming even more difficult while analyzing past situations when time leaps took place, and it became more challenging when software running is not aware about the possibility of these time travels.

Beyond philosophical implications this paper emphasizes the importance to analyse Time Service in large Telescope control platforms as a way to avoid many mysterious and eventual issues that normally are difficult to diagnose with standard FMECA analysis in an environment where many CPU collaborate to perform tasks while their respective clocks are forward or backward changed every few seconds while they believe their time reference is immutable.

Furthermore, as an example, GTC Time Service issue is presented jointly with corrective actions taken and several recommendations for future developments in terms of real-time distributed process design, test and acceptance, now considering time frame health as baseline analysis of every single side of a Telescope control system.

9906-199, Session PS10

An observatory control system for the University of Hawai'i 2.2m Telescope

Luke J. McKay, Univ. of Hawai'i (United States); Christopher Erickson, Donn Mukensnable, Anthony Stearman, Brad Straight, Summit Kinetics (United States)

The University of Hawai'i 2.2m telescope at Maunakea has operated since 1970, and has had several controls upgrades to date. Previous incarnations include a console-driven LSI computer with custom servo control electronics, installed in the late 1970s, and a more recent system built around a GNU/Linux server with Galil PCI motion controller card which was developed starting in 1999. This outgoing system has proven itself over the past 15 years, but also represents a compromise between a fully modern, easily maintainable and upgradable system, and a low-cost replacement for mainly the central software and servo controls while using original wiring and relay logic. As parts and subsystems have been replaced due to failure, new instruments have required control software modification, and typical operations move towards fully robotic and unattended, a complete replacement and upgrade was deemed appropriate. The new system will operate as a distributed hierarchy of GNU/Linux central server, networked single-board computers, microcontrollers, and a modular motion control processor for the main axes. The software is written to modern standards, and will be shared under "open source" license terms. Design hardware is widely available and inexpensive where possible, including Raspberry Pi and Arduino systems. Rather than just a telescope control system, this new effort is towards a cohesive, modular, and robust whole observatory control system, with design goals of fully robotic unattended operation, high reliability, and ease of maintenance and upgrade. We discuss the design methodology, software and hardware implementation details, and process of installing and testing this highly modular and robust observatory control system.

9906-200, Session PS10

A new mix of power for the ESO installations in Chile: greener, more reliable, cheaper

Giorgio Filippi, Roberto Tamai, Dimitrios Kalaitzoglou, Wolfgang Wild, Alain Delorme, European Southern Observatory (Germany); Diego Rioseco, European Southern Observatory (Chile)

The highest quality demands for astronomical research impose to locate observatories often in areas not easily reached by the existing power infrastructures. At the same time, availability and cost of power is a primary factor for sustainable operations. Power may also be a potential source for CO2 pollution. As part of its green initiatives, ESO is in the process of replacing the power sources for its own, La Silla and Paranal, and shared, ALMA, installations in Chile in order to provide them with more reliable, affordable, and smaller CO2 footprint power solutions. The connectivity to the Chilean interconnected power systems (grid) which is to extensively use non-conventional renewable energy (NCRE) as well as the use of less polluting fuels wherever self-generation cannot be avoided are key building blocks for the solutions selected for every site. In addition, considerations such as the environmental impact and - if required - the partnership with other entities have also to be taken into account. After years of preparatory work to which the Chilean Authorities provided great help and support, ESO has now launched an articulated program to upgrade the existing agreements/facilities in i) the La Silla Observatory, from free to regulated grid client status due to an agreement with a Solar Farm private initiative, in ii) the Paranal Observatory, from local generation using liquefied petroleum gas (LPG) to connection to the grid which is to extensively use NCRE, and last but not least, in iii) the ALMA Observatory where ESO participates together with North American and East Asian partners, from replacing the LPG as fuel for the turbine local generation system with the use of less polluting natural gas (NG) supplied by a pipe connection to eliminate the pollution caused by the LPG trucks (currently 1 LPG truck from the VIII region, Bio Bio, to the II region, ALMA and back every day, for a total of 3000km). The technologies used and the status of completion of the different projects, as well as the expected benefits are discussed in this paper.

Go green is a common buzzword nowadays and the expectations are high. 100% green energy may not always be economically affordable. The paper provides insight on the technical and economical drivers for each of the three different solutions ESO has adopted. Each following a different philosophy, but all aimed to reduce the overall CO2 footprint, for which a calculation of the expected benefit is also provided. Last but not least, the paper dedicates some space to the discussion of the handling of the environmental permits needed to allow this type of projects to take place in Chile, an aspect that need due attention when new projects and/or improvement to existing one is planned.

9906-201, Session PS10

New-life for the THEMIS solar telescope

Bernard F. Gelly, Themis S.L. (Spain); Maud P Langlois, Gilberto Moretto, Ctr. de Recherche Astronomique de Lyon (France); Richard Douet, Themis S.L. (Spain); Michel Tallon, Observatoire de Lyon (France); Claude Le Men, L'Ingénierie des Systèmes Biologiques et des Procédés (France); Arturo López Ariste, Institut de Recherche en Astrophysique et Planétologie (France)

The THEMIS telescope is a 90 cm solar telescope designed for multiline spectropolarimetry in the 400-1100 nm range. Its main application is for solar surface studies, although Mercury and other planets have been important targets within a 15 years exploitation period. The alt-az helium-filled telescope is connected to a large predispersor/ spectropgraph through a complex optical relay. Themis routinely delivers high SNR polarized spectra with a polarimetric accuracy of 10-4 to 10-5. The polarimetric system uses a modulated dual beam principle with an analyzer located at the prime focus. Due to this configuration, Themis has been called a "polarization -free" telescope (although a better qualification would be "calibration-free"). Speckle imaging has been successfully implemented showing that the telescope has excellent imaging capabilities whenever the seeing is above r0=8cm. The present upgrades aim at correcting a number of limiting issues: i) Polarized spectra require high-SNR hence long exposure times, and the mapping the solar surface is also a time consuming process: as a result, the spectropolarimetry spatial resolution is never better than 0.5" which is no longer a competitive number, ii) The current dual beam polarimetry requires a severe field limitation to 15" in one spatial direction, which is both an observing limitation and makes impossible the implementation of any wavefront sensor, and iii) There is a flaw at system level in the placement of the current scanning device.

To solve what precedes, a 2 years study was necessary. A re-designed optical path starting from the M2 is being implemented, changing the f/ratio from f/63 to f/52.9. The optical relay is simpler with an improved transmission, and an AO bench will be located just before the spectrograph entrance. This AO is designed to start operating at r0=4.7 cm (half of the time at our site) with a ~100 actuator high-speed and high-stroke DM. The new polarimetric concept is now a superimposed modulated dual beam with no field limitation: this is the most challenging part of the work as it implies to control the behaviour of the Mueller matrix of a time-varying complex optical system. Based on a complete model of the optical path, with detailed simulations of the effect of ad-hoc surface coatings, deviation from the ideal situation can be controlled to an almost arbitrary low level . We expect from this renewed telescope a very large improvement of the spatial resolution of the polarized spectra, an excellent performances in spectrolarimetric mapping of the solar surface. It will available during a second exploitation period within 2018 -2025 and will then stop operating at the dawn of the future European Solar Telescope (EST).

9906-202, Session PS10

Commensal low frequency observing on the NRAO VLA: VLITE status and future plans

Tracy Clarke, Namir E. Kassim, U.S. Naval Research Lab. (United States); Walter Brisken, National Radio Astronomy Observatory (United States); Joseph Helmboldt, Wendy Peters, Paul S. Ray, Emil J. Polisensky, Simona Giacintucci, U.S. Naval Research Lab. (United States)

The National Radio Astronomy Observatory's Jansky Very Large Array (NRAO VLA) has undergone an upgrade to a broadband system operating in the frequency range of 1-50 GHz. The US Naval Research Laboratory (NRL) has collaborated with NRAO to develop a new broadband low frequency receiver operating at 56-86 MHz (4-band) and 240-470 MHz (P-band). The P-band system is in regular operation as a user facility on the VLA and the 4-band system is currently undergoing new feed development.

The low frequency feeds on the VLA are located at the prime focus while the 1-50 GHz feeds are at the Cassegrain focus. NRL has taken advantage of this uniqueness in feed location to expand the VLA low frequency capabilities in an experimental system. NRL and NRAO have developed, installed, and commissioned a new commensal system called the VLA Lowband Ionospheric and Transient Experiment (VLITE). Dedicated samplers and fibers tap the signal from 10 VLA P-band receivers and correlate those through a custom-designed real-time DiFX correlator. The operation of VLITE requires no additional resources from the VLA system running the primary science program. VLITE commensal operations run in parallel during nearly all Cassegrain programs.

VLITE operates with a 64 MHz bandwidth centered at 352 MHz with 100 kHz spectral resolution and 2 s temporal resolution. The low band feeds provide linear polarization to the correlator and all four correlation products are produced. The key components of the VLITE system are the large field-of-view (5 square degrees) and continual operation. The commensal system greatly expands the science capabilities of the VLA through enhanced data products to the primary science program while at the same time opening a new window on searches for astrophysical transients, enabling stand-alone astrophysics, and allowing real-time ionospheric studies.

In the first year of operation VLITE recorded data at 71% wall time for a total of 6300 hours on the sky and VLITE scans have covered more than 50% of the sky above declinations of -40 degrees to depths greater than 30 seconds. The total on-sky time for the VLITE system over a year is nearly 30 times the on-sky time for the PI-driven low frequency system on the VLA in the year prior to VLITE deployment.

The narrow bandwidth (64 MHz) and small number of antennas (10) allowed the initial experimental system to be built through an expansion of the CPU-based DiFX correlator. Plans to expand the test system to a full Lowband Observatory (LOBO) correlating all 27 VLA antennas across the full low frequency band would require an increase of a factor of 50 in correlation capability.

9906-203, Session PS10

Implementation of W. M. Keck Observatory's Telescope control system upgrade

Tomas Krasuski, W. M. Keck Observatory (United States); Peter M. Thompson, Systems Technology, Inc. (United States); Shui Hung Kwok, Kevin Tsubota, Ben McCarney, Ean James, Jeffrey A. Mader, Kevin L. McCann, Michael L. Pollard, John Fumo, W. M. Keck Observatory (United States)

The W. M. Keck Observatory's two 10 m telescopes have been operating for the past 25 years with the original technology and infrastructure for its major control systems. Decreasing performance and equipment break-downs have put a heavy burden on the operations and maintenance crew keeping performance at the level needed for efficient and reliable science operations. In 2009, the Telescope Control System Upgrade (TCSU) project was launched to address the need for improved telescope pointing, tracking, and offsetting performance as well as better maintainability and reliability. The TCSU project has replaced all of the major elements of the telescope control system, rotator and secondary mirror controls, and safety system. Obsolete and custom equipment is being replaced with new solutions based on commercial off the shelf equipment. New telescope encoders and the addition of tilt meters are providing better position sensing. An improved pointing model and new telescope mount control architecture are providing better closed loop position and velocity control. Finally, a switching solution using solid state relays and dual network switches was installed to provide seamless and rapid switching between the old and new systems. This has successfully minimized testing impact on operations during commissioning. The implementation of the TCSU project has been successful and provides performance improvements and maintainability that will meet the demanding needs of the observatory over the coming decades.

9906-204, Session PS10

LSST communications middleware implementation

Dave Mills, LSST (United States)

The LSST communications middleware is based on a set of software abstractions; which provide standard interfaces for common communications services.

The observatory requires communication between diverse subsystems, implemented by different contractors, and comprehensive archiving of subsystem status data.

The Service Abstraction Layer (SAL) is implemented using open source packages that implement open standards of DDS (Data Distribution Service) for data communication and SQL (Standard Query Language) for database access.

The OpenSplice (Prismtech) Community Edition of DDS provides an LGPL licensed distribution which may be freely re-distributed. The availability of the full source code provides assurances that the project will be able to maintain it over the full 10 year survey, independent of the fortunes of the original providers.

For each subsystem, abstractions for each of the Telemetry datastreams, along with Command/Response and Events, have been agreed with the appropriate component vendor (eg Dome, TMA, Hexapod) and captured in ICD's (Interface Control Documents).

The definition of instances of these abstractions is tightly controlled by reference to a system dictionary. All code referencing them is automatically generated and includes real-time consistency checking on a per-transaction basis. All Command transactions, Telemetry, and Event messages, are automatically stored in a system wide "Facility Database" system.

The EFD cluster is comprised of a set of COTS 1U rack mount servers, each supporting 4x 8Gb storage units (currently baselined as SATA HD, but solid state may be substituted depending upon price/performance).

The full set of defined transactions (per subsystem) is formally described using XML Schema. The XML is then used to automatically generate DDS compliant Interface Definition Language (IDL). The IDL is also extended with a set of SAL specific metadata which provides real-time consistency checking, clock slew detection, and full traceability on a per message basis.

The code (supported languages include C++,Java,Python,LabVIEW) to support the complete set of SAL mediated communications is automatically generated, along with a comprehensive set of unit tests, and extensive documentation. Application writers need only the appropriate runtime packages (SAL + DDS Shared libraries or Jar archives) in order to communicate with any other subsystem.

9906-205, Session PS10

Scientific planning for the VLT and VLTI

Bruno Leibundgut, Jean-Philippe Berger, European Southern Observatory (Germany)

An observatory system like the VLT/I requires careful scientific planning for operations and future instruments. Currently the system includes four 8m telescopes, four 1.8m telescopes used exclusively for interferometry, two 4m telescopes and 2 survey telescopes. The VLT offers a large range of scientific capabilities and setting the corresponding priorities depends on community interactions and the definition of future instrumentation. Coordinating the existing and planned instrumentation is an important aspect for strong scientific return. The current scientific priorities for the VLT and VLTI are pushing for the development of the highest angular resolution imaging and astrometry, integral field spectroscopy and multi-object spectroscopy. The ESO 4m telescopes on La Silla will be dedicated to time domain spectroscopy and exo-planet searches with special instruments. The next decade will also see a significant rise in the scientific importance of massive ground and space-based surveys. We discuss how future developments in astronomical research could shape the VLT/I evolution.

9906-206, Session PS10

Planet imaging polarimetry with the solar telescope GREGOR

Svetlana V. Berdyugina, Daniel Gisler, Thomas Berkefeld, Svetlana V. Berdyugina, Kiepenheuer-Institut für Sonnenphysik (Germany)

Polarimetry of planets and planetary systems provide unique information on physics and chemistry of planetary atmospheres. We have built a new system which includes fast polarimetric modulation, high-rate readout CCD, and adaptive optics. It operates at the solar telescope GREGOR on Tenerife, Canary Islands, and it benefits from the possibility to calibrate the entire optical train after the secondary mirror. Here we presents the system design, performance tests, and first scientific data. This research is supported by the ERC Advanced Grant HotMol.

9906-61, Session 17

SOFIA: the first two years of full operation *(Invited Paper)*

Alfred Krabbe, Deutsches SOFIA Institut (Germany) and Univ. Stuttgart (Germany)

The Stratospheric Observatory for Infrared Astronomy (SOFIA) is about two years into its regular operation.

After ramping up the flight frequency and the observing efficiency, SOFIA is now operating at about 90% of its schedulable science flight capacity. While SOFIA is the only astronomical observatory addressing the far infrared electromagnetic spectrum, its suite of cameras and spectrometers covers nearly 3 orders of magnitude in wavelength space. During the last two years, three instruments have been commissioned: FIFI-LS, upGREAT, and FPI+. More upgrades and instruments are awaiting their deployment at the telescope. The presentation will touch on the status and progress of SOFIA and also demonstrate its unique science capabilities by sharing some of the highlights, which have been obtained.

9906-62, Session 17

SOFIA secondary mirror mechanism heavy maintenance and improvements

Yannick Lammen, Deutsches SOFIA Institut (Germany); Andreas Reinacher, Univ. Stuttgart (Germany); Ivar Kjelberg, Serge Droz, Ctr. Suisse d'Electronique et de Microtechnique SA (Switzerland); Holger Jakob, Univ. Stuttgart (Germany); Friederike M. Graf, Michael Lachenmann, Alfred Krabbe, Deutsches SOFIA Institut (Germany)

The Stratospheric Observatory For Infrared Astronomy (SOFIA) reached its full operational capability in 2014 and completed hundreds of observation flights. Since its installation in 2002, the secondary mirror mechanism was subject to thousands of operating hours equivalent to millions of load cycles. During the aircraft heavy maintenance in fall 2014, a four month time window enabled the removal of the mechanism from the telescope structure for improvements and service. Next to visual corrosion- and crack-inspection of the flexures, critical electronic components (in particular the set of three eddy current position sensors that determine the mirror tilt) were replaced. Moreover a detailed temperature dependent position calibration of the system was performed in a cold chamber to improve the pointing accuracy. Until then, a simple temperature independent linear gain was used to translate the sensor output voltage into a position. For accurate positioning over the whole temperature range, a temperature dependent correction function had to be developed. This calibration would have cost hours of observing time when performed in flight which made it an essential goal for completion during the maintenance period. An autocollimator was used as optical reference camera to measure the tip-tilt position of the secondary mirror in the cold chamber. Using this calibration setup, a pattern of many mirror positions in the tip-tilt domain was approached at several temperature points to provide a high resolution data set for the new multidimensional calibration function. Later in-flight verification measurements confirmed a large improvement in pointing accuracy when including the temperature measurements into the position correction. Improvements were especially noticed in the lower temperature range of up to a factor of 10. This contribution provides an insight into the work performed during the SOFIA - Secondary Mirror Mechanism maintenance with the focus on the temperature dependent position calibration.

9906-63, Session 17

The design and development of a high-resolution visible-to-near-UV telescope for balloon-borne astronomy: SuperBIT

Javier L. Romualdez, Univ. of Toronto (Canada); Paul Clark, Durham Univ. (United Kingdom); Christopher J. Damaren, Univ. of Toronto (Canada); Tim Eifler, Jet Propulsion Lab. (United States); Aurelien A. Fraisse, Princeton Univ. (United States); Mathew N. Galloway, John W. Hartley, Univ. of Toronto (Canada); William C. Jones, Princeton Univ. (United States); Lun Li, Leeav Lipton, Univ. of Toronto (Canada); Thuy Vy T. Luu, Princeton

Univ. (United States); Richard J. Massey, Durham Univ. (United Kingdom); Calvin B. Netterfield, Univ. of Toronto (Canada); Jason D. Rhodes, Jet Propulsion Lab. (United States); Jurgen Schmoll, Durham Univ. (United Kingdom); Steven J. Benton, Princeton Univ. (United States); Ivan Padilla, Univ. of Toronto (Canada)

Balloon-borne astronomy is unique in that it allows for a level of image stability and resolution that is comparable to space-borne systems due to greatly reduced atmospheric interference, but at a fraction of the cost and over a significantly reduced development time-scale. As such, for instruments operating within the visible-to-near-UV bands, a theoretical diffraction limited resolution of 0.01" is achievable from the stratosphere (35-40 km altitude) without the need for extensive adaptive optical systems required by ground-based systems. The Balloon-borne Imaging Telescope (aka. SuperBIT) is an wide-field instrument operating in the visible-to-near-UV bands (300-900 um) that is designed to achieve 20 milliarcsecond image stability over a 0.5 degree field-of-view for integration periods ranging from 10-30 minutes, where it is estimated that a 900 second exposure on SuperBIT can resolve point sources of magnitude 24 at the 10? level. As such, SuperBIT is well suited for weak lensing experiments of galaxy clusters over high redshifts that require high image resolution over a wide field of view, and for other proposed experiments related to solar planet spectroscopy and exoplanet studies. The design, implementation, and flight performance to-date of the attitude determination and control systems (ADCS) for SuperBIT are the focus of this work, where emphasis is placed on mitigating and, in fact, exploiting the sub-orbital disturbance environment driven by compound pendulation and other stratospheric effects. The ADCS architecture is designed for real-time, high-gain feedback to compensate for sub-orbital disturbances down to 1-2" at the telescope level in addition to a high bandwidth piezoelectric tip-tilt actuator that removes any remaining disturbances on the focal plane down to 0.02". Furthermore, design methodologies from spacecraft dynamics and control are implemented to emphasize control robustness and autonomy from the stratosphere. Performance from the first test 8 hour test flight from Timmins, Ontario in September 2015 is presented here, where subarcsecond performance is demonstrated at the telescope level and at the science camera focal plane over hour long tracking periods. Current work and progress to-date in preparation for the fully operational three month flight of SuperBIT from New Zealand in 2018 is discussed within the context proposed of astronomical and cosmological experiments.

9906-64, Session 17

Pointing and control system performance and improvement strategies for the SOFIA Airborne Telescope

Friederike M. Graf, Univ. Stuttgart (Germany) and NASA Ames Research Ctr. (United States); Andreas Reinacher, Univ. Stuttgart (Germany); Holger Jakob, Univ. Stuttgart (Germany) and Armstrong Flight Research Ctr. (United States); Enrico Pfueller, Manuel Wiedemann, Jürgen Wolf, Univ. Stuttgart (Germany) and NASA Ames Research Ctr. (United States); Stefanos Fasoulas, Univ. Stuttgart (Germany)

The Stratospheric Observatory for Infrared Astronomy (SOFIA) has already successfully conducted over 240 flights. In its early science phase, SOFIA's pointing requirements and especially the image jitter requirements of less than 1 arcsec rms have driven the design of the control system.

Since the first observation flights, the image jitter has been gradually reduced by various control mechanisms. The resulting current control structure consists of two parts, the rigid body attitude control system and a feed forward based compensator of flexible telescope deformation (so-called Flexible Body Compensation system, FBC). The rigid body control loop is based on fiber-optic gyros as well as on three tracking cameras. Additionally, the FBC feeds accelerometer data through fixed-gain filters to the secondary mirror for compensation. This system allows us to achieve the standards set for early science on SOFIA.

Notably, the increasing demands on the image size require an image jitter of less than 0.4 arcsec rms to reach SOFIA's scientific goals. The major portion of the remaining image motion is caused by deformation and excitation of the telescope structure in a wide range of frequencies due to aircraft motion and aero-acoustic effects.

Thorough testing of the current system under various flight conditions have revealed a variety of opportunities for dramatic improvements. The currently applied filters have solely been developed based on a FEM analysis. By implementing the inflight measurements in a simulation and optimization, an improved fixed-gain compensation method was identified. After implementing the new filter, jitter measurements with up to 400 Hz sampling frequency using the fast imaging tracking camera show promising results and will be discussed in this paper.

Flight data analysis indicates that the currently used sensors for the FBC are one of the bottlenecks, as they do not measure all relevant Eigenmodes of the telescope. In addition, the implemented filters cannot optimally estimate the image motion. This leads to the necessity of new strategies for compensation, especially in bumpy flight conditions. This issue will be addressed in this paper.

The precisely balanced interaction of both control parts is crucial to achieve unprecedented image quality. With the changes in the FBC the assigned responsibilities in both control loops has to be revisited and will be discussed.

9906-65, Session 18

A high-sensitivity EM-CCD camera for the open port telescope cavity of SOFIA

Manuel Wiedemann, Jürgen Wolf, Univ. Stuttgart (Germany) and NASA Ames Research Ctr. (United States); Paul McGrotty, Chris Edwards, Andor Technology plc (United Kingdom); Hans-Peter Röser, Univ. Stuttgart (Germany)

The Stratospheric Observatory for Infrared Astronomy (SOFIA) has three target acquisition and tracking cameras. All three imagers originally used the same cameras, which did not meet the sensitivity requirements, due to low quantum efficiency (QE) and high dark current. The Focal Plane Imager (FPI) suffered the most from high dark current, since it operated in the aircraft cabin at room temperatures without active cooling. In early 2013 the FPI was upgraded with an iXon3 888 from Andor Techonolgy. Compared to the original cameras, the iXon3 has a factor five higher QE, thanks to its back-illuminated sensor, and orders of magnitude lower dark current, due to a thermo-electric cooler and "inverted mode operation". This leads to an increase in sensitivity of about five stellar magnitudes.

The Wide Field Imager (WFI) and Fine Field Imager (FFI) shall now be upgraded with equally sensitive cameras. However, they are exposed to stratospheric conditions in flight (typical conditions: T ≈ -40°C, p ≈ 0.1 atm) and there are no off-the-shelf CCD cameras with the performance of an iXon3, suited for these conditions. Therefore, Andor Technology and the Deutsches SOFIA Institut (DSI) are jointly developing and qualifying a camera for these conditions, based on the iXon3 888. These changes include replacement on electrical components with Mil-Spec components and various system optimizations, a new data interface that allows the image data transmission over ~30 m of cable from the camera to the controller, a new power converter in the camera to generate all necessary operating voltages of the camera locally and a new housing that fulfills airworthiness requirements.

A prototype of this camera has been built and tested in an environmental test chamber at temperatures down to T = -62°C and pressure equivalent

to 50,000 ft altitude. In this paper, we will report about the development of the camera and present results from the environmental testing.

9906-66, Session 18

SOFIA design history: optics, structure, and mechanics

Hans J. Kärcher, MT Mechatronics GmbH (Germany); Jörg Wagner, Deutsches SOFIA Institut (Germany)

The paper describes the development of the optical subsystem, the telescopes structure, the telescope mount and the interface to the aircraft from the conceptual design up to the finally as-built telescope and comments their influence on the overall observatory performance.

9906-67, Session 19

A feasibility study for airborne calibration of the Cherenkov Telescope Array

Anthony M. Brown, Paula M. Chadwick, Miranda Frizzelle, Durham Univ. (United Kingdom); Markus Gaug, Univ. Autònoma de Barcelona (Spain)

Currently in its pre-construction phase, the Cherenkov Telescope Array (CTA) will be the next generation very high energy gamma-ray observatory. CTA is designed to achieve an order of magnitude improvement in sensitivity, a much wider energy coverage and greatly improved energy and angular resolution compared to the current imaging atmospheric Cherenkov telescope facilities. To achieve these ambitious goals, CTA will comprise three telescope size classes: Small (SST), Medium (MST) and Large (LST). Operating an array of different telescope sizes introduces significant challenges, particularly with regard to cross-calibration. Accurately characterising the different optical throughput of the individual telescopes is helped if a common known calibration light source can be used.

To achieve all-sky coverage, the CTA observatory will consist of two arrays, one in each hemisphere. The northern array will contain approximately 20 telescopes (LSTs and MSTs) spread over about 1 km2, while the southern array will contain over 100 telescopes (LSTs, MSTs and SSTs) spread over an area of a few square kilometers. For practical reasons, IACTs are generally exposed instruments and thus subject to the effects of weathering, which contribute to the degradation of the telescopes' optical systems. To determine this degradation, we must calibrate the optical throughput of the individual CTA telescopes. To meet the CTA requirements on systematic uncertainties means determining the wavelength-dependency of the optical throughput, thus motivates the periodic use of a multi-wavelength-capable calibration light source to monitor the optical throughput of each individual CTA telescope.

The advances in battery life, flight control software and carbon fibre technology over recent years have made the use of small unmanned aerial vehicles (UAVs) as an airborne calibration platform for astronomical facilities a possibility. Early work by the Pierre Auger and Telescope Array cosmic ray detectors took advantage of these advances to use UAVs to calibrate their fluorescence telescopes. CTA will take advantage of this possibility of using UAVs as the basis of an airborne calibration system. While the primary purpose of an airborne calibration system for CTA would be the cross-calibration of different telescope types and the monitoring of the multi-wavelength performance of CTA telescopes' optical throughput, the versatility of the UAV platform allows for a wide variety of calibration and monitoring procedures to be performed, such as the mapping the atmospheric dust content above the array.

As part of CTA's efforts to realising the possibility of an airborne calibration system, we have recently completed a feasibility study to use a UAV to cross-calibrate the relative sensitivity of the CTA telescopes for the current array designs. In this contribution, the cross-calibrating performance of an airborne calibration device is described, together with the ongoing work to characterise the flight performance of a UAV carrying the calibration payload.

9906-68, Session 19

Low cost multi-purpose balloon-borne platform for wide-field imaging and video observation

Francisco Ocaña, Alejandro Sánchez de Miguel, Univ. Complutense de Madrid (Spain); Collaboration Daedalus Team, Daeadalus Team (Spain)

Atmosphere layers, especially the troposphere, hinder the astronomical observation. For more than 100 years astronomers have tried observing from balloons to avoid turbulence and extinction. New developments in card-size computers, RF equipment and satellite navigation have democratised the access to the stratosphere.

As a result of a ProAm collaboration with the Daedalus Team we have developed a low-cost multi-purpose platform with stratospheric balloons carrying up to 3 kg of scientific payload. The Daedalus Team is an amateur group that has been launching sounding probes since 2010. Since then the first two authors have provided scientific payloads for nighttime flights with the purpose of technology demonstration for astronomical observation.

It is a passive craft, with basic stabilisation and 2-hour length nominal mission. Current design has up to 4 observational ports, three at the sides of the square-shaped probe and one aiming at nadir for Earth Observation. The probe uses one or two meteorological sounding balloons to get out of the troposphere. The probe usually rises to 30km of altitude and then falls free with a parachute. The probe has GSM, RF and GPS beacons and some missions had also bidirectional communication. During the flight the probe is chased from ground using the beacons in order for recovery as all the data is stored inside.

The first of these flights was in 2010 as an instrumental test to monitor light. The same year a second flight over the city of Jaén successfully took the first images for scientific use. In 2014 the project was repeated over the city of Madrid, acquiring images of quality comparable to the ones from airborne instruments with a hundredth of the cost.

The other scientific objective of these night flights is the estimation of meteoroid influx at Earth through the observation of meteor showers. Observing meteors from the stratosphere improves detection efficiency thanks to much lower extinction and less background brightness. Other teams had already demonstrated the benefits of airborne observations for these objects. In 2011 the team sent a low-light video camera to observe the Draconids 2011 outburst. Unfortunately the recording system failed and then mission had to be redesigned. For Geminids 2012, Camelopardalids 2014 and Geminids 2015 the instruments have worked flawlessly and the data are under analysis. Imaging and video devices with broad-band filters have been employed and results are comparable with airborne and satellite products, especially for high-resolution images.

9906-69, Session 19

Optical design for the large balloon reflector

German Cortes-Medellin, Cornell Univ. (United States) and Univ. de Antioquia (Colombia); Christopher K. Walker, Stefan O'Dougherty, The Univ. of Arizona (United States); Paul F. Goldsmith, Jet Propulsion Lab. (United States); Chris Groppi, Arizona State Univ. (United States); I. Steve

Smith, Southwest Research Institute (United States)

Balloon-borne telescopes have enabled terahertz observations of astrophysical objects which would otherwise be blocked or severely attenuated by the Earth's atmosphere. Successful missions such as BLAST (Balloon-borne Large Aperture Sub-millimeter Telescope) and now STO (Stratospheric THz Observatory) have proven that hanging a telescope from a balloon is a very economical approach for terahertz astronomy compared to the cost of flying space-borne instruments.

Nevertheless, one of the drawbacks is the ultimate pointing accuracy of the hanging telescope, which restricts the use of large apertures at very high frequencies.

A new concept, the Large Balloon Reflector (LBR) has been proposed and funded through the NASA Innovative Advanced Concepts (NIAC) program. In this approach the main reflector of the telescope is the metalized hemisphere of a smaller spherical balloon, 5 to 20 m in diameter, inflated inside the much larger carrier balloon. A spherical corrector optics and terahertz receiver sit in the interior of the sphere. The initial astrophysical targets of interest are the spectral lines of water at 557 GHz and Lithium at 444 GHz associated with star formation and Hi-z galaxies.

We will present the details of the optical design, corrector system, mechanical layout, tolerances, pointing requirements, and overall performance of LBR.

9906-70, Session 20

Telescope performance and results from the KMTNet 1.6 meter project completion

Wade M. Poteet, Harold K. Cauthen, CP Systems, Inc. (United States); Sang-Mok Cha, Yongsoek Lee, Chung-Uk Lee, Seung-Lee Kim, Byeong-Gon Park, Dong-Joo Lee, Korea Astronomy and Space Science Institute (Korea, Republic of)

The KMTNet telescope Project, sponsored by The Korea Astronomy and Space Science Institute (KASI), commissioned three wide-field equatorial mount telescopes of 1.6 meter aperture in 2015, and all three are now fully operational. The mission of this project is to conduct continuous observations of the Galactic bulge region to search for extra-solar planets. Southern latitude sites where installation of these telescopes is now complete include SAAO (South Africa), CTIO (Chile), and SSO (Australia). A prime-focus configuration, along with a three-lens coma corrector achieves the 2.8 degree diagonal FOV, and a fourth lens serves both as a detector dewar window and field-flattener. Four spectral filters are selectable remotely, and a variable-speed shutter is located at the corrector assembly. The basic mechanical design utilizes a scaled-up version of the successful 2MASS Telescopes built by the authors in the late 1990's. The efficient method for installation at the sites is described, typically 5 weeks of on-site work per site. Enclosures and fully operational domes were in place preceding each telescope installation that were identical to the Tucson, Arizona test facility, making the fit-up both efficient and quickly successful. Collimation and final optical adjustment was straightforward and resulted in star images better than 0.8 arcseconds in the astronomical "I" band (local seeing limited). Absolute pointing accuracy is 8 arcseconds above 60º from zenith. The flexure-style focus mechanism, driven by three precision actuators, moves the entire headring assembly and provides real-time focus capability along with tip/tilt, and active primary mirror cooling was successfully implemented for the Zerodur primary to prepare it for nighttime thermal conditions at each observatory. An extensive testing and verification program following installation shows that performance of mechanical and optical systems is to specification for the project. Initial optical performance was verified using small cameras placed at various positions in the focal plane. Later tests using the final science cameras shows that this method was effective in spot-checking the image at the focal plane. One critical factor in the rapid installation and first light at each site was assembling each telescope and enclosure in our test facility in Tucson, AZ prior to shipping the hardware. This method verified observatory interfaces tracking, optical characteristics at various attitudes, and overall observatory functionality. Mount manipulation, using T-Point® and star positions was well within adjustments provided for East-West rotations as well as declination axis angle. The three science cameras, fabricated by The Ohio State University Department of Astronomy, Imaging Sciences Laboratory (ISL), are now installed and are operational at each site. A significant performance achievement is the one-hour tracking accuracy in right ascension of 0.05 arcseconds, reducing the necessity for star-offset guiding under many circumstances. A review of the final mechanical and optical design are presented, along with the testing protocols, and detailed results of telescope optical and mechanical performance.

9906-71, Session 20

Customized overhead cranes for installation of India's largest 3.6m optical telescope at Devasthal, Nainital, India

Tarun Bangia, Shobhit Yadava, Brijesh Kumar, Aryabhatta Research Institute of Observational Sciences (India); Arun Savalaram Ghanti, P. M. Hardikar, Precision Precast Solutions Pvt. Ltd. (India)

India's largest 3.6m optical telescope has been recently installed at Devasthal site of Aryabhatta Research Institute of Observation Sciences (ARIES), an autonomous Institute under Department of Science and Technology, Government of India. Devasthal (29o 21'N, 79o 41'E), a prime astronomical site at an altitude of about 2450m above mean sea level is located in Kumaon region of Uttarakhand, India. The 3.6m modern technology telescope with active optics was designed, manufactured, factory tested and supplied to ARIES by Advanced Mechanical and Optical Systems (AMOS), Belgium. A steel building with rotating cylindrical steel dome was erected to house telescope and its accessories in its dome and supporting structure while mirror aluminizing plant was installed in the extended part of building at hilltop of Devasthal site. Customized overhead cranes were essentially required inside the telescope building as their were space constraints around the building for operating big external heavy duty cranes from outside, transportation constraints in route for bringing heavy weight cranes, altitude of observatory and sharp bends etc. to Devasthal site. To meet the challenge of telescope installation from inside the telescope building by lifting components through its 5.5m x 5.5m hatch opening, two single girder cranes and two under slung cranes of 10 ton capacity each were specifically designed, developed and installed by ARIES in consultation with Precision Precast Solutions (PPS), Pune India. All the four overhead cranes were custom built to specifically achieve the goal of handling telescope mirrors and its various components during telescope integration. Cranes were manufactured at Indiana Machine Tools (IMT), Gobindgarh, India and factory tested to meet AMOS requirements of telescope installation. Two customized single girder cranes of 10 ton capacity each were installed in extended building with a span of 11.15m and bay length of 24m whereas, two more customized 10 ton capacity under slung cranes were installed in dome building with a span of 4.9m and bay length of 14.7m. Cranes were installed in limited available space inside the building and tested as per IS 3177 using specifically prepared dummy loads to ensure safety of telescope components and its delicate mirror during installation and assembly. Apart from important contribution of cranes in successful integration of mechanical, optical and electrical components of telescope by AMOS, they also served in installation of mirror aluminizing plant, first aluminization of 3.7m diameter primary mirror of telescope, refurbishing activities and in various other maintenance activities. Cranes were specifically equipped with many features like VVVFD compatibility, provision for tandem operation with encoders, digital load display, anti-collision mechanism, electrical interlocks, radio remote, low hook height and compact carriage etc. Single girder cranes are capable of hoisting at very slow speed of the order of 3.3 mm/s and under slung cranes at about 5.8 mm/s for precise installation of fragile telescope mirror, various heavy

critical telescope components and during mirror aluminizing activities etc. Present paper presents design, development and testing of four customized overhead cranes and their vital role in successful installation of 3.6m telescope over its eccentric pier inside the building.

9906-72, Session 20

Status and performance of Lowell Observatory's Discovery Channel Telescope in its first year of full science operations

Stephen E. Levine, William T. DeGroff, Lowell Observatory (United States)

Lowell Observatory's Discovery Channel Telescope (DCT) is a 4.3-m telescope designed and constructed for optical and near infrared astronomical observation. The DCT is equipped with a cube capable of carrying five instruments along with the wave front sensing and guider systems at the f/6.1 RC focus. The facility formally finished commissioning at the end of 2014. In 2015 the DCT ran in full science operations mode. This report addresses operational methods, instrumentation integration and the performance of the facility as determined from delivered science data, lessons learned and plans for future work and instruments.

9906-73, Session 20

Current status of the facility instrumentation suite at the Large Binocular Telescope Observatory

Barry Rothberg, Michelle L. Edwards, John M. Hill, Olga P. Kuhn, David Thompson, Christian Veillet, R. Mark Wagner, Large Binocular Telescope Observatory (United States)

The current status of the facility instrumentation for the Large Binocular Tele-scope (LBT) is reviewed. The LBT consists of two 8.4 m primary mirrors and fully adaptive f/15 Gregorian secondary mirrors on a single mount yielding an effective collecting area of 11.8 m and an interferometric baseline of up to 23 m. The three facility instruments at the LBT include: 1) the Large Binocular Camera (LBC), a pair of blue and red optimized optical CCD imagers mounted at the prime foci each telescope with a 23'x25' field of view (FOV). The available filter suite covers the 0.3-1.1 ?m region, including the addition of new medium-band filters centered on TiO (0.78 ?m) and CN (0.82 ?m) for stellar population studies; 2) the Multi-Object Double Spectrograph (MODS), a pair of identical optical spectrographs mounted at the straight through f/15 Gregorian focus of each telescope. The capabilities of MODS include imaging with SDSS filters (u, g, r, i, and z) and medium resolution (R ~ 2000) or low resolution prism (R~200-500) spectroscopy with 24 inter-changeable masks (multi-object or long-slit) over a 6'x6' FOV. Each MODS is capable of individual blue (0.32-0.6 ?m) and red (0.5-1.05 ?m) spectroscopic coverage or both instruments can employ a dichroic beam splitter for 0.32-1.05 ?m wavelength coverage in a single exposure; and 3) the two LBT NIR Spectroscopic Utility with Camera Instruments (LUCI), mounted at each bent-front Gregorian f/15 foci and accessible by a rotating tertiary mirror. LUCI is designed for seeing-limited (4' x 4' FOV) and diffraction-limited (0.5' x 0.5' FOV) imaging and spectroscopy over the wavelength range of 0.95-2.5 ?m with spectroscopic resolutions of 400 ? R ? 20,000. The spectroscopic capabilities include 32 interchangeable multi-object or long-slit masks which are cryogenically cooled.

Recently, LUCI1 was upgraded to include a new detector with better quantum efficiency; to install a high-resolution camera to best utilize the exceptional image quality afforded by the adaptive optics system; and to install a grating designed primarily for use with the adaptive optics system. Thus, like MODS both LUCI instruments now have nearly identical imaging and spectroscopic configurations and as well as performance. The software interface for LUCI has also been replaced, allowing both instruments to be run together from a single user interface.

Although both primary mirrors reside on a single fixed mount, they are capable of operating as independent entities within a defined "co-pointing" limit. This provides users with the additional capability to independently dither each mirror or center observations on two different sets of spatial coordinates within this limit. With the installation of the facility instruments now complete, we also report on the first science use of "mixed-mode'' operations, defined as the combination of different paired instruments with each mirror (i.e. LBC+MODS, LBC+LUCI, LUCI+MODS).

9906-74, Session 20

Completion of the 3.6m Devasthal Optical Telescope project and the first results

Brijesh Kumar, Amitesh Omar, Maheswar Gopinathan, Aryabhatta Research Institute of Observational Sciences (India); Ram Sagar, Indian Institute of Astrophysics (India); Basant B. Sanwal, Wahab Uddin, Anil K. Pandey, Alok C. Gupta, Biman J. Medhi, Krishna Reddy Bheemireddy, Hum Chand, Jayshreekar Pant, Jeewan C. Pandey, Kuntal Misra, Shobhit Yadava, Mahendra Singh, Mohit K. Joshi, Mukeshkumar B. Jaiswar, Nanjappa N., Purshottam Jangid, Ramakant K. S. Yadav, Sanjit Sahu, Santosh Joshi, Saurabh S., Shashi Bhushan Pandey, Sneh Lata, Tarun Bangia, Tripurari S. Kumar, Yogesh C. Joshi, Aryabhatta Research Institute of Observational Sciences (India)

The 3.6 meter Devasthal Optical Telescope (DOT) Project was initiated bythe Aryabhatta Research Institute of Observational Sciences, Nainital, India, in 2007 with a partnership with Belgium. Recently, the telescope has been successfully installed and commissioned at Devasthal. The telescope site, Devasthal was chosen after carrying out extensive surveys in the Kumaun regions of central Himalayas. Devasthal is a low-wind good photometric astronomical site with a measured ground-level median seeing of about one arc sec. The location of this telescope assumes global importance for observing transient celestial objects since it is located in the middle of crucial longitudinal gap between the locations of 4-m class global optical telescope observing facilities in Australia in East and the Canary Islands in West. The primary goals of the 3.6m DOT is to carry out seeing-limited photometric imaging and the high resolution spectral observations at visible and near-infrared wavelengths.

The telescope manufacturing was contracted to a Belgian Company named Advanced Mechanical and Optical Systems (AMOS). The telescope has Ritchey-Chretien optics, alt-azimuth mount, active control of primary and a field-of-view of 30 arc min at the Cassegrain focus. The telescope enclosure, aluminizing and other auxiliary facilities were designed and built in India. The building was completed in June 2014. The building houses the concrete pier, the telescope, four overhead-cranes and a 3.7 m mirror coating plant. Considering the limited available space at site, a very compact telescope enclosure was designed in which the telescope pier is off-centered. The assembly and integration of entire telescope has been completed inside the enclosure. The primary mirror of telescope is mounted about 15m above the ground, where the contribution from ground level seeing is expected to be less than 0.5 arc sec. The telescope floor level is at 11m and a total of 12 ventilation fans are installed on dome-support enclosure for thermalisation of telescope before start of observations. The primary mirror of the telescope was coated with Aluminium for the first time using on site coating facility at Devasthal before its integration into the telescope. The design and implementation of synchronization of dome with the telescope has also been successfully

achieved. The first engineering light with the telescope was obtained on 22nd March 2015.

The on-sky performance of telescope has been tested with CCD camera and wave-front-sensor during March to December 2015. The measured pointing accuracy of the telescope is 2 arc sec RMS and the tracking accuracy is better than 0.1 arc sec RMS in an hour. Test images were recorded using a 4kx4k Imager as first light instrument. The binary stars with separation down to 0.4 arc sec have been clearly resolved implying that seeing at site is close to what was expected during site characterizations. In this contribution, a brief overview and status of installation activities at site and preliminary on-sky test results is presented.

9906-207, Session PS11

Smart co-phasing system for segmented mirror telescopes

Juan F. Simar, Ctr. Spatial de Liège (Belgium) and Univ. de Liège (Belgium); Yvan G. Stockman, Ctr. Spatial de Liège (Belgium) and Univ. de Lèige (Belgium); Jean Surdej, Univ. de Liège (Belgium) and Astrophysique Extragalactique et Observations Spatiales (Belgium)

One of the main challenging tasks in nowadays segmented mirror telescopes is to perform an efficient co-phasing of the sub-apertures. The dynamic range of such a co-phasing starts from several tenths of micrometers corresponding to the mechanical accuracy to a few nanometers required for the piston and tip/tilt corrections. A system able to perform the complete co-phasing task of a telescope made of maximum seven sub-apertures is described. The system needs basic hardware and is relatively simple to implement. Coarse and fine measure technics are first addressed. The proposed setup is then presented. It is divided into three sub-systems: Coarse phasing, Fine phasing and Locking feedback system. The guide lines to improve the system speed and to increase the number of sub-apertures are evaluated.

First, the coarse sensor records the Point Spread Function (PSF) in the focal plane of the telescope by means of a CCD. Then, calculates the piston with the inverse of the Gaussian function that is proportional to the coherence level of the PSF. The coherence level is linked to the Modulation Transfer Function (MTF).

The coarse sensor measures piston between three different ranges (3 filters) that are overlapped in their limits in order to cover a range from 160µm to 100nm.

After the coarse measurement, an actuator moves the mirror by a distance equals to the measured error in order to correct it. This actuator has a range of 400µm and a resolution of 4nm.

The fine phasing system has a measurement range of +/- 310nm and is able to correct piston and tip/tilt errors. The fine piston error is proportional to the peak height in the OTF phase component, i.e. the phase transfer function (PTF). These piston error are calculated by multiplying the height of the peaks by a constant. The fine tip/tilt errors are proportional to the inclination of the top of the peaks of the PTF. These tip/tilt errors are then calculated by measuring the derivate of the top of the peaks and multiplying it by a constant. The actuator corrects then the measured fine errors.

Once the fine tuning achieved, the system needs to stay co-phased. A locking feedback system is used to maintain the piston and tip/tilt errors smaller than 10nm and 1 arcsec. It consists in a control algorithm that measures the errors 3 times per second in order to correct them in real time. By this way a diffraction limited segmented telescope can be realized.

The speed of the system can be improved with a capacitive locking feedback system. This can be achieved with capacitive sensors that are very fast (several hundreds of times per second) and precise (nm scale) but they shall be calibrated before utilization. The fine sensor is then be used for calibration before the turn ON of the capacitive feedback locking system. The quantity of segments can be increased with a dynamic mask. This can be realized with a LCD (liquid crystal display) system. With the dynamic mask, it will be possible to co-phase infinite sub-pupil quantity (7 each time).

9906-208, Session PS11

SOAR Telescope seismic performance II: seismic mitigation

Jonathan Elias, Freddy Muñoz Arancibia, Michael Warner, Gerardo Gomez, Cerro Tololo Inter-American Observatory (Chile)

We describe design modifications to the SOAR telescope intended to reduce the impact of future major earthquakes, based on the facility's experience during recent events, most notably the September 2015 Illapel earthquake. Specific modifications include a redesign of the encoder systems for both azimuth and elevation, seismic trigger for the emergency stop system, and additional protections for the telescope secondary mirror system. The secondary mirror protection may combine measures to reduce amplification of seismic vibration and "fail-safe" components within the assembly. The status of these upgrades is presented.

9906-209, Session PS12

Glycol leak detection system

Paul Rabe, Keith R. J. Browne, Janus Brink, South African Astronomical Observatory (South Africa)

SALT, the Southern African Large Telescope, consists of many subsystems that require cooling and was accomplished by using Ethelyne glycol coolant throughout the telescope. The risk of glycol pipes leaking and potentially causing damage to not only electrical equipment and instruments, but also to the primary mirror, was identified and needed to be addressed. Damage to equipment could result in science downtime for up to a year. A study was conducted to determine the best way of detecting a glycol leak. The first concept, which is explained in Sec. 1, was to use differential pressure readings between Supply and Return glycol pipes and trigger the system when this resulted in in a difference larger than a predefined setpoint. The second accepted concept which is in operation is the use of leaf wetness sensors and is also explained.

1 . Differential Pressure Controlled Detection

The first concept was to use differential pressure readings between the glycol supply and return line. This would require pressure transmitters on both lines been monitored by a micro controller. On power up, the controller would initialize whereby average pressure is calculated over a 60 second period on both sensors. After this period the controller would switch to ready mode and would continue to monitor the pressure readings. If the difference between the supply and return pressure readings become greater than averaged limits, the valve on the supply side would close and the alarm relay would activate. The controller would be manually reset by the technician after checks are performed. On ground level, this system worked without any problems where the pressure readings are stable and between 1.4 and 2.1 Bar. The pressure on each line would not vary more than 0.3 Bar and the pressure difference between the supply and return would not vary more than 0.5 Bar.

The system was tested on payload level which is over 20 meters above ground level and retested. Due to the various splits and height of the glycol pipes, the pressure readings had given different results, and was found to be very erratic causing the system to not find a suitable differential reading to operate from. The return pressure would give readings of 0 to -1 bar and supply would be between 1 and 2 bar. This tolerance would be too large and unreliable to be used to determine whether there is a leak in the pipe

or not and would only be suitable for a pipe burst. We needed glycol to be detected on its early stages of a leak.

2. Leaf Wetness Sensor Controlled Detection

The second concept which was tested was to rely solely on leaf wetness sensors. These sensors made of a PC board with a fork design copper track is plugged into a controller. This would trigger if the resistance between the tracks become smaller than a preset amount. These sensors would be placed in various critical areas around the payload where leaks are more likely to occur. The controller would respond as with the previous concept would, when triggered, would close the valve and could only be reset if the alarm is cleared. The alarm is in a cleared state when the sensor is replaced and free from glycol.

The final concept is tested as part of our maintenance tasks and is currently performing as required.

9906-210, Session PS12

The MROI Array telescopes: the relocatable enclosure domes

Gianpietro Marchiori, Andrea Busatta, EIE Group s.r.l. (Italy); Ifan Payne, New Mexico Institute of Mining and Technology (United States); Francesco Rampini, EIE Group s.r.l. (Italy)

The MROI - Magdalena Ridge Interferometer is a project which comprises an array of up to 10 1.4m diameter mirror telescopes arranged in a “Y” configuration. Each of these telescopes will be housed inside a Unit Telescope Enclosure (UTE) which are relocatable onto any of 28 stations.

EIE GROUP Srl, Venice – Italy, was awarded the contract for the design, the construction and the erection on site of the MROI by the New Mexico Institute of Mining and Technology.

The close-pack array of the MROI - including all 10 telescopes, several of which are at a relative distance of less than 8m center to center from each other - necessitated an original design for the Unit Telescope Enclosure (UTE). This innovative design enclosure incorporates an unique dome/observing aperture system to be able to operate in the harsh environmental conditions encountered at an altitude of 10,460ft (3,188m).

The main characteristics of this Relocatable Enclosure Dome are: a Light insulated Steel Structure with a dome made of composites materials (e.g. glass/carbon fibres, sandwich panels etc.), an aperture motorized system for observation, a series of louvers for ventilation, a series of electrical and plants installations and relevant auxiliary equipment.

The first Enclosure Dome is now under construction and the completion of the mounting on site id envisaged by the end of 2016.

The Project includes a relocation systems with a rail based system, wheels fixed to the bottom of the enclosure and various lifting mechanisms. The relocation system utilizes a modified reachstacker (a transporter used to handle freight containers) capable of manoeuvring between and around the enclosures, capable of lifting the combined weight of the enclosure with the telescope (40tons), and can manoeuvre the enclosure with minimal vibrations.

9906-211, Session PS12

SOAR Telescope seismic performance: impact of the 2015 Illapel earthquake

Jonathan Elias, Michael Warner, Freddy Muñoz Arancibia, Gerardo Gomez, National Optical Astronomy Observatory (Chile)

The response of the SOAR telescope to the September 2015 Illapel earthquake is documented and placed in the context of other recent, nearby seismic events. Accelerometer data collected on the telescope during these events suggest that observed intensities due to events occurring to the south of the SOAR telescope site are higher than predicted by simple models. Amplification of accelerations occurs at several places within the telescope system, most notably the telescope top end and secondary mirror assembly, and the azimuth encoder system. Damage in these areas is described, and an overview of the earthquake recovery effort is presented.

9906-216, Session PS13

The GCT camera for the Cherenkov Telescope Array

Anthony M. Brown, Durham Univ. (United Kingdom); A. Abchiche, Ctr. National de la Recherche Scientifique (France); D. Allan, Durham Univ. (United Kingdom); Jean-Philippe Amans, Observatoire de Paris à Meudon (France); Thomas P. Armstrong, Durham Univ. Vink, Univ. van Amsterdam (Netherlands); Jason J. Watson, Univ. of Oxford (United Kingdom); Richard White, Max-Planck-Institut für Kernphysik (Germany); Andréas Zech, Observatoire de Paris (France); Adrian Zink, Erlangen Ctr. for Astroparticle Physics (Germany)

The Cherenkov Telescope Array (CTA) is the next generation ground-based imaging atmospheric Cherenkov telescope (IACT) array and will operate as an Observatory. Building on the strengths of current IACTs, CTA is designed to achieve an order of magnitude improvement in sensitivity, with unprecedented energy and angular resolution. Importantly, CTA will also increase the energy reach of ground-based gamma-ray astronomy, from ~0.02 TeV to beyond 100 TeV.

To meet these ambitious goals, CTA will consist of three telescope classes: Small, Medium and Large Sized Telescopes (SST, MST and LST respectively). To achieve all-sky coverage, CTA will consist of two arrays, one in each hemisphere. The northern array will contain approximately 20 telescopes spread over about 1 km2, while the southern array will contain over 100 telescopes spread over an area of several square kilometers.

The Gamma-ray Cherenkov Telescope (GCT) is a dual-mirror SST prototype proposed for CTA. The dual-mirror optical design allows reduction of the telescope's plate scale, enabling small form-factor photosensor elements to be used in the camera. Additionally, the good off-axis point spread function allows a large field-of-view camera to be built from these photosensors. There are two prototypes for the GCT camera: one based on multi-anode photomultipliers (CHEC-M) and one based on silicon photomultipliers (CHEC-S). Both of these prototypes contain 32 modules, totalling 2048 pixels. During event read out, the analogue signal from each pixel is pre-amplified before being passed to the camera front-end electronics modules. These modules digitise the signal and read out the full waveform of each pixel, for every event triggering the camera. In total there are 32 camera modules, with each camera module containing four custom TARGET ASICs. The use of ASICs in the camera module affords the GCT fast data readout, with a large amount of flexibility. This allows for optimisation of the event read-out window, buffering of triggered events and variations in the resolution which the event waveforms are sampled.

The first GCT prototype camera (CHEC-M) was recently been commissioned, with on-telescope tests taking place at the Paris Observatory, Meudon, on the prototype telescope. The culmination of the commissioning is the recording of the first Cherenkov images from a SC telescope, and the first Cherenkov images recorded by a CTA prototype. In this contribution we give a detailed description of the GCT camera and present preliminary results from CHEC-M tests.

9906-218, Session PS13

Challenges for QTT structure

Qian Xu, Na Wang, Xinjiang Astronomical Observatory (China)

An amazing radio telescope called QTT (the short form of QiTai radio Telescope) will be constructed in Qitai County, Xinjiang, China. QTT is a 110-m aperture fully steerable radio telescope with zenith range about 83o, reaching 11o south of the Galactic center and its observing frequency range covers from 150MHz-115GHz. The main reflector surface accuracy achieves 0.2mm (rms) after long term adjustment, and the sub-reflector surface accuracy is 0.07mm (rms) while the pointing accuracy is less than 2.5arcs above 6mm observation wave length. The application goal accords with the demands of Chinese deep space exploration, to satisfy the Chinese strategic plan and to make a good preparation for Chinese technology and science.

Anyhow for an antenna like QTT will meet many challenges for its structure design. Here we will introduction the structure problems we meet including: antenna weight vs. stiffness, azimuth track, alidade, reflector panel, reflector and alidade connecting, actuator, feeds switching, sensor use, etc. and show the current progress.

9906-220, Session PS13

Status of the Trans-Neptunian Automated Occultation Survey (TAOS II)

Matthew J. Lehner, Academia Sinica (Taiwan) and Univ. of Pennsylvania (United States) and Harvard-Smithsonian Ctr. for Astrophysics (United States); Shiang-Yu Wang, Academia Sinica (Taiwan); Mauricio Reyes Ruiz, Observatorio Astronómico Nacional (Mexico); You-Hua Chu, Academia Sinica (Taiwan); William H. Lee, Univ. Nacional Autónoma de México (Mexico); Charles Alcock, Harvard-Smithsonian Ctr. for Astrophysics (United States); Zhi-Wei Zhang, Dae-Won Kim, Kem H. Cook, Academia Sinica (Taiwan); Chung-Kai Huang, National Central Univ. (Taiwan) and Academia Sinica (Taiwan); Wei-Ling Yen, Academia Sinica (Taiwan); Liliana Figueroa, Observatorio Astronómico Nacional (Mexico); Andrew Szentgyorgyi, Timothy J. Norton, Harvard-Smithsonian Ctr. for Astrophysics (United States); Wen Ping Chen, National Central Univ. (Taiwan)

The Transneptunian Automated Occultation Survey (TAOS~II) will aim to detect occultations of stars by small (sim1~km diameter) objects in the outer Solar System. Such events are very rare ($<10^{-3}$ events per star per year) and short in duration (sim200~ms), so many stars must be monitored at a high readout cadence. TAOS~II will operate three 1.3~meter telescopes at the Observatorio Astron'{o}mico Nacional at San Pedro M'{a}rtir in Baja California, M'{e}xico. With a 2.3~square degree field of view and high speed cameras comprising CMOS imagers, the survey will monitor 10,000~stars simultaneously with all three telescopes at a readout cadence of 20~Hz. Construction of the site began in the fall of 2013. This poster will present the status of the survey infrastructure and future plans for the completion of the site development and telescope installation.

9906-221, Session PS13

Characterizing the vibration environments of the Gemini telescopes

Thomas L. Hayward, Gemini Observatory (Chile); Mathew J. Rippa, Gemini Observatory (United States); Henri M. Bonnet, European Southern Observatory (Germany); Charles Cavedoni, Gemini Observatory (United States); Ramon L. Galvez, Gaston Gausachs, Gemini Observatory (Chile); Myung Kyu Cho, National Optical Astronomy Observatory (United States)

We report the results of a multi-year program to measure the vibration characteristics of the two Gemini telescopes, evaluate the effect of vibrations on image quality, and implement solutions to mitigate some of the vibrations. At Gemini North, the investigation was motivated by frequent instances of elongated and irregular images, particularly when conducting adaptive optics observations. Wavefront sensor data at 200 Hz frame rate revealed a principal source of image degradation to be a 12

Hz periodic oscillation induced by the GNIRS instrument cryocoolers that was strongest at a specific angle of the Cassegrain Rotator. To investigate the oscillation further, the telescope was outfitted with a network of accelerometers on both the primary (M1) and secondary (M2) mirrors and their support systems. The accelerometers revealed harmonics from all the instrument cryocoolers throughout the telescope, but the 12 Hz oscillation was specifically detected in M1 and its cell. The relative phases measured across M1 showed the mirror to be oscillating in tilt with an amplitude sufficient to cause the image motion measured by the WFS. Detailed FEA analysis of the mirror cell and its support system corroborate the hypothesis that the cryocoolers excite a resonance near 12 Hz, producing the optical oscillation. In mid-2014, a real-time vibration tracking algorithm was added to the M2 fast-guiding system to compensate the 12 Hz oscillation. At Gemini South, a simpler accelerometer network was implemented to study image oscillations reported by GPI. A similar analysis indicated that the GPI cryocoolers were injecting a 60 Hz oscillation into M1, in this case impulsing the center of the mirror to cause an aberration similar to defocus. Attempts to compensate the oscillation within GPI and add passive vibration dampers were only partially successful, but in 2015 an active cancellation system installed on the cryocoolers substantially reduced the vibration level. We also identified and suppressed additional sources of vibration affecting both GPI and the GeMS AO system. Our work demonstrates the importance of monitoring the vibration environment of modern telescopes, in particular when using adaptive optics to achieve diffraction-limited image quality.

9906-212, Session PS14

Performance evaluation method on Antarctic survey telescopes

Xiaoyan Li, Shihai Yang, Fujia Du, Nanjing Institute of Astronomical Optics & Technology (China)

Antarctic Survey Telescopes deployed to Dome A, Antarctica are less-intrusive during observation for its unattended and automatic design. So it is important to evaluate the performance of control system automatically. The analysis trees are constructed to get the performance evaluation result of the control system based on the data from the collection system. The result was used to help determine when to adjust and optimize the system and how to maintenance the equipment in next expedition.

9906-213, Session PS14

Experience with the operation of the European ALMA antennas

Stefano Stanghellini, Silvio Rossi, Robert A. Laing, Wolfgang Wild, European Southern Observatory (Germany)

The 25 European antennas of ALMA were delivered by ESO to the ALMA project in Chile between April 2011 and September 2013. Since then they have been in operation without substantial problems. Their combined time of operation is already significant and allows us to draw conclusions regarding their ability to fulfill the original specification, in terms of both scientific performance and operational availability. This latter aspect is of central importance for the ALMA observatory, which has to operate and be routinely maintained at 5000m. In this paper, we will summarize the experience gained during the past five years of operation. We will characterize the performance of the antennas in routine operation and compare with the data obtained during acceptance testing. We will also describe the few technical issues experienced while operating at 5000m and the way in which these were treated during these first years of operation. We will evaluate the effective reliability obtained in service based on field data and draw some conclusions as to the way in which reliability and maintainability aspects were covered during the process which led to the final design of the antenna. We will discuss the smart use of software to handle redundancy in a flexible way and to exclude failed components without affecting overall antenna operability. This approach is based on remote access to the antennas, which is routinely used to read the status and to control modes of the Antenna Control Unit. The use of low- level diagnostics enabled by remote access allows us to shorten the trouble- shooting cycle and to optimize physical interventions on the antennas, which are sometimes located far from the centre of the ALMA array. Finally, the paper will cover the maintenance manuals delivered by ESO with the antennas, which were produced using an industrial interactive standard. It will be explained why this advanced and innovative concept has not achieved the success that was expected, and why the traditional form is preferred at the ALMA Observatory.

9906-214, Session PS14

The LLAMA Observatory: a new sub-mm facility for Latin America

Marcelo E. Arnal, Univ. Nacional de la Plata (Argentina); Jacques Lepine, Univ. de São Paulo (Brazil); Mattheus W. M. de Graauw, European Southern Observatory (Chile) and Univ. de São Paulo (Brazil); Zulema Abraham, Univ. de São Paulo (Brazil); Cristina E. Cappa, Univ. Nacional de la Plata (Argentina); Elisabethe M. de Gouveia Dal Pino, Univ. de São Paulo (Brazil); Guillermo Gimenez de Castro, UPM (Brazil); Juan Jo Larrarte, Ricardo Morras, Univ. Nacional de la Plata (Argentina); Jose German Viramonte, Univ. Nacional de Salta (Argentina); Jacob W. Kooi, California Institute of Technology (United States); Ricardo Finger, Univ. de Chile (Chile); Rodrigo A. Reeves, Univ. de Concepción (Chile)

The Large Latin American Millimeter Array (LLAMA) is a joint scientific and technological undertaking of Argentina and Brazil whose final goal is to install and operate a submm array. As a first step one antenna will be constructed and operated in a single dish mode and as an element of a VLBI observatory in Latin American network that may include ALMA, APEX, LMT and ASTE and participate in the Event Horizon Telescope (EHT). The antenna will be located in the Argentinean High Andes, at Cerro Alto Chorrillos, at an altitude of 4800 meters, 180 km south-east of ALMA, with atmospheric conditions similar to those for ALMA. It is located 20 km from the town of San Antonio de los Cobres from where remote operations will take place. The antenna will be assembled in the second half of 2016, followed by commissioning and operations will start in 2017.

LLAMA is to have a North American ALMA-type antenna, constructed by VERTEX, complemented with two Nasmyth cabins equipped with 6 ALMA-like receiver cartridges in two cryostats. The Cassegrain focus area will be used for a bolometric camera or a heterodyne array receiver but it will contain a beam re- distribution optics to the two Nasmyth cabins. The novel design allows simultaneous observations between two receiver bands in both polarizations and between four bands in one polarization.

The LLAMA antenna is, as for ALMA, suitable for solar observations and will be unique for its capability to make simultaneous observations in 4 bands. This is also of interest for (sub-)mm VLBI observations as has been demonstrated with the Korean VLB array. LLAMA is planned to participate in the Event Horizon Telescope.

The First Light equipment will include a band-5 and a band-9 receiver.

The LLAMA is one of the first observatories to take advantage of the open ALMA Common Software package for its software development. This facilitates considerably the software development effort for equipment monitor and control.

9906-215, Session PS14

Power supply system design and build for Antarctica telescope

Fujia Du, Hao Li, Aiai Li, Nanjing Institute of Astronomical Optics & Technology (China)

Currently, more and more telescopes were built and installed in Dome A of Antarctic. The telescopes are remote controlled, unattended operation due to Dome A's environment. These telescopes must be work successfully at least one year without any failure. According to past experience, the power supply system is the weakest point in whole system. The telescopes have to stop if the power system have a problem, even a minor problem. So the high requirement for power supply system are presented. The requirement include high reliability, the self-diagnosis and perfect monitor system. Furthermore, the optic telescope only can work at night. The power source mainly relay on diesel engine. To protect the Antarctic environment and increase the life of engines. The power capacity is limited during observation. So it need the power supply system must be high power factor, high efficient. To meet these requirement, one power supply system was design and built for Antarctic telescope. The power supply system have the following features. First, we give priority to achieve high reliability. The reliability of power system was calculated and the redundant system is designed to make sure that the spare one can be work immediately when some parts have problems. Second, the perfect monitor system was designed to monitor the voltage, current, power and power factor for each power channel. The status of power supply system can be acquired by internet continuously. All the status will be logged in main computer for future analysis. Third, the PFC (Power Factor Correction) technology was used in power supply system. This technology can dramatically increase the power factor, especially in high power situation. The DC-DC inverter instead of AC-DC inverter was used for different voltage level to increase the efficient of power supply.

9906-222, Session PS15

The Telescopio San Pedro Martir project

Michael G. Richer, William H. Lee, Jesús Gonzalez-Hernandez, Univ. Nacional Autónoma de México (Mexico); Buell Jannuzi, The Univ. of Arizona (United States); Beatriz S. Sánchez, Fabian Rosales Ortega, Univ. Nacional Autónoma de México (Mexico); Charles Alcock, Harvard-Smithsonian Ctr. for Astrophysics (United States); Alberto Carramiñana, Instituto Nacional de Astrofísica, Óptica y Electrónica (Mexico); Teresa Garcia Diaz, Leonel Gutierrez Albores, Joel Herrera Vazquez, Univ. Nacional Autónoma de México (Mexico); Derek Hill, M3 Engineering & Technology Corp. (United States); Timothy J. Norton, Harvard-Smithsonian Ctr. for Astrophysics (United States); Maria H. Pedrayes, Univ. Nacional Autónoma de México (Mexico); Ana Pérez Calpena, FRACTAL S.L.N.E (Spain); Mauricio Reyes Ruiz, Hazael Serrano Guerrero, Gerardo Sierra Diaz, Univ. Nacional Autónoma de México (Mexico); Jose Teran, M3 Engineering & Technology Corp. (United States); David Urdaibay, Univ. Nacional Autónoma de México (Mexico); Jorge A. Uribe, Ctr. de Ingenieria y Desarrollo Industrial (Mexico); Alan M. Watson, Univ. Nacional Autónoma de México (Mexico); Dennis Zaritsky, The Univ. of Arizona (United States)

The Telescopio San Pedro Mártir (TSPM) project intends to construct a 6.5m telescope to be installed at the Observatorio Astronómico Nacional in the Sierra San Pedro Mártir in northern Baja California, Mexico. The project is an association of Mexican institutions, lead by the Instituto Nacional de Astrofísica, Optica y Electrónica (INAOE) and UNAM's Instituto de Astronomía (IA-UNAM), in partnership with the Smithsonian Astrophysical Observatory (SAO) and the University of Arizona's Department of Astronomy and Steward Observatory (UA). The project is currently in the design stage, with the goal of holding its preliminary design review in mid-2016.

The telescope will be a Magellan-like mechanical design, whose principal change is to move the Nasmyth focal stations slightly higher from the primary to allow a wider field of view. The primary mirror cell will be completely compatible with the MMT telescope's Cassegrain focus. This design is being lead by the Centro de Ingeniería y Desarrollo Industrial (CIDESI) in Querétaro, Mexico. Initially, the telescope is to operate in a f/5 Cassegrain configuration, before future definition and expansion to its other focal stations, including Nasmyth and folded Casssegrain configurations.

The enclosure is being designed by M3 Engineering and Technology Corp., through their branch in Hermosillo, Mexico. The design borrows elements from the Magellan telescopes (Las Campanas, Chile), but incorporating the particular needs of the San Pedro Mártir site. The primary mirror will be polished at the Steward Observatory Mirror Lab (Richard F. Caris Mirror Lab). The telescope will initially use the f/5 Cassegrain secondary currently at the Magellan II Clay telescope. The first light instruments are likely to be the Megacam and MMIRS instruments, currently at the Magellan II and MMT telescopes, respectively.

Once completed, we anticipate that the collaboration and coordination of the two observatories will provide their communities the benefits of a binational astrophysical observatory serving astronomers from all partner institutions, with each site focussing upon its strengths. The TSPM, thanks to its wide field imaging capability, will allow state-of-the-art research on planetary, Galactic and extragalactic astronomy, variable sky studies, and large scale surveys. TSPM will be complementary not only to the MMT for large scale, high-impact programs, but also to multi-frequency collaborations that could exploit current Mexican facilities, such as the Gran Telescopio Milimétrico Alfonso Serrano (GTM) and the High-Altitude Water Cherenkov Gamma-Ray Observatory, HAWC. The TSPM will also represent a excellent follow-up complement for +20m class telescopes after 2020.

9906-223, Session PS15

The ASTRI prototype and mini-array: telescopes precursors for the Cherenkov Telescope Array (CTA)

Giovanni Pareschi, INAF - Osservatorio Astronomico di Brera (Italy)

In the framework of the Cherenkov Telescope Array (CTA) Observatory, the Italian National Institute of Astrophysics (INAF) has recently inaugurated in Sicily (Italy), at the Serra La Nave astronomical site on the slopes of Mount Etna, a large field of view (9.6 degrees) dual-mirror prototype (ASTRI SST-2M) of the CTA small size class of telescopes. CTA plans to install about 70 small size telescopes in the southern site to allow the study of the gamma rays from a few TeV up to hundreds of TeV. The ASTRI SST-2M telescope prototype has been developed following an end- to-end approach, since it includes the entire system of structure, mirror's optics (primary and secondary mirrors), camera, and control/acquisition software. A remarkable improvement in terms of performance could come from the operation of the ASTRI mini-array, led by INAF in synergy with the Universidade de Sao Paulo (Brazil) and the North-West University (South Africa). The ASTRI mini-array will be composed of nine ASTRI SST-2M units and it is proposed as a precursor and initial seed of CTA to be installed at the final CTA southern site. Apart from the assessment of a number of technological aspects related to CTA, the ASTRI mini-array will extend and improve the sensitivity, similar to the H.E.S.S. one in the 1-10 TeV energy range, up to about 100 TeV.

9906-224, Session PS16

ALMA long baseline phase calibration using phase referencing

Yoshiharu Asaki, National Astronomical Observatory of Japan (Japan) and Joint ALMA Observatory (Chile); Satoki Matsushita, Academia Sinica (Taiwan); Edward B. Fomalont, National Radio Astronomy Observatory (United States) and Joint ALMA Observatory (Chile); Stuartt A. Corder, Lars-Åke Nyman, William R. F. Dent, Neil M. Philips, Akihiro Takahashi, Satoko Takahashi, Baltasar Vila-Vilaro, Joint ALMA Observatory (Chile); Bojan Nikolic, Cavendish Lab. (United Kingdom); Todd R. Hunter, Anthony Remijan, Catherine Vlahakis, National Radio Astronomy Observatory (United States)

The Atacama Large Millimeter/submillimeter Array (ALMA) is the world's largest millimeter/submillimeter telescope and provides unprecedented sensitivities and spatial resolutions. The highest spatial resolution is achieved with the longest antenna spacings (baselines). Because the most extended array configuration of ALMA has up to 15 km baselines, the highest spatial resolutions are 60, 25, and 17 milli arcseconds at the receiving wavelengths of 3, 1, and 0.3 mm, respectively. With these resolutions, ALMA is expected to reveal unseen astrophysical phenomena in a variety of celestial objects. To achieve the highest imaging capabilities, interferometric phase calibration for the long baselines is one of the most important subjects: The longer the baselines, the worse the phase stability becomes because of turbulent motions of the Earth's atmosphere, especially, the water vapor in the troposphere. To overcome this subject, ALMA adopts a phase calibration scheme using a water vapor radiometer (WVR) to estimate the amount of water vapor content along the antenna line of sight. An additional technique is phase referencing, in which a science target and a nearby calibrator are observed by turn by quickly changing the antenna pointing. The WVR phase calibration is useful to mitigate phase fluctuations due to the water vapor while the phase referencing can largely remove phase noises which are commonly seen both in the interferometer phases of a target and nearby calibrator. We conducted feasibility studies of the combination technique with the WVR phase correction and phase referencing for the ALMA 15 km longest baselines in cases that (1) the same observing wavelength both for a target and calibrator is used, and (2) shorter and longer wavelengths for a target and calibrator, respectively, with a typical switching cycle time of 20 to 25 s. The latter technique is called band-to-band and fast switching (B2B+FS). It was found that the phase calibration performance of the combined technique is promising where a nearby calibrator is located within 3 degrees from a science target. The currently trial phase calibration method shows the same performance independent of the observing wavelengths. This result is especially important for the shorter wavelength observations because it becomes difficult to find a bright calibrator close to an arbitrary sky position, so that the B2B+FS can be a very useful metho especially for shorter wavelengths. In the series of our experiments, it is also found that, for ALMA, phase errors affecting the image quality come from not only the water vapor content but also a large structure of the atmosphere with a typical cell scale of a few tens of kilometers.

9906-225, Session PS16

The design of the local monitor and control system of SKA dishes

Francesco Schillirò, Corrado Trigilio, Ugo Becciani, Alessandro Costa, Adriano Ingallinera, Simone Riggi, Alessandro Marassi, Roberto Cirami, Veronica Baldini, Gaetano Nicotra, Carlo Nocita, Istituto Nazionale Astrofisica (Italy)

The Square Kilometer Array (SKA) project aims at building the world's largest radio observatory to observe the sky with unprecedented sensitivity and collecting area.In the first phase of the project (SKA1), an array of dishes, SKA1-MID, will be build in South Africa. It will consist of 133 15m-dishes, which will include the MeerKAT array, for the 0.350-20 GHz frequency band observations.

Each antenna will be provided with a local monitor and control system (LMC), enabling operations both to the Telescope Manager remote system, as the to engineers and maintenance staff; it provides different environment for the telescope control (positioning, pointing, observational bands), metadata collection for monitoring and database storaging, operational modes and functional states management for all the telescope capabilities.

In this paper we present the LMC software architecture designed for the detailed design phase (DD),where we describe functional and physical interfaces with monitored and controlled sub-elements, and highlight the data flow between each LMC modules and its sub-element controllers from one side, and Telescope Manager to other side.

We also describe the complete Product Breakdown Structure (PBS) created in order to optimize resources allocation in terms of calculus and memory, able to perform required task for each element according the proper requirements. Among them, time response and system reliability are the most important, considering the complexity of SKA dish network and its isolated placement.

Performances obtained by software implementation using TANGO framework will be discussed, matching them with technical requirements derived by SKA science drivers.

9906-226, Session PS16

Design and analysis of a large cylinder antenna array in Tianlai

Zhiping Chen, Rongli Wang, Hangzhou Dianzi Univ. (China); Jeffrey B. Peterson, Carnegie Mellon Univ. (United States); Xuelei Chen, National Astronomical Observatories (China); Juyong Zhang, Hangzhou Dianzi Univ. (China); Hu-li Shi, National Astronomical Observatories (China)

In order to make a large area survey, precisely measure a large scale space and detect dark energy, a large radio interference array with a large number of feeds is required. However, the cost and the deformation measurement are very important in designing a large antenna array. This paper presents a structure design of one cylinder parabolic antenna array with 45m x 40m, which was built for "Tianlai" project in Xinjiang, China in 2015. In order to largely reduce the weight and the cost, we divided it into many assemble units which were optimized in mechanical design by MSC.Patran/Nastran, then analyzed the deformation of the reflector under various load cases of gravity, snow and wind. For the feed support structure, we designed and compared some supporting types such as arch bridge, tower, cable and pole. Mechanical and electromagnetic field simulations show that the arch bridge is very useful to complete the large span, and the antenna structure is very light and stable. Finally some measurement methods and experiments for the deformation are discussed. These results will be used to extend this array to 100m x 100m in the future.

9906-227, Session PS16

Measuring dark energy and radio transients with HIRAX

Laura B. Newburgh, Univ. of Toronto (Canada); Jon Sievers, HIRAX (South Africa)

The Hydrogen Intensity and Real-time Analysis eXperiment (HIRAX) is a new 400-800MHz radio interferometer under development for deployment in the Karoo Desert, South Africa. It will have 1024 5-m parabolic dishes on a compact grid, and will map the entire Southern sky over the course of 2 years. HIRAX has two primary science goals: to constrain Dark Energy and measure structure at high redshift and to study radio transients and pulsars.

HIRAX will measure unresolved sources of neutral hydrogen via their redshifted 21cm emission line (hydrogen intensity mapping). The resulting maps of large scale structure at redshifts 0.8--2.5 can be used to measure Baryon Acoustic Oscillations (BAO). BAO are a preferential scale in the matter distribution created with the Cosmic Microwave Background which we can use to chart the expansion history of the Universe and thus understand the nature of Dark Energy. BAO measurements with HIRAX will improve current error bars from galaxy surveys by observing a larger cosmological volume (both from increased survey area and redshift range), and will also measure BAO at high redshift when the expansion of the Universe transitioned to Dark Energy-dominated. HIRAX will complement CHIME, a hydrogen intensity mapping effort in the Northern Hemisphere, by completing the sky coverage in the same redshift range. HIRAX's location in the Southern Hemisphere also allows a variety of correlation measurements with surveys of structure at many wavelengths.

Daily maps of 15,000 square degrees of the southern hemisphere will also be a new approach for discovering and monitoring radio transients. With access to the entire plane of the Milky way galaxy, HIRAX is building into its correlator the ability to rapidly and efficiently detect transients. The results will shed light on the poorly understood nature of Fast Radio Bursts (FRBs), have a critical monitoring role in pulsar timing arrays to detect long-wavelength gravitational waves, and find new radio transient phenomena.

In this paper, I will discuss the HIRAX instrument, science goals, and current status.

9906-228, Session PS16

Super-resolution with Toraldo pupils: analysis with electromagnetic numerical simulations

Luca Olmi, INAF - Osservatorio Astrofisico di Arcetri (Italy) and Univ. of Puerto Rico (United States); Pietro Bolli, INAF - Osservatorio Astrofisico di Arcetri (Italy); Daniela Mugnai, Istituto di Fisica Applicata "Nello Carrara" (Italy); Luca Cresci, INAF - Osservatorio Astrofisico di Arcetri (Italy); Amleto Ignesti, Istituto di Fisica Applicata "Nello Carrara" (Italy); Renzo Nesti, Dario Panella, INAF - Osservatorio Astrofisico di Arcetri (Italy); Lorenzo Stefani, Istituto di Fisica Applicata "Nello Carrara" (Italy); Vincenzo Natale, INAF - Osservatorio Astrofisico di Arcetri (Italy)

The concept of superresolution refers to various methods for improving the angular resolution of an optical imaging system beyond the classical diffraction limit. In optical microscopy, several techniques have been developed with the aim of narrowing the central lobe of the illumination Point Spread Function (PSF). In Astronomy a few methods have been proposed to achieve reflector telescopes and antennas with resolution significantly better than the diffraction limit, from the use of "metamaterials" (May & Jennetti, 2004) to exploiting the "quantum cloning" effect (Kellerer, 2014). However, no working system is in operation, yet. A more practical approach consists of using the so-called "Toraldo Pupils" (TPs) or variable transmittance filters. These pupils were introduced by G. Toraldo di Francia in 1952, and consist of a series of concentric circular coronae providing specific optical transparency and dephasing in order to engineer the required PSF. The first successful laboratory test of TPs in the microwaves was achieved by Mugnai et al. (2003), and in the present work we build upon these initial measurements to perform electro-magnetic (EM) numerical simulations of TPs, using a commercial full-wave software tool. These simulations were used to study various EM effects that can mask and/or affect the performance of the pupils and to analyze the near-field as well as the far-field response.

Our EM analysis confirms that at 20 GHz the width of the central lobe in the far-field generated by a TP significantly decreases compared to a clear circular aperture with the same diameter. We also used these EM simulations to prepare more comprehensive laboratory testing, with the final goal to study a prototype TP to be mounted on a radio antenna. Some preliminary experimental results confirming the EM simulations and the early measurements by Mugnai et al. (2003) will be discussed.

9906-229, Session PS16

Simulating photogrammetric measurements of the Sardinia Radio Telescope

Andrea Saba, INAF - Osservatorio Astronomico di Cagliari (Italy); Andrea Pinna, Univ. degli Studi di Cagliari (Italy); Franco Buffa, INAF - Osservatorio Astronomico di Cagliari (Italy); Giannina Sanna, Univ. degli Studi di Cagliari (Italy); Gian Luigi Deiana, Sergio Poppi, INAF - Osservatorio Astronomico di Cagliari (Italy)

The Sardinia Radio Telescope (SRT) is a fully steerable 64-metre diameter quasi-parabolic radio telescope located in Sardinia (Italy), equipped with active surface system to recover deformations due to gravity, wind and temperature gradients. Its primary mirror is composed by 1008 panels supported by electromechanical actuators, digitally controlled, together with a 6-degrees of freedom mechanical movement of the subreflector.

To observe at its highest operating frequency, SRT needs an antenna pointing angular precision of about 1 arcsec and a primary mirror surface accuracy better than 300 microns RMS. Furthermore, the performances improvement of the active systems needs an independent measuring system to control movements and deformations during the telescope operations.

Photogrammetry is a non-contact measuring technique which can accurately measure the shape and the orientation by means of photographs. Concerning SRT, It showed the capability to achieve the required performances. In fact, it has been used during the first alignment of the SRT optics, as well for the surface accuracy improvement of several other radio telescope. However this technique can not be used during the operations of a radio telescope, because their large structures requires cranes and operators to take the needed photographs.

We developed a photogrammetric measurements simulator: starting from accurate 3D model of the SRT, the simulator can generate of synthetic photo realistic images as a function of the number and geometry of survey, and of the camera parameters like focal length and resolution.

Hence, we simulated several survey geometries, selecting those that allowed the best measurement accuracy. Moreover the complete 3d model allows us to perform photogrammetric simulations over the whole structure.

The simulator, in fact, is aimed to general purpose, open to each scenario having an accurate 3d model, optimising the needed resources for a photogrammetric survey.

9906-230, Session PS16

AM-AM/AM-PM distortion versus complex Volterra kernels for modeling RF transceiver blocks

Rosario F. Cimmino, Consorzio Nazionale Interuniversitario per i Transporti e la Logistica (Italy); Pietro Monsurro, Sapienza Univ. di Roma (Italy); Francesco Romano, EExSKA (Italy); Giuseppe Scotti, Alessandro Trifiletti, Sapienza Univ. di Roma (Italy)

Power amplifiers and other RF blocks are often modeled using the AM-AM / AM-PM distortion model. This model turns the input complex envelope (the signal before distortion) into an output complex envelop (the signal after distortion) where both the gain and the phase shift depend nonlinearly on the input power (the norm of the complex envelope).

Working in the complex domain of the complex envelop, simulations can be carried out at a sample rate as low as the RF/IF bandwidth of the signal, while a model working in the RF domain would need to work at more than twice the maximum RF frequency, because the bandwidth of the complex envelop is half that of the real signal. This reduces the cost of system modeling and simulation.

The traditional AM-AM/AM-PM model can be accurate for narrowband signals, but it is increasingly less accurate as the bandwidth of the signal increases. In this paper, it is shown that the standard AM-AM/AM-PM model can be considered a Volterra kernel without lags, and that adding lags to the Volterra kernel improves the accuracy of the model.

The traditional model and the proposed complex Volterra model are used to model distortions in a real receiver mixer (RF-to-IF downconversion), in a real transmit mixer (IF-to-RF upconversion), in an IF receiver amplifier, and in an RF power amplifier.

Digital complexity versus accuracy is the main trade-off where models are compared, as accurate models tend to have a larger number of parameters and require more operations to simulate the system in real time. Iterative pruning techniques are used to minimize the complexity of Volterra kernels given a certain level of accuracy.

These models can be used for the calibration of RX and TX systems, as digital calibration consists in cascading the inverse digital model to the original analog system to obtain a combined model with higher linearity.

Calibration can be logically separated in three steps. The first is modeling, when a parametric model of the system (ideally both simple and accurate) is obtained. Then estimation, when the parameters are estimated to obtain the best fit (either offline or online). Finally correction, when the output of the inverse model is computed and applied to the distorted output of the analog system to obtain a linearized cascaded system.

In order to compute the inverse model, an accurate model of the system shall be obtained, and the parameters shall be estimated, either online or offline. In the case of online (background) calibration, the number of free parameters in the model also increases the computational cost of the estimation step. The correction step is instead always performed in real-time and its cost is the same in offline and online calibration.

9906-231, Session PS16

An innovative, highly sensitive receiver system for the Square Kilometre Array Mid Radio Telescope

Gie Han Tan, SKA Organisation (United Kingdom) and European Southern Observatory (Germany); Bhushan Billade, Onsala Space Observatory (Sweden); Krzysztof Caputa, NRC - Herzberg Astronomy & Astrophysics (Canada); Stéphane Gauffre, Lab. d'Astrophysique de Bordeaux (France); Robert Lehmensiek, EMSS Antennas (Pty) Ltd. (South Africa); Zoran Ljusic, National Research Council Canada (Canada); Miroslav G. Pantaleev, Onsala Space Observatory (Sweden); Adriaan Peens-Hough, SKA South Africa (South Africa); Isak P. Theron, EMSS Antennas (Pty) Ltd. (South Africa); Benjamin Quertier, Ctr. de Recherche Paul-Pascal (France)

The Square Kilometre Array (SKA) project is a global science and engineering project aiming at designing and constructing the next-generation radio telescope operating in the metre and centimetre wavelengths regions. The first phase of construction of the telescope (SKA1), which represents roughly 10% of the full SKA (SKA2), is currently well advanced with its design and expected to be operational early next decade. The SKA radio telescopes will be co-hosted in two locations with central array sites in Australia, SKA1-Low (50 – 350 MHz), and South Africa, SKA1-Mid (350 MHz – 13.8 GHz with an option for > 20 GHz).

This paper addresses design concepts of the broadband, exceptionally sensitive receivers and reflector antennas deployed in the SKA1-Mid radio telescope.

SKA1-Mid will consist of 133 reflector antennas using an off-set Cassegrain configuration with an effective diameter of 15 m. The unblocked aperture results in increased aperture efficiency and lower side-lobe levels compared to a traditional on-axis configuration. The low side-lobe level reduces the noise contribution due to ground pick-up but also makes the antenna less susceptible to ground-based RFI sources. The addition of extra shielding on both main and sub-reflectors provides a further reduction of ground pick-up. The optical design of the SKA1_mid reflector antenna has been tweaked using advanced EM simulation tools in combination with sophisticated models for sky, atmospheric and ground noise contributions.

Initially SKA1_Mid will be equipped with three receiver bands, Band 1 (350 – 1050 MHz), Band 2 (950 – 1760 MHz), and Band 5 (4.6 – 13.8 GHz). Despite the relatively large RF frequency band, up to a ratio of 1:3, the sensitivity is very competitive compared with other radio telescopes.

For Band 1 both cooled and uncooled concepts have been investigated. The advent of new semiconductor devices in this frequency range enables a design solution which has comparable sensitivity to the traditional alternative using cryogenically cooled low noise amplifiers. A quad-ridged feed horn will be used to illuminate the reflector antenna. This feed design provides the required wideband performance while still having relatively compact dimensions. Nevertheless, due to the feed dimensions, the feed itself cannot be cooled. The absence of any cryogenic cooling for this band will be a major advantage in the operations phase of the radio telescope because of reduced power and maintenance costs.

The Band 2 receiver makes extensive use of cryogenic cooling for the low noise amplifiers and part of the feed system. This approach has resulted in a sensitivity which is probably best in class for cm radio telescopes.

The Band 5 receiver is a recent addition to the SKA1-Mid telescope based on revisited science priorities. Like Band 2 it will make extensive use of cryogenic cooling.

Another novel concept for radio telescopes is that in SKA1-Mid no frequency conversion in the analogue front end is foreseen. Instead all RF signals are directly digitized after amplification. Except for broadband, anti-aliasing, filtering in the RF chain all bandpass filtering and frequency conversion will be performed in the digital domain. This direct digitization concept avoids the need for local oscillator signals, introducing the risk of unwanted spurs, and gives increased flexibility in catering the different back-ends dedicated to different types of astronomical science.

9906-249, Session PS16

Preliminary running and performance test of huge cable robot of FAST telescope

Hui Li, National Astronomical Observatories (China)

The highly flexible huge cable-driven parallel robot is one of the innovations of FAST that makes FAST different from many other radio telescopes. It connects dynamically the airborne feed with the main reflector, and controls preliminarily the feed pose in process of following transient focus point of the telescope in the observation mode. Although feasibility of the design has been preliminarily proved via Sino-Germany end-to-end simulation in 2007 and demonstrations of a few downscale models, a lot of details are expected to be testified on prototype especially after the detailed design had been finished in 2013.

In the middle of 2015 the construction of the prototype was nearly complete. On November 15 the movable platform, namely the focus cabin, was successfully pulled airborne by six parallel steel cables from the cabin harbor on the bottom of the depression. Although the cabin brings nothing but the outer main structure and necessary sensors, both its size and weight as well as mass distribution are quite similar to the real one. It gracefully drifted in the air along designated trajectory with small vibration under gentle breeze.

During the following two months, a set of performance tests were done to verify a few key design parameters. First, 6 actual cable tensions were measured throughout all important cabin positions on the focal surface. The comparisons between the data and analytical values show good consistency except that maximal force error of 3 tons exists on the edge of the focal surface. Second, some dynamic parameters like natural frequency and damping ratio are tested via vibration analysis for the flexible cabin-cable suspension system. The natural frequencies are quite near to the values given by the end-to-end simulations, but the damping ratio is obviously a little higher than that in the simulation on several typical cabin positions.

Higher damping assures better energy dissipation and in turn increases the controllability of positioning the feed via flexible cable robot. Finally the positioning/pointing accuracy is analyzed via running the cable robot to follow a set of carefully prepared trajectories. The tests help evaluate the control algorithms and parameters and then finalize them. The results prove that the cable robot is capable of driving the feed to desired pose with translational error less than 48mm and orientation error less than 1 angular degree, meeting the requirement given in the end-to-end simulation.

FACT: the self-calibrating camera of the first G-APD Cherenkov telescope

Adrian Biland, ETH Zurich (Switzerland)

The First G-APD Cherenkov Telescope (FACT) is pioneering the usage of solid state photosensors (G-APD aka SiPM) for Imaging Atmospheric Cherenkov Telescopes (IACT) that measure the very short and dim flashes of Cherenkov light induced by high energetic particles entering the atmosphere.

The strong temperature dependence of the SiPM gain poses a challenge for IACTs. Applying corrections during the analysis stage is not sufficient, since the gain changes by about 4% per K while environmental temperature variations can reach 30 K. To avoid hampering the trigger, it is necessary to ensure stable gain during operation. Instead of a complicated system for temperature stabilization of the SiPM, we have chosen to adjust the applied bias voltage according to the temperature. Initial intention was to use a temperature independent external light pulser to regularly illuminate the camera, as is usually done for IACTs, analyze the signals in real time and apply the calculated corrections to the power supplies. For cross-checks, about 30 temperature sensors were installed in the sensor compartment. These temperature sensors are not directly measuring the temperature of the individual SiPM and their distribution was not optimized. Nevertheless, during early operation it became soon evident that this temperature information is sufficient to adjust the bias voltages at least as precise as can be done with the light-pulser. Therefore, FACT is now fully relaying on the measured temperatures and there is no need for any external light-pulser, simplifying operation and maintenance.

In addition, analyzing the dark-noise and crosstalk signals intrinsic to SiPM allows to directly extract the gain of each sensor with high precision. This delivers the necessary information to homogenize the gain among all 1440 sensors of the FACT camera. The measured gain-difference over the full FACT camera is less than 2.1%, dominated by the resolution of the power supplies used.

Last but not least, the amount of measured Cherenkov flashes induced by the constant flux of charged cosmic ray particles as well as the analysis of ring-like images due to atmospheric muons deliver additional information about timing and stability of each individual sensor as well as about performance of the complete system.

In this presentation we will describe the methods used in FACT to reach a very stable SiPM camera and the experience gained. We will show the excellent stability reached during more than four years of operation of FACT so far. In addition, we will propose improvements to the methods for future systems.

9906-233, Session PS17

The DAG project, a 4m-class telescope: the telescope main structure performances

Gianpietro Marchiori, Francesco Rampini, Andrea Busatta, Cristiana Manfrin, Cristina Battistel, Enrico Marcuzzi, EIE Group s.r.l. (Italy); Olivier Pirnay, Carlo Flebus, AMOS Ltd. (Belgium); Onur Keskin, Cahity Yesilyaprak, Sinan Kaan Yerli, Atatürk Üniv. (Turkey)

Dogu Anatolu Gözlemevi (DAG-Eastern Anatolia Observatory) Project is a 4m class optical, near-infrared Telescope and suitable enclosure which will be located at an altitude of ~3.170m in Erzurum, Turkey.

The DAG telescope is a project fully funded by Turkish Ministry of Development and the Atatürk University of Astrophysics Research Telescope - ATASAM.

The Project is being developed by the Belgian company AMOS (project leader), which is also the optics supplier and EIE GROUP, the Telescope Main Structure supplier and responsible for the final site integration.

The design of the Telescope Main Structure fits in the TBO Program which aims at developing at a Dome/Telescope systemic optimization process for both performances and competitive costs based on previous project commitments like NTT, VLT, VST and ASTRI.

The optical Configuration of the DAG Telescope is a Ritchey-Chretien with two Nasmyth foci and a 4m primary thin mirror controlled in shape and position by an Active Optic System.

The main characteristics of the Telescope Main Structure are: an Altitude-Azimuth light and rigid structure system with Direct Drive Systems for both axis, AZ Hydrostatic Bearing System and Altitude standard bearing System; both axes are equipped with Tape Encoder System.

An innovative Control System characterizes the telescope performances.

9906-234, Session PS17

A control system of a mini survey facility for photometric monitoring

Hironori Tsutsui, National Astronomical Observatory of Japan (Japan); Takumi Hanaue, Tohoku Univ. (Japan); Kenshi Yanagisawa, National Astronomical Observatory of Japan (Japan); Yoshifusa Ita, Tohoku Univ. (Japan); Yasuhiro Shimizu, Hideyuki Izumiura, National Astronomical Observatory of Japan (Japan)

We have built a control system of a mini survey facility dedicated for photometric monitoring of nearby bright (K<5) stars in the near-infrared. The facility is composed of a rotating dome with 4-m diameter, a small sized (30 mm aperture) wide-field (2 x 2 sq.deg. F.O.V.) infrared (1.0-2.5 micron) camera equipped on a fork-equatorial mount, power sources, etc. All of these components, except for the camera, are controlled by a micro-computer based I/O board which has developed in-house and used in many open-use instrument of our observatory. In this paper, we will present the specifications and configuration of the facility hardware as well as the structure of the control software.

The near-infrared camera is dedicated for photometry of bright nearby stars. The camera consists of single calcium-fluoride lens(30 mm in diameter) and a 2K x 2K HgCdTe array detector, yields 2 x 2 square degrees field of view and enables precise measurement of bright (K<5) stars. Recent rapid progress of near-infrared array detectors and telescope technology have broadened the infrared universe toward dark-end. However the infrared bright-end universe has left almost un-explored since the Two Micron Sky Survey (1969). Therefore we have started a new project to monitor all the bright stars in the near-infrared visible from Okayama Astrophysical Observatory, Japan.

It is required to make the observation fully robotic. The control system is designed to be simple.

The hardware of the control system consists of a host computer, a terminal server, I/O boards, terminals and peripheral devices. All the peripherals, except for the camera, are locally controlled by a micro-computer (H8S/2633R) based I/O board which has developed in-house and has been improved over a decade. The board has 50 bit inputs, 18 bit outputs for the peripherals, and two RS232C interfaces to communicate with the host computer. The board can be widely applied to most of devices. One can freely set up the I/O ports by writing own built-in code to match control targets.

The host computer is installed software of the own making coded in Java. The software consist of three parts, calculating the position of stars, logging status and communication with several devices, such as I/O boards, external weather sensor and observation instrument. Status obtained from devices is displayed on graphical user interface.

In addition, as safety measure, the system shuts down immediately and automatically in an emergency, such as suddenly raining or when the equatorial attitude approaches horizontally. The emergency system doesn't depend on I/O boards and software, so if I/O boards or the host PC malfunctions, the emergency system would function.

9906-235, Session PS18

MeerLICHT and BlackGEM: custom-built telescopes to detect faint optical transients

Steven Bloemen, Paul Groot, Radboud Univ. Nijmegen (Netherlands); Patrick Woudt, Univ. of Cape Town (South Africa); Marc Klein Wolt, Radboud Univ. Nijmegen (Netherlands); Vanessa McBride, Univ. of Cape Town (South Africa) and South African Astronomical Observatory (South Africa); Gijs Nelemans, Elmar Körding, Radboud Univ. Nijmegen (Netherlands); Retha Pretorius, Univ. of Oxford (United Kingdom); Ronald Roelfsema, Felix C. M. Bettonvil, NOVA Optical Infrared Instrumentation Group (Netherlands); Harry Balster, Peter Dolron, Radboud Univ. Nijmegen (Netherlands); Arjen van Elteren, Leiden Univ. (Netherlands); Arno Engels, Marc Fokker, Radboud Univ. Nijmegen (Netherlands); Menno de Haan, Rik ter Horst, NOVA Optical Infrared Instrumentation Group (Netherlands); Stanis?aw K. Koz?owski, Cilium Engineering (Poland); Jan W. Kragt, NOVA Optical Infrared Instrumentation Group (Netherlands); Grzegorz M. Lech, Sybilla Technologies (Poland); Dirk Lesman, NOVA Optical Infrared Instrumentation Group (Netherlands); Johan Morren, KU Leuven (Belgium); Ramón Navarro, NOVA Optical Infrared Instrumentation Group (Netherlands); Willem Jelle Paalberends, Airborne Composites B.V. (Netherlands); Rafal K. Paw?aszek, Sybilla Technologies (Poland); Wim Pessemier, Gert Raskin, KU Leuven (Belgium); Harrie Rutten, Castor Optical Design (Netherlands); Bart Scheers, Ctr. voor Wiskunde en Informatica (Netherlands); Menno Schuil, NOVA Optical Infrared Instrumentation Group (Netherlands); Piotr W. Sybilski, Sybilla Technologies (Poland)

A consortium led by the Radboud University (Nijmegen, NL) is currently developing wide-field optical telescopes to study transient phenomena, gravitational wave counterparts and variable stars. The telescopes have 65cm primary mirrors and are equipped with an STA1600 detector which provides a 2.7 square degree field of view at 0.56 arcsec /pixel. A prototype telescope, called MeerLICHT, is currently being built and will be commissioned at Sutherland (South-Africa) at the end of 2016. MeerLICHT will co-point with the MeerKAT radio array, to collect optical data commensurate with the radio observations. This novel combination of a radio telescope and a dedicated co-pointing optical telescope will, amongst other things, allow us to obtain unique data on fast radio transients, by eliminating the time consuming step of triggering optical follow-up after a radio event is detected.

In parallel with the first MeerLICHT observations, three identical telescopes will be commissioned in La Silla (Chile), currently planned for the end of 2017. These telescopes form the first phase of the BlackGEM array, which aims at detecting and characterizing optical counter parts of gravitational wave events detected by the Advanced LIGO and Virgo interferometers.

The telescopes have been designed to operate robotically with limited maintenance and human intervention. The modified Dall-Kirkham optical design and the carbon-fibre mechanical design are optimized to take full advantage of the excellent observing conditions at La Silla to rapidly find faint transient sources in large areas of the sky. Advanced systems have been designed to maximize the performance, including an actively controlled secondary mirror and a novel Atmospheric Dispersion Corrector (ADC) which works by displacing one of the corrector lenses so that extra optical elements can be avoided. A limiting magnitude of 23 can be reached in less than five minutes in a wide optical bandpass.

In this contribution, we will present the design and main science goals of the telescopes.

9906-236, Session PS18

The first year of operation of MASCARA: on-sky results and the upcoming southern station

Remko Stuik, Leiden Observatory (Netherlands); Anna-Léa Lesage, Julien F. P. Spronck, Geert Jan Talens, Leiden Univ. (Netherlands); Gilles P. P. L. Otten, Ignas A. G. Snellen, Leiden Observatory (Netherlands)

MASCARA, the Multi-site All-Sky CAmeRA, is a project aimed at finding exoplanets transiting the brightest stars, in the V = 4 to 8 magnitude range, currently probed neither by space- nor by ground-based surveys. The target population for MASCARA consists mostly of hot Jupiters, for which the average transit depth is around 1%, and hot Neptunes. In order to achieve consistently a signal-to-noise-ratio of better than 100 per hour at magnitude 8, MASCARA is based on three main concepts; simplicity stability and calibration.

MASCARA was designed with a minimum number of moving components. Five fixed, shutter-less, Peltier-cooled cameras, fitted with standard Canon 24 mm f/1.4 lenses are operating in a temperature controlled environment. Each camera constantly stares at the same patch of the sky. The exposure time is set to 6.4 seconds, keeping trailing of stars and saturation to a minimum while allowing for continuous exposures. Each camera is connected to its own control- and data processing computer, allowing for fully independent operation of each of the cameras. Each camera takes between 4,000 and 7,000 exposures per night, which are reduced locally to produce un-calibrated light curves for the up to ~40,000 pre-selected stars, as well as image stacks of 50 images. For each set of 50 images, astrometry of the solution is verified to monitor drifts in the station. Currently both reduced data as well as raw data (~500 GB/night) are transferred to a central data repository, but for stations with less bandwidth, potentially only the reduced data could be transferred. MASCARA currently only permanently stores the reduced light curves and binned image stacks, deleting the raw images after one month.

After transfer, the raw light curves are self-calibrated in batches of 2-4 weeks, removing the spatially-varying transmission of the camera, the impact of crowding and spatially-variable PSF, and the time-variable transmission of the atmosphere. Using a combination of SysRem and flagging of data points that are impacted by known artifacts (moon, sun, clouds, etc), we have demonstrated a photometric stability of MASCARA down to 0.3% at magnitude V=7.7 within 5.3 minutes.

In this paper we present the results obtained with the first MASCARA station, lessons learned and a preview to our second station, to become operational in mid-2016.

9906-238, Session PS18

First results of the Test-Bed Telescopes (TBT) project: Cebreros telescope commissioning

Francisco Ocaña, Univ. Complutense de Madrid (Spain) and ISDEFE, S.A. (Spain); Aitor Ibarra Ibaibarriaga, Elena Racero, Ángel Montero, Vicente Ruiz, ISDEFE, S.A. (Spain)

The TBT project is being developed under ESAs General Studies and Technology Programme, and shall implement a test-bed for the validation of an autonomous optical observing system in a realistic scenario within the Space Situational Awareness (SSA) programme of ESA.

The system consists of two telescopes, one in Spain and the second one in the Southern Hemisphere. The telescope is a fast astrograph with a large FoV of 2.5º x 2.5º and a plate scale of 2.2 arsec/pixel. The tube is mounted on a fast direct-drive mount moving with speeds up to 20º/sec. The focal plane hosts a 2-port 4k x 4k 15-micron pixels back-illuminated CCD with read-out speeds up to 1MHz per port. All these characteristics ensure good survey performance for transients and fast moving objects.

Detection software and hardware are optimised for the detection of NEOs and objects in high Earth orbits (objects moving from 0.1-40 arsec/second). Nominal exposures are in the range from 2 to 30 seconds, depending on the observational strategy. Part of the validation scenario involves the scheduling concept integrated in the robotic operations for both sensors. Every night it takes all the input needed and prepares a schedule following predefined rules allocating tasks for the telescopes. Telescopes are managed by RTS-2 control software, that performs the real-time scheduling of the observation and administers all the devices at the observatory. Appart from all the weather sensors, the safety system has redundant sensors to monitor weathear and other possible hazards for the observatory. At the end of the night the observing systems report astrometric positions of the objects detected.

The first telescope was installed in Cebreros Satellite Tracking Station in mid 2015. It is currently in the commissioning phase and we present here the first results of the telescope. We evaluate the site characteristics and the performance of the TBT Cebreros telescope in the different modes and strategies. We present the final figures of the telescope parameters and the first results of NEOs surveys and follow-ups. Telescope has good pointing capabilities (10 pixels rms) and overall astrometric precision is 0.4" rms. Objects down to magnitude 20 are regularly observed in moonless nights. The telescope is a valid prototype and the Southern Hemisphere counterpart, with astronomical-quality skies, is going to be a very competitive survey instrument. The second telescope is foreseen to be installed and commissioned by Autumn 2016.

9906-239, Session PS18

Final design of the LSST secondary mirror assembly

Douglas Neill, LSST (United States); Gregory N. Bogan, Dale Zajac, Harris Corp. (United States); Constanza Araujo Hauck, William J. Gressler, Joseph DeVries, Edward A. Hileman, Paul J. Lotz, Dave Mills, Jacques Sebag, LSST (United States); Thomas A. Sebring, Xoptx LLC (United States); Oliver Wiecha, Michael Warner, LSST (United States)

The Large Synoptic Survey Telescope (LSST) has a 10 degrees square field of view which is achieved through a 3 mirror optical system comprised of an 8.4 meter primary, 3.5 meter secondary (M2) and a 5 meter tertiary mirror. The M2 is a 100mm thick meniscus convex asphere. The mirror surface is actively controlled by 72 axial electromechanical actuators (axial actuators). Transverse support is provided by 6 active tangential electromechanical actuators (tangent links). The final design has been completed by Harris Corporation. They are also providing the fabrication, integration and testing of the mirror cell assembly, as well as the figuring of the mirror. The final optical surface will be produced by ion figuring. All the actuators will experience 1 years of simulated life testing to ensure that they can withstand the rigorous demands produced by the LSST survey mission. Harris Corporation is providing optical surface metrology to demonstrate both the quality of the optical surface and the correctablility produced by the axial actuators. As a result of the difficulties involved in providing surface metrology for a large convex optic, it is not practical to produce a single image of the optical surface. Consequently, multiple images will be stitched together during metrology to evaluate the optical surface.

9906-241, Session PS18

Wavefront-based PSF estimation

Christopher Davis, SLAC National Accelerator Lab. (United States) and Kavli Institute for Particle Astrophysics & Cosmology (United States); Jamie Rodriguez, SLAC National Accelerator Lab. (United States); Aaron J. Roodman, SLAC National Accelerator Lab. (United States) and Kavli Institute for Particle Astrophysics & Cosmology (United States)

A new method to estimate the Point Spread Function from measurements of optical wavefront is described. Out-of-focus (engineering) Dark Energy Camera (DECam) images are analyzed, using the donut algorithm from the DECam Active Optics System, to characterize the Blanco + DECam optical wavefront with a pupil Zernike decomposition. Our PSF model consists of the measured wavefront combined with physically motivated adjustments with up to three parameters per Zernike term. Next, the adjustable parameters of the PSF model are fit to stars are selected from Dark Energy Survey (DES) Science Verification (SV) images, using just adaptive second moments of the stars and the PSF model. Results from SV r, i and z band images are presented. To account for remaining differences between stars the the PSF model, we use the Richardson-Lucy deconvolution algorithm to estimate the difference kernel. Lastly, we interpolate across each CCD to characterize the difference between data and the wavefront PSF model. We perform a detailed comparison of the Wavefront-based PSF estimator against the DES PSF model.

9906-242, Session PS19

Fast tip-tilt segment alignment for segmented mirrors

Jure Skvar?, Isaac Newton Group of Telescopes (Spain)

Optical alignment of segments is one the recurring tasks when using segmented mirrors, for example in telescopes. Although edge sensors maintain mirror shape for a long time, new alignment is needed regularly after the segments are changed and the calibration might be lost. The alignment is particularly demanding when the segments are misaligned in tip and tilt to such extent that each of the segments forms a separate image on the focal plane, possibly scattered over an area of several arc-minutes and identification of the segments is difficult. A method to treat this problem has been developed at the Isaac Newton Group of Telescopes. First it was used for alignment and calibration of the 76-segment deformable mirror for NAOMI adaptive optics system at the 4.2-metre William Herschel Telescope (WHT). Later it was adapted for alignment of the 36-segment primary mirror of the 10.4-metre Gran Telescopio Canarias (GTC). In the latter case the time necessary for alignment is on average about 10 minutes after the guide star is acquired. Most of the time is spent waiting for the segments to stabilise after they are moved and waiting for the acquired image to appear in the file system.

A dedicated application was written in Python to support this task. It allows visual representation of segments and triggering of different actions from the GUI such as identification of selected segments, fine alignment after the identification and spiral search for badly misaligned segments.

The method relies on known and well-calibrated relations between the change of tip and tilt of individual segments and the amount of image motion in the focal plane. Using these relations, it is possible to identify images of the alignment star made by different segments. By moving each segment by a different amount and in a different direction it is possible to apply the method to many segments at once. The segments are identified by a pattern-matching algorithm which finds spots that have moved by a segment-specific predicted vector from one image to another. To minimise chances of confusion, several images are used, usually 5. In the case of the GTC mirror, this method allows for the simultaneous alignment of all segments.

The method does not need any special optical setup; only an imaging camera with a field of view of a few arc-minutes is required. This will typically be an existing imaging or acquisition camera.

The applicability of the method for alignment of the primary mirrors of the giant future telescopes such as the E-ELT and the TMT is discussed. Due to the large number of segments this is more complicated than for the GTC because a larger number of background stars appears in the field of view. Simulated images based on real star catalogues are used for increased realism of the simulation. Different strategies are examined and the results presented for aligning a completely misaligned mirror, as well as for cases when only a subset of segments needs alignment.

9906-243, Session PS19

The alignment and phasing system for the Thirty Meter Telescope: risk mitigation and status

Mitchell Troy, Jet Propulsion Lab. (United States); Gary Chanan, Univ. of California, Irvine (United States); Scott Michaels, Thirty Meter Telescope (United States); Frank G. Dekens, Randy Hein, Robert Karban, Carl R. Nissly, Jennifer E. Roberts, Michael Rud, Byoung-Joon Seo, Jet Propulsion Lab. (United States)

The Alignment and Phasing System (APS) is responsible for the optical alignment via starlight of the approximately 10,000 degrees of freedom in the primary, secondary and tertiary mirrors of the Thirty Meter Telescope (TMT). APS is based on the successful Phasing Camera System (PCS) used to align the Keck Telescopes. Since the successful APS conceptual design in 2007, work has concentrated on risk mitigation, use case generation, and alignment algorithm development and improvement. Much of the risk mitigation effort has centered around development and testing of prototype APS software which will replace the current PCS software used at Keck. We present an updated APS design, example use cases and discuss, in detail, the risk mitigation efforts.

9906-244, Session PS19

Self-coherent camera as a focal plane phasing sensor

Pierre Janin-Potiron, Lab. J.L. Lagrange (France); Patrice Martinez, Observatoire de la Côte d'Azur (France) and Univ. de Nice Sophia Antipolis (France); Pierre Baudoz, Lab. d'Etudes Spatiales et d'Instrumentation en Astrophysique (France) and Observatoire de Paris (France) and Ctr. National de la Recherche Scientifique (France); Marcel Carbillet, Observatoire de la Côte d'Azur (France) and Univ. de Nice Sophia Antipolis (France)

Forthcoming generation of space- and ground-based observatories will deliver considerably large angular resolution. So as to reach this unprecedented angular resolution, and because the primary mirror of these telescopes will be segmented, each segment will require to be positioned with high accuracy.

With the increased dimension and complexity of telescopes (missing segments, island effect, pupil shear, etc.), co-phasing technics and in particular pupil plane approaches will be severely affected. To overcome these effects, we propose to adapt the Self-Coherent Camera as a focal plane phasing sensor in order to provide a powerful and straightforward solution directly analyzing the signal from the segment surface.

After presenting the principle of the sensor, we present results obtained by means of intensive numerical simulations.

We explore the parameter space of this new sensor through an in-depth analysis of the system calibration, closed-loop performance, sky coverage, and sensitivity to misalignments.

Finally, laboratory testing of this new co-phasing sensor on the Segmented Pupil Experiment for Exoplanet Detection (SPEED) will be detailed. The SPEED bench makes use of a 169-segments mirror from IrisAO vendor controllable in piston, tip and tilt that will be operated in a switchable optical configuration providing ambivalent analysis in both pupil and focal plane for comparison purpose with other co-phasing techniques.

9906-245, Session PS19

Calibration and operation of the active surface of the Large Millimeter Telescope

F. Peter Schloerb, Univ. of Massachusetts Amherst (United States); David Sánchez-Argüelles, Instituto Nacional de Astrofísica, Óptica y Electrónica (Mexico); Gopal Narayanan, Neal Erickson, Kamal Souccar, Grant W. Wilson, Univ. of Massachusetts Amherst (United States); David M. Gale, David Hughes, Instituto Nacional de Astrofísica, Óptica y Electrónica (Mexico); David R. Smith, MERLAB, P.C. (United States)

The Large Millimeter Telescope relies on an active primary surface to achieve its specified surface accuracy. The active primary has two functions: (1) it provides a means to correct the surface for gravitational deformations with changing elevation; and (2) it provides a capability to improve the shape of the surface in real time due to transient effects of thermal gradients within the structure. At LMT, our development work has addressed both problems and in this paper we describe the derivation of the gravity deformation model and the schemes developed to measure and improve the antenna surface during regular scientific observations. The LMT's active surface consists of 180 trapezoidal surface segments arranged in 5 annular rings. Each segment is attached to the antenna backup structure with an actuator at its four corners, which allows segments to be repositioned in order to maintain a precise parabolic surface. Once the active surface system is in place, the challenge is to measure the response of the antenna to stresses that tend to deform it, and to put models in place that will allow compensation.

Gravitational deformations of the structure should be straightforward since they depend only on the orientation of the structure with respect to gravity. In principle, the gravitational deformations may be measured and then compensated using an open-loop lookup table. At the LMT, our approach has been to use a radio holography technique to measure the surface using a set of geostationary satellites at different elevation angles. Maps of the surface obtained at each elevation that is sampled are then used to derive the lookup table. The holography maps excel at setting the relative positions of the segments accurately. However, experience with implementing this procedure in practice shows that systematic errors in the measurements and the limited elevation sampling of the surface mapping can lead to significant uncertainties in the extrapolation of models beyond the elevation range that is sampled. Moreover, in measurements of a real structure, the gravitational deformations must be separated from other effects of the environment which lead to changes from night-to-night and within a given night.

Deformations due to environmental effects, such as those induced by temperature gradients within the structure, must also be dealt with by the active surface system. Holography measurements during the course of the night have shown that the main feature of the LMT's thermal deformation is an astigmatism. Thus, the appearance of this particular deformation is easy to identify during routine focusing of the telescope, and it is straightforward to correct simply by adjusting the shape of the surface using Zernike astigmatism term to optimize the gain. Development of out-of-focus holography techniques is underway to provide a means to measure and correct other low-order Zernike terms.

9906-246, Session PS19

Performance of the Giant Magellan Telescope phasing system

Fernando Quirós-Pacheco, Rodolphe Conan, Benjamin A. Irarrazaval, Antonin H. Bouchez, GMTO Corp. (United States); Brian McLeod, Harvard-Smithsonian Ctr. for Astrophysics (United States)

The 25.4m Giant Magellan Telescope consists of seven 8.4 m primary mirror (M1) segments with matching segmentation of the Gregorian secondary mirror (M2). When operating the telescope in the diffraction-limited Adaptive Optics (AO) observing modes, the M1-M2 pairs of segments must be phased to a small fraction of the observing wavelength. To achieve this level of correction, the phasing system relies on edge sensors to sense high temporal frequency disturbances (mainly due to wind buffeting against M1 and M2 segments), and uses multiple natural guidestar phasing sensors deployed across the field of view to provide an absolute phasing reference on minute timescales.

We will present in this paper the performance characterization of the GMT phasing system based on end-to-end numerical simulations performed with the Dynamic Optical Simulation (DOS) tool, which integrates the optical and mechanical dynamics models of the GMT with the Fourier optics models of AO and phasing sensors. The simulation also includes most major optical disturbances, and captures the interactions between the multiple nested wavefront control loops. The expected phasing performance under different observing conditions will be presented.

9906-247, Session PS19

Focal plane wavefront sensing for active optics in the VST based on an analytical optical aberration model

Ronald Holzlöhner, European Southern Observatory (Germany); Andrew P. Rakich, GMTO Corp. (United States); Lothar Noethe, Stefan Taubenberger, European Southern Observatory (Germany); Pietro Schipani, INAF - Osservatorio Astronomico di Capodimonte (Italy); Konrad Kuijken, Leiden Observatory (Netherlands)

We report on successful closed-loop active optics control of the 2.6 m VST survey telescope using focal plane wavefront sensing. The method extracts a large number of stars from the science images observed with the 256-Mpixel OmegaCAM visible-light camera and measures their PSF sizes and ellipticities. Starting from an analytical telescope aberration model based on 5th-order geometrical optics, we then solve the inverse problem of matching the observed seeing-corrected ellipticity pattern across the field to a set of mirror misalignment and disfigure degrees of freedom. We then compute the maximum likelihood telescope misalignment state using all recently recorded images and correct it in real time. This novel type of active optics control does not require additional hardware. Moreover, it validates our aberration model which we believe has a number of other potential applications.

9906-248, Session PS19

Phasing the segments of the Keck and Thirty Meter Telescopes via the narrowband phasing algorithm

Gary Chanan, Univ. of California, Irvine (United States); Mitchell Troy, Nasrat A. Raouf, Jet Propulsion Lab. (United States)

We have developed two methods of phasing the segments of the Keck telescopes: narrowband (NB) phasing, in which the length standard is the wavelength of one or more narrowband filters, and broadband (BB) phasing, in which the standard is the coherence length of a generally broader filter or filters. The NB approach incorporates the familiar technique of making measurements at multiple wavelengths in order to form a large artificial wavelength and thereby extend the capture range. NB phasing is faster and more accurate (~10 nm) than BB phasing (~30 nm), but in practice it suffers from an apparent instability in which the solution jumps to the wrong branch of the quasi-periodic response curve a few percent of the time. For this reason, we have favored the more stable BB algorithm at Keck, but the increased speed and accuracy of the NB algorithm will be needed to phase the segments of the Thirty Meter Telescope. Consequently we have undertaken a detailed study of NB phasing at Keck. We have shown that the apparent instability is in fact due to small systematic wavelength-dependent errors associated with the edge height measurements. These appear to originate at the segments themselves, and not inside of the phasing camera. Possible sources of these wavelength-dependent errors will be discussed. We will present data on their stability over time, their potential consequences, and the extent to which they can be calibrated out.

9906-75, Session 21

SKA Telescope update through re-baselining and preliminary design phase *(Invited Paper)*

Alistair M. McPherson, SKA Organisation (United Kingdom)

During the past year the Square Kilometre Array Project has progressed aggressive development phase. Since 2008, the global radio astronomy community has been engaged in the development of the SKA in a major effort - the ‘Preparatory’ phase of the project. The Preparatory phase ended in December 2011 and, following a number of major changes, the international SKA project has now progressed to the ‘Pre-Construction’ phase (2012-17). The Member Nations have set up the SKA Organisation, a not-for-profit company founded in the UK to lead activities and the Pre-Construction work has been organised into a series of design work packages to be delivered by consortia from the Member Nations. During the past 12 months the project has moved through a re-baselining phase to reduce the observatory to fit into funding available. In addition, the project has moved through a series of Preliminary Design Reviews. This paper describes the organisation and scope of the work packages as the project begins the work of preparing for SKA1 construction. It will cover issues of management and value engineering, as well as risk management and systems engineering. In addition, lessons learned from PDR and Re-Baselining.

9906-76, Session 21

MeerKAT: a project status report

Ray Brederode, Lize van den Heever, Justin Jonas, SKA South Africa (South Africa)

The MeerKAT radio telescope is currently in full production in South Africa’s Karoo region, and by association, so is the Square Kilometre Array Phase 1 (SKA1) MID telescope. MeerKAT will be the largest and most sensitive radio telescope array in the centimetre wavelength regime in the southern skies until the SKA1 MID telescope is operational, and is well on its way to realising the MeerKAT vision of being a world class instrument that exceeds its original specification. This paper identifies the key telescope specifications, discusses the high-level architecture and current progress to meet the specifications and lastly reports on lessons learnt in the process.

Sensitivity was set as a key specification for MeerKAT, with a requirement to achieve a sensitivity of 220m2/K at L-band. The measured performance of the L-band receiver currently indicates a ~40% improvement in sensitivity. With high sensitivity comes the requirement to have a matching imaging dynamic range, with signal stability over the imaging period. The offset Gregorian dish configuration provides for a clean optical path, with low sidelobe levels and good rejection of radio frequency interference. MeerKAT will consist of 64 offset Gregorian dishes at 13.5m diameter each, with manufacturing, installation and assembly of 14 dishes by year-end 2015, completing the dish roll-out in 2017. Seventy percent of the dishes will be deployed in a compact core, with an extended array providing for high fidelity imaging performance over a range of resolutions from 6 arcsec to approximately 100 arcsec.

L-band and UHF band receivers spanning 0.9-1.67GHz and 0.58-1.015GHz respectively will allow neutral hydrogen to be detected up to a redshift of z=1.45, probing back 9.2 Gyrs into the distant universe. Plans are being put in place to fit X-band (8-14.5 GHz) and S-band (1.75-3.5 GHz) frequency receivers onto each dish’s receiver indexer. MeerKAT science projects include pulsar timing, deep neutral hydrogen surveys, galaxy surveys, searching for carbon monoxide lines, fast radio bursts and other radio transients. Large survey project teams have been invited to present updated project plans during 2016 given the updated technical specifications and capabilities of MeerKAT.

All telescope subsystems are currently in production, including dishes, receivers, digitisers, correlator/beamformer, receptor fibre network, control and monitoring and science processing. Qualification, integration and acceptance testing is taking place at all levels.

Several valuable lessons have been learnt thus far. Problems downstream in the signal chain are generally symptoms of neglect upstream. Science requirements, operations model and lifetime costs are essential from concept exploration through to a critical design review, and are particularly necessary when re-scoping or making trade-off studies. Prototyping and deploying early and often is essential to retire risks and to triage. Science commissioning provides the most insightful testing and uncovers unexpected results. Verification at all levels is essential, with independent quality assurance involvement reporting directly to top management. System engineering is necessary, however it is not sufficient, and is no replacement for thinking and good design. A generalist “floor walker” with broad knowledge of science and telescope elements is needed to ask probing questions at each stage of the project.

9906-77, Session 21

A new 50m class single dish telescope: Large Submillimeter Telescope (LST)

Ryohei Kawabe, National Astronomical Observatory of Japan (Japan); Kotaro Kohno, Yoichi Tamura, Shun Ishii, The Univ. of Tokyo (Japan); Tai Oshima, Tatsuya Takekoshi, National Astronomical Observatory of Japan (Japan)

We report on a new plan to construct a 50m class millimeter and submillimeter single dish telescope, the Large Submillimeter Telescope (LST). The conceptual design and key science of LST will be presented together with its tentative specifications. This telescope is optimized for wide area imaging and spectroscopic surveys in a frequency range of 70 to 420 GHz, which just covers main atmospheric windows at millimeter

and submillimeter wavelengths in good observing sites such as the ALMA site in Chile. We are also aiming at observations at higher frequency up to 1 THz (corresponding to a wavelength of 0.3 mm) with the limited use of the higher-precision inner surface, e.g., with the under-illumination of the surface. The active surface control is needed for correcting gravitational and thermal deformations of the surface, and might be used for the correction of the wind-load deformation. One of the major science goals is unveiling the large-scale structure of high-z universe in 3D and cosmic star formation history with the wide area spectroscopic surveys of dusty starbursts in [CII] and CO lines as well as continuum surveys. With exploiting synergy with ALMA and possibly TMT/SPICA, LST can contribute to the breadth of astronomy and astrophysics; e.g., astrochemistry, star formation in the Galaxy and galaxies, evolution of clusters via the SZ effect, millimeter and submillimeter VLBI, and time-domain science for transients such as GRBs. The surface should have an accuracy of 45 micron (rms) in total or better under a normal nighttime operation condition (when a wind velocity is less than 10 m/s). Ritchey-Chretien optics will be essential in order to achieve a wide field of view of 0.5 deg^2 (up to 1 deg^2) which is required to conduct extremely large area (> a few 100 -- 1000 deg^2a) cosmological deep surveys. The LST will have 3 receiver cabins, i.e., 2 Nasmyth foci and a Cassegrain focus, to accommodate a couple of the proposed state-of-the-art instruments, including wide-field multi-band continuum camera utilizing TES and/or MKID technologies under development in NAOJ and other institutes, large format heterodyne receiver arrays based on the experience of ALMA receiver development in NAOJ, and ultra wide-band multi-object spectrograph whose concept is being tested by DESHIMA and MOSAIC proposed by Delft University of Technology and SRON.

9906-78, Session 21

The next generation very large array

Mark M. McKinnon, Chris L. Carilli, Anthony J. Beasley, National Radio Astronomy Observatory (United States)

Inspired by the ground-breaking results coming from the Atacama Large (sub)Millimeter Array (ALMA), and the Jansky Very Large Array (JVLA), the North American astronomical community is considering a future large area radio array optimized to perform imaging of thermal emission down to milliarcsecond scales. Currently designated the `Next Generation Very Large Array' (ngVLA), such an array would entail ten times the effective collecting area of the JVLA, operate from 1GHz to 115GHz, with ten times longer baselines (300km) providing milliarcsecond resolution, and include a dense core on kilometer scales for high surface brightness imaging. Such an array bridges the gap between ALMA, a superb sub-millimeter array, and the future Square Kilometer Array phase 1 (SKA1-Mid), optimized for a few centimeter and longer wavelengths. The ngVLA opens unique new parameter space in the imaging of thermal emission from cosmic objects ranging from protoplanetary disks to distant galaxies, as well as unprecedented broad band continuum polarimetric imaging of non-thermal processes.

We summarize the design, capabilities, and some of the priority science goals of the ngVLA. As currently envisioned, the continuum resolution of the ngVLA will reach nine milliarcseconds at 1 cm wavelength, with a brightness temperature sensitivity of 6K in one hour. For spectral lines, the array at one arcsecond resolution will reach 0.3K surface brightness sensitivity at 1 cm wavelength and 10 km/s spectral resolution in one hour. These capabilities are the only means with which to answer a broad range of critical scientific questions in modern astronomy, including direct imaging of planet formation in the terrestrial-zone, studies of dust-obscured star formation and the cosmic baryon cycle down to pc-scales out to the Virgo cluster, making a cosmic census of the molecular gas which fuels star formation back to first light and cosmic reionization, and novel techniques for exploring temporal phenomena from milliseconds to years.

We are considering the current VLA site in the high desert plains of the southwest USA as a possible location for the ngVLA. At over 2000m elevation, this region provides good observing conditions for the frequencies under consideration, including reasonable phase stability and opacity at 3mm wavelength over a substantial fraction of the year.

Scientific and technical discussions of the ngVLA are well underway. Science working groups have been formed and are actively refining the ngVLA science case. Two technical workshops have been held to review enabling technologies ranging from antennas, receivers, and correlators to data transmission, time and frequency distribution, and computing architecture. The principal and encouraging conclusion from the workshops is that the technical requirements for achieving a scientifically transformational ngVLA demand only a plausible extrapolation of current technologies.

9906-79, Session 22

The SKA1 low telescope: system architecture and design performance

Mark F. Waterson, Maria Grazia Labate, Wallace Turner, Peter E. Dewdney, SKA Organization (United Kingdom); Hermine Schnetler, Science and Technology Facilities Council (United Kingdom) and UK Astronomy Technology Ctr. (United Kingdom); Jeff Wagg, SKA Organization (United Kingdom)

The SKA1 Observatory will consist of two radio telescope systems, a low-frequency (50-350 MHz) aperture array in Western Australia, and a mid-frequency (0.35-13.8 GHz) dish array in South Africa. Its scientific objectives will prioritize imaging and spectral observations of the highly red-shifted 21 cm hyperfine line of neutral hydrogen from the Epoch of Reionization and earlier, and will also be well suited for low radio frequency observations of pulsars, magnetized plasmas both in the Galaxy and intergalactic space, radio recombination lines, and potentially extrasolar planets. In addition, a tied-array beamformer and time-domain search engine will be provided to enable pulsar search and timing studies using the tightly concentrated core-area antennas. Development of the SKA1-Low Telescope has been allocated to separate consortia who are responsible for designing the aperture array front end, timing distribution, signal and data transport, correlation and beamforming signal processors, infrastructure, monitor and control systems, and science data processing.

Following a re-scoping activity in 2015, the system has been defined as an array of ~131,000 dual-polarized, log-periodic antenna elements (~512 stations of 256 antennas in a 35m diameter area) arranged in a log-spiral distribution of approximately 40Km radius on the Murchison Radio Observatory site, located at Boolardy Station, Western Australia. The RF signals will be transmitted from the antennas over analog fiber-optic links to a nearby processing facility where the receiver system will directly digitize each antenna signal to process a passband of 50 – 350 MHz, filter into a set of 384 coarse-channels and beamform them at the station level. The packetized data will be routed via a network to an F-X digital correlator and to the pulsar search and timing equipment. Data will be further processed to produce science-ready products at the Pawsey Supercomputing facility, located in suburban Perth, WA. Monitor and control of the telescope components will be provided by a hierarchical, distributed software system enabling automated operation and minimal on-site staffing. This paper will describe the system architectural design and key performance parameters of the telescope in further detail, and summarize the high-level subsystem designs of the consortia.

9906-80, Session 22

Dynamic analysis of DATE5 based on the physically realistic environmental disturbances

Hairen Wang, Yuan Qian, Zheng Lou, Purple Mountain Observatory (China); Hans Kaercher, MT Mechatronics GmbH (Germany); Yingxi Zuo, Ji Yang, Purple Mountain Observatory (China)

The observation bands of the 5 meter Dome A Terahertz Explorer (DATE5) are primarily over the wavelength of 350 and 200 μm. Thus, the pointing performance of DATE5 require high accuracy. However, the pointing performance of DATE5 is affected by the unsteady wind, which either acts directly on the telescope structure or transmits through the ice and foundation. The main influence of the disturbances acting on the telescope is forces and torques due to wind gusts. Alternating forces and torques cause displacements of the telescope as well as structural oscillations. Both effects lead to pointing errors and therefore have to be compensated as much as possible by the main axes servo controllers. Wind acting on the telescope can be treated as random event, whose expectancy values depends on the specific site. The wind velocity throughout a given time interval can be described as a randomly varying velocity superimposed upon a constant average or mean velocity. For the dynamic analysis, the two components are separated and only the fluctuating component is used. In this paper, the dynamic analysis (mode analysis, harmonic analysis and spectrum analysis) of DATE5 is carried out based on the physically realistic environmental disturbances of dome A. Here, the davenport spectrum of the wind gust, the relation between the gust wind velocity and the wind torque, the power spectrum of wind torque and the telescope response are analyzed and presented in details.

9906-81, Session 22

The Australian SKA Pathfinder: an update

Antony E. Schinckel, Douglas C. Bock, Commonwealth Scientific and Industrial Research Organisation (Australia)

The Australian Square Kilometre Array Pathfinder (ASKAP) will be the fastest dedicated cm-wave survey telescope, and will consist of 36 12-meter 3-axis antennas, each with a large chequerboard phased array feed (PAF) operating from 0.7 to 1.8 GHz, and digital beamformer preceding the correlator. The 96 dual-polarization elements (192 receivers) of the PAF and the subsequent beamformer will provide about 30 beams (at 1.4 GHz) to produce a 30 square degree field of view, allowing rapid, deep all-sky surveys. The large raw data rates involved (~ 100 Tb/sec) and the need to do pipeline processing has led to the antenna incorporating a third axis to fix the parallactic angle with respect to the entire optical system (blockages and phased array feed). It also results in innovative technical solutions to the data transport and processing issues.

ASKAP is located at the Murchison Radio-astronomy Observatory (MRO), a new observatory developed for the Square Kilometre Array (SKA) 315 kilometres north-east of Geraldton, Western Australia. The site was selected through a rigorous process assessing many characteristics, including the RFI “quietness” of the site, which was determined to be outstanding. The MRO will host the initial low frequency instrument of the SKA, “SKA1-LOW”, and the first five years of “lessons learned” at the MRO are informing SKA1-LOW design and operations planning. This observatory is powered by a hybrid power station with a high component of solar sourced power.

Commissioning using six antennas equipped with first-generation phased-array feeds is now complete and CSIRO is in the process of installing second-generation phased-array feeds and receiving systems on all antennas. The Early Science program with the new Mk II PAFs will begin in mid-2016, with a comprehensive science survey program will follow.

ASKAP has attracted over 380 astronomers to join the 10 major survey projects that will form some of the key science projects.

ASKAP is owned and operated by CSIRO as part of the Australia Telescope National Facility (ATNF). The ATNF also includes the Australia Telescope Compact Array (ATCA), the Parkes 64-m Telescope, the Mopra Telescope, and the Murchison Radio-astronomy Observatory, which also hosts ASKAP, EDGES and the Murchison Widefield Array. Recent progress on these other facilities will also be provided.

This scientific work uses data obtained from the Murchison Radio-astronomy Observatory. We acknowledge the Wajarri Yamatji people as the traditional owners of the Observatory site.

9906-82, Session 23

Partially filled aperture interferometric telescopes: achieving large aperture and coronagraphic performance

Gilberto Moretto, Ctr. de Recherche Astronomique de Lyon (France); Jeffrey R. Kuhn, Institute for Astronomy (United States); Svetlana V. Berdyugina, Kiepenheuer-Institut für Sonnenphysik (Germany); Maud P. Langlois, Ctr. de Recherche Astronomique de Lyon (France)

Telescopes larger than currently planned 30-m class instruments must break the mass-aperture scaling relationship of the Keck-generation of multi-segmented telescopes. Partially filled aperture, but highly redundant baseline interferometric instruments may achieve both large aperture and high dynamic range. The Colossus design group has explored hybrid telescope-interferometer concepts for narrow-field optical systems.that exhibit coronagraphic performance over narrow fields-of-view. This paper describes how the Colossus and ParFAIT 100m telescope designs achieve 10x lower moving masses than current ELTs.

9906-83, Session 23

Unveiling the dynamic infrared sky with Gattini-IR

Anna M. Moore, Mansi K. Kasliwal, Christopher R. Gelino, Jacob E. Jencson, J. Davy Kirkpatrick, Ryan M. Lau, Roger M. Smith, California Institute of Technology (United States); Eric Steinbring, NRC - Herzberg Astronomy & Astrophysics (Canada); Lin Yan, California Institute of Technology (United States)

Optical and radio transient surveys are undergoing a renaissance this decade, however, the infrared sky remains virtually unexplored. The fundamental roadblocks in studying the infrared time-domain have been the overwhelmingly bright sky background, limiting the attainable depth per unit time, and the narrow field-of-view of infrared cameras. To address these challenges and opportunities, we present Gattini-IR, a dual hemisphere, infrared-optimized, ultra-wide field high cadence machine. To take advantage of the low sky background at 2.5 um, two identical systems will be located at the polar sites of the South Pole, Antarctica and near Eureka on Ellesmere Island, Canada. Gattini-IR will survey 15,000 sq. degrees to a depth of 20AB, the same depth of the VISTA VHS survey, every 4 hours with a survey efficiency of 97%. Gattini-IR will enable transformative science in areas such as the detection of stellar mergers, core collapse supernovae, binary neutron star mergers, variability of and planetary transit detections around Brown Dwarfs and long term monitoring of dust production from Wolf Rayet Carbon (WC) stars.

9906-84, Session 24

Telescopio San Pedro Martir Observatory preliminary design and project approach

Jose Teran, M3 Engineering & Technology Corp. (United States); William H. Lee, Michael G. Richer, Beatriz S. Sánchez, David Urdaibay, Univ. Nacional Autónoma de México (Mexico); Derek Hill, David Adriaanse, M3 Engineering & Technology Corp. (United States)

The Instituto de Astronomia of the Universidad Nacional Autónoma de México (UNAM) along with Instituto Nacional de Astrofisica, Optica y Electronica, the University of Arizona and the Smithsonian Astrophysical Observatory are developing the Telescopio San Pedro Martir (TSPM) project, a 6.5m diameter optical telescope. M3 Engineering & Technology Corp. (M3) is the design and construction management firm responsible for all site infrastructure, enclosure and support facilities.

The Telescopio San Pedro Martir project (TSPM) will be located within the San Pedro Martir National Park in Baja California, Mexico at 2,830 m. above sea level, approximately 65 km. east of the Pacific Ocean, 55km west of the Sea of Cortes (Gulf of California) and 180km south of the United States and México border.

The aim of the paper is to present the preliminary design of the site infrastructure, enclosure and support facilities to date and share the design and construction approach.

Based on the Magellan Telescopes located on Las Campanas, Chile the TSPM enclosure and support facilities design utilizes the successfully proven functional and space organization layout and adapts the design to UNMA's unique requirements and site challenges.

The paper also shares M3's design approach, tools, BIM software used to create the construction documents and the construction method utilizing an engineering, procurement and construction management (EPCM) contract to cost effectively build an observatory on a remote mountain with limited nearby construction resources for a project of this scale and complexity.

9906-85, Session 24

Mechanical conceptual design of 6.5 meter telescope: Telescopio San Pedro Mártir (TSPM)

Jorge A. Uribe, Vicente Bringas-Rico, Noe Reyes-Elias, Carlos Tovar, Aldo López, Xóchitl Caballero, César Martínez, Gengis Toledo, Ctr. de Ingenieria y Desarrollo Industrial (Mexico); William H. Lee, Univ. Nacional Autónoma de México (Mexico); Alberto Carramiñana, Instituto Nacional de Astrofísica, Óptica y Electrónica (Mexico); Jesús Gonzalez-Hernandez, Michael G. Richer, Beatriz S. Sánchez, Univ. Nacional Autónoma de México (Mexico); Diana Lucero, Rogelio Manuel, Saúl Rubio, Germán González, Obed Hernández, José Segura, Eduardo Macias, Mary García, José Lazaro, Ctr. de Ingenieria y Desarrollo Industrial (Mexico); Fabián Rosales Ortega, Instituto Nacional de Astrofísica, Óptica, y Electronica (Mexico); Luis del Llano, Ctr. de Ingenieria y Desarrollo Industrial (Mexico)

Telescopio San Pedro Mártir (TSPM) project intends to build a 6.5 meters telescope with alt-azimuth design, currently completing the preliminary design. The project is an association between Instituto de Astronomía de la Universidad Nacional Autónoma de México (IA-UNAM) and the Instituto Nacional de Astrofísica, Óptica Electrónica (INAOE) in partnership with department of Astronomy and Steward Observatory of University of Arizona and Smithsonian Astrophysical Observatory of Harvard University. Conceptual design of the telescope is lead and developed by the Centro de Ingeniería y Desarrollo Industrial (CIDESI). An overview of the feasibility study and the structural conceptual design are summarized in this paper. The telescope concept is based on telescopes already commissioned such as MMT, and the Baade and Clay Magellan telescopes, building up on these proven concepts. The main differences relative to the Magellan pair are; the elevation axis is located 1 meter above the Primary mirror vertex, allowing for a similar field of view at the Cassegrain and both Nasmyth focal stations; instead of using a vane ends to position the secondary mirror TSPM considers an hexapod like MMT; finally TSPM has a larger floor to m1 cell than its previous cousins. Initially TSPM will operate with a f5 Cassegrain station, but the design considers further Nasmyth configurations from a classical f5 up to a Gregorian. The telescope design includes 7 focal stations: 1 Cassegrain; 2 Nasmyth; and 4 folded-Cassegrain.The telescope will be design and manufactured in Mexico, will be design in Queretaro by CIDESI and built between Queretaro and Michoacán manufacturing facilities; it will be preassembled in these facilities and disassembled to send it to the San Pedro Mártir Observatory for final integration. The azimuth and altitude structure is planned to be constructed in modules and transported by truck and shipped to Ensenada and finally to the OAN where is going to be finally assembled, verified and tested.

9906-86, Session 24

Opto-mechanical design and development status of an all spherical five lenses focal reducer for the 2.4 m Thai National Telescope

Christophe Buisset, National Astronomical Research Institute of Thailand (Thailand); Alexis Deboos, National Astronomical Research Institute of Thailand (Thailand) and Institut d'Optique Graduate School (France); Apirat Prasit, National Astronomical Research Institute of Thailand (Thailand); Thierry Lepine, Institut d'Optique Graduate School (France) and Lab. Hubert Curien (France) and Univ. de Lyon (France); Saran Poshyachinda, Boonrucksar Soonthornthum, National Astronomical Research Institute of Thailand (Thailand)

The 2.4 m Thai National Telescope (TNT) is the main instrument of the Thai National Observatory (TNO) which is located near the summit of the Doi Inthanon, situated in the Chiang Mai Province of Thailand at altitude 2,457 meters. The maximum Field Of View (FOV) covered in 1 exposure is provided by the so-called "4K camera" and is equal to 8.8' x 8.8'square.

The National Astronomical Research Institute (NARIT) is currently developing a focal reducer to image a FOV circular of diameter ?? = 14.6' on the 4K camera with a pixel scale equal to 0.42''/pixel. The spatial resolution will be better than 1.2'' over the full visible spectral domain [400 nm, 800 nm]. The relative irradiance between the ghost and the science images will lower than 0.1%. The maximum distortion will be lower than 1% and the maximum angle of incidence on the filters will be equal to 8 degree.

The design complies with the stringent mechanical and design constrains. First, the position of the 4K camera with and without the focal reducer are similar. Then, the overall dimensions comply with the tiny available volumes. Finally, The optical design comprises only common glasses, only spherical surfaces and the mechanical tolerances can be achieved by using common manufacturing facilities and alignment methods.

The focal reducer comprises 1 doublet L1 located at the fork entrance and 1 triplet L2 located in front of the camera. The doublet L1 will be mounted

on a tip-tilt mount placed on a robotic sliding rail. L1 will thus be placed in the optical path during the observations with the 4K camera and will be removed during the observations with the other instruments. The triplet L2 will be installed on the instrument cube in front of the camera equipped with the filter wheel.

The glass will be manufactured in a specialized company and the mechanical parts will be manufactured by using the NARIT Computer Numerical Control machines. The Lenses will be integrated at NARIT. The verification of the mounting will be performed by using the TNT optical beam simulator currently in development.

The alignment will comprise 4 steps. In a first step, we will measure the in-field variations of the TNT output WFE over a circle of angular diameter equal to 13'. In a second step we will calculate and apply the decentering corrections to the secondary mirror to guaranty the TNT image quality over the specified FOV. The third step will consist of aligning L1 on the elevation axis by using 1 alignment telescope placed at the instrument cube level, 2 targets installed on the TNT elevation axis and 1 target placed on the L1 mount. In a fourth step, we will install the lens L2 on the instrument cube and we will measure the PSF size in-field variations.

Conference 9907: Optical and Infrared Interferometry and Imaging V

Monday - Friday 27–1 July 2016

Part of Proceedings of SPIE Vol. 9907 Optical and Infrared Interferometry and Imaging V

9907-1, Session 1

The Navy Precision Optical Interferometer: an update *(Invited Paper)*

J. Thomas Armstrong, U.S. Naval Research Lab. (United States); Donald J. Hutter, U.S. Naval Observatory (United States); Gerard T. van Belle, Lowell Observatory (United States)

We describe the current status of the Navy Precision Optical Interferometer (NPOI), including developments since the last SPIE meeting. The NPOI group has added stations as far as 250 m from the array center and added numerous infrastructure improvements. Science programs include stellar diameters and limb darkening, binary orbits, Be star disks, exoplanet host stars, and progress toward high-resolution stellar surface imaging. Technical and infrastructure work includes on-sky demonstrations of baseline bootstrapping with five array elements, the VISION beam combiner, and control system updates.

9907-2, Session 1

An update on the CHARA array *(Invited Paper)*

Theo A. ten Brummelaar, Douglas R. Gies, Harold A. McAlister, CHARA (United States); Stephen T. Ridgway, National Optical Astronomy Observatory (United States); Judit Sturmann, Laszlo Sturmann, Gail H. Schaefer, Nils H. Turner, Christopher D. Farrington, Nicholas J. Scott, CHARA (United States); John D. Monnier, Univ. of Michigan (United States); Michael J. Ireland, The Australian National Univ. (Australia)

The CHARA Array, operated by Georgia State University, is located at Mount Wilson Observatory just north of Los Angeles in California. The CHARA consortium includes many groups, including LIESA in Paris, Observatoire de la Cote d'Azur, the University of Michigan, Sydney University, the Australian National University, and the NASA Exoplanet Science Institute. The CHARA Array is a six element optical/NIR interferometer, and for the time being at least, has the largest operational baselines in the world. In this talk I will give a brief introduction to the array infrastructure with a focus on our Adaptive Optics program, and then discuss some of the more recent scientific results coming out of the array.

The AO program is divided into two Phases. Phase I includes wavefront sensors at each telescope and a non-common-path AO system in the laboratory. Phase II will include the DMs for the telescopes. Both phases are fully funded and we expect to complete the program by 2018.

CHARA has a unique imaging capability and so I will focus on results from the MIRC imaging system, including our work on imaging rotating stars and binary stars. A very important part of our work in recent years has been the study of exoplanet host stars - it is as important to know about the star as it is the planet - and I will give a summary of these results. Other highlights will include our recent paper on NOVA Delphini, including the first images of the expanding fireball of a Nova and our recent images of spots on the star Zeta And.

9907-3, Session 1

Overview of LBTI: a multipurpose facility for high spatial resolution observations *(Invited Paper)*

Philip M. Hinz, Denis Defrère, The Univ. of Arizona (United States); Andrew J. Skemer, The Univ. of Arizona (United States); Vanessa Bailey, Stanford Univ. (United States); Jordan Stone, The Univ. of Arizona (United States); Eckhart Spalding, The Univ. of Arizona (United States); Enrico Pinna, Alfio T. Puglisi, Simone Esposito, INAF - Osservatorio Astrofisico di Arcetri (Italy); Oscar Montoya, Elwood Downey, Jarron M. Leisenring, William F. Hoffmann, The Univ. of Arizona (United States); Olivier Durney, John M. Hill, The Univ. of Arizona (United States); Rafael Millan-Gabet, California Institute of Technology (United States); William Danchi, NASA Goddard Space Flight Ctr. (United States); Bertrand Mennesson, Jet Propulsion Lab. (United States); Amali Vaz, Paul Grenz, The Univ. of Arizona (United States); Michael Skrutskie, Univ. of Virginia (United States); Steve Ertel, The Univ. of Arizona (United States)

The Large Binocular Telescope Interferometer (LBTI) is a broad-use facility developed for coherent imaging and nulling interferometry using the 14.4 m baseline of the 2x8.4 m LBT. The unique telescope design, comprising of the dual apertures on a common elevation-azimuth mount, enables some unique interferometric modes. The full system is comprised of dual adaptive optics systems, a near-infrared phasing camera, a 1-5 micron camera (called LMIRcam), and an 8-13 micron camera (called NOMIC). The key program for LBTI is the Hunt for Observable Signatures of Terrestrial planetary Systems (HOSTS), a survey using nulling interferometry to constrain the typical brightness from exozodiacal dust around nearby stars. Additional observations focus on the detection and characterization of giant planets in the thermal infrared, and high spatial resolution imaging of complex scenes such as Jupiter's moon, Io, or forming planets in transition disks. Currently upgrades are underway for doubling the LMIRcam field size from 10 to 20 arcseconds, improving the AO performance and limiting magnitude, adding an integral field spectrometry mode, and tracking path length dispersion due to water vapor. We present the current performance of LBTI, an overview of the upgrades, and the driving science cases for the new LBTI capabilities.

9907-4, Session 2

A new path to first light for the Magdalena Ridge Observatory Interferometer *(Invited Paper)*

Michelle J. Creech-Eakman, Ifan Payne, Van Romero, New Mexico Institute of Mining and Technology (United States); Christopher A. Haniff, David F. Buscher, John S. Young, Univ. of Cambridge (United Kingdom)

The Magdalena Ridge Observatory Interferometer (MROI) was the most ambitious IR interferometric facility conceived of in 2003 when funding began. Today, despite having suffered some financial short-falls, it is still one of the most ambitious interferometric imaging facilities ever

designed. With an innovative approach to attaining the original goal of fringe tracking to H = 14th magnitude via completely redesigned mobile telescopes, and a unique approach to the beam train and delay lines, the MROI will be able to image faint and complex objects with milliarcsecond resolutions for a fraction of the cost of giant telescopes or space-based facilities. The design goals of MROI have been optimized for studying stellar astrophysical processes such as mass loss and mass transfer, the formation and evolution of YSOs and their disks, and the environs of nearby AGN.

The global needs for Space Situational Awareness (SSA) have moved to the forefront in many communities as Space becomes a more integral part of a national security portfolio.

These needs drive imaging capabilities ultimately to a few tens of centimeter resolution at geosynchronous orbits. Any array capable of producing images on faint and complex geosynchronous objects in just a few hours will be outstanding not only as an astrophysical tool, but also for these types of SSA missions. With the recent infusion of new funding from the Air Force Research Lab (AFRL) in Albuquerque, NM, MROI will be able to attain first light, first fringes, and bootstrapping with three telescopes by 2020.

MROI's current status along with a detailed sketch of our activities over the coming 5 years will be presented, as well as clear opportunities to collaborate on various aspects of the facility as it comes online. Further funding is actively being sought to accelerate the capability of the array for interferometric imaging on a short time-scale so as to achieve the original goals of this ambitous facility.

The MRO Interferometer is supported through AFRL Cooperative Agreement, FA 9453-15-2-0086 and via the generous support of the Congressional Delegation of the State of New Mexico.

9907-5, Session 2

The 2nd generation VLTI roadmap to performance *(Invited Paper)*

Julien Woillez, Jean-Philippe Berger, Sebastian Egner, Frédéric Yves J. Gonté, European Southern Observatory (Germany); Pierre Haguenauer, Antoine Mérand, European Southern Observatory (Chile); Lorenzo Pettazzi, Markus Schöller, European Southern Observatory (Germany); Nicolas Schuhler, European Southern Observatory (Chile)

By mid-2016, the upgrade of the basic VLTI infrastructure will be completed with the transformation of the laboratory and installation of star separators on both the 1.8-m Auxiliary Telescopes, and the 8-m Unit Telescopes. The GRAVITY fringe tracker will have had a full semester of commissioning on the ATs, and a first look on the UTs. The CIAO infrared wavefront sensor will start demonstrating its performance relative to the visible wavefront sensor MACAO. First astrometric measurements on the ATs and astrometric qualification of the UTs will be on-going. This will be a good time to revisit the VLTI roadmap initiated in 2014.

This VLTI roadmap aims at developing the infrastructure in order to provide functionalities and performances compatible with the new generation of instruments: GRAVITY and MATISSE. This contribution will provide a summary of the current performance, the improvements planned for the next three years, the limitations, and the latent potentials of VLTI.

This contribution focuses on the mid-range future of VLTI. It aims at stimulating a reflection on where we, as a community, want to take VLTI. It is complementary to F. Gonté's presentation covering what was recently accomplished, as part of the VLTI shutdown: the infrastructure upgrade in preparation to the arrival of Gravity, CIAO, and Matisse.

9907-6, Session 3

First light for GRAVITY *(Invited Paper)*

GRAVITY is the new VLTI instrument for precision narrow-angle astrometry and interferometric phase referenced imaging of faint objects. With its fibre-fed integrated optics, sub-electron readnoise fringe tracker, active beam stabilization and a novel three-beam metrology concept, GRAVITY will push the sensitivity and accuracy far beyond what is offered today. The instrument has seen first light with the four 1.8m Auxiliary Telescopes in fall 2015, and we are expecting first light with the four 8m Unit Telescopes in time for the conference. In our presentation we will give an overview of the instrument and we will present its current performance and the plans for the upcoming science exploration.

9907-7, Session 3

First results on-sky of the GRAVITY integrated optics beam combiners

Laurent Jocou, Karine Perraut, Jean-Baptiste Le Bouquin, Institut de Planétologie et d'Astrophysique de Grenoble (France); Pierre Kervella, Observatoire de Paris (France); Vincent Lapeyrère, Observatoire de Paris à Meudon (France); Oliver Pfuhl, Max-Planck-Institut für extraterrestrische Physik (Germany); Sylvain Guieu, Institut de Planétologie et d'Astrophysique de Grenoble (France); Pierre R. Labeye, CEA-LETI (France); Jean-Philippe Berger, Institut de Planétologie et d'Astrophysique de Grenoble (France); Sylvestre Lacour, Observatoire de Paris à Meudon (France); Marcus Haug, Andreas Pflüger, Frank Eisenhauer, Max-Planck-Institut für extraterrestrische Physik (Germany); Guy S. Perrin, Observatoire de Paris à Meudon (France); António Amorim, Fundacão da Faculdade de Ciências da Univ. de Lisboa (Spain); Wolfgang Brandner, Max-Planck-Institut für Astronomie (Germany); Christian Straubmeier, Univ. zu Köln (Germany)

GRAVITY is the VLTI second generation instrument operating in the K band that aims at studying physics close to the Galactic Centre black hole. The beam combiner instrument obtained its first fringes on sky in November 2015, giving a first promising trend of the instrument performance. This first commissioning and the next ones planned in the beginning of 2016 will allow to fully validate the performance in real conditions of the two integrated optics beam combiners at the heart of GRAVITY. After a brief recall of the concept of the integrated optics devices, we will present their characterization results obtained during the commissioning runs.

9907-8, Session 3

Dual field interferometry with GRAVITY: the largest optical telescope in the world opens its second eye

Oliver Pfuhl, Max-Planck-Institut für extraterrestrische Physik (Germany) and European Southern Observatory (Chile); Frank Eisenhauer, Max-Planck-Institut für extraterrestrische Physik (Germany); Guy S. Perrin, Observatoire de Paris à Meudon (France); Karine Perraut, Institut de Planétologie et d'Astrophysique de Grenoble (France); Antonio Amorim, Fundacão da Faculdade de Ciências da Univ. de Lisboa (Portugal); Christian Straubmeier, Univ. zu Köln (Germany); Sylvestre Lacour, Observatoire de Paris à Meudon (France); Stefan Gillessen, Max-Planck-Institut für extraterrestrische Physik (Germany); Wolfgang Brandner, Max-Planck-Institut für Astronomie (Germany); Senol Yazici, Magdalena Lippa, Thomas Ott, Marcus Haug, Ekkehard Wieprecht, Reinhard Genzel, Max-Planck-Institut für extraterrestrische Physik (Germany)

We recently commissioned the dual field mode of GRAVITY. This mode uses one object to track and stabilize fringes allowing for coherent integration times of the order 100s on a second faint object. The first object pair where this was successfully demonstrated was a mK ~ 4.5 fringe-tracking star and a mK ~ 8.5 science object observed at a spectral resolution of 500. The dual field mode opens uncharted territory in interferometry. It allows interferometric observations of objects about 5 magnitudes fainter that the current limit with up to 4000 spectral resolution in K-band. In combination with the dedicated laser metrology it provides phase-referenced imaging on 6 baselines. Furthermore it is the key for the envisioned 10 micro-arcsecond dual-field astrometry. The primary science driver of GRAVITY is the capability of astrometry. The system is designed to measure accretion dynamics and relativistic effects in the vicinity of the Galactic Center black hole. The implementation of the dual field mode is a big leap towards that goal. I will introduce the technology, present the latest scientific achievements and discuss challenges and future prospects of dual field interferometry.

9907-9, Session 3

An overview of the mid-infrared spectro-interferometer MATISSE: science, concept, and current status *(Invited Paper)*

Alexis Matter, Bruno Lopez, Observatoire de la Côte d'Azur (France)

MATISSE is the second generation mid-infrared spectrograph and imager for the Very Large Telescope Interferometer (VLTI) at Paranal. This new interferometric instrument will allow significant advances by opening new avenues in various fundamental research fields: studying the planet-forming region of disks around young stellar objects, understanding the surface structures and mass loss phenomena affecting evolved stars, and probing the environments of black holes in active galactic nuclei. As a first breakthrough, MATISSE will enlarge the spectral domain of current optical interferometers by offering the L & M bands in addition to the N band. This will open a wide wavelength domain, ranging from 2.8 to 13 ?m, exploring angular scales as small as 3 mas (L/M band) / 10 mas (N band). As a second breakthrough, MATISSE will allow mid-infrared imaging - closure-phase aperture-synthesis imaging - with up to four Unit Telescopes (UT) or Auxiliary Telescopes (AT) of the VLTI. Moreover, MATISSE will offer a spectral resolution range between R~30 to ~5000. Here, we present one of the main science objectives, the study of protoplanetary disks, that drives the instrument design and has motivated several VLTI upgrades (GRA4MAT & NAOMI). We introduce the physical concept of MATISSE including a description of the signal on the detectors and an evaluation of the expected performances. We also discuss the current status of the MATISSE instrument, which is entering its testing phase, and the foreseen schedule for the next two years that will lead to the first light at Paranal.

9907-10, Session 3

Imaging capabilities of the VLTI/MATISSE spectra-interferometric instrument *(Invited Paper)*

Joel Sanchez, Jörg-Uwe Pott, Thomas Henning, Roy van Boekel, Max-Planck-Institut für Astronomie (Germany); Bruno Lopez, Alexis Matter, Observatoire de la Côte d'Azur (France); Fabien Baron, Georgia State Univ. (United States); Florentin Millour, Observatoire de la Côte d'Azur (France); Gerd Weigelt, Karl-Heinz Hofmann, Dieter Schertl, Max-Planck-Institut für Radioastronomie (Germany)

During the last decade, the first generation of beam combiners at the Very Large Telescope Interferometer has proved the importance of optical interferometry for high-angular resolution astrophysical studies in the near- and mid-infrared. With the advent of 4-beam combiners at the

VLTI, the u-v coverage per pointing increases significantly, providing an opportunity to use reconstructed images as powerful scientific tool.

We present studies to characterize the imaging capabilities of the Multi-AperTure mid-infrared SpectroScopic Experiment (MATISSE), a second generation instrument for the Very Large Telescope Interferometer (VLTI). Its six-baselines, optics and high-spectral resolution (R~5000) will deliver for the first time thermal-IR interferometric data with enough u-v coverage and differential phase information for imaging. In this work, we report detailed image reconstruction studies carried out with four image reconstruction packages: PAINTER, MIRA, IRBIS and SQUEEZE. For our studies, we use realistic simulated MATISSE data from radiative transfer simulations of two astrophysical objects: a proto-planetary disk and the surface of a giant star with hot-spots. In particular, we will discuss the roles of the regularization function, u-v coverage, and of the initial brightness distribution. MATISSE will perform observations at three different mid-infrared bands: L, M and N. Hence, due to its large bandwidth, chromatic effects should be taken into account when image reconstruction is attempted. We will also discuss the capabilities of the different packages to perform multi-wavelength image reconstruction. Finally, we discuss the implementation of Compress Sensing to recover interferometric images, a technique that has demonstrated fruitful results to restore signals from data with missing information and that has recently demonstrated its applicability to image reconstruction in current and future radio interferometers (e.g., LOFAR, SKA). Since it has been barely tested with the optical ones, we explore the performance of interferometric imaging using Compress Sensing in the context of the upcoming interferometric instrumentation. The work here presented is being carried out within the Opticon FP7-2 joint research activity on interferometric imaging.

9907-11, Session 3

MATISSE: integration and test phase first results

Fatmé Allouche, Sylvie Robbe-Dubois, Stéphane Lagarde, Pierre Antonelli, Bruno Lopez, Sébastien Morel, Philippe Bério, Observatoire de la Côte d'Azur (France); Udo Beckmann, Max-Planck-Institut für Radioastronomie (Germany); Felix Bettonvil, ASTRON (Netherlands); Uwe Graser, Michael Lehmitz, Max-Planck-Institut für Astronomie (Germany); Paul Bristow, Andreas Glindemann, Juan-Carlos Gonzalez, Markus Schöller, European Southern Observatory (Germany); Lars Venema, ASTRON (Netherlands); Walter Jaffe, Leiden Observatory (Netherlands)

MATISSE (Multi AperTure mid-Infrared SpectroScopic Experiment) is the spectro-interferometer of the European Southern Observatory VLT operating in the spectral bands L, M and N, and combining up to four beams from the unit or the auxiliary telescopes. MATISSE will offer new breakthroughs in the study of circumstellar environments by allowing the mapping of the material distribution, the gas and essentially the dust.

The instrument consists in a warm optical system (WOP) accepting four beams from the VLTI and relaying them after a dichroic splitting (for the L/M- and N- spectral bands) to cold optical benches (COB) located in two separate cryostats. The Observatoire de la Côte d'Azur is in charge of the WOP providing the functions of spectral band separation, optical path equalization and modulation, pupil positioning, beam anamorphosis, beam commutation, and calibration. NOVA-ASTRON is in charge of the COB providing the functions of beam selection, reduction of thermal background emission, spatial filtering, pupil transfer, photometry and interferometry splitting, additional beam anamorphosis, spectral filtering, polarization selection, image dispersion, and image combination. The Max Planck Institut für Radioastronomy is in charge of the operation and performance validation of the two detectors, a HAWAII-2RG from Teledyne for the L/M-band and a Raytheon AQUARIUS for the N-band, provided by the European Southern Observatory. The Max Planck Institut für Astronomie is in charge of the cryostats for which the requirements on space limitations and vibration stability resulted on very specific choices on the design.

The integration and test of the two cryogenic systems, including the cold benches and detectors, have been conducted at MPIA in parallel with the integration of the WOP at OCA. At the end of 2014, the complete instrument was integrated at OCA. Following the integration, a period of interface and alignment took place resulting in the first interference fringes in the L-band during summer 2015.

After a period of optimization of both the instrument reliability and the environmental working conditions, the test plan is presently being conducted in order to evaluate the complete performance of the instrument and its compliance with the high-level requirements.

The present paper gives the first results of the integration and tests of the MATISSE instrument.

9907-12, Session 4

Imaging protoplanets: observing transition disks using non-redundant masking *(Invited Paper)*

Stephanie Sallum, Joshua Eisner, Laird M. Close, Philip M. Hinz, The Univ. of Arizona (United States); Katherine B. Follette, Stanford Univ. (United States); Kaitlin Kratter, Andrew J. Skemer, The Univ. of Arizona (United States); Vanessa P. Bailey, Stanford Univ. (United States); Runa Briguglio, INAF - Osservatorio Astrofisico di Arcetri (Italy); Denis Defrère, The Univ. of Arizona (United States); Bruce A. Macintosh, Stanford Univ. (United States); Jared R. Males, Katie M. Morzinski, The Univ. of Arizona (United States); Alfio T. Puglisi, INAF - Osservatorio Astrofisico di Arcetri (Italy); Timothy J. Rodigas, Carnegie Institution of Washington (United States); Eckhart Spalding, The Univ. of Arizona (United States); Peter G. Tuthill, The Univ. of Sydney (Australia); Amali Vaz, The Univ. of Arizona (United States); Alycia Weinberger, Carnegie Institution of Washington (United States); Marco Xomperio, INAF - Osservatorio Astrofisico di Arcetri (Italy)

Transition disks provide an opportunity to study planet formation in situ. While explaining these inner clearings is a challenge, young planets accreting material that would have otherwise fallen onto the star likely play a major role. The novel imaging technique of non-redundant masking (NRM) can achieve the angular resolution and contrast needed to detect forming planets within known transition disk gaps. NRM transforms a filled aperture into an interferometric array through the use of a pupil plane mask, allowing for better point-spread function characterization than even an adaptive-optics-corrected telescope and expanding the observable companion parameter space. We present new NRM+AO observations of the T Cha and LkCa 15 transition disks. We also re-analyze archival data from the VLT and Keck, performing new and statistically rigorous error analysis. T Cha hosts a posited substellar companion detected in single-epoch NRM observations taken at the Very Large Telescope (VLT). However, multi-epoch datasets from both the VLT and the Magellan Adaptive Optics system (MagAO) show a lack of orbital motion and are incompatible with a companion orbiting in the plane of the outer disk. A model based on forward scattering from the edge of the outer disk is more consistent with the observations. Conversely, NRM observations of LkCa 15 taken at the Large Binocular Telescope confirm the structure seen in previous observations, and suggest multiple forming planets. We detect three infrared point sources within the disk clearing. Orbital fits to these

and re-analyzed archival Keck NRM data show that the source positions are consistent with distinct Keplerian orbits. The observed infrared fluxes agree with theoretical predictions for circumplanetary disks and are inconsistent with those expected for hot-start models. We also detect one of the infrared sources in new MagAO H-alpha observations, tracing hot (~10,000 K) gas falling deep into the potential well of a protoplanet. We discuss the characteristics of this forming planetary system and its implications for future planet formation studies.

9907-13, Session 5

Single aperture interferometry: masking and beyond *(Invited Paper)*

Peter G. Tuthill, Univ. of Sydney (Australia)

Interferometric techniques developed to recover information up to and beyond the diffraction limit of a large telescope aperture have a long and successful pedigree. Stretching back to the dawn of interferometry itself, Fizeau's original 1867 proposal to measure stellar sizes is the genesis of our entire field. The startlingly durable technique he proposed - going by several modern names including aperture masking, SAM and NRM, thrives today nearly 150 years later, unaltered in basic principles. It continues to produce unique science, flouting all reasonable expectations for experimental longevity. New approaches inspired by these successes have branched in many exciting directions including a coming generation of photonic interferometers which reformulate the underlying ideas in a format exploiting guided-wave optics.

This invited review will cover the history and present science being accomplished with aperture masking interferometry. This spans the astrophysical spectrum from young stars to evolved, and from exoplanets to supergiants. Further advances and refinements to the technique are presently showing enormous promise. This talk will discuss kernel phase interferometry, pupil fragmentation and remapping techniques, refinements such as interferometric polarimetry and other differential approaches, as well as interferometry from space platforms such as JWST.

9907-14, Session 5

VAMPIRES: a polarimetric non-redundant-masking interferometer for diffraction-limited imaging of dusty circumstellar environments

Barnaby R. Norris, Peter G. Tuthill, The Univ. of Sydney (Australia); Nemanja Jovanovic, Subaru Telescope, National Astronomical Observatory of Japan (United States); Guillaume Schworer, Observatoire de Paris à Meudon (France) and Lab. d'Etudes Spatiales et d'Instrumentation en Astrophysique (France) and The Univ. of Sydney (Australia); Nick Cvetojevic, The Univ. of Sydney (Australia) and Australian Astronomical Observatory (Australia) and Ctr. for Ultrahigh bandwidth Devices for Optical Systems (Australia); Paul Stewart, The Univ. of Sydney (Australia); Olivier Guyon, Subaru Telescope, National Astronomical Observatory of Japan (United States); Frantz Martinache, Observatoire de la Côte d'Azur (France); Julien Lozi, Subaru Telescope, National Astronomical Observatory of Japan (United States); Danielle Doughty, Subaru Telescope, National Astronomical Observatory of Japan (United States) and The Univ. of Arizona (United States); Garima Singh, Subaru Telescope, National Astronomical Observatory of Japan (United States)

The direct imaging of the process of solar system formation, where planets are formed within a protoplanetary disk, can potentially resolve many mysteries in this poorly understood process. Along with imaging the dusty atmospheres of evolved stars, these observations pose a huge technical challenge due to the high angular-resolutions and contrasts required. The major stumbling block is the problem of the Earth's own atmospheric turbulence. One solution to this problem is aperture masking interferometry, which transforms the pupil of a single 8 m class telescope into an interferometric array of smaller sub-pupils by way of a mask placed in the telescope's pupil plane. The other difficulty is that precise calibration is required to combat the extremely high contrast ratios and high resolutions faced. By taking advantage of the fact that starlight scattered by dust in the circumstellar region is polarised, differential polarimetry can be used to achieve this calibration, as well as making polarimetric measurements.

VAMPIRES (Visible Aperture Masking Polarimetric Interferometer for Resolving Exoplanetary Signatures) is a newly commissioned high-angular resolution imager which capitalises on these techniques. Developed by the University of Sydney in conjunction with the SCExAO extreme adaptive-optics project, it is currently deployed on the Subaru telescope as part of the SCExAO system.

In contrast to conventional coronagraphic techniques, aperture masking interferometry has demonstrated the ability to image faint companions at resolutions well beyond the diffraction limit. VAMPIRES leverages this technique in combination with polarimetry, to directly image structure in the inner-most regions of protoplanetary systems and evolved stars, at visible wavelengths. VAMPIRES uses starlight scattered by dust in the inner region of such systems to precisely map the disks, shell, gaps, knots and waves that are key to understanding disk evolution and planet formation, along with the mass-loss process of dying stars. With a spatial resolution of ~10 mas and with a maximum field of view of ~500 mas, VAMPIRES perfectly compliments coronagraphic observations in the near-IR, and in fact can operate simultaneously with IR coronagraphic observations by utilising the otherwise unused visible wavelengths. High resolutions and dynamic ranges are enabled by VAMPIRES' triple-layered polarimetric differential calibration system, using simultaneous polarised channel splitting, fast liquid-crystal channel switching and half-wave-plate based channel switching. Multiple opto-mechanical systems allow various aperture-masks, polarisation devices and imaging subsystems to be deployed, with the final interferogram imaged at high cadence using an EMCCD detector.

Now commissioned on-sky, VAMPIRES has demonstrated polarised differential visibility precisions of 1 part in 1000, and differential closure phases of a fraction of a degree. The instrument has recently produced its first science results, resulting in milliarcsecond, high-contrast imaging of dusty circumstellar regions.

9907-15, Session 5

FIRST-IR instrument: latest development and results of nulling capabilities

Lucien Gauchet, Sylvestre Lacour, Observatoire de Paris (France) and Lab. d'Etudes Spatiales et d'Instrumentation en Astrophysique (France); Takayuki Kotani, National Astronomical Observatory of Japan (Japan); Elsa Huby, Univ. de Liège (Belgium); Guy S. Perrin, Observatoire de Paris (France) and Lab. d'Etudes Spatiales et d'Instrumentation en Astrophysique (France)

In the context of direct detection of exoplanets and disks, the use of high angular resolution and high contrast techniques is essential. The issue is to detect the light from a companion located at a small angular separation from its parent star and at the same time to deal with the high difference

of their respective luminosity.

FIRST-IR (Fibered Instrument foR a Single Telescope) is an interferometric instrument developed at the Observatoire de Paris-Meudon (LESIA) to fulfill the aforementioned requirements. This demonstrator is operating in the near infrared (H band: $lambda=1.65 mu m$) and leans upon pupil remapping using single mode fibers and integrated optic for recombination.

Pupil remapping derives from sparse aperture masking, transforming the pupil of the telescope into a interferometric array, but pushes the concept further, aiming at making interfere every sub-division of the main pupil, two by two. This allows to get rid of non-coherent addition of the perturbed wavefront due to redundancy in the pupil.

The light from each sub-pupil is injected into its respective fiber, dispatching it into the integrated optic beam combiner.

Integrated optics, originally developed for telecommunications were implanted successfully in astronomy. The PIONIER instrument at the VLTI and the soon-coming GRAVITY instrument are perfect examples of the strong potential of such devices. They offer an advantageous technical solution that is stable and compact and easy to integrate in an instrument for the recombination of light.

They consist of a substrate on which waveguides are engraved and whose disposition and geometry allow multiple configurations of recombination. The information on the phase delay between the input beams is coded in the outputs of the integrated optic: the intensity of interference fringes are sampled on a quadruplet of pixels for each pair of recombined sub-pupils.

In this study, we present the current state of the FIRST-IR instrument which combines pupil remapping with nulling to cancel the stellar light, and thus decrease the photon noise outshining the light from the companion. We will present the first light results of this prototype component, in particular the closure phase signal after nulling

9907-16, Session 6

The Dragonfly interferometer: on-sky demonstration of a photonic pairwise beam combiner with on-chip pupil reformatting using hybridized 2D-3D architecture

Nick Cvetojevic, The Univ. of Sydney (Australia) and Australian Astronomical Observatory (Australia); Barnaby R. Norris, The Univ. of Sydney (Australia); Simon Gross, Alexander Arriola, Macquarie Univ. (Australia); Takayuki Kotani, National Astronomical Observatory of Japan (Japan); Sylvestre Lacour, Observatoire de Paris à Meudon (France); Michael J. Withford, Macquarie Univ. (Australia); Jonathan S. Lawrence, Australian Astronomical Observatory (Australia); Peter G. Tuthill, The Univ. of Sydney (Australia)

Aperture masking, wherein the pupil of a single large telescope is divided into a number of sub-apertures, has a proven track record in enabling diffraction-limited imaging and high contrast detections on seeing-limited 8m class telescopes. However only a small fraction of the telescope's total aperture can be used this way, since the holes must be arranged in a non-redundant configuration, and variations in phase across the sub-apertures due to atmospheric fluctuations introduce closure-phase error.

A newer technique is pupil remapping, wherein the holes in the mask are replaced by a number of single mode optical waveguides. This offers a number of advantages: firstly, the arrangement of the waveguide's inputs at the pupil plane need not be non-redundant, hence a large portion of the telescope's aperture can be used. Secondly, the single-mode nature of the waveguides means the phase is flat across each sub-aperture, allowing precise closure phases to be measured. Thirdly, the 2D input pattern can be remapped to 1D output, allowing the use of an integrated photonic chip based beam combiner.

The Dragonfly instrument is a photonic pupil remapping interferometer, utilizing a hybridized 2D-3D architecture to perform the injection, remapping, and on-chip beam combination, all on a single self-contained structure. The current iteration of the Dragonfly chipset consists of an 8-port pairwise beam combiner, which combines all 28 possible baselines in quadrature on-chip, outputting 112 flux channels from which the visibilities and phases of the fringes are extracted, and a further 8 photometric taps allowing the time-varying, asymmetric input coupling to be calibrated for (resulting in significantly improved visibility calibration). To remap the telescope pupil to the 8 input ports of the beam combiner chip, a series of waveguides are manufactured in three dimensions within a block of glass, using ultrafast laser inscription, and directly bonded with the beam-combining chip forming a single monolithic device. Due to the short coherence length of the starlight (~ 10 microns for a typical NIR bandpass) the path lengths of each waveguide must be matched to micron precision. One advantage of Dragonfly's approach is that the path lengths of waveguides within the chip are extremely robust against changes in optical path length from the environment. Further, a series of side-steps and masks are integrated to remove the impact of stray-light. Lastly, a micro-lens array is bonded to the input of the chipset, matching the waveguide array that segments the pupil. The Dragonfly chipset requires no ongoing alignment between any of the photonic components, making the device far more robust even under a changing gravity vector (cassegrain deployment), and only requires that the telescope pupil be aligned to the input of the chip, achieved using a single translation stage, greatly reducing the complexity of implementing photonic interferometers.

Here, we present results from the recent Dragonfly commissioning run on the 3.9 m Anglo-Australian Telescope, along with the latest performance measurements from our laboratory testbed. When wavefront error above 2pi radians is applied to an input waveguide, closure phase RMS of 0.9 degrees is obtained.

9907-17, Session 6

New results with aperture masking interferometry from Keck and VLT: discovery of scaled-up exoplanets?

Sasha Hinkley, Univ. of Exeter (United Kingdom); Adam L. Kraus, The Univ. of Texas at Austin (United States); Michael J. Ireland, The Australian National Univ. (Australia); Anthony C. Cheetham, The Univ. of Sydney (Australia); John M. Carpenter, California Institute of Technology (United States); Peter G. Tuthill, The Univ. of Sydney (Australia); Sylvestre Lacour, Observatoire de Paris à Meudon (France); Thomas M. Evans, Univ. of Exeter (United Kingdom); Xavier Haubois, The Univ. of Sydney (Australia)

We report the detection of seven low-mass companions to intermediate-mass stars in the Scorpius–Centaurus (Sco–Cen) Association using non-redundant aperture masking interferometry at Keck and VLT. Our newly detected objects have L-band contrasts 4–6 magnitudes fainter than their host star, corresponding to masses as low as 20 Jupiter masses and mass ratios as small as 1%, depending on the assumed age of the target stars. With projected separations of 10–30 AU, our aperture masking detections sample an orbital region totally out of reach to previous, conventional adaptive optics imaging of intermediate-mass Sco–Cen stars that covered much larger orbital radii (30–3000AU). At such orbital separations, these objects resemble higher-mass versions of the directly imaged planetary mass companions to the 10–30 Myr, intermediate-mass stars HR 8799, beta Pictoris, and HD 95086. These newly discovered companions span the brown dwarf desert, and their masses and orbital radii provide a new

constraint on models of the formation of low-mass stellar and substellar companions to intermediate-mass stars.

9907-18, Session 7

Speckle imaging at large telescopes: current results and future prospects
(Invited Paper)

Elliott P. Horch, Southern Connecticut State Univ. (United States)

The development of electron-multiplying CCD cameras (EMCCDs) has changed the landscape and prospects for speckle imaging in recent years. These detectors have quantum efficiencies above 90% through most of the visible range and effective read noise of much less than one electron when the electron-multiplying gain amplifier is used. They are, therefore, effectively photon-counting devices with nearly maximal collection of photons. In addition, the best commercially available devices have low dark current and yet are very easy to use, requiring no liquid nitrogen cooling. Compared with intensified-CCDs more traditionally used in speckle work, they have much greater sensitivity and read out at approximately the same speed. These properties make them extremely efficient devices for speckle imaging, and their use in this application has allowed for progress in certain problems in high-resolution imaging in the single-aperture regime, including in searching for faint stellar companions near exoplanet host stars and in satellite imaging. Crucial to the science in both of these applications is the photometric linearity of the devices in the context of speckle imaging; this has now been demonstrated by multiple teams of observers.

This situation has led to an increased and more consistent use of speckle imaging at mid-sized and large telescopes. Most notably, there are now speckle visitor instrument programs that use EMCCDs available to the community at several observatories throughout the world including the Gemini North and Gemini South telescopes and the WIYN telescope at Kitt Peak National Observatory. Both the SOAR telescope in Chile and Special Astrophysical Observatory 6-m telescope in Russia have speckle cameras in their suite of permanent instruments. A new community of users has responded to this availability and is using these cameras for a range of astronomical observations. An overview of the science applications will be described, and some results of these efforts will be discussed. The outlook for the future of speckle imaging will be given, in three main areas: (1) the development of future instrumentation, (2) prospects for more robust image reconstruction algorithms, and (3) scientific problems that could benefit from these developments, including those that could involve the combined use of both speckle and other high-resolution techniques.

9907-19, Session 7

SRAO: the southern robotic speckle + adaptive optics system

Nicholas M. Law, Carl Ziegler, The Univ. of North Carolina at Chapel Hill (United States); Andrei Tokovinin, National Optical Astronomy Observatory (Chile)

We will present plans for SRAO, the first Southern Robotic AO system. SRAO, based at the 4m SOAR telescope, will use AO-assisted speckle imaging and Robo-AO-heritage high efficiency observing to confirm and characterize thousands of planet candidates produced by major new transit surveys like TESS. SRAO is the first AO system to have the resolution and efficiency to build a comprehensive several-thousand-target multiplicity survey at sub-AU scales across the main sequence. We will also describe results from Robo-AO, the first robotic LGS-AO system. Robo-AO has observed tens of thousands of Northern targets, often using a similar speckle or Lucky-Imaging assisted mode.

SRAO will be a "moderate-order" natural-guide-star adaptive optics system which uses an innovative photon-counting wavefront sensor and EMCCD speckle-imaging camera to guide on faint stars with the 4.1m SOAR telescope. The system will produce diffraction-limited imaging in the NIR on targets as faint as mV=16. In AO-assisted speckle imaging mode the system will attain the 30-mas visible diffraction limit on targets at least as faint as mV=17. The system will be the first Southern hemisphere robotic adaptive optics system, with overheads an order of magnitude smaller than comparable systems. Using Robo-AO's proven robotic AO software, SRAO will be capable of sub-minute observing overheads, allowing the observation of at least 200 targets per night. SRAO will attain three times the angular resolution of the Palomar Robo-AO system in the visible, and will complement the ongoing Northern Kitt Peak Robo-AO survey.

9907-20, Session 8

The role of Fizeau interferometry in solar system studies

Albert R. Conrad, Large Binocular Telescope Observatory (United States)

Historically, two types of interferometer have been applied to the study of solar system objects: coaxial and Fizeau. While coaxial interferometers are well-suited to a wide range of galactic and extra-galactic science cases, solar system science cases are, in most cases, better carried out with Fizeau imagers. Targets of interest in our solar system are often bright and compact, and the science cases for these objects often call for a complete, or nearly complete, image at high angular resolution. For both methods, multiple images must be taken at varying baselines to reconstruct an image. However, with the Fizeau technique that number is far fewer than it is for the aperture synthesis method employed by co-axial interferometers.

In our solar system, bodies rotate and their surfaces are sometimes changing over yearly, or even weekly, time scales. Thus, the need to be able to exploit the high angular resolution of an interferometer with only a handful of observations taken on a single night, as is the case for Fizeau interferometers, gives a key advantage to this technique.

The aperture of the Large Binocular Telescope (LBT), two 8.4 circular mirrors separated center-to-center by 14.4 meters, is optimal for supporting Fizeau interferometry. The first of two Fizeau imagers planned for LBT, the LBT Interferometer (LBTI), saw first fringes in 2010 [Hinz et al, SPIE, 2012] and has proven to be a valuable tool for solar system studies. Recent studies of Jupiter's volcanic moon Io have yielded results that rely on the angular resolution provided by the full 23-meter baseline of LBT [Leisenring et al, SPIE, 2014; Conrad et al, AJ, 2015; Skrutskie et al, Icarus, in prep]. Future studies of the aurora at Jupiter's poles and the shape and binarity of asteroids are planned.

While many solar system studies can be carried out on-axis (i.e., using the target of interest as the beacon for both adaptive optics correction and fringe tracking), studies such as Io-in-eclipse, full disk of Jupiter and Mars, and binarity of Kuiper belt objects, require off-axis observations (i.e., using one or more nearby guide-moons or stars for adaptive optics correction and fringe tracking). These studies can be plagued by anisoplanatism, or "cone effect." LINC-NIRVANA (LN), the first multi-conjugate adaptive optics system (MCAO) on an 8-meter class telescope in the northern hemisphere, provides a solution to the ill-effects of anisoplanatism. Longer term, an upgrade planned for LN will establish its original role as the second LBT Fizeau imager. The full-disk study of several solar system bodies, most notably large and/or nearby bodies such as Jupiter and Mars which span tens of arcseconds, would be best studied with LN.

We will review the past accomplishments of Fizeau interferometry with LBTI, present plans for using that instrument for future solar system studies, and, lastly, explore the unique solar system studies that require the LN MCAO system combined with Fizeau interferometry.

9907-21, Session 9

Intensity interferometry: optical imaging with kilometer baselines *(Invited Paper)*

Dainis Dravins, Lund Observatory (Sweden)

Microarcsecond resolution imaging requires multi-element and kilometer-scale interferometers operated at their diffraction limit. However, the high stability requirements for measuring first-order optical coherence with amplitude and phase interferometers limit the construction of such complexes on either the ground or in space. Intensity interferometry, correlating intensity fluctuations between independent telescopes to measure the second-order optical coherence, circumvents atmospheric turbulence and is immune to telescopic imperfections. Telescopes are connected only electronically (rather than optically), and the error budget relates to electronic timescales of perhaps a few nanoseconds (light-travel distance on the order of a meter), enabling observations at short optical wavelengths (even through large airmasses far from zenith), as well as the use of optically imperfect telescopes. Once pioneered by Hanbury Brown and Twiss, this two-photon method is generally seen as the first quantum optics experiment. As a modern digital technique, it has now been demonstrated with arrays of small laboratory telescopes, observing artificial stars over hundreds of optical baselines, reconstructing diffraction-limited images. With telescopes linked only by electronic software, the technique can readily be expanded to large arrays, analogous to current radio interferometers. Baselines of a few km will provide resolutions in visual light on tens of microarcseconds, adequate for viewing details on stellar surfaces or perhaps even the silhouettes of transiting exoplanets. However, as shown in numerical simulations, observations are currently practical only for bright and hot objects (such as naked-eye stars hotter than the Sun); fainter targets will be reached once suitable photon-counting and energy-resolving detectors become available.

In this review, an overview of the method is given from its beginnings some 50 years ago; its later non-astronomical applications in high-energy particle physics; current optical experiments by various groups, and the prospects for future observations using either the large arrays of optical air Cherenkov telescopes now under construction for primarily gamma-ray studies, or on extremely large single-aperture telescopes.

9907-22, Session 9

Intensity interferometry with Aqueye+ and Iqueye in Asiago

Luca Zampieri, INAF - Osservatorio Astronomico di Padova (Italy); Giampiero Naletto, Carlo Barbieri, Univ. degli Studi di Padova (Italy); Mauro Barbieri, Univ. of Atacama (Chile); Enrico Verroi, Gabriele Umbriaco, P. Favazza, Univ. degli Studi di Padova (Italy); Luigi Lessio, Giancarlo Farisato, INAF - Osservatorio Astronomico di Padova (Italy)

Since a number of years our group is engaged in the design, construction and operations of instruments with very high time resolution in the optical band for applications to Quantum Astronomy and more conventional Astrophysics. Two instruments were built to perform photon counting with sub-nanosecond temporal accuracy. The first of the two, Aqueye+, is regularly mounted at the 1.8m Copernicus telescope in Asiago, while the second, Iqueye, was mounted at the NTT telescope in Chile, and at the WHT and TNG telescopes on the Roque (La Palma, Canary Islands). Both instruments deliver extraordinarily accurate results in optical pulsar timing.

Recently, Iqueye was moved to Asiago to be mounted at the 1.2m Galileo telescope to attempt, for the first time ever, experiments of optical intensity interferometry (à la Hanbury Brown and Twiss) on a baseline of a few kilometers. This application was one of the original goals for the development of our instrumentation. To carry out these measurements, we are experimenting a new way of coupling the instruments to the telescopes, by means of moderate-aperture, low-optical-attenuation multi-mode optical fibers with a double-clad design. Fibers are housed in dedicated optical interfaces attached to the focus of other instruments of the 1.8m telescope (Aqueye+) or to the Nasmyth focus of the 1.2m telescope (Iqueye). This soft-mount-solution has the adavantage to facilitate the mounting of the photon counters, to keep them under controlled temperature and humidity conditions (reducing potential systematics related to varying ambient conditions), and to mitigate scheduling requirements. Here we will describe the first successful implementation of the Asiago intensity interferometer and future plans for improving it.

9907-23, Session 9

HBT SII imaging studies at the University of Utah

David B. Kieda, Nolan Matthews, The Univ. of Utah (United States)

This talk will describe the development of a fully digital implementation of the Hanbury-Brown-Twiss (HBT) intensity interferometry technique. This implementation uses a high-speed (250 Mhz) streaming digitizer to continuously record the light intensity observed by fast light sensors (photomultipliers, APDs, SiPM) at the focus of large (3-10 m) diameter Imaging Air Cherenkov Telescopes (IACTs). The digitized waveforms are sent to a high-speed computational facility to perform post-observation multi-telescope correlations. This strategy increases the scale and complexity of interferometry combinations that can be measured with a km-scale distributed array of 10-100 IACT telescopes, such as the future Cherenkov Telescope Observatory (CTA).

The talk will include recent progress made in image reconstruction of laboratory-simulated stars using pseudo-random light sources, and in reconstruction of source characteristics from these tests. The lecture will also describe SII observations performed using a pair of twin 3-m diameter optical telescopes, located at StarBase Utah, for the measurement of stellar diameters of several nearby stars. The talk includes a description of plans for testing SII capabilities at the VERITAS observatory in concert with the construction of the 9.6 m diameter Schwartzchild Couder telescope prototype, an ideal SII and IACT telescope for CTA.

9907-24, Session 9

Measurement of intensity correlations from laboratory and astronomical sources with single photon avalanche photodiodes and superconducting nanowire single photon detectors

Edward Schroeder, Philip Mauskopf, Nathan D. Smith, Genady Pilyavsky, Adrian Sinclair, Hamdi Mani, Arizona State Univ. (United States); Dmitry V. Morozov, Cardiff Univ. (United Kingdom); Karl K. Berggren, Di Zhu, Massachusetts Institute of Technology (United States)

We describe a detector module containing superconducting nanowire single photon detectors (SNSPDs) to be used for intensity interferometry to measure the angular diameters of stars. The SNSPDs are mounted in a small, easily transportable, cryostat coupled to single mode fiber optic cables through a hermetic feed-through. The detectors are read out with multistage microwave amplification and FPGA-based coincidence electronics. We successfully coupled these detectors to the Bok 2.3-m telescope on Kitt Peak and were able to obtain a count rate of 1 MHz for photons with a wavelength of 1.5 microns with a 12 nm bandwidth through

a single mode fiber from Capella, a 0.08 apparent magnitude star. This corresponds to an overall system efficiency of approximately 0.2%. The efficiency of coupling the single mode fiber to the telescope was primarily limited by the effects of atmospheric seeing which spreads the incident light from the star over approximately 100 modes in the focal plane. We will present progress on measurements with these detectors of correlations from two incoherent sources: a gas-discharge lamp with a laboratory set-up and a star with a rooftop set-up. The use of superconducting photon counting detectors for interferometry has a number of potential advantages over traditional Michelson interferometry and over the original set-up of Hanbury Brown and Twiss for intensity interferometry. The high time resolution of the SNSPDs enables measurements of diameters of bright stars with relatively small telescopes (~30 cm) that can have high efficiency for coupling to a single mode fiber even in the presence of atmospheric turbulence. In the future, the diameters of highly luminous, compact objects such as white dwarfs and black hole accretion disks may be measured with SNSPDs or other single photon detectors on larger telescopes with adaptive optics to provide high coupling efficiencies and baselines on the order of kilometers. This is not achievable through conventional methods of amplitude interferometry that rely on physical beam interference.

9907-25, Session 10

The orbit of the mercury-manganese binary 41 Eridani

Christian Hummel, Markus Schöller, European Southern Observatory (Germany); Gilles Duvert, Institut de Planétologie et d'Astrophysique de Grenoble (France) and Univ. Grenoble Alpes (France); Jean-Baptiste Le Bouquin, Institut de Planétologie et d'Astrophysique de Grenoble (France) and Univ. Joseph Fourier (France); Swetlana R. Hubrig, Leibniz Institute for Astrophysics Potsdam (Germany)

The mercury-manganese (HgMn) stars are a class of peculiar main-sequence late-type B stars. Their members show a wide variety of abundance anomalies with both depletions (e.g., He) and enhancements (Hg, Mn) and tend to be slow rotators relative to their normal analogs. These stars form a sub-class of the chemically peculiar (CP) stars. The chemical alterations are thought to be due to diffusion in quiet stellar atmospheres. More than two thirds of the HgMn stars are known to belong to spectroscopic binaries (Hubrig & Mathys 1995) with a preference of orbital periods ranging from 3 to 20 days.

Interferometric orbits were already measured for Phi Herculis (Zavala et al. 2007), Chi Lupi (Le Bouquin et al. 2013), and Alpha Andromedae (Pan et al. 1992). Here we report on a program to study the binarity of HgMn stars with the PIONIER near-infrared interferometer at the VLTI on Cerro Paranal, Chile. Among some 30 stars, companions were found for 10 of them, and the data allowed the determination of the orbital elements of 41 Eridani, with a period of just 5 days and a semi-major axis of under 2 mas.

Including the radial velocity measurements published by Hubrig et al. (2012), we derived masses of 3.10 +/- 0.06 times solar for each of the almost identical B9V stars (magnitude difference measured less than 0.1 mag). The orbital parallax is 18.14 +/- 0.16 mas, in good agreement with the Hipparcos trigonometric parallax of 18.33 +/- 0.15 mas. The stellar diameters are resolved as well at 0.38 +/- 0.03 mas. Using the sedFit tool (A. Boden, G. van Belle, priv. comm.) to estimate the bolometric flux, we derived an effective temperature of 10700 K for each of the stars, as well as diameters of 0.39 mas, in agreement with the measurements.

With other measurements of binary orbits in CP stars including Sigma Orionis A (Schaefer 2013), Lambda Virginis (Zhao et al. 2007), and Beta Arietis (Pan et al. 1990), allowing to derive stellar masses and luminosities, optical interferometry has provided important contributions to the understanding of CP stars in general.

9907-26, Session 11

IR-interferometric observations of AGNs: a diversity of dusty tori *(Invited Paper)*

Leonard Burtscher, Max-Planck-Institut für extraterrestrische Physik (Germany)

Interferometric observations in the infrared have resolved dusty structures on parsec and sub-parsec scales in more than two dozen AGNs by now -- a giant leap when considering that the first infrared interferometric observation of an extragalactic object is only 13 years old. Since then, studies have confirmed the existence of dust in AGNs at its sublimation radius and have clearly dismissed models of very extended tori. A few very well studied sources have been instrumental to reveal that the parsec-scale dust is distributed in multiple distinct components. It has come as a surprise for nearly everyone that the largest and brightest of these substructures is elongated in polar direction. Statistical studies have shown a perplexing diversity in the population as a whole. Surprisingly, the size-luminosity relation does not show the expected bimodality between optical type 1 and type 2 AGNs -- which are thought to arise from face-on and edge-on tori, respectively. This central premise of viewing-angle dependent unified models is challenged if not dismissed by interferometric observations.

9907-27, Session 12

The path to interferometry in space *(Invited Paper)*

Stephen A. Rinehart, NASA Goddard Space Flight Ctr. (United States)

For over two decades, astronomers have considered the possibilities for interferometry in space. The first of these missions was the Space Interferometry Mission (SIM), but that was followed by missions for studying exoplanets (e.g Terrestrial Planet Finder, Darwin), and then far-infrared interferometers (e.g. the Space Infrared Interferometric Telescope, the Far-Infrared Interferometer). Unfortunately, following the cancellation of SIM, the future for space-based interferometry has been in doubt, and the interferometric community needs to reevaluate the path forward. While interferometers have strong potential for scientific discovery, there are technological developments still needed, and continued maturation of techniques is important for advocacy to the broader astronomical community. We review the status of several concepts for space-based interferometry, and look for possible synergies between missions oriented towards different science goals.

9907-28, Session 12

Balloon experimental twin telescope for infrared interferometry: delay lines and optical alignment

Arnab Dhabal, Univ. of Maryland, College Park (United States); Stephen A. Rinehart, NASA Goddard Space Flight Ctr. (United States); Maxime Rizzo, Univ. of Maryland, College Park (United States); John E. Mentzell, Todd Veach, Dale Fixsen, Robert F. Silverberg, NASA Goddard Space Flight Ctr. (United States)

We present updates on the optics of Balloon Experimental Twin Telescope for Infrared Interferometry (BETTII) as it gets ready for launch. BETTII is an 8-meter baseline far-infrared (30-90 microns) interferometer mission with capabilities of spatially resolved spectroscopy aimed at studying

star formation and galaxy evolution. The instrument collects light from its two arms, makes them interfere, divides them into two science channels (30-50 um and 60-90 um), and focuses them onto the detectors. It also separates out the NIR light (1-2.5 um) and uses it for tip-tilt corrections of the telescope pointing.

Currently, we have almost all the optical elements that have been heat treated, coated appropriately and are ready for use. We are presenting the procedure of mounting and aligning them using a LUPI interferometer. We also discuss the development of our inductive grid dichroic for separating the FIR from the NIR.

The warm and cold delay lines are an important part of this optics train. The warm delay line corrects for path length differences between the left and the right arm due to balloon pendulation, while the cold delay line is aimed at introducing a systematic path length difference, thereby generating our interferograms from where we can derive information about the spectra. The details of their design and the results of the testing of these opto-mechanical parts are discussed.

We also present results of interferometric simulations performed in FRED software to ascertain sensitivities of different optical elements on the interferograms produced. The limits of tip-tilt corrections on the external optics alignment errors have been taken into account in this analysis.

9907-29, Session 12

Recent experiments conducted with the Wide-field Imaging Interferometry Test bed (WIIT)

David T. Leisawitz, Roser Juanola-Parramon, Matthew R. Bolcar, NASA Goddard Space Flight Ctr. (United States); James R. Fienup, Alexander S. Iacchetta, Univ. of Rochester (United States); Stephen F. Maher, Science Systems and Applications, Inc. (United States) and NASA Goddard Space Flight Ctr. (United States); Stephen A. Rinehart, NASA Goddard Space Flight Ctr. (United States)

The Wide-field Imaging Interferometry Testbed (WIIT) was developed at NASA's Goddard Space Flight Center to demonstrate and explore the practical limitations inherent in wide field-of-view "double Fourier" (spatio-spectral) interferometry. The testbed delivers high-quality interferometric data and is capable of observing spatially and spectrally complex hyperspectral test scenes. Although WIIT operates at visible wavelengths, by design it delivers data that are representative of those from a space-based far-infrared observatory. WIIT was recently used to observe a calibrated, independently characterized test scene of modest spatial and spectral complexity, and an astronomically realistic test scene of much greater spatial and spectral complexity. In this presentation we will describe the experimental setup and the data acquired, along with an assessment of the performance of the testbed and a comparison of the data with analytical results.

9907-30, Session 13

The innermost astronomical unit of protoplanetary disks *(Invited Paper)*

Myriam Benisty, Jacques Kluska, Institut de Planétologie et d'Astrophysique de Grenoble (France)

Circumstellar disks around young stars are the birthsites of planets. It is thus fundamental to study the disks in which they form, their structure and the physical conditions therein. Of particular interest is the first astronomical unit in which terrestrial-planets form, and angular momentum is controled via mass-loss through winds/jets. With its milli-arcsecond resolution, optical interferometry is the only technics able to spatially resolve the first few AUs of the disk. In this review, I will present a broad overview of studies of young stellar objects with interferometry, and discuss prospects for the future.

9907-31, Session 14

Progress in polychromatic interferometry *(Invited Paper)*

Michel Tallon, Ctr. de Recherche Astrophysique de Lyon (France); Jacques Kluska, Univ. of Exeter (United Kingdom); Anthony Schutz, Lab. J.L. Lagrange (France) and Ctr. de Recherche Astrophysique de Lyon (France); Férréol Soulez, Ecole Polytechnique Fédérale de Lausanne (Switzerland); André Ferrari, Lab. J.L. Lagrange (France); Éric M. Thiébaut, Ctr. de Recherche Astronomique de Lyon (France); Bernard Lazareff, Fabien Malbet, Institut de Planétologie et d'Astrophysique de Grenoble (France); Isabelle Tallon-Bosc, Ctr. de Recherche Astronomique de Lyon (France); Gilles Duvert, Institut de Planétologie et d'Astrophysique de Grenoble (France)

By combining the light from several telescopes, Optical Interferometry provides the highest angular resolution (milliarcsecond resolution) in many fields such as stellar physics, star and planet formation, and environment of extra galactic black holes. In such fields, adding chromatic information allows insights in the physics and the dynamics of the observed objects. Besides astrophysical needs, a limited spectral bandwidth is also necessary for instrumental reasons like a larger coherence length or field of view. Thus considering collected light, instrumental performance also pushes toward a chromatic diversity of the interferometric measurements, making spectro-differential measurements accessible as well. This is why most of the current and future instruments provide a rich multi-spectral information.

Conversely, the availability of polychromatic data allows various improvements in processing interferometric data. Examples can be found in processing raw dispersed fringes, cophasing, image reconstruction, or model fitting.

The presentation will overview the ongoing work on Polychromatic Interferometry. In particular, it will draw on the results obtained by the POLCA project that combined experts in signal processing and Optical Interferometry to find out new methods to jointly process spatial and spectral information, and to improve both the performances (limiting magnitude, precision) and the observational capabilities (physics of the objects).

Particularly, evolving from monochromatic to polychromatic image reconstruction is challenging. Algorithms like SPARCO or the Self-Calibration Method combine monochromatic reconstruction in a smart way, but new approaches relying on the latest achievements in signal processing like alternating direction method of multipliers (ADMM) may open the way to an efficient global spatio-spectral reconstruction. MiRA-3D and PAINTER are on this track, allowing various spatio-spectral regularizations and constraints, including sparse approaches. Further, an optimal way to globally merge interferometric data with different chosen spectral resolutions is welcome to yet increase the performances of future large arrays.

Besides the expected efficient multi-spectral image reconstructors, optimal processing of dispersed fringes can improve fringe detection and cophasing, or even yield new unbiased observables or observables with a much better statistical distribution, yielding more accurate measurements.

Spreading the benefits of polychromatic processing will be made easier with the new version of the OIFITS standard format for interferometric data that now conveys spectral information like spectra, spectro-differential measurements, or spectral noise correlations.

9907-32, Session 14

Making high-accuracy null depth measurements for the LBTI exozodi survey

Bertrand P. Mennesson, Jet Propulsion Lab. (United States); Denis Defrère, The Univ. of Arizona (United States); Mathias Nowak, Observatoire de Paris à Meudon (France); Philip M. Hinz, The Univ. of Arizona (United States); Rafael Millan-Gabet, NASA Exoplanet Science Institute (United States) and Infrared Processing and Analysis Ctr. (United States); Olivier Absil, Lindsay Marion, Univ. de Liège (Belgium); Eugene Serabyn, Jet Propulsion Lab. (United States); William C. Danchi, NASA Goddard Space Flight Ctr. (United States)

The NASA sponsored LBTI-HOSTS mid-infrared survey aims at measuring the exozodiacal dust emission level of nearby main sequence stars down to an accuracy level (1?) of the order of 10 times the solar zodi level per star, and 2 zodis or less (1?) for the median emission level of the sample. To this end, extremely accurate null depth measurements must be made, typically down to the 500 ppm uncertainty level or less (1?) per star, roughly an order of magnitude better than previous state-of-the-art mid-infrared interferometry. We present here the data reduction method developed specifically for this task, together with commissioning and science grade measurements demonstrating a final on-sky calibrated null depth accuracy of 500 ppm or better around a wavelength of 11 microns. The reduction approach is based on the "null self-calibration technique" that we developed earlier in the context of single-mode infrared interferometry and showed significant improvements over classical reductions techniques. We discuss in this paper how we have further improved the technique to account for high-frequency path length fluctuations and the specifics of mid-infrared nulling observations at LBTI.

9907-33, Session 14

Data reduction of the VLTI/GRAVITY interferometric instrument

Pierre Kervella, Observatoire de Paris à Meudon (France) and Univ. de Chile (Chile); Vincent Lapeyrère, Sylvestre Lacour, Nabih Azouaoui, Observatoire de Paris à Meudon (France); Jean-Baptiste Le Bouquin, Institut de Planétologie et d'Astrophysique de Grenoble (France); Cesar E. Garcia-Dabo, European Southern Observatory (Germany); Sylvain Guieu, Institut de Planétologie et d'Astrophysique de Grenoble (France); Thibaut Paumard, Observatoire de Paris à Meudon (France); Antoine Mérand, Xavier Haubois, European Southern Observatory (Chile); Guy S. Perrin, Observatoire de Paris à Meudon (France); Julien Woillez, European Southern Observatory (Germany); Frank Eisenhauer, Max-Planck-Institut für extraterrestrische Physik (Germany); Wolfgang Brandner, Max-Planck-Institut für Astronomie (Germany); Christian Straubmeier, Univ. zu Köln (Germany); Karine Perraut, Institut de Planétologie et d'Astrophysique de Grenoble (France); António Amorim, Univ. de Lisboa (Portugal)

The new VLTI/GRAVITY instrument is a four telescope beam combiner installed at the VLT Interferometer. The principal novelty of this instrument is the availability of a dual field mode enabling narrow-angle relative astrometry at 10 micro-arcsecond accuracy between two objects separated by several arcseconds. The fringe tracker (FT) stabilizes the interference fringes at up to 1 kHz frequency, allowing for long exposures with the science combiner (SC) as well as phase referenced imaging and differential astrometry (in dual field mode). The FT and SC beam combiners are integrated optics (IO) components, whose 24 outputs are (optionally) polarization-split and spectrally dispersed. The processing of the photometric signals from the IO components is based on the pixel-to-visibility matrix (P2VM) formalism, that translates them into complex visibilities. The retrieval of the relative phase of the two objects subsequently relies on the combination of the phases measured from the FT, SC and the laser metrology. We will present the adopted algorithms, and an overview of the structure of the developed software. The calibration of the wavelength scales of the FT and SC at the required accuracy presents specific difficulties that we will briefly discuss. Preliminary examples of the reduction of on-sky data obtained during the commissioning will also be presented.

9907-34, Session 15

The second version of the OIFITS data exchange format for optical/IR interferometry *(Invited Paper)*

Gilles Duvert, Institut de Planétologie et d'Astrophysique de Grenoble (France) and Univ. Grenoble Alpes (France); John S. Young, Univ. of Cambridge (United Kingdom); Christian Hummel, European Southern Observatory (Germany)

We present the second version of the OI Exchange Format (OIFITS2), the standard for exchanging calibrated data from optical (visible/infrared) interferometers. This new version provides definitions of several new tables addressing the needs of future interferometric instruments such as GRAVITY and MATISSE. Also included are optional data columns for a more rigorous description of measurement errors and their correlations. It also introduces many new header keywords allowing more effective data discovery by providing useful metadata. OIFITS2 may also be considered as a new step towards the design of a common data model for optical interferometry. In this paper, we outline the new features of OIFITS2 and describe their anticipated usage. The ongoing community efforts to adopt OIFITS2 and stress-test it in the real world are also presented.

9907-35, Session 15

Aspro2: get ready to 2nd generation instruments (GRAVITY and MATISSE)

Laurent Bourgès, Observatoire des Sciences de l'Univers de Grenoble (France); Gilles Duvert, Institut de Planétologie et d'Astrophysique de Grenoble (France)

Aspro 2 is a complete observation preparation tool developed and maintained by the JMMC that allows to prepare interferometric observations with the VLTI or other interferometers (CHARA, SUSI, NPOI).

Available since 2010, it is regularly updated to provide new features (analytical and user models) and an up-to-date configuration corresponding to ESO & CHARA Call For Proposals.

As new instruments GRAVITY & MATISSE, the 2nd generation VLTI instruments, will be soon available to the community, Aspro 2 is evolving to support them:

The noise modeling has been improved for the future MATISSE instrument (L/M & N bands): thermal noise contribution and atmospheric transmission.

Moreover, the OIFITS simulation has been rewritten to generate correlated

quantities (VIS2, VIS, T3) and will support OIFITS-2 soon.

It is already supporting GRAVITY observations (commissioning) by providing a preliminary configuration and exporting Observing Blocks (P2PP).

9907-36, Session 15

Spectrally dispersed Fourier-phase analysis for redundant apertures

Frantz Martinache, Observatoire de la Côte d'Azur (France)

It has now been demonstrated that well AO-corrected images produced by ground based telescopes can be used to produce interferometric observables robust against residual wavefront errors called kernel-phase which are a generalization of the more common notion of closure-phase. Since it preserves the full instrument throughput and leads to a potentially large number of observables, the kenel-phase analysis of conventional images is, given sufficient AO-correction, emerging to be a more satisfactory option than its sparse aperture masking counterpart.

It has also been shown, by the same token that, assuming this time some level of asymmetry in the pupil, information about the wavefront can also be extracted from images of a point source, this time relying on the complementary eigen-phase relations, provided by the linear phase transfer model at the heart of both kernel- and eigen-phase data analysis.

Because it relies on a linearization of the phase transfer equation, this model is intrinsically limited to a regime of aberration where the rms error is less than the wavelength. This paper describes a possible extension of the Fourier-phase analysis method, here applied to a set of spectrally dispersed data, similar to those produced by an intergral field spectrograph. In this dispersed case, the original residual aberration constraint is considerably relaxed as it now needs to be less than the coherence length. Given sufficient wavelength coverage, the phase-transfer model can be used to produce novel spectrally dispersed kernel-phase information on a target of interest, or be used for wavefront sensing purposes, for any aberration regime.

9907-37, Session 16

Enabling the direct detection of Earth-sized exoplanets with the LBTI HOSTS project: a progress report

William C. Danchi, NASA Goddard Space Flight Ctr. (United States); Philip M. Hinz, Denis Defrère, The Univ. of Arizona (United States); Vanessa P. Bailey, The Univ. of Arizona (United States) and Stanford Univ. (United States); Geoffrey Bryden, Jet Propulsion Lab. (United States); Christopher A. Haniff, Grant Kennedy, Univ. of Cambridge (United Kingdom); Bertrand P. Mennesson, Jet Propulsion Lab. (United States); Rafael Millan-Gabet, California Institute of Technology (United States); George H. Rieke, The Univ. of Arizona (United States); Aki Roberge, NASA Goddard Space Flight Ctr. (United States); Eugene Serabyn, Jet Propulsion Lab. (United States); Andrew J. Skemer, The Univ. of Arizona (United States); Karl R. Stapelfeldt, NASA Goddard Space Flight Ctr. (United States); Alycia Weinberger, Carnegie Institution of Washington (United States); Mark Wyatt, Univ. of Cambridge (United Kingdom)

NASA has funded a project called the Hunt for Observable Signatures of Terrestrial Systems (HOSTS) to survey nearby solar type stars to determine the amount of warm zodiacal dust in their habitable zones. The goal is not only to determine the luminosity distribution function but also to know which individual stars have the least amount of zodiacal dust. It is important to have this information for future missions that directly image exoplanets as this dust is the main source of astrophysical noise for them. The HOSTS project utilizes the Large Binocular Telescope Interferometer (LBTI), which consists of two 8.4 m apertures separated by a 14.4-m baseline on Mt. Graham, Arizona. The LBTI operates in a nulling mode in the mid-infrared spectral window (8-13 microns), in which light from the two telescopes is coherently combined with a 180 degree phase shift between them, producing a dark fringe at the location of the target star. In doing so the starlight is greatly reduced, increasing the contrast, analogous to a coronagraph operating at shorter wavelengths. The LBTI is a unique instrument, having only three warm reflections before the starlight reaches cold mirrors, giving it the best photometric sensitivity of any interferometer operating in the mid-infrared. It also has a superb Adaptive Optics (AO) system giving it Strehl ratios greater than 98% at 10 microns. During the past year LBTI has been undergoing commissioning, and the HOSTS project team passed its Operational Readiness Review (ORR) in April, 2015. The team recently published papers on the target sample, modeling of the nulled disk images, and initial results such as the detection of warm dust around eta Corvi. Additional papers are in preparation on beta Leo and on the data pipeline. We will report recent progress, new results, and plans for the science verification phase that started in February 2016, and for the survey.

9907-60, Session PSWed

How to create space inside the VLTI: PIONIER 3D project

Pierre Bourget, Gérard Zins, Nicolas Schuhler, European Southern Observatory (Chile); Sylvain Guieu, Institut de Planétologie et d'Astrophysique de Grenoble (France) and European Southern Observatory (Chile); Jean-Philippe Berger, European Southern Observatory (Germany)

PIONIER is a four beams combiner instrument developed by the Astrophysics Laboratory of Grenoble (LAOG). This instrument arrived at the ESO Paranal Interferometer in 2010 as a visitor instrument and was supposed to be decommissioned with the arrival of the second generation instruments GRAVITY and MATISSE. The success of PIONIER induced the needs to keep it available for the scientific community inside the already full environment of the VLTI. This paper presents the technical solutions that were applied to place the instrument in mezzanine without impact on the performance and with the constraint of reducing the workload in operation.

9907-61, Session PSWed

The intrinsic limitations of the VLTI Auxiliary Telescopes array

Antoine Mérand, European Southern Observatory (Chile); Julien Woillez, Jean-Philippe Berger, European Southern Observatory (Germany); Nicolas Schuhler, Pierre Bourget, European Southern Observatory (Chile)

The VLTI AT array is composed of 4 relocatable telescopes, a network of stations and 6 delay lines. This array is used in operations to offer various configurations covering a large range of u,v spatial frequencies. We present here the current configurations offered and the rationale and limitations behind the current offering. We present also some speculative reflections on how we could address these limitations in the future.

9907-62, Session PSWed

Fundamental gain in high-contrast imaging with the Large Binocular Telescope Interferometer

Fabien Patru, INAF - Osservatorio Astronomico di Arcetri (Italy); Simone Esposito, Alfio T. Puglisi, Armando Riccardi, Enrico Pinna, INAF - Osservatorio Astrofisico di Arcetri (Italy); Carmelo Arcidiacono, INAF - Osservatorio Astronomico di Arcetri (Italy); John M. Hill, Philip M. Hinz, Large Binocular Telescope Observatory (United States)

Numerical simulations for the Large Binocular Telescope Interferometer have shown a fundamental gain in contrast when using two 8m adaptive optic telescopes instead of one in a high Strehl regime. The global gain is improved by a factor 2 in contrast by using the long exposures and by a factor of 10 in contrast by using the short exposures. Indeed, fringes are still present in the short exposure, contrary to the long exposure where the fringes are smoothed. Thus, there is some gain in grouping some short exposures with high gain G. This makes the LBTI well suitable for the Angular Differential Imaging technique. A planet will be alternatively located in the fringes (G ~ 10 to 100) and either in the dark rings (G ~ 4 to 20) or in the white rings (G ~ 1), depending on its radial distance. A rotation of 30° is sufficient to pass through at least one gain zone. The LBTI can provide in the visible wavelength not only high angular resolution (~ 6.5 mas at 750 nm) and high sensitivity (by a factor 4), but also a gain in contrast (by a factor 10 to 100) compared to the stand-alone adaptive optic used on each LBT aperture.

9907-63, Session PSWed

Sensitivity to differential piston and to adaptive optic errors with the Large Binocular Telescope Interferometer

Fabien Patru, Simone Esposito, Alfio T. Puglisi, Armando Riccardi, Enrico Pinna, Carmelo Arcidiacono, INAF - Osservatorio Astrofisico di Arcetri (Italy); John M. Hill, Philip M. Hinz, Large Binocular Telescope Observatory (United States)

On-sky adaptive optic wavefront screens have been used and random optical path fluctuations have been included in numerical simulations for the Large Binocular Telescope Interferometer. We characterize the Point Spread Function (PSF) and the Optical Transfer Function (OTF) by computing respectively the Strehl and the interferometric visibility criteria. We study the contribution of the wavefront disturbance induced by each adaptive optic system and by the optical path difference (differential piston) between the arms of the LBTI. We study separately both effects. To provide an image of quality suitable with standard science cases, the requirements for a LBTI mode at the visible wavelength (750 nm) must be at least an adaptive optic wavefront RMS fluctuation below ?/32 ~ 25 nm, or a Strehl above 90% provided by each adaptive optic system, and a differential piston RMS fluctuation below ?/8 ~ 100nm in the overall LBTI system. The adaptive optic wavefront errors - mainly the differential tilt - appear to be more critical than the differential piston.

9907-64, Session PSWed

Performance of the MROI fast tip-tilt correction system

John S. Young, David Buscher, Martin Fisher, Christopher A. Haniff, Alexander Rea, Eugene Seneta, Xiaowei Sun, Donald Wilson, Univ. of Cambridge (United Kingdom); Allen Farris, Andres Olivares, Magdalena Ridge Observatory (United States)

The fast tip-tilt correction system for the Magdalena Ridge Observatory Interferometer (MROI) has been designed, manufactured and tested by the University of Cambridge. The system uses passive thermal compensation to maintain the stability of the tip-tilt reference direction over a 5 degree Celsius ambient temperature change, and an electron-multiplying CCD camera and optimised centroiding algorithm to reach faint limiting magnitudes. We present results from a programme of laboratory tests to validate the system performance. The experiments verifying the opto-mechanical stability comprised tests of the mounts supporting individual optics as well as end-to-end "integrated" tests of the entire system. We also report measurements of the closed-loop tilt correction performance in the presence of synthetic atmospheric tilt disturbances, as a function of the target brightness. In the best 0.7 arcscecond seeing, we find that the system operates reliably at a visual magnitude of 15.9 and delivers two-axis tilt residuals of 0.060 arcsec for a magnitude 14.0 target. On-sky tests of the system are planned for summer/fall 2016, following the commissioning of the first MROI Unit Telescope.

9907-65, Session PSWed

GRA4MAT: combining GRAVITY and MATISSE at the VLTI

Sebastian Egner, Julien Woillez, Roberto Abuter, Eszter Pozna, Christian Schmid, Gérard Zins, Jean-Philippe Berger, Frédéric Yves J. Gonté, European Southern Observatory (Germany); Pierre Antonelli, Observatoire de la Côte d'Azur (France); Philippe Bério, Observatoire de la Cote d'Azur (France); Roderick Dembet, Observatoire de Paris (France); Frank Eisenhauer, Max-Planck-Institut für extraterrestrische Physik (Germany); Walter Jaffe, Leiden Observatory (Netherlands); Sylvestre Lacour, Observatoire de Paris à Meudon (France); Stéphane Lagarde, Bruno Lopez, Florentin Millour, Observatoire de la Cote d'Azur (France); Sébastien Morel, Observatoire de la Côte d'Azur (France); Guy S. Perrin, Observatoire de Paris à Meudon (France); Romain G. Petrov, Observatoire de la Côte d'Azur (France); Oliver Pfuhl, Ekkehard Wieprecht, Max-Planck-Institut für extraterrestrische Physik (Germany); Andreas Glindemann, Paul Bristow, European Southern Observatory (Germany)

MATISSE is the 2nd generation interferometric instrument for the ESO VLTI, covering the L, M and N-bands. MATISSE does not have an internal fringe-tracker and will thus be limited to exposure times, which are shorter than the atmospheric coherence time. This obviously puts severe constraints on the achievable limiting magnitude and thus observable science objects with MATISSE in stand-alone mode. The approach to overcome these limitations is to use the fringe-tracker of another 2nd generation VLTI instrument, namely GRAVITY to measure the OPD fluctuations and the delay-lines of VLTI to correct them. In this paper we will give a motivation for this approach and the boundary conditions. Furthermore, the concept of the software architecture and the expected performances will be discussed.

9907-66, Session PSWed

SCSI: the Southern Connecticut Stellar Interferometer

Elliott P. Horch, Samuel A. Weiss, Justin D. Rupert, Alex J. DiMaio, Southern Connecticut State Univ. (United States); Daniel A. Nusdeo, Georgia State Univ. (United States); Pietro Peronio, Ivan Rech, Angelo Gulinatti, Politecnico di Milano (Italy); Andrea Giudice, Micro Photon Devices S.r.l. (Italy)

The technique of intensity interferometry, also known as the Hanbury-Brown and Twiss effect, has largely been neglected in astronomy since the late 1970's, mainly because it is inherently limited in terms of the signal-to-noise ratio, meaning that large telescopes were needed to collect enough light to observe even the brightest stars in the sky. Compared with amplitude-based interferometry, generally done with much smaller apertures and yet reaching considerably fainter magnitudes, there appeared to be little reason to pursue intensity interferometry after the success of the precursors to the current generation of amplitude-based interferometers was demonstrated. However, it is time to revisit this technique because commercially available electronics can time events with precision on the level of picoseconds and detector development has led to the pixel arrays with comparable precision in photon arrival times. This has the possibility to mitigate the sensitivity issue, as the signal-to-noise ratio in intensity interferometry is proportional to the square root of the detection bandwidth.

At Southern Connecticut State University (SCSU), we are building a stellar intensity interferometer based on single photon avalanche diode (SPAD) arrays. In this paper, we describe the instrument that is now under construction, which uses an 8-pixel SPAD array, and we present initial engineering data and performance estimates. The main use of the system will be on the campus of the university in New Haven, Connecticut, but we also plan to take the detectors and timing correlators to other observatories in order to use them with larger telescopes than we will have available on campus. By implementing SPAD arrays, it will be possible to conduct several independent intensity interferometry observations at the same time using the same pair of telescopes by putting light of a different wavelength on each pixel of the SPAD device. This is a key technology demonstration that, together with the SPAD detectors and fast electronics, could make the signal-to-noise ratio achievable with the technique more comparable to that of amplitude-based interferometers in the coming years. In addition, if the technique can be made wireless, then the maximum baseline could be significantly larger than current amplitude-based interferometers.

9907-67, Session PSWed

Monitoring a decade of seeing at the NPOI site with quad cell measurements

Henrique R. Schmitt, J. Thomas Armstrong, Sergio R. Restaino, U.S. Naval Research Lab. (United States)

As a part of regular operations, the NPOI uses Narrow Angle Trackers for atmospheric tip-tilt correction. This correction is done using a quad cell array for each siderostat, and is based on the error signals measured by these arrays. We compiled error signal information from these quad cells for the period between 2004 and 2015. This information is correlated with atmospheric coherence times measured using NPOI data and quasi simultaneous seeing measurements done with another telescope on Anderson Mesa. This combined dataset allowed us to convert the quad cell error information into atmosphere coherence length values. We will present details about this technique, and the calibration procedure. We will also present seeing statistics and the investigate the evolution of the atmospheric conditions of the NPOI site over the last decade.

9907-68, Session PSWed

Magdalena Ridge Interferometer: UT#1 site installation, alignment, and test

Olivier Pirnay, Vincent Moreau, Eric Gabriel, Carlo Flebus, AMOS Ltd. (Belgium)

The deployment of the Magdalena Ridge Optical Interferometer has resumed in 2015 thanks to additional funding from Air Force Research Laboratory spread over 5 years granted to New Mexico Tech (NMT).

In the first stage of the project, AMOS was awarded for the design and construction of the unit telescopes mounts to be installed on the optical array. The first telescope mount (UTM#1) has been delivered to NMT after successful completion of factory test in Belgium. The main parts for UTM#2 and UTM#3 have been manufactured and pre-assembled at AMOS.

The project restarts with the installation of UTM#1 on the Ridge and the site acceptance tests. These tests demonstrate the ability of the telescope to perform according to the somewhat uncommon requirements since the telescope are dedicated to interferometry.

The site activities occurs in three phases for which appropriated teams of technicians and engineers come on-site to complete their work: a.) the installation on the pier and mechanical integration, b.) the alignment of the optics and c.) the site acceptance test.

Thanks to the compactness of the elevation-over-elevation mount, the telescope is brought on the Ridge in one piece. Only the optics and their supports are transported in a separate crates. The telescope is installed on a concrete pier dedicated to the site acceptance and commissioning of the telescope.

The optical configuration is a Mersenne beam compressor. From the 1425 mm primary mirror to the 95 mm output collimated beam in line with the outer axis of the mount, the light hits only three surfaces: the primary and secondary rotating with the inner axis and the tertiary located at the pivot point, intersection of inner and outer axis and rotating half of the inner elevation angle.

The first task of the alignment consists of co-aligning the tertiary mirror rotating axis with the inner axis of the telescope. Then, the primary and secondary are aligned so that their optical axes are concurrent with the pivot point. This can be done efficiently by using a laser tracker and other metrology. The mechanical alignment is further validated and optimized by measuring the pupil stability in the entire field of regard of the telescope thanks to a long focal imaging lens.

The next step of alignment does not requires further mechanical alignments but only correction of the secondary mirror position using a motorized high-accuracy hexapod. The quality of alignment is evaluated using a built-in Shack Hartmann wavefront sensor. In addition to the baseline alignment of the optics, the hexapod provides the ability to compensate for the misalignment of the optics due to gravity and temperature changes. This correction can be performed either on the basis of the wavefront measurement feedback or on the basis of an open-loop correction law for simultaneous image quality and pupil stability optimization.

Once the telescope alignment is completed and the correction laws for pointing and M2 position are consistent, the final acceptance tests take place in order to assess the performance of the telescope and its ability to meet the stringent requirements for interferometry.

9907-69, Session PSWed

VLT Interferometer upgrade for the 2nd generation of interferometric instruments

Frédéric Yves J. Gonté, European Southern Observatory (Germany)

ESO is undertaking a large upgrade of the infrastructure on Cerro Paranal

in order to integrate the 2nd generation of interferometric instruments Gravity and MATISSE but also to increase its performance. This upgrade has started at the beginning of March 2015 and will end with the implementation of the adaptive optics system for the Auxiliary telescope (NAOMI) in 2018. This upgrade has an impact on the infrastructure of the VLTI as well as its systems and scientific instruments.

MIDI has been decommissioned. PIONIER has been moved to a new position inside the VLTI laboratory. The power, cooling and network capabilities have been increased in the VLTI laboratory but also in the basement of the UTs and in the Combined Coude Laboratory for the instrument ESPRESSO. A new maintenance station for the Auxiliary telescope (AT) has been opened on the VLTI platform. The star separators in the ATs and Unit Telescope (UTs) have been commissioned and delivered to science operation. The Gravity beam combiner has been integrated and is under commissioning as well as its metrology system. The Infrared Adaptive optics system is being implemented in the Coude of the UTs. The visible adaptive optics system which are already in use since 2003 has been upgraded.

The Coude train of the ATs will be replaced to gain a better transmission at the end of 2016 and beginning 2017. MATISSE will be delivered to Paranal at the end of 2017 and it will use Gravity as fringe tracker to increase its performance. Finally in 2018 NAOMI will be delivered and commissioned.

We give here a description of this global upgrade and also the expected performances.

9907-70, Session PSWed

NAOMI: a low-order adaptive optics system for the VLT Interferometer dual-feed light beams

Reinhold J. Dorn, Emmanuel Aller-Carpentier, Luigi Andolfato, Jean-Philippe Berger, Françoise Delplancke-Strobele, Christophe Dupuy, Sebastian E. Egner, Frédéric Yves J. Gonté, Stefan Huber, Norbert Hubin, Jean-Paul Kirchbauer, Miska Le Louarn, Paul Lilley, Paul Jolley, Alessandro Martis, Jérôme Paufique, Luca Pasquini, Jutta Quentin, Robert Ridings, Javier Reyes, Marcos Suarez, Thanh Phan Duc, Julien Woillez, European Southern Obsevatory (Germany); Jean-Baptiste Le Bouquin, Jean-Luc Beuzit, Sylvain Rochat, Institut de Planétologie et d'Astrophysique de Grenoble (France); Christophe Vérinaud, Institut de Planétologie et d'Astrophysique de Grenoble (France); Thibaut Moulin, Alain Delboulbé, Laurence Michaud, Jean-Jacques Correia, Alain Roux, Didier Maurel, Eric Stadler, Yves Magnard, Institut de Planétologie et d'Astrophysique de Grenoble (France)

The New Adaptive Optics Module for Interferometry (NAOMI) will be developed for and installed at the 1.8-metre Auxiliary Telescopes (ATs). The four ATs are designed for interferometry applications. Currently the ATs are equipped with a visible tip/tilt sensor called STRAP (System for Tip/tilt Removal with Avalanche Photodiodes) and the corrections are applied with a fast steering mirror. Under good seeing conditions this provides a reasonable correction of the atmospheric turbulence in the K and N -bands, but as soon as the seeing degrades below 1 arcsecond, the instantaneous Strehl ratio delivered by the telescopes degrades significantly. The goal of the project is to equip all four ATs with a low-order Shack–Hartmann adaptive optics system operating in the visible, in place of the current STRAP, in order to overcome the current limitations.

By improving the wavefront quality delivered by the ATs for guide stars brighter than R = 13 mag, NAOMI will make the existing interferometer performance less dependent on the seeing conditions. The quality of interferometric data will therefore improve as a result. Fed with better and more stable image quality, the fringe trackers will achieve the fringe stability necessary to reach the full performance of the second generation instruments GRAVITY and MATISSE.

NAOMI has passed its preliminary design review in 2015 and the first system is planned to be installed in 2018. ESO has teamed up with the Institut de Planétologie et d'Astrophysique de Grenoble by the end of 2015 to strengthen the project team for the development of the corrective optics unit and production of the full systems.

9907-71, Session PSWed

On sky effects of synchronizing the real-time computers of the GRAVITY fringe tracker

Roberto Abuter, European Southern Observatory (Germany); Sylvestre Lacour, Roderick Dembet, Observatoire de Paris à Meudon (France); Thanh Phan Duc, Nicola Di Lieto, Frédéric Yves J. Gonté, European Southern Observatory (Germany); Frank Eisenhauer, Max-Planck-Institut für extraterrestrische Physik (Germany)

Gravity fringe tracker is able to stabilize the K-band fringes on six baselines at the same time. I has been designed to achieve a performance for average seeing conditions of a residual OPD lower than 300 nm with objects brighter than K = 10. The control loop of the tracker is composed of a three stage real time system compromising: a sensor where the detector pixels are read in and the OPD and GD are calculated; a controller receiving the computed sensor quantities and producing commands for the piezo actuators and a third stage where current measurements are monitored in real time and used to update the control parameters based on a Kalman estimation. The hardware and software implementation of this design compromises three independent real time computers (one per stage) running asynchronously and communicating data via the Reflective Memory Network. With the purpose of improving the performance of the GRAVITY fringe tracking control loop, a deviation from the standard asynchronous communication mechanism has been proposed and implemented. This new scheme operates the three real time computers involved in the tracking loop synchronously using the Reflective Memory Interrupts as coordination signal. This has the desired effect of reducing the total pure delay of the loop from 4 [ms] to 2.5 [ms] which then translates on a better stabilization of the fringes as the bandwidth is substantially improved. This paper will explain in detail the real time architecture of the system in its synchronous implementation. Using commissioning data, the improvements will be quantified in detail. Finally, a path for a further reduction of the pure delay will be described including the expected gains in terms of bandwidth and residual OPD for the nominal observation case.

9907-73, Session PSWed

The metrology system of the VLTI instrument GRAVITY

Magdalena Lippa, Stefan Gillessen, Max-Planck Institute für Extraterrestrische Physik (Germany); Nicolas Blind, Univ. de Genève (Switzerland); Yitping Kok, The Univ. of Western Australia (Australia); Johannes Weber, Oliver Pfuhl, Marcus Haug, Stefan Kellner, Ekkehard Wieprecht, Frank Eisenhauer, Reinhard Genzel, Oliver Hans, Frank Haußmann, David Huber, Tobias Kratschmann, Thomas Ott, Markus Plattner, Christian Rau, Eckhard Sturm, Idel Waisberg, Erich Wiezorrek, Senol Yazıcı, Max-Planck

Institute für Extraterrestrische Physik (Germany); Guy S. Perrin, Observatoire de Paris (France); Karine Rousselet-Perraut, Institut de Planétologie et d'Astrophysique de Grenoble (France); Christian Straubmeier, Univ. zu Köln (Germany); António Amorim, Fundacão da Faculdade de Ciências da Univ. de Lisboa (Portugal); Wolfgang Brandner, Max-Planck-Institut für Astronomie (Germany); Markus Schöller, European Southern Observatory (Germany)

The VLTI instrument GRAVITY combines the beams from four telescopes interferometrically and provides high-resolution phase-referenced imaging as well as narrow-angle astrometry together with spectroscopic and polarimetric capabilities. For this purpose, the beam combiner observes two celestial objects simultaneously in dual-field mode in order to extract the differential optical path difference (dOPD) resulting from their angular separation on sky. This measurement is provided by the metrology system of GRAVITY, which traces and subtracts the internal dOPDs within the interferometer from the detected ones between the targets to obtain their actual dOPD on sky.

Here, we present the general overview of this novel metrology system. We developed a three-beam laser system injected via fiber optics to the beam-combiner instrument of GRAVITY and a homodyne detection scheme for three-beam interference using phase-shifting interferometry in combination with lock-in amplifiers. The technical details of the three-beam and homodyne detection concept will be described in the contribution of Blind et al. (AS104-159).

In this way, backscattering of the metrology light onto the science detector is minimized as well as non-common path effects caused by temperature fluctuations from variations of high-power laser radiation. In addition, the metrology traces all the optical paths from the beam combination of the astronomical light back to the telescopes. Since there the dOPD measurements are performed in the pupil planes, the definition of astrometric baselines is essentially free of systematics. Via this approach the metrology system measures dOPDs on a nanometer-level corresponding to precision astrometry of order 10μas.

9907-74, Session PSWed

Data reduction for the MATISSE instrument

Florentin Millour, Philippe Bério, Observatoire de la Côte d'Azur (France); Karl-Heinz Hofmann, Dieter Schertl, Matthias Heininger, Max-Planck-Institut für Radioastronomie (Germany); Florence Guitton, Bruno Lopez, Anthony Soulain, Observatoire de la Côte d'Azur (France); Gerd Weigelt, Max-Planck-Institut für Radioastronomie (Germany)

We will present the data reduction software of the MATISSE instrument. It combines several neat features seen in previous pipelines to make the most out of the MATISSE data, and includes brand new features that will make MATISSE an imaging instrument. It will estimate the optical path difference (OPD), will process the OPD modulation of the instrument as it was done in the MIDI instrument, it will correct for photometric imbalance as is done in the FLUOR and AMBER instruments, and will calibrate the observations the same way as it is done in AMBER. On the other hand, the MATISSE pipeline will provide the IRBIS software, which makes available image reconstruction to the end user. The whole software is packaged to be used together with the flexible Reflex environment developed by ESO to make available instruments pipelines to the end user. These features make the MATISSE software unique.

9907-75, Session PSWed

ALOHA/CHARA at 1.55 μm: sensitivity improvement and on-sky ability to detect astronomical sources in H band

Pascaline Darré, Ludovic Grossard, Laurent Delage, François Reynaud, XLIM Institut de Recherche (France); Nicholas J. Scott, Judit Sturmann, Theo A. Ten Brummelaar, CHARA (United States)

Our research team has developed an innovative fibre stellar interferometer using properties of nonlinear optics. This concept named ALOHA (Astronomical Light Optical Hybrid Analysis) offers an alternative for high resolution imaging at very low flux level in the mid-infrared wavelength domain (3-20 μm range) where the required devices are not yet available or currently have poor performance. Thanks to a sum frequency generation (SFG) process achieved in a nonlinear crystal on each arm of the interferometer, the light is shifted to the visible or the near-infrared domain and then processed by available components (optical fibres, guided components, detectors...) from the telecommunications domain. The current laboratory setup is a prototype of interferometer with two arms using periodically poled Lithium Niobate (PPLN) waveguides powered by a 1.06-μm laser pump source to convert a signal at 1.55 μm to 630 nm. The upconversion process is only efficient on a 0.6-nm window centred at 1.55 μm. The coherent recombination of the two arms is achieved through guided optics components in the visible domain. The performance of the overall interferometric instrument is reliant on the quality of the hybrid process in terms of PPLN waveguide conversion efficiency and additional noise control.

To validate our proposal for high resolution imaging, the prototype is tested on-sky thanks to collaboration with the CHARA team. A preliminary mission in May 2014 has allowed to validate the on-site implementation of the SFG process and to lead a sensitivity test in H band with a single arm of the interferometer to predict the performance of the complete instrument in its interferometric configuration. With the atmospheric conditions during the observing run, a 2.2 magnitude star has been detected with a signal-to-noise ratio (SNR) of 3 for an integration time of 15 min and only observing 0.6 nm of the object spectral bandwidth. In summary, thanks to this photometric calibration combined with a numerical simulation and laboratory tests on the prototype, we can predict the sensitivity of the interferometer within specific conditions. Thus we have determined that with a seeing radius of 6 cm (typical value in April-May at CHARA) and a measured contrast of 70 % with a 34-m baseline, an astronomical object of Hmag = 2 can be detected over an integration time of 16 minutes. Currently the main goal is to achieve the first fringes on-sky with ALOHA at 1.55 μm.

Furthermore the next step involves extending the concept to a wide-band analysis. We therefore propose to use a frequency comb as a pump source to sample the broadband spectrum and to enlarge the analysed spectral bandwidth by simultaneous SFG process in the nonlinear waveguide. A first laboratory experiment was performed in high flux regime with only a dual-line pump to investigate the spectral filtering effect on the temporal coherence behaviour. We demonstrated a modification of the temporal coherence properties of the converted wave due to a spectral compression effect that only acts on the gap between the spectral samples.

The new classic instrument for the Navy Precision Optical Interferometer

Anders M. Jorgensen, New Mexico Institute of Mining and Technology (United States); Henrique R. Schmitt, J. Thomas Armstrong, Ellyn K. Baines, Robert B. Hindsley, U.S. Naval Research Lab. (United States); David

Mozurkewich, Seabrook Engineering (United States); Gerard T. van Belle, Lowell Observatory (United States)

The New Classic instrument was built as an electronics and computer upgrade to the existing Classic beam combiner at the Navy Precision Optical Interferometer (NPOI). The classic beam combiner is able to record 32 of 96 available channels and has a data throughput limitation which results in a low duty cycle. Additionally the computing power of the Classic system limited the amount of fringe tracking that was possible. The New Classic system implements a high-throughput data acquisition system which is capable of recording all 96 channels continuously. It also has a modern high-speed computer for data management and data processing. The computer is sufficiently powerful to implement more sophisticated fringe-tracking algorithms than the Classic system, including multi-baseline bootstrapping. In this paper we described the New Classic hardware and software, including the fringe-tracking algorithm, performance, and the user interface.

A triple modulation to optimize the accuracy of the VLTI instrument MATISSE

Romain G. Petrov, Philippe Bério, Observatoire de la Côte d'Azur (France); Walter Jaffe, Leiden Observatory (Netherlands); Stéphane Lagarde, Alexis Matter, Florentin Millour, Martin Vannier, Bruno Lopez, Observatoire de la Côte d'Azur (France)

MATISSE is the 4 beams 2nd generation VLTI instrument. It will work in the middle infrared in the L, M and N bands at several spectral resolutions ranging from Low (30) to High (5500 in L). The observations in L-M and N will be simultaneous, as the light is send in two different cryostats, each with its own spectrograph and detector. In N band the dominant noise results from the variations of the thermal background, that are 10e4 to 1e05 times more important than the second source of noise that is the background photon noise. In optical interferometry, these background variations result in variations of the intensity of the low frequency peak (LFP). Therefore, the low frequency peak must be reduced by more than 10e5 at the frequencies of the first fringe peak. The first modulation, which is the built-in spatial modulation introduced by an all-in-one multi-axial beam combiner, reduces the LFP down to a few percent below the first fringe peak. Using a Hanning filter on the interferometric window can reduce this to a few 10e-4 but with a cost of about 2 in equivalent transmission. In MATISSE, an additional attenuation is obtained by a temporal modulation of the fringes. As we have anyway to record about 10 frames in a coherence time, to avoid detector saturation, we introduce an OPD step of about lambda/10 before each new frame. Then the fringe signals are demodulated before being coherently added within the coherence time, but the demodulation of each fringe peaks modulates the LFP (and the other fringe peaks) and reduces its average well below 10e-5 even with a very reduced Hanning filtering. This combination of spatial and temporal modulation has two other advantages. First it also reduces the crosstalk between fringe peaks at different baselines well below 10e-5, which is necessary to expect the 0.1 milliradian closure phase accuracy needed for the most extreme high contrast goals of MATISSE that are the direct detection of exoplanets. Second, it can also be applied in L band, where it is not possible to make a modulation cycle in the coherence time, but even with one step per coherence time, the modulation introduced on the LFP and other fringe peaks reduces the systematic effects in the instrumental phase. The last modulation present is the Beam Commutation Device that switches beams (1 <-> 2) and (3 <-> 4) at the end of each exposure, typically every minute. Such a beam commutation changes the sign of the source closure phase and differential phase without modifying the instrument systematic and slowly variable contributions to these measures. Then the combination ("BCD+" - "BCD-") eliminates these instrument contributions without SNR cost. This is a decisive feature to obtain the high accuracy wavelength dependent closure and differential phases necessary for high contrast polychromatic imaging and model fitting over the full 3 to 13 microns MATISSE spectral coverage.

GRAVITY acquisition camera software: characterization results

Narsireddy Anugu, Paulo J. V. Garcia, Univ. do Porto (Portugal); Erich Wiezorrek, Ekkehard Wieprecht, Frank Eisenhauer, Max-Planck-Institut für extraterrestrische Physik (Germany); António Amorim, Fundacão da Faculdade de Ciências da Univ. de Lisboa (Portugal); Thomas Ott, Oliver Pfuhl, Max-Planck-Institut für extraterrestrische Physik (Germany); Paulo R. S. Gordo, Fundacão da Faculdade de Ciências da Univ. de Lisboa (Portugal); Guy S. Perrin, Observatoire de Paris à Meudon (France); Karine Perraut, Institut de Planétologie et d'Astrophysique de Grenoble (France); Christian Straubmeier, Univ. zu Köln (Germany); Wolfgang Brandner, Max-Planck-Institut für Astronomie (Germany)

GRAVITY acquisition camera implements four optical functions to track multiple beams of Very Large Interferometer (VLTI): a) pupil tracker: images four pupil reference lasers mounted on the spiders of each telescope M2 using a 2 x 2 lenslet; b) field tracker: images science stars; c) pupil imager: reimages telescopes pupil; d) aberration tracker: implements four Shack-Hartmann images. The estimation of beam stabilization parameters from the acquisition camera detector image is carried out, for every 1 s, with a dedicated data reduction software. It measures the pupil shifts (lateral and longitudinal), field tip-tilts and beams higher order aberrations of four telescopes of the VLTI.

The development of acquisition camera data reduction software is challenging due to the involvement of complex imaging system, field rotations and the software is required to work for all four telescopes simultaneously in the closed loop.

The field tracker software evaluates brightest star's position in the 4 x 4 field of view. It is implemented in two steps. In the first step, stars in the field are scanned using a predetermined star FWHM as a threshold. In the second setp, the detected stars are sorted out on the flux order. A Gaussian fit is applied to the brightest star to obtain its accurate position.

The determined star position is used in stabilizing the star light injection into single mode fibers, which carry the telescope beams to the coherent beam combination. The acquisition camera works in the H-band and the science beam combination is implemented in the K-band. The position error caused by the atmospheric dispersion between the H and K-bands is measured and corrected. Stars with different spectral types will have different amounts of atmospheric dispersion. Therefore, in these calculations, the color of the star is taken into account.

The pupil tracker evaluates lateral and longitudinal pupil positions for each telescope. As a first step in the software, positions of the pupil tracker spots (2 x 2 lenslet images of four pupil reference laser beams) are computed using a predetermined spot FWHM as a threshold. Secondly, these spot positions are compared with the reference grid to calculate the spot shifts. Spot shifts in x and y directions allow one to measure the lateral pupil positions. The amount of divergence or convergence of spot shifts allows one to evaluate the longitudinal pupil positions.

The aberration sensor measures quasi-static aberrations of beam in the Zernike polynomials. As a first step in the software, Shack-Hartmann spot positions are computed using standard algorithms: a) for a point source, a weighted centroid algorithm is used; b) for an extended scene, a correlation algorithm is used. Secondly, by comparing the spot positions with the reference grid, wavefront slopes and thereby corresponding Zernike polynomials coefficients are evaluated.

The measured parameters are updated in the instrument online database. These parameters are used in: a) alignment of GRAVITY with the VLTI; b) active pupil and field stabilization; c) the wavefront aberrations are currently being used for defocus correction and for an engineering purpose. The pupil imager is used to monitor the pupil visually during the observations.

The acquisition camera software is now successfully operational on-sky in closed loop. The software is characterized with the experimentally simulated stars using GRAVITY calibration unit and also on-sky during GRAVITY installation and verification phase at Paranal. The characterization performance results show that the acquisition camera beam sensing accuracies are within GRAVITY specifications.

The relevant data reduction, the calibration procedures and their characterization results are reported.

MATISSE: specifications and expected performances

Alexis Matter, Stéphane Lagarde, Romain G. Petrov, Philippe Bério, Sylvie Robbe-Dubois, Bruno Lopez, Pierre Antonelli, Fatmé Allouche, Pierre Cruzalebes, Florentin Millour, Observatoire de la Côte d'Azur (France); Klara Shabun, European Southern Observatory (Germany); Laurent Bourgès, Institut de Planétologie et d'Astrophysique de Grenoble (France)

MATISSE is the next generation spectro-interferometer at the European Southern Observatory VLTI operating in the spectral bands L, M and N, and combining four beams from the unit and auxiliary telescopes. The instrument will be entering its testing phase early 2016. This paper presents the equations describing the MATISSE signal and the associated sources of noise. The specifications and the expected performances of the instrument are then evaluated taking into account the current characteristics of the instrument and the VLTI infrastructure, including transmission and contrast degradation budgets. We present as well the MATISSE simulation tools that will be made available to the future users.

9907-80, Session PSWed

GRAVITY: the new metrology concept

Nicolas Blind, Stefan Gillessen, Magdalena Lippa, Yitping Kok, Johannes Weber, Max-Planck-Institut für extraterrestrische Physik (Germany); Oliver Pfuhl, Max-Planck Institute für Extraterrestrische Physik (Germany); Frank Eisenhauer, Max-Planck-Institut für extraterrestrische Physik (Germany)

GRAVITY is a dual-feed four-telescope K-band combiner for the VLTI, aiming at precision narrow-angle astrometry and phase-referenced interferometric imaging. To this end, a metrology system traces the differential optical path difference (dOPD) between the science and the reference targets, inside the GRAVITY BCI and the VLTI infrastructure, backward from the spectrometers to the telescopes spiders. The metrology receivers placed there measure temporally modulated fringes between the two beams, from which the metrology dOPD is estimated. Subtracting these measurements from the stellar fringe phases of both targets determines their astrometric distance on sky.

During the integration at MPE, it was discovered that GRAVITY suffers from an extremely strong Raman and fluorescence back-scattering from the 20-m fluoride fibers, excited by the metrology laser. Stellar fringes were then contaminated on the spectrometers detectors by a strong incoherent light background, dramatically reducing the instrument sensitivity by more than 10 stellar magnitudes.

Hence a new metrology scheme has been developed to mitigate this issue. We present here in details this new concept, based on two innovative solutions: a three-beam metrology concept and the heavy use of lock-in amplifiers. The addition of a third, bright (>50mW) metrology beam allows decreasing the laser power in fibers by a factor of 100-1000, decreasing proportionally the back-scattering as well as non-common path thermal effects, while preserving the signal-to-noise ratio. But performance is ultimately limited by laser power fluctuations. Lock-in amplifiers (LIAs) are then used to demodulate the metrology fringe signal. They act as narrowband bandpass filters (bandwidth ~ 100 Hz) for any freely selectable modulation frequency up to ~15 kHz. Hence, they efficiently filter out the three-beam laser power fluctuations, as well as vibrations in the system. This new concept proved to mitigate the back-scattering effect to a level where GRAVITY can operate again with optimal performance

Note that the present contribution focuses on a detailed description of this new metrology concept. Its implementation in GRAVITY as well as the overview of the metrology system is presented in another contribution from our team (Lippa et al., AS104-58).

Co-phasing progress of a Fizeau interferometry telescope

Congcong Zhang, Shanghai Astronomical Observatory (China)

Fizeau interferometer produces direct image from a combined primary mirror, and a wide field of view. It's very useful in high resolution astronomical imaging. We have studied Fizeau optical interferometry, and carried out some experiments. A sparse aperture interferometry system is established, the primary mirror constitutes of several parabolic mirror (sub-aperture is 150mm). We have achieved a preliminary co?phasing deviation of 1?m, by means of a FISBA interferometer. Then, dispersed Rayleigh interferometry method is used for more precise measurement.

9907-82, Session PSWed

Robust control for fringe tracking in optical interferometry

Jean-Pierre Folcher, Univ. de Nice Sophia Antipolis (France)

Fringe tracking (FT) is a critical component of an Optical Long Baseline Interferometer (OLBIN) in particular for high spectral resolution spectro-interferometric observations. The next generation of FT is intended to allow continuous fringe observation and to improve significantly the sensitivity of the interferometer. In this paper, a promising control approach is presented to cope with contradictory requirements. The FT system must be accurate and stable, which implies high frequency sampling of the optical path differences introduced by the atmosphere and the interferometer vibrations. It must also be as sensitive as possible, which needs to minimize the sampling frequency. The optimum between these concurrent requirements must be maintained through atmospheric and instrument conditions that change very rapidly. The proposed approach considers a discrete time feedback system and the controller design is based on H-infinity optimization. This approach provides the best trade-off between the largest sampling time and the validity of the discrete time feedback system. It is also well-suited to mitigate the vibrations. The effectiveness of the presented approach is illustrated through dedicated simulations involving a realistic case study : parameters for VLTI on AT, photon and detector noise, and identified frequencies of vibrations.

Multi-baseline chain bootstrapping with new classic at the NPOI

Anders M. Jorgensen, New Mexico Institute of Mining and Technology (United States); David Mozurkewich, Seabrook Engineering (United States); J. Thomas Armstrong, Henrique R. Schmitt, Ellyn K. Baines, U.S. Naval Research Lab. (United States); Gerard T. van Belle, Lowell Observatory (United States)

Imaging with optical interferometers requires fringe measurements on baseline long enough to resolve the target. These long baselines typically have low fringe contrast. Phasing them requires fringe tracking on shorter baselines which typically have greater fringe contrast and combining the fringe-tracking signals on the short baselines to phase the long baselines in a baseline bootstrapping configuration. On long resolving baselines coherent integration also becomes necessary in order to shorten the integration time. This paper addresses both the baseline bootstrapping and the coherent integration. The Navy Precision Optical Interferometer (NPOI) is laid out in a way which permits long-baseline phasing from shorter baselines in a multi-baseline scheme. The New Classic instrument for NPOI was designed specifically to implement the multi-baseline bootstrapping capability and multi-baseline observations can now be carried out routinely at the NPOI. This paper provides details about the bootstrapping scheme at NPOI and shows some initial results. We also discuss the bootstrapping error budget, describe our new Bayesian coherent integration algorithm and compare its performance to theory.

The Kalman controller of the GRAVITY fringe tracker

Sylvestre Lacour, Observatoire de Paris à Meudon (France); Roderick Dembet, Lab. d'Etudes Spatiales et d'Instrumentation en Astrophysique (France); Roberto Abuter, European Southern Observatory (Germany); Guy S. Perrin, Observatoire de Paris à Meudon (France); Senol Yazici, Frank Eisenhauer, Ekkehard Wieprecht, Oliver Pfuhl, Max-Planck-Institut für extraterrestrische Physik (Germany)

GRAVITY is a second generation interferometer for the VLTI. It combines 4 telescope beams together and is equipped with two combiners: one to correct the atmosphere and the other to do long exposure for high spectral resolution information. The beam combiner used for atmospheric correction is called the fringe tracker. It's nominal speed is 1kHz with a band-pass of 300Hz. The controller of the fringe tracker use the information from all 6 baselines to estimate the piston, and apply a correction on 4 piezos internal to GRAVITY. The controller is Kalman based, which estimate in real time the evolution of the atmosphere. It is a predictive algorithm which is used by the controller to anticipate the effect of piston variation, and apply the correction before it happens. We will present in this poster the Kalman controller, as well as first on-sky results obtained during the recent commissioning of the GRAVITY instrument.

The first light imaging C-RED infrared camera using the 320x256 Selex Saphira e-APD detector

Philippe Feautrier, First Light Imaging S.A.S. (France) and Institut de Planétologie et d'Astrophysique de Grenoble (France); Jean-Luc Gach, First Light Imaging S.A.S. (France) and Lab. d'Astrophysique de Marseille (France); Eric Stadler, First Light Imaging S.A.S. (France) and Institut de Planétologie et d'Astrophysique de Grenoble (France); Timothée Greffe, Fabien Clop, Stéphane Lemarchand, David Boutolleau, First Light Imaging S.A.S. (France); Ian M. Baker, SELEX ES Infrared Ltd. (United Kingdom)

Developed by First Light Imaging and based on the Saphira HgCdTe APD detector developed by Selex, the C-RED infrared camera is offering the new APD (Avalanche Photo Diodes) disruptive technology in the area of infrared detectors for interferometry. This is in strong contrast to what is observed with APDs made out of III-V material or Si, which have typical excess noise factors of F~4-5 for III-V semi-conductors and F~2-3 for Si respectively. The exceptional characteristics of HgCdTe APDs are due to a nearly exclusive impaction ionization of the electrons, and this is why these devices have been called electrons avalanche photodiodes or e-APDs. These characteristics have inspired a large effort in developing focal plan arrays using HgCdTe APDs for low photon number applications such as active imaging in gated mode (2D) and/or with direct time of flight detection (3D imaging) and, more recently, passive imaging for infrared wave front correction and fringe tracking in astronomical observations. Use of e-APD arrays has already been reported for interferometric applications within the RAPID research programme (SPIE Montreal 2014, S. Guieu et al). C-RED is using the commercial SAPHIRA 320x256 24 microns pixel pitch HgCdTe e-APD array allowing to obtain sub-electron readout noise, taking advantage of the APD noise-free multiplication gain and non destructive readout ability of its readout circuit. C-RED is also capable of multiple regions of interest (ROI) readout allowing faster image rate (10's of KHz) while maintaining unprecedented sub-electron readout noise. The detector is placed in a sealed vacuum environment and cooled down to cryogenic temperature (90K) using a zero vibration integrated pulse tube, with a high reliability (MTBF > 90 000 h) which is much higher than standard Stirling coolers used usually with cooled infrared arrays. A cold filter and a cold pupil are used to limit the camera background, both are tunable for the needs of the application. Sensitive between 0.8 and 2.5 micron with the latest version of the Saphira detector, the C-RED camera offers a peak QE of 70% and can be operated up to 3500 frames per second with 16 bit data. The Cameralink full interface offers Ultra low latency data transmission to the control system, which is particularly useful for fast fringe tracking. Trigger input/output connectors are offered for synchronous operation of the camera.

Available by last quarter of 2015, the full C-RED camera design and performances will be presented in this paper.

9907-87, Session PSWed

Final performance of the GRAVITY detector systems

Leander H. Mehrgan, Gert Finger, European Southern Observatory (Germany); Frank Eisenhauer, Max-Planck-Institut für extraterrestrische Physik (Germany); Johana Panduro, Max-Planck-Institut für Astronomie (Germany)

GRAVITY is a second generation instrument for the VLT Interferometer,

designed to enhance the near-infrared astrometric and spectro-imaging capabilities of VLTI. The GRAVITY instrument uses all together five eAPD detectors, from which four for wavefront sensor, one for the Fringe tracker. In addition two Hawaii2RG are used, one for Acquisition camera and one for the spectrometer. A compact bath cryostat is used for each WFS unit, one for each of the VLT Unit Telescopes. Both Hawaii2RG detectors have a cutoff wavelength of 2.5 microns.

A new and unique element of GRAVITY is the use of infrared wavefront sensors. For this reason SELEX-Galileo has developed a new high speed avalanche photo diode detector for ESO. The SAPHIRA detector, which stands for Selex Avalanche Photodiodes for High-speed Infra Red Applications, has been already evaluated by ESO. At a frame rate of 1 KHz a read noise of less than one electron could be demonstrated.

9907-88, Session PSWed

Frequency stability characterization of a fiber Fabry-Perot interferometer

Jeff Jennings, Gabriel Ycas, Scott Diddams, National Institute of Standards and Technology (United States) and Univ. of Colorado Boulder (United States); Samuel P. Halverson, Suvrath Mahadevan, The Pennsylvania State Univ. (United States)

A fiber Fabry-Perot (FFP) interferometer consists of a short piece of single mode optical fiber with highly reflective coatings on the end facets. For stability the FFP is encased in a thermally stabilized ferrule. Light is coupled both into and out of the interferometer with butt-coupled single mode optical fibers. When illuminated by a white light source, the FFP output is a broad array of optical frequency markers that can serve as a simple and robust spectroscopic calibration source for precise radial velocity (RV) measurements. In previous work we have demonstrated the potential benefits of such an FFP for <1 m/s RV short-term measurements at the Apache Point Observatory Galactic Evolution Experiment (APOGEE) instrument. Here we report a full laboratory-based characterization of an FFP that we have constructed for operation in the 750-1350 nm spectral region.

We use a pair of tunable continuous wave (CW) lasers at 1319 and 1064 nm (227 and 282 THz) to simultaneously measure and track the positions of the modes of an FFP having free spectral range, FSR = 41 GHz (0.33 nm), and finesse, F = 100. While the FFP is held at constant temperature, the 1064 and 1319 nm lasers are scanned across FFP resonances, and the optical power transmitted through the cavity from each laser is photodetected and digitized. Simultaneously, the frequencies of the two CW lasers are measured and recorded with respect to an atomically-stabilized laser frequency comb, which provides absolute stability at the sub-kilohertz level (<0.1 mm/s equivalent RV). The transmission signals have a Lorentzian functional form and the fit residuals reveal a centroid precision of ~1 MHz, limited by the achieved signal-to-noise ratio in a single 100 s frequency scan.

Using this technique we accurately determine the sensitivities of the FFP transmission peaks to temperature, optical power and input polarization. Of particular significance, our results demonstrate a means to characterize and correlate environmentally-driven perturbations of and among the FFP transmission modes across broad spectral bandwidths. For example, our approach will allow us to determine if the temperature dependence of the FFP mode frequencies is a linear function of frequency, or if other factors must be considered (such as wavelength dependence of dispersion or material thermo-refractive properties) in assessing the relative stability and frequencies of the FFP modes. These results and the techniques we introduce should have significance not only for passive etalons, but for a variety of actively-stabilized etalon spectral calibration sources that are proposed or are presently being constructed.

Experimental demonstration of a crossed cubes nuller for coronagraphy and interferometry

François B. Hénault, Institut de Planétologie et d'Astrophysique de Grenoble (France); Alain Spang, Observatoire de la Côte d'Azur (France)

In this communication are presented the first experimental results obtained on the Crossed-cubes nuller (CCN), that is a new type of Achromatic phase shifter (APS) based on a couple of crossed beamsplitter cubes. We review the general principle of the CCN, now restricted to two interferometric outputs for achieving better performance, and describe the experimental apparatus developed in our laboratory. It is cheap, compact, and easy to align. The results demonstrate a high extinction rate in monochromatic light and confirm that the device is insensitive to its polarisation state. Finally, the first lessons from the experiment are summarized and discussed in view of future space missions searching for extra-solar planets located in a habitable zone, either based on a coronagraphic telescope or a sparse-aperture nulling interferometer

9907-90, Session PSWed

Khayyam: progress and prospects of coupling a Spatial Heterodyne Spectrometer (SHS) to a Cassegrain telescope for optical interferometry

Sona Hosseini, Jet Propulsion Lab. (United States); Walter Harris, The Univ. of Arizona (United States); Guillaume Gronoff, NASA Langley Research Ctr. (United States)

In the temporal study of faint, extended sources at high resolving power, Spatial Heterodyne Spectrometer (SHS) can offer significant advantages about conventional dispersive grating spectrometers. SHS produces integrated spectra over a wide field-of-view (FOV from few arcsec to about one degree) in high spectral resolution (R about 105) using no (or a small < 1m) primary mirror. SHS's layout is a compact two-beam cyclical interferometer, and it produces wavenumber dependent 2-D Fizeau fringe pattern from which an input spectrum can be obtained via a Fourier transform. The architecture of SHS combines the high étendue of a Fourier Transform Spectrometer (FTS) with higher optomechanical tolerance and simpler optomechanical design associated with grating spectrometers.

Here, we describe a four-year continuous progress toward development of a prototype reflective SHS instrument-telescope configuration to combine all of the capabilities necessary to obtain high resolving power visible band spectra of diffuse targets from small aperture on-axis telescopes where significant observing time can be obtained. This instrument, Khayyam, is a tunable all-reflective spatial heterodyne spectrometer (TSHS) that is mounted to a fixed focal plane shared by the 0.6m Coude Auxiliary Telescope at Lick Observatory, CA. Khayyam has up to 55 arcsec input field of view, resolving power up to 176000, and a tunable bandpass covering ???>100nm. Khayyam was field tested to study spatially extended astronomical targets where high resolving power is necessary to separate multimodal signals, crowded molecular bands, and to sample low (<10 km/s) velocities at rapid temporal cadence. Here we will discuss the design considerations going into this new system, installation, testing of the interferometer-telescope combination, the technical challenges and plans.

9907-92, Session PSWed

Progress in two-dimensional far-IR double-Fourier modulation: a test bed with a rotating collimated source

Giorgio Savini, Univ. College London (United Kingdom); Peter A. R. Ade, Amber Hornsby, Cardiff Univ. (United Kingdom); Roser Juanola-Parramon, NASA Goddard Space Flight Ctr. (United States); Enzo Pascale, Rashmi V. Sudiwala, Cardiff Univ. (United Kingdom); Nicola Baccichet, Univ. College London (United Kingdom); Colm P. Bracken, Anthony Donohoe, Anthony Murphy, Créidhe O'Sullivan, National Univ. of Ireland, Maynooth (Ireland)

We present recent developments in the shorter wavelength upgrade of the Far-IR double-modulation testbed originally working between 300 microns and 3mm. With the replacement of the original beam-combiner with a high-frequency metal-mesh beam combiner and improved metrology, the testbed is now working in a narrow atmospheric band (21-27 microns) and performs spectro-spatial interferometer efficiently and with sufficient precision to extract and analyse a number of higher precision system non-ideal behaviours. In this presentation we show the recent improvements in the testbed development, the data algorithms applied and verification, the optical analysis of the phase distribution for non-ideal optics and finally, the implementation of an asymmetric calibration source placed in a rotating mount centred at the focus of a collimator which together act as a sky simulator. The rotation of the latter allows to simulate the rotation of the two-telescope variable baseline to generate the equivalent of a 2-D uv coverage and apply reconstruction algorithms to produce the first 2D FIR double-Fourier reconstructed images.

9907-93, Session PSWed

Results from a multi-aperture Fizeau interferometer ground test bed: demonstrator for a future space-based interferometer

Nicola Baccichet, Univ. College London (United Kingdom); Amandine Caillat, Eddy Rakotonimbahy, Kjetil Dohlen, Lab. d'Astrophysique de Marseille (France); Giorgio Savini, Univ. College London (United Kingdom); Michel Marcos, Lab. d'Astrophysique de Marseille (France)

The construction of a space-based, long-baseline, far-infrared, imaging interferometer represents one of the most difficult challenges of the coming decades in Astrophysics. One of the solutions envisioned is the hyper-telescope which concept is based on a multi-aperture interferometer with more than two elements, arranged on kilometric-large baselines. The entrance pupil consists on several free-flying satellites, each one carrying a single mirror segment that is aligned and phased in a shape equivalent to a filled aperture of a kilometer in diameter. All these segments direct the light towards a common secondary collector, which is carried by an additional satellite, containing the necessary optics needed to recombine all the beams into a common focus. This will allow, thanks to accurate data processing, to image astronomical objects with a resolution equal to the longest baseline permitted by the interferometer's design.

In the framework of the European FP7-FISICA (Far Infrared Space Interferometer Critical Assessment) program, we developed a miniaturized version of the hyper-telescope to demonstrate multi-aperture interferometry on the ground. The demonstrator consists in a miniaturized version of a sparse-aperture system that mimics that of a space interferometer with a highly diluted collecting area. This would be ultimately integrated into a CubeSat platform, therefore providing the first real demonstrator of a Fizeau interferometer in space. Overall, the project objective is to prove its image reconstruction capabilities using a CubeSat platform to image bright celestial bodies outside Earth's atmosphere. The concept consists in a pupil mask with seven apertures, with a distribution optimized to provide a non-redundant coverage of the u,v plane followed by a lens which focalizes the interferometric images on a CCD camera. The mask is then rotated to generate the data set used to reconstruct the real image. This experiment in particular, is designed to test the suitability of such a design, optimize the mask's aperture layout and select the best manufacturing process.

In this paper we give a description of the instrument and present the results of the tests conducted both indoor, with a rectangular source, and outdoor using the Sun as target. We describe the image processing pipeline and the algorithm used to reconstruct the object image. To enforce the reliability of the software, a comparison with synthetically generated interferometric images is made, showing good agreement with the ones obtained experimentally. In addition, as a scientific application, we use aperture synthesis techniques to fit a limb-darkening model to our data and provide a measurement of the Sun diameter. Finally, we propose a first design of such an instrument implemented into a CubeSat platform.

9907-94, Session PSWed

Fiber-based heterodyne infrared interferometry: an instrumentation study platform on the way to the proposed Infrared Planet Formation Imager

Felipe E. Besser, Clemente Pollarolo, Miguel I. Pina, Ernest A. Michael, Univ. de Chile (Chile)

We present concept and first experimental lab results for a low-cost near-infrared heterodyne interferometer based on commercial 1.55μm fiber components with relative phase-stabilization between both telescopes, near to shot noise heterodyne detection with ambient temperature operated photodiodes, an ultra-coherent and noise-reduced fiber laser, and an FPGA-based digital correlator of 1 GHz bandwidth. After we will have advanced to a first demonstration with two and then three 14"-telescopes, the concept should be upgradable to connect larger numbers of mid- or large-class telescopes. Given that the employed fiber phase stabilization scheme should enable the operation of long baselines, we discuss the applicability of this concept for long-baseline, high telescope number systems (scalability of the concept) and mid-infrared wavelength. This could finally result in contributions to the design of the large infrared Planet Formation Imager which is being proposed currently.

9907-95, Session PSWed

Near infrared nulling interferometry: performance and results the Palomar fiber nuller and future possibilities

Eugene Serabyn, Jet Propulsion Lab. (United States)

Nulling interferometry at near-infrared wavelengths has advanced markedly over the past several years, proving its ability to provide unique high-contrast astronomical observations at small angles from bright stars. The Palomar Fiber Nuller has been the basis of several of these advances, including the use of a single mode fiber beam combiner, and the development of the statistical null self calibration approach to astrophysical null depth extraction, which has essentially done away with the need for fringe stabilization beyond that provided by an extreme adaptive optics system. These techniques have yielded high-accuracy on-sky nulls, and have enabled a unique survey for near-infrared exozodiacal emission that complements other observations. These demonstrated techniques, as well as several other new approaches to be discussed, now

allow us to consider next steps for near-infrared nulling interferometry. In particular, the incorporation of very simple nullers into facility high-contrast imaging coronagraphs at large astronomical telescopes now seems a feasible route forward.

9907-96, Session PSWed

First results obtained with the self-coherent camera at Palomar Observatory

Jacques-Robert Delorme, Observatoire de Paris (France) and Lab. d'Etudes Spatiales et d'Instrumentation en Astrophysique (France); Raphaël Galicher, Pierre Baudoz, Observatoire de Paris (France) and Lab. d'Etudes Spatiales et d'Instrumentation en Astrophysique (France); Dimitri Mawet, California Institute of Technology (United States); Eugene Serabyn, Jet Propulsion Lab. (United States); Johan Mazoyer, Space Telescope Science Institute (United States); James K. Wallace, Jet Propulsion Lab. (United States); Olivier Dupuis, Observatoire de Paris (France) and Lab. d'Etudes Spatiales et d'Instrumentation en Astrophysique (France)

During the last few years, the imaging of circumstellar disks and exoplanets has become one of the priorities to constraint models of planetary system formation and of planetary atmospheres. However, direct imaging of faint sources around bright objects is very challenging. The study of such objects therefore requires dedicated techniques such as coronagraphs that attenuate the light from the host star. However, because of phase and amplitude aberrations, a part of the stellar light reaches the detector and form speckles brighter than most of planets in the science images. Behind ground-based telescopes most of the speckles are due to the atmosphere turbulence. These dynamic wavefront errors are estimated and corrected by conventional adaptive optics (AO) systems that measure the wavefront error using a wavefront sensor in a dedicated optical channel. Because of the beam splitting, quasi-static non-common path aberrations (NCPA) are generated by the instrument optics between the wavefront sensing channel and the science image channel, which limits the accuracy of the AO correction.

VLT/SPHERE and Gemini/GPI are two instruments designed to detect young Jupiter-like planets. They minimize the quasi-static NCPA in open loop before the observations but cannot control them during the observations. However, as NCPA evolve during the observations, the calibration degrades with time and the contrast performance is limited by quasi-static speckles to 1e-4 ~ 1e-5 at 0.5'' in raw images. Space-based telescopes are atmosphere turbulence free but the variations of temperature and gravity also induce quasi-static aberrations. In order to reach higher contrast it is thus mandatory to estimate and compensate them in closed loop during the observations.

Our team proposes the use of the Self-Coherent Camera (SCC) as a focal plane wavefront sensor (FPWFS). It is a non invasive device based on spatial modulation of speckles. Unlike techniques based on temporal modulation, the SCC is able to estimate and correct speckles using only one focal plane image.

In laboratory, we can reach contrast levels of 2e-8 at a few ?/D in monochromatic light (? = 635 nm) and contrast levels of 4.5e-8 between 5 and 17 ?/D in polychromatic light (?? = 80nm around ? = 635 nm).

Attractive features and laboratory performance of the SCC led us to move on to the next stage of development. That is precisely what we do. Indeed, since spring 2015, we developed collaboration with Palomar team to test the SCC on sky.

During this presentation I will present first results obtained on sky with the SCC on the stellar double coronagraph bench.

9907-97, Session PSWed

Automated alignment and closed loop guiding of multiple telescope beams

Narsireddy Anugu, Univ. do Porto (Portugal); António Amorim, Paulo R. S. Gordo, Fundacão da Faculdade de Ciências da Univ. de Lisboa (Portugal); Frank Eisenhauer, Oliver Pfuhl, Ekkehard Wieprecht, Erich Wiezorrek, Marcus Haug, Thomas Ott, Max-Planck-Institut für extraterrestrische Physik (Germany); Paulo J. V. Garcia, Univ. do Porto (Portugal); Guy S. Perrin, Observatoire de Paris à Meudon (France); Karine Perraut, Institut de Planétologie et d'Astrophysique de Grenoble (France); Christian Straubmeier, Univ. zu Köln (Germany); Wolfgang Brandner, Max-Planck-Institut für Astronomie (Germany)

Atmospheric turbulence and telescope pupil motions are the two major challenges in implementing long baseline interferometric astrometry (Lacour et al. 2014, A&A). The telescope beams enter a coherent beam combiner via optical delay lines of the interferometric laboratory. These beams usually contain field tip-tilts due to atmospheric seeing and pupil motions caused by the optical train vibrations while tracking the object of interest. Previous projects (the Keck Outrigger astrometry, the ESO's PRIMA) have shown that difficulties can arise in the astrometry measurements if an efficient pupil tracking and stabilization mechanism is not implemented.

GRAVITY is a powerful interferometric imaging (4 milliarcseconds) and precise astrometric instrument (10 microarcseconds) and has been installed at the Very Large Telescope Interferometer (VLTI) of ESO. Due to the field and pupil errors, the performance of GRAVITY can be severely limited in two ways: a) coupling efficiency of stars light injection into single mode fibers, which carry the beams for coherent beam combination; b) astrometric errors. The precise astrometry requires the field and pupil stabilization to be implemented within 2 milliarcseconds RMS and 4 millimeters RMS at the UT (8 m) scale. A multiple beam guiding instrument, acquisition camera, has been built to meet these challenges for the GRAVITY beam combiner and for the fringe tracker. It tracks efficiently the pupil, field and higher order aberrations of four VLTI beams simultaneously, for every 1 s. Thereby it enables: a) active pupil and field stabilization; b) stabilization of star light injection into single mode fibers; c) characterization of wavefront profile and defocus correction.

The acquisition camera has four optical functions: a) pupil tracker: images four pupil reference lasers using 2 x 2 lenslets that are mounted on the spiders of telescope secondary mirror; b) field tracker: images science field; c) pupil imager: reimages telescope pupil; d) aberration tracker: implements a Shack-Hartmann image.

The detector images are analyzed with a dedicated data reduction software to extract tip-tilts of stars from the field tracker image, pupil motions (lateral and longitudinal) from the pupil tracker image and wavefront higher order aberrations from the Shack-Hartmann image.

The measured field and pupil measurements are used in two ways: a) for the alignment of GRAVITY with the VLTI; b) for the field and pupil stabilization. The wavefront aberrations are currently being used for an engineering purpose and defocus correction. In future, these can be used for non-common path errors correction. The pupil imager is used to visually monitor the pupil during the observations.

The validity of the design and the concepts of the acquisition camera are demonstrated with the telescope beams generated with GRAVITY calibration unit and also at the observatory during commissioning phase of GRAVITY. Currently it is successfully operational in the closed loop beam guiding. The instrument concepts and the characterization results are detailed.

The work carried out here leads to the PhD thesis of Anugu.

9907-98, Session PSWed

Recent developments with the Visible Nulling Coronagraph

Brian A. Hicks, Richard G. Lyon, NASA Goddard Space Flight Ctr. (United States); Peter Petrone III, Sigma Space Corp. (United States); Matthew R. Bolcar, Mark Clampin, NASA Goddard Space Flight Ctr. (United States); Michael A. Helmbrecht, Iris AO, Inc. (United States); Udayan Mallik, NASA Goddard Space Flight Ctr. (United States); Ian J. Miller, LightMachinery Inc. (Canada)

A wide array of general astrophysics studies including detecting and characterizing habitable exoplanets could be enabled by a future large segmented UV-Optical-Infrared (UVOIR) telescope. In order to achieve the sensitivity for studying a habitable planet through direct imaging, such an observatory would be paired with a starshade or internal coronagraph for broadband starlight suppression to reach off-axis contrasts exceeding a billion to one – a formidable challenge for any high-contrast imaging system. Over the past several years, a laboratory-based Visible Nulling Coronagraph (VNC) has evolved to reach requisite contrasts over a ~ 1 nm bandwidth at narrow source angle separation using a segmented deformable mirror in one arm of a Mach-Zehnder layout. More recent efforts presented here target broadband performance following the addition of two sets of half-wave Fresnel rhomb achromatic phase shifters (APS) with the goal of reaching 10?9 contrast, at a separation of 2l/D, using a 40 nm (6%) bandwdith single mode fiber source. New developments in this broadband nulling effort will be presented along with example considerations for future long-term application.

9907-38, Session 17

Imaging transient events at high angular resolution *(Invited Paper)*

Gail H. Schaefer, Georgia State Univ. (United States)

Resolving the spatial structure of transient events provides insights into their physical nature and origin. Recent observations using long baseline optical/infrared interferometry have revealed the size, shape, and angular expansion of bright novae within a few days after their outbursts. This has implications for understanding the timescale for the development of asymmetric features in novae ejecta. Additionally, combining spectroscopic measurements of the expansion velocity with the angular expansion rate provides a way to measure a geometric distance to the nova. I will provide a review of interferometric observations of novae, with a focus on recent results of the expansion and spatial structure of Nova Del 2013. I will also discuss other promising applications of interferometry to transient sources, such as measuring the image size and centroid displacements to measure planetary masses in gravitational microlensing events. Given the timescales of transient events, it is critical for interferometric arrays to respond rapidly to targets of opportunity in order to optimize the instrumental sensitivity and baselines required to resolve the source while its brightness and size change over time.

9907-39, Session 18

Fast sub-electron detectors review for interferometry *(Invited Paper)*

Philippe Feautrier, Institut de Planétologie et d'Astrophysique de Grenoble (France); Jean-Luc Gach, First Light Imaging S.A.S. (France) and Lab. d'Astrophysique de Marseille (France)

New disruptive technologies are now emerging for detectors dedicated to interferometry. The detectors needed for this kind of applications need antonymic characteristics: the detector noise must be very low, especially when the signal is dispersed but at the same time must also sample the fast temporal characteristics of the signal. This paper will describe the new fast low noise technologies that have been recently developed for interferometry and adaptive optics. The presentation will be didactic and will present the operation of these new detectors.

The first technology is the Avalanche PhotoDiode (APD) infrared arrays made of HgCdTe. I will present the two programs that have been developed in that field: the Selex Saphira 320x256 and the 320x255 RAPID detectors developed by Sofradir/CEA LETI in France. Status of these two programs and future developments will be presented. Sub-electron noise can now be achieved in the infrared using this technology. The exceptional characteristics of HgCdTe APDs are due to a nearly exclusive impaction ionization of the electrons, and this is why these devices have been called electrons avalanche photodiodes or e-APDs. These characteristics have inspired a large effort in developing focal plan arrays using HgCdTe APDs for low photon number applications such as active imaging in gated mode (2D) and/or with direct time of flight detection (3D imaging) and, more recently, passive imaging for infrared wave front correction and fringe tracking in astronomical observations. In addition, a commercial camera called C-RED, based on Selex Saphira and commercialized by First Light Imaging, will be presented.

Some groups are also working with instruments in the visible. In that case, another disruptive technology is showing outstanding performances: the Electron Multiplying CCDs (EMCCD) developed mainly by e2v technologies in UK. The OCAM2 camera, commercialized by First Light Imaging, uses the 240x240 EMMCD from e2v and is successfully implemented on the VEGA instrument on the CHARA interferometer (US) by the Lagrange laboratory from Observatoire de la Cote d'Azur. By operating the detector at gain 1000, the readout noise is as low as 0.1 e and data can be analyzed with a better contrast in photon counting mode.

In conclusion, the development of new detectors dedicated to fast applications is offering sub-electron readout in the visible and in the infrared, opening a new era in terms of sensitivity to the detectors for interferometry.

9907-40, Session 18

Progress towards photon-counting infrared arrays for interferometry

David F. Buscher, Eugene B. Seneta, Xiaowei Sun, John S. Young, Univ. of Cambridge (United Kingdom); Gert Finger, European Southern Observatory (Germany)

The advent of low-dark-current eAPD arrays in the near infrared ushers in the possibility for photon-counting, high quantum efficiency detectors at these wavelengths. Such detectors would revolutionise the sensitivity of interferometry because near-infrared wavelengths are at the "sweet spot" between the corrupting effects of atmospheric seeing at shorter wavelengths and thermal noise at longer wavelengths. We report on laboratory experiments with cooled Selex SAPHIRA detectors aimed at demonstrating photon-counting performance with these devices by exploiting enhanced avalanche gain and multiple non-destructive readouts. We explain the optimum modes for employing these detectors in interferometry.

9907-41, Session 19

Opportunities for interferometric studies of disk-eclipsed binary star systems *(Invited Paper)*

Robert Stencel, Univ. of Denver (United States)

As sky surveys document an increasing number of transient celestial phenomena, an intriguing subset of objects are emerging that show variations in brightness, interpretable as the transit of a circumstellar disk in front of a companion star in a binary system. The brightest member of this class is the F0 supergiant + disk system epsilon Aurigae, along with more than a dozen new candidates sharing similarities. Well-known cases include EE Cep, BM Ori and KH15D. Characteristics of all of these will be discussed in terms of their suitability for interferometric study. Next generation interferometric imaging offers the potential to detect disk structure features that are driven by dynamical forces, chemical transitions and thermal gradients. These include observable effects of tidal spiral density waves, dust and planetessimal formation/evolution in disks, and orbital phase-dependent heating of the disk by the external companion star - see http://adsabs.harvard.edu/abs/2015ApJ...798...11P .

9907-42, Session 20

Astrophotonics in the context of optical/IR interferometry *(Invited Paper)*

Lucas Labadie, Univ. zu Köln (Germany); Jean-Philippe Berger, European Southern Observatory (Germany); Nick Cvetojevic, The Univ. of Sydney (Australia); Sylvestre Lacour, Observatoire de Paris à Meudon (France); Guillermo Martin, Institut de Planétologie et d'Astrophysique de Grenoble (France); Stefano Minardi, Friedrich-Schiller-Univ. Jena (Germany); Guy S. Perrin, Observatoire de Paris à Meudon (France); Martin M. Roth, Leibniz Institute for Astrophysics Potsdam (Germany); Robert R. Thomson, Heriot-Watt Univ. (United Kingdom)

In the era of large telescopes and multi-aperture interferometer, the increasing complexity of the hosted instruments poses new challenges to astronomers. "Complexity" encompasses here issues related to size and weight, nature of the required optical functions in imaging and spectroscopy, mechanical and thermal stability, versatility, age reliability and cost-driven requirements. Astrophotonics, a relatively young field at the interface between photonics and astronomical instrumentation, has grown significantly in the last decade, enabling radically new solutions in response to the need for advanced instrumentation. Interferometry and spectroscopy techniques represent prime beneficiaries from these new technologies, as for instance in the case of the near-infrared interferometric instrumentation at the VLTI.

In this paper, we first review some fundamental aspects of photonic science which drove the emergence of astrophotonics, namely the conditions for low-loss guiding, the modal properties of waveguides, the achievable optical passive or active functions, the chromatic boundaries and the associated fabrication technologies. We emphasize the diversity of optical designs that astrophotonics allows, from the simplest photons passive combiner to some more visionary concepts of integrated spectrographs, laser sources or detectors. We highlight what the effective outcome has been for observational astrophysics, in particular in the field of high angular resolution, and we analyze the prospects for further technological development also considering the potential synergies with other fields of physics, where specific needs may result in a direct return for astronomy (e.g. non-linear optics in condensed matter physics). We also stress the central role of fiber optics in routing and transporting light, delivering complex filters, or interfacing instruments and telescopes, more specifically in the context of a growing usage of adaptive optics. We believe astrophotonics has a unique role to play in the forthcoming era of new ground-based astronomical facilities, and possibly in the field of space science, which is strongly driven by high-maturity low-risk instrumental solutions.

9907-43, Session 20

Increasing the spectral coverage of interferometric integrated optics: K/L and N-band laser-written beam combiners

Jan Tepper, Univ. zu Köln (Germany); Romina Diener, Friedrich-Schiller-Univ. Jena (Germany); Lucas Labadie, Univ. zu Köln (Germany); Stefano Minardi, Friedrich-Schiller-Univ. Jena (Germany); Balaji Muthusubramanian, Univ. zu Köln (Germany); Jörg-Uwe Pott, Max-Planck-Institut für Astronomie (Germany); Alexander Arriola Martiarena, Macquarie Univ. (Australia); Gillian E. Madden, Debaditya Choudhury, William N. MacPherson, Robert R. Thomson, Heriot-Watt Univ. (United Kingdom)

The recent advent of Gravity at the VLTI, preceded by the significant scientific outcome of PIONIER, strongly suggests that the small-scale and stiff integrated optics concept in interferometry is a very promising one, either for scientific observations or fringe tracking operations, and may well become mainstream whenever the beams of more than four telescope are to be interferometrically recombined. This platform has been so far very successful at near-IR wavelengths shorter than 2.2 microns. For wavelengths longer than 2.4 microns, alternatives to silica-based technologies need to be implemented. Solutions based on chalcogenide glasses are following slow but constant maturation. Over the last years, it has been shown that laser writing technique in IR chalcogenide glasses is a valuable solution for the mid-IR range. These glasses are transparent up to 10μm and the ultrafast laser writing technique allows light-guiding structures to be written in 3D in the glass substrate. Therefore, such chips simultaneously open a new wavelength range for integrated optics and support a more flexible 2D arrangement remapping of the chip output. Previous work has demonstrated the proof-of-concept at 10 microns.

In this paper we extend, in the context of our ALSI project (Advanced Laser-writing for Stellar Interferometry), our work on chalcogenide-based mid-IR integrated optics to both the K and L bands, a spectral range where modal filtering and integrated beam combination is particular valuable, but have not yet been experimentally explored using laser writing techniques. We have investigated the properties of beam combiners based on commercial GLS glass and conducted a series of measurements. We fabricate 2-telescope directional couplers for which we measure the reachable interferometric contrast in the lab to >90%. Progress is being made towards components combining more sub-apertures. We demonstrate the single-mode properties of the sample at 3.4 microns and investigate the spectral splitting ratio of our directional couplers, which is an important parameter for broadband operation. We also measure the low-level of birefringence of the laser-written components by measuring no significant alteration of the polarization state of a HeNe Laser at 3.39μm for a statistically significant set of waveguides with different writing parameters. In the context of this work, the propagation losses for L band laser written waveguides have been demonstrated to be as low as 0.25 dB/cm, which are among the lowest measured so far. We have also studied the option of a fiber-fed component using commercial fluoride fibers, and we find that the fibers are likely the limiting sub-system in terms of degradation of the light polarization. We finally verify the thermal behavior of the components after undergoing different cooling cycles. We draw first conclusions on the potential of chalcogenide integrated optics components for stellar interferometry in a wavelength range which is essential to address relevant questions for the understanding of planet formation and the physics in in young stellar objects. We believe this is a step forward in the maturation of integrated optics concepts for mid-IR interferometry.

9907-44, Session 20

ALOHA project: how nonlinear optics can boost interferometry to propose a new generation of instrument for high-resolution imaging

François Reynaud, Pascaline Darré, Ludovic Szemendera, Ludovic Grossard, Jean-Thomas Gomes, Laurent Delage, XLIM Institut de Recherche (France)

The ALOHA research program aims to propose a breakthrough generation of instrument for high resolution imaging in astronomy in the infrared spectral domain. This fully innovative concept arises from our simultaneous competence in nonlinear optics and high resolution imaging with telescope arrays. Acting like a mixer in a radio receiver, the nonlinear process (sum frequency generation) shifts the infrared radiations emitted by the observed astrophysical source to a NIR or visible spectral domain. This way, the light beam is more easily processed by mature optical devices and detectors.

The purpose of this talk, will be to make a presentation of the concept and an overview of progresses of the ALOHA project. The general principle of frequency conversion implemented in the interferometric arms of a stellar interferometer will be described and a focus will be laid on the technological inputs. By shifting the astronomical spectrum into a propitious spectral domain compatible with the use of silica fibers, we propose to use an instrumental chain working in a technologically-mature wavelength of telecom windows. This completely new approach allows to design a new generation of instrument ables to address the problem of the mid-infrared high resolution imaging very informative for astrophysical studies (Active Galaxy Nuclei, Young Star Objects, exoplanets...).

In this new concept, the key point is the possibility to convert the light from a mid-infrared radiation to the visible / near infrared range through an "up-conversion stage". For this purpose it is possible to use nonlinear optics taking care that the nonlinear process makes necessary the use of intense pump copropagating with the faint astronomical beam. As the imaging process uses a spatial coherence analysis, the up conversion stage has to preserve the mutual coherence of the waves and to operate with a minimum additional noise. On the other hand, there are several advantages of using such a frequency conversion, especially from mid-infrared to near-infrared or visible wavelengths: the possibility of using spatially single-mode and polarization maintaining components which are easy to handle and have low optical losses (optical fibers and integrated optical combiners), the availability of efficient detectors (high quantum efficiency, low noise, room temperature operation) and not to be compelled to use complex cooling systems over the entire instrument (assuming that the frequency conversion takes place right after the telescope focus).

In this framework, an historic overview of the different experimental steps overcome in the last decade will be proposed in order to give an exhaustive description of the current potential of the ALOHA project.

This paper will be introductive to two other papers:

The first one on the implementation of the ALOHA @1.55 µm prototype on the CHARA array with an evaluation of the potential results for on-sky observation in H band.

The second one on in lab experimental development in the L band up to photon counting regime.

9907-45, Session 21

Evolved stars at high angular resolution: present and future *(Invited Paper)*

Claudia Paladini, Univ. Libre de Bruxelles (Belgium)

The late evolutionary stages of stellar evolution are a key ingredient for our understanding in many fields of astrophysics, including stellar evolution and the enrichment of the interstellar medium (ISM) via stellar yields.

Already the first interferometric campaigns identified evolved stars as the primary targets because of their extended and partially optically thin atmospheres, and the brightness in the infrared.

Interferometric studies spanning different wavelength ranges, from visual to mid-infrared, have greatly increased our knowledge of the complex atmospheres of these objects where different dynamic processes are at play. In less than two decades this technique went from measuring simple diameters to produce the first images of stellar surfaces.

By scanning the extended atmospheres we constrained theoretical models, learnt about molecular stratification, dust formation, and stellar winds, and there is still a lot to be done.

In this contribution I will review the recent results that optical/infrared interferometry has made on our current understanding of cool evolved stars. The presentation will focus on red giant branch (RGB) stars, asymptotic giant branch (AGB) stars, and red supergiants (RSGs).

I will discuss the challenges of image reconstruction, and highlight how this field of research will benefit from the synergy of the current interferometric instrument(s) with the second generation VLTI facilities GRAVITY and MATISSE. Finally I will conclude with a short introspection on applications of a visible interferometer and of the the Planet Formation Imager (PFI) to the field of evolved stars.

9907-46, Session 22

Image reconstruction: techniques and results *(Invited Paper)*

Fabien Baron, Georgia State Univ. (United States)

Optical/near-IR interferometry now benefits from the availability of several stable image reconstruction packages, thanks to the large amount of development work undertaken in the last 5 years. Software initiatives such as the ANR Project POLCA and the Optical WP4 Joint Research Activity have especially stimulated research in Europe, with a focus on polychromatic reconstructions and sparse representations. In the US, image reconstruction has been driven by specific astronomical cases (e.g. rotating spotted stars), with a focus on compressed sensing and imaging on spheroids.

This talks gives a short yet complete overview of the software landscape, presenting all the state-of-the-art algorithms while also emphasizing the relevant science cases.

9907-47, Session 22

7th edition of the "interferometric imaging beauty contest" *(Invited Paper)*

Joel Sanchez, Max-Planck-Institut für Astronomie (Germany); Éric M. Thiébaut, Ctr. de Recherche Astronomique de Lyon (France)

Image reconstruction in optical interferometry has gained considerable importance for astrophysical studies during the last decade. This has been mainly due to the improvements of the imaging capabilities of the existing interferometers (e.g., PIONIER/VLTI, MIRC-6T/CHARA) and of the expected facilities in the coming years (e.g., GRAVITY and MATISSE at the VLTI or the Planet Formation Imager initiative). However, despite the advances made so far, image synthesis in optical interferometry is still an open field of research. Since 2004, the optical Interferometry community has organized a biennial contest to formally test the different methods and algorithms for image reconstruction. In 2016, we will celebrate the 7th edition of the "Interferometric Imaging Beauty Contest". This initiative is an open call to the community to participate in the reconstruction of a selected

set of simulated targets with a wavelength-dependant morphology as they could be observed by the current and coming instruments (e.g., MATISSE, GRAVITY or MIRC/CHARA). This contest will represent a unique opportunity to benchmark, in a systematic way, the current advances and limitations in the field, as well as to discuss the future lines of action. In this contribution, we will summarize: (a) the rules of the contest; (b) the different used data sets and how they were selected; (c) the methods and results obtained by each one of the participants; (d) the metric used to select the best reconstructed images and the winners of the contest.

9907-48, Session 22

Effective global optimization for image restoration in optical/IR interferometry

Férréol Soulez, Ecole Polytechnique Fédérale de Lausanne (Switzerland); Éric M. Thiébaut, Observatoire de Lyon (France); Matthew Ozon, Jonathan Léger, Ctr. de Recherche Astrophysique de Lyon (France)

Many image reconstruction algorithms have been proposed to cope with optical/IR interferometric data. A first difficulty is to deal with the sparsity of the data and the uneven u-v coverage. This is usually overcome by imposing a priori constraints to the sought image. The reconstruction then amounts to solving an optimization problem where fidelity to the data and to the priors must both be satisfied to a chosen level. Due to the type of interferometric measurements, the image restored by the current algorithms depends on some initial guess and on the optimization strategy. Even though the resulting image is often satisfactory, there are no guarantees that the best image is obtained given the data and the constraints. This is a strong defect which may badly impact the interpretation of interferometric observations by astronomers. We propose a new image reconstruction approach where a minimum amount of unmeasured data is introduced to make the image reconstruction process a convex problem whose solution is thus unique. Then, combining the convex image reconstruction and a Monte Carlo strategy to sample the unmeasured data, it is possible to retrieve a much better solution in a reasonable computational time. Compared to previously proposed global optimization strategies, e.g. based on Monte Carlo Markov Chain (MCMC), our approach has a very limited number of variables to sample randomly (i.e. much less than the number of pixels) which explain its effectiveness. We demonstrate on a number of cases the advantages of our strategy implemented in MiRA algorithm. The proposed method is completely flexible and can be extended to any kind of data and priors, in particular the case of multi-spectral image reconstruction is considered.

9907-100, Session PSTh

A new dual-channel speckle instrument for Gemini and WIYN

Nicholas J. Scott, Steve B. Howell, NASA Ames Research Ctr. (United States); Elliott P. Horch, Southern Connecticut State Univ. (United States)

GemSpec is a new dual-channel instrument based on the existing DSSI (Differential Speckle Survey Instrument), but the new instruments will have both speckle and “wide-field” imaging capabilities. Identical copies of the instrument will be installed on permanent loan at the Gemini-N and WIYN telescopes. A third instrument could potentially be added to the Gemini-S telescope. GemSpec is expected to be a versatile and high-demand community instrument. Many exoplanet targets will come from K2 and TESS as well as the already large number of RV exoplanets that will desire follow-up high-resolution imaging. Most of these stars will be brighter than R~13, excellent targets for the instrument at Gemini. The faint limiting magnitude, for speckle observations, will remain around 16 to 16.5 depending on observing conditions, while wide-field, high speed operation should be able to go to 21+. Each instrument will use two identical Andor iXon Ultra 888 EMCCD cameras for a blue reflective channel and a red transmissive channel. Additionally, Sloan g, r, i, and z filters will be available in wide field mode and narrow-band filters for speckle that have approximate center wavelengths similar to Johnson filters. The speckle field of view will be 2.4 x 2.4” while the wide-field mode will have an approximate field of view of 26 x 26”. Full frame readout of 26 frames per second is possible with much higher frame rates possible within subarrays for the speckle imaging mode. The instrument will be remotely operable via a VNC connection from either the mid-level facility at Hale Pohaku or Hilo. The instrument is expected to be an official visitor instrument, run in pre-designated observing blocks, or it may be permanently mounted at the telescope, to be operated in a queued observing mode. A speckle data reduction pipeline will be provided to the community. These new instruments will facilitate a wide range of science projects and fulfill observatory needs in the coming years.

9907-101, Session PSTh

COvariancE of Lucky Images (COELI): resolution limit as a function of the atmosphere conditions

Manuel P. Cagigal, Pedro J. Valle, Hugo Villegas, Univ. de Cantabria (Spain); Miguel A. Cagigas, Instituto de Astrofísica de Canarias (Spain); Isidro Perez-Villó, Antonio Pérez Garrido, Univ. Politécnica de Cartagena (Spain)

In this paper, we show a new algorithm which takes advantage of temporal fluctuations of the image intensity along a frame series to uncover possible companions surrounding the main star. If we consider a series of short-exposure images which have been selected applying the Lucky Imaging technique, the intensity of those pixels where a faint companion is placed will fluctuate in phase with the main star intensity along the image series. However, the pixels containing incoherent speckles will fluctuate in counter phase. Hence, for detecting hidden objects, it would be enough to find those pixels in the image series which fluctuate in phase with pixels gathering light from the main star. The technique is based on the estimate of the COvariancE of Lucky Images (COELI) for all the pixels contained in the image and it is appropriate for detecting objects placed in an area surrounding the host star within a radius of ?/r0, where r0 is the Fried parameter.

The image of a point source obtained by a perfect optical system is described by the Airy pattern. In ground-based telescopes this image consists of a central peak surrounded by a number of speckles whose temporal average is commonly known as halo. The central peak is due to the coherent part of wavefront energy whilst the surrounding speckle comes from the incoherent one. Hence, to increase the central peak energy it is enough to have a less aberrated incoming wavefront or to compensate it by an Adaptive Optics system. In this analysis, we will not consider the use of any Adaptive Optics system.

The procedure we followed was to calculate the normalized covariance given by the expression:

C[isp , i(r)] = Conv[isp , i(r)] / ?sp ?ir

The convolution product is given by:

Conv[isp , i(r)] = < isp i(r) > ? < isp > < i(r) >,

where isp stands for the star peak intensity, i(r) is the intensity detected at a position r from the star peak, ? is the standard deviation and <> is the ensemble average (frame series average).

The goal of this paper is to show the COELI performance when detecting faint objects close to the host star. In a recent paper we have applied COELI to a series of images taken by the CAHA 2.2 m telescope. The technique allowed us to detect a star companion at a distance as short as one Airy ring. This implies that, under certain conditions, the Rayleigh

diffraction limit can be reached from a 2.2 m ground-based telescope.

However, there are other parameters to be considered. In particular, we are interested in checking the influence of the atmosphere conditions on the capability of the technique for reaching the Rayleigh diffraction limit.

Sparse aperture masking with SPHERE

Anthony C. Cheetham, The Univ. of Sydney (Australia); Julien Girard, ESO (Chile); Guillaume Schworer, Sylvestre Lacour, Observatoire de Paris (France); Xavier Haubois, ESO (Chile); Jean-Luc Beuzit, IPAG (France)

Sparse Aperture Masking (SAM) has recently been commissioned on SPHERE, the VLT's new adaptive optics high resolution imager. SAM extends the capabilities of SPHERE by providing high contrast measurements at and beyond the traditional diffraction limit. SAM can be used in conjunction with each of the SPHERE sub-instruments, allowing dual band imaging in the visible and near-infrared, near-infrared integral field spectroscopy, and polarized differential imaging in the visible and near-infrared. We report on the results of commissioning, including the measured and expected performance and some early scientific results on nearby debris and transition disks.

9907-103, Session PSTh

Interferometric direct imaging properties of a BIGRE-DAM device in laboratory

Fabien Patru, Jacopo Antichi, INAF - Osservatorio Astrofisico di Arcetri (Italy); Patrick Rabou, Institut de Planétologie et d'Astrophysique de Grenoble (France); Enrico Giro, Jacopo Farinato, Raffaele Gratton, Daniele Vassallo, INAF - Osservatorio Astronomico di Padova (Italy); Christophe Verinaud, Institut de Planétologie et d'Astrophysique de Grenoble (France); Denis Mourard, Observatoire de la Côte d'Azur (France); Julien Girard, European Southern Observatory (Chile)

DAM (Discretized Aperture Mapping) is an original filtering device able to improve the performance in high angular resolution and high contrast imaging by the present class of large telescopes equipped with adaptive optics (Patru et al. 2011, 2014, 2015). By discretising the entrance pupil of a large telescope into an array of many coherent sub-apertures, DAM provides unique imaging and filtering properties by means of spatial filtering and interferometric techniques. DAM is a high spatial frequency filter able to remove part of the phase residuals in a wavefront. Moreover, the object-image convolution relationship is preserved on a finite field of view. DAM can be achieved either with a bunch of optical fibers, or an integrated optic, or simply with an innovative BIGRE micro-lenses array. BIGRE-DAM is a simple integrated optic component formed of an afocal double lenslet array (Antichi et al. 2009, 2011). This paper deals with the first in-lab experiment of a BIGRE-DAM device at visible wavelength. The optical properties of such component are shown, including both diffractive and interferometric effects. The interferometric pattern produced by the array of DAM reproduce the same diffractive pattern of the whole entrance aperture. However, the field of view is limited by interferometry due to the spatial aliasing effect, for which the field is periodically replicated across the image, preventing wide field on extended objects. We study the aliasing by imaging the point spread function (PSF) when observing a point-like object located either on-axis or at various off-axis positions across the field of view. The experimental results are in good agreement with the numerical simulations. The next objective will be to test a DAM with an adaptive optic system, first in laboratory and then on sky.

Combining super-resolution and spectroscopy in the visible with FIRST at Subaru: application to binary systems and evolved stars

Elsa Huby, Univ. de Liège (Belgium); Danielle Doughty, Subaru Telescope, National Astronomical Observatory of Japan (United States); Lucien Gauchet, Observatoire de Paris (France); Guy S. Perrin, Sylvestre Lacour, Observatoire de Paris à Meudon (France); Franck Marchis, SETI Institute (United States); Gaspard Duchêne, Univ. of California, Berkeley (United States) and Institut de Planétologie et d'Astrophysique de Grenoble (France); Takayuki Kotani, National Astronomical Observatory of Japan (Japan); Olivier Guyon, Nemanja Jovanovic, Julien Lozi, Subaru Telescope, National Astronomical Observatory of Japan (United States)

FIRST (Fibered Imager foR a Single Telescope) is a high resolution and high contrast instrument being developed by Observatoire de Paris. After a successful observing campaign of binary systems on the 3-m Shane telescope at Lick Observatory from 2010 to 2013, FIRST is now part of the the SCExAO project. FIRST has been integrated with the visible bench of SCExAO and is currently being commissioned as a visible module aiming at hitting the diffraction limit at visible wavelengths.

The principle of FIRST is based on the combination of aperture masking and spatial filtering. The pupil is divided into 37 sub-pupils that feed single mode fibers. 18 of them are recombined in two sets of nine fibers, positioned on a line with non-redundant spacings, thus avoiding the blurring of the fringes and allowing the cross-dispersion (spectral resolution of 300). This setup offers several advantages over the classical aperture masking technique, such as: (i) potentially better visibility accuracy thanks to the spatial filtering performed by the single-mode fibers, (ii) a better (u,v) plane coverage for the same size of sub-pupils, (iii) the capability of cross-dispersion with in-line recombination.

The optical and mechanical setup have been updated on several aspects (see Doughty et al., these proceedings). In this presentation, we report on our latest on-sky results obtained with FIRST at Subaru. We have observed and detected several binary systems, and in particular two tight binary systems with separation below the diffraction limit of the telescope (lambda/D = 15 mas at 600nm, the shortest wavelength of the spectral range): Alpha Equ with a separation of 11mas and contrast of 0.5 in the visible, and Alpha And with a separation of 11mas and contrast of 0.2. We will also show that with the fine angular resolution provided by FIRST, stellar disks of evolved stars are resolved at visible wavelengths. The data reduction is in progress and should soon allow to measure potential asymmetries in the surface brightness of the stars we have observed.

Coupling high angular resolution and spectral resolution in the visible, FIRST is a promising instrument in the context of the characterization of faint companions, in particular on the future extremely large telescopes. In the near future, the current classical recombination of FIRST will be upgraded with an integrated optics chip, thus dramatically improving the sensitivity and dynamic range (see Martin et al., and Gauchet et al., these proceedings).

9907-105, Session PSTh

Current standing and upgrades to FIRST at the Subaru Telescope

Danielle Doughty, The Univ. of Arizona (United States) and Subaru Telescope, National Astronomical

Observatory of Japan (United States); Elsa Huby, Univ. de Liège (Belgium) and Observatoire de Paris (France) and Lab. d'Etudes Spatiales et d'Instrumentation en Astrophysique (France); Lucien Gauchet, Observatoire de Paris (France) and Lab. d'Etudes Spatiales et d'Instrumentation en Astrophysique (France); Guy S. Perrin, Observatoire de Paris à Meudon (France) and Lab. d'Etudes Spatiales et d'Instrumentation en Astrophysique (France); Sylvestre Lacour, Observatoire de Paris (France) and Lab. d'Etudes Spatiales et d'Instrumentation en Astrophysique (France); Nemanja Jovanovic, Subaru Telescope, National Astronomical Observatory of Japan (United States); Gaspard Duchêne, Univ. of California, Berkeley (United States) and Ctr. National de la Recherche Scientifique (France) and Institut de Planétologie et d'Astrophysique de Grenoble (France); Franck Marchis, SETI Institute (United States); Julien Lozi, Subaru Telescope, National Astronomical Observatory of Japan (United States); Olivier Guyon, Subaru Telescope, National Astronomical Observatory of Japan (United States) and The Univ. of Arizona (United States)

FIRST (Fibered Imager foR a Single Telescope) is a current module developed by Observatoire de Paris on the SCExAO (Subaru Coronagraphic Extreme Adaptive Optics) instrument at the 8-m Subaru Telescope on Maunakea. FIRST is a visible interferometer working from 600-900 nm and makes use of techniques such as non-redundant pupil remapping, spatial filtering, and cross-dispersion. With these combined techniques FIRST is capable of both high resolution and high contrast imaging; thus, making it ideal for observing close binaries within the diffraction limit of telescopes, stellar disks of evolved stars, asymmetries in the surface brightness of stars, and in the future with ELTs and an upgrade to an integrated optic chip it will being capable of characterizing faint and low-mass companions (see Martin et al., and Gauchet et al., these proceedings). Recent results from a current campaign on the Subaru telescope are described elsewhere (see Huby et al., these proceedings).

The instrument since arriving at the Subaru telescope in 2013 from its binary star campaign at the 3-m Shane telescope at Lick Observatory, has been undergoing optical and mechanical upgrades to improve its stability and performance. This presentation will be focusing on these improvements as well as tests done in conjunction with a simulated model to identify the sources of the biases which has limited the capability of the previous generation instrument and the strategies used by our team to mitigate them.

9907-106, Session PSTh

Discretized aperture mapping for wavefront sensing

Fabien Patru, Jacopo Antichi, INAF - Osservatorio Astrofisico di Arcetri (Italy); Marcel Carbillet, Observatoire de la Côte d'Azur (France); Laurent Jolissaint, Haute Ecole Spécialisée de Suisse occidentale (Switzerland); Dimitri Mawet, Jet Propulsion Lab. (United States)

DAM (Discretized Aperture Mapping) is an original filtering device able to improve the performance in high angular resolution and high contrast imaging by the present class of large telescopes equipped with adaptive optics (Patru et al. 2011, 2014, 2015). DAM is a high spatial frequency filter able to remove the problematic phase errors produced by the small scale defects in the wavefront. Various effects are related to the high-spatial frequency content which is neither seen by any wavefront sensor (WFS) nor corrected by any adaptive optic (AO) and is transmitted up to the final detector. In particular, any wavefront sensor, due to its finite sub-apertures size, is fundamentally limited by the well-known aliasing effect, where high spatial frequencies are seen as spurious low frequencies. DAM can be used as an anti-aliasing filter in order to improve both the accuracy of the WFS measurements and the stability of the AO compensation. This paper deals with a new spatially filtered wavefront sensor, named DAM-WFS, where DAM, located at the front of a WFS, serves as an anti-aliasing filter providing accurate and stable measurements. Among the WFS concepts, the spatially filtered Shack-Hartmann WFS (SF-SH-WFS) (Poyneer & Macintosh 2004) is the unique concept of passive filtering proposed until now, which consists in using a pinhole at the front of the sensor. However, it is a non-linear filter which generates spurious low spatial frequencies, contrary to DAM which is a priori linear and may exceed the performance of its precursor. DAM upstream of a Shack-Hartmann WFS (DAM-SH-WFS) is free of aliasing. In addition, it reduces the spot distortion and improves the centroid computation. DAM upstream of a Pyramid WFS (Ragazzoni et al. 1996) (DAM-PYR-WFS) cancels out the aliasing as well, even if it is not so strong in the Pyramid WFS wrt Shack-Hartmann WFS. However, the Pyramid WFS shows more phase residuals at the high spatial frequencies, whereas the SF-SH-WFS is more sensitive to low frequencies (Verinaud 2005). Significant noise propagation remains at the highest frequencies closed to the WFS cutoff frequency (function of the number of lenslet of the WFS). In this domain, DAM may help to reach the highest sensitivity of a Pyramid WFS thanks to its high spatial frequency filtering properties. Finally, the anti-aliasing DAM filter is efficient and easy to operate with any wavefront sensor (DAM-SH-WFS, DAM-PYR-WFS, etc.).

9907-107, Session PSTh

SPIDER: a chip-scale interferometric imaging sensor

Danielle Wuchenich, Chad E. Ogden, Richard L. Kendrick, Alan L. Duncan, Lockheed Martin Space Systems Co. (United States); Samuel T. Thurman, Lockheed Martin Coherent Technologies (United States); S. J. Ben Yoo, Tiehui Su, Univ. of California, Davis (United States)

The Lockheed Martin Advanced Technology Center is collaborating with the University of California, Davis to develop an ultra-thin optical imaging sensor called SPIDER (Segmented Planar Imaging Detector for Electro-optical Reconnaissance). SPIDER combines interferometric imaging concepts with photonic integrated circuit (PIC) technology to enable an electro-optic sensor with orders of magnitude reduction in size, weight, and power compared to an imager based on a conventional telescope design.

SPIDER consists of many photonic integrated circuit cards arranged azimuthally in a ring design, like spokes on a wheel. SPIDER images the object in the Fourier domain and reconstructs the image computationally. Lenslet arrays focus light from the scene into the waveguides on the photonic integrated circuits. Light from different pairs of lenslets are routed on the PICs via waveguides and combined interferometrically on the chip to produce fringes. By forming many lenslet pair combinations with varying lenslet spacing, a variety of interferometer baselines are created. The spatial frequency information of the scene is captured by measuring the phase and amplitude of the interference fringes of each baseline. An image is formed computationally by reconstructing the intensity distribution from the spatial frequency information via a 2D Fourier Transform through the van Cittert-Zernike theorem.

A high-resolution image can be formed in a small amount of time as the thousands of channels containing the spatial frequency information can be sampled simultaneously. Compared to the complex, mechanical delay lines required by many direct detect imaging interferometers, the interferometer path lengths in the photonic integrated circuits can be matched to micron precision and thus no scanning is required to form the interference fringes. SPIDER is inherently a multi-spectral device—light received at each lenslet

is spectrally demultiplexed on the chip and interfered with light received by a different lenslet in the same spectral bin. This spectral demultiplexing allows the Fourier domain u-v plane to be filled in more efficiently using multiple spectral bins from the same lenslet pair.

Under the DARPA-funded SeeMe program in 2014, we fabricated a four channel (two baseline) photonic integrated circuit on silica and demonstrated the spectral splitting and interferometric beam combination measurement concepts. Under current DARPA funding for the SPIDER Zoom program, we are fabricating a complete chip (one spoke of the wheel) with 12 baselines and hundreds of waveguides using silicon nitride. We are testing this new PIC in our laboratory test bed built specifically for this task.

In this talk we will give a brief summary of previous work, provide an overview of the test bed and scene generator, and present the first imaging results obtained with this experiment to validate the measurement concept. Comparison with the expected performance and other designs trades also will be discussed.

Ultrafast laser inscribed waveguides for mid-infrared interferometry

Alexander Arriola Martiarena, Simon Gross, Martin Ams, Thomas Gretzinger, Macquarie Univ. (Australia) and Ctr. for Ultrahigh bandwidth Devices for Optical Systems (Australia); David Le Coq, Univ. de Rennes (France); Rongping Wang, The Australian National Univ. (Australia) and Ctr. for Ultrahigh bandwidth Devices for Optical Systems (Australia); Heike Ebendorff-Heidepriem, Univ. of Adelaide (Australia) and Ctr. for Nanoscale BioPhotonics (Australia); Jasbinder Sanghera, Shyam Bayya, Brandon Shaw, U.S. Naval Research Lab. (United States); Michael J. Ireland, The Australian National Univ. (Australia); Peter G. Tuthill, The Univ. of Sydney (Australia); Michael J. Withford, Macquarie Univ. (Australia) and Ctr. for Ultrahigh bandwidth Devices for Optical Systems (Australia)

The direct detection of exoplanets is one of the major goals of astrophysics in the next couple of decades. The black-body radiation of a cool stellar object like a planet sits in the mid-infrared, between 2.0 and 12.0 ?m. Moreover, the contrast between a M-class star and the orbiting planet around it becomes most favorable in the astrononomical L-band (3.5 - 4.1 ?m) by many orders of magnitude. This makes the L-band the most promising wavelength for nulling interferometry.

Dragonfly is a pupil remapper interferometer aiming to provide a fully integrated photonic solution for direct imaging astrophysical targets through the turbulent atmosphere. This instrument has already been successfully demonstrated in the NIR and now we are translating this platform to the MIR. The core of this instrument is an integrated photonic device fabricated using the ultrafast laser inscription technique, where a femtosecond laser is tightly focused inside a transparent material (usually glass or crystal).

With the femtosecond laser direct-write technique we can induce, by cause of nonlinear processes, a permanent refractive index change within the focal volume. The glass/crystal sample is placed on a XYZ translation stage, allowing for the fabrication of highly repeatable full-3D photonic microstructures inside the material. The femtosecond laser direct-writing has already been demonstrated as a viable solution for 3D integrated photonics for astronomy.

The main restriction for an efficient photonic stellar interferometer is to have low-loss waveguides (usually <1 dB/cm losses). Therefore, we will present a comprehensive study of materials compatible with the direct-write technique and that are transparent in the mid-infrared. The materials range from commercial to custom-engineered chalcogenide and fluoride glasses. These waveguides were fabricated using two laser systems with repetition rates between 1 kHz and 5.1 MHz and pulse durations between ~50 fs and ~1.5 ps. The characterization and single-mode transmission properties of the waveguides in the mid-IR was done free-space coupling the light of a 3.4 ?m HeNe laser.

Using chalcogenide architecture for mid-IR photonic on-chip nulling interferometers

Harry-Dean Kenchington Goldsmith, The Australian National Univ. (Australia); Nick Cvetojevic, Ctr. for Ultrahigh bandwidth Devices for Optical Systems (Australia) and The Australian Astronomical Observatory (Australia) and Sydney Institute for Astronomy, Univ. of Sydney (Australia); Michael J. Ireland, The Australian National Univ. (Australia); Benjamin Eggleton, Ctr. for Ultrahigh bandwidth Devices for Optical Systems (Australia); Peter G. Tuthill, The Univ. of Sydney (Australia) and Sydney Institute for Astronomy (Australia); Jon S. Lawrence, The Australian Astronomical Observatory (Australia) and Macquarie Univ. (Australia); Stephen J. Madden, The Australian National Univ. (Australia)

Direct imaging of exoplanets, where a planet is separately resolved at the image plane, promises to provide critical answers to questions of planetary evolution and formation. New photonic technologies have enabled light to be precisely channelled; delayed; and interfered, all on a monolithic chip: facilitating a new generation of interferometric instrumentation for astronomy. To date, the materials used to create photonic chips have focused on interferometers in the visible and near-IR wavelengths. However; the contrast ratio between the planets and host star becomes favourable in the Mid-IR wavelengths, beyond ~3.5um. Hence, new materials are required to extend the reach of photonics into this regime.

To enable high contrast detection for the next-generation photonic interferometers we present a laboratory characterization of an on-chip Bracewell nulling interferometer prototype, operating at a wavelength of 4um. This chipset was lithographically fabricated using a mid-IR transparent glass – Chalcogenide. The low loss of this glass, already established to be 0.3 dB/cm, makes the nuller similar in performance and architecture to existing chips used in instruments like GRAVITY, PIONEER and Dragonfly, but with the added ability to operate upwards of 10 um in wavelength.

Using this novel approach to MIR fabrication we present a beam combiner using Multimode-Interference couplers (MMIs) that operate over a broader wavelength range and more robust in terms of fabrication tolerances– as opposed to modified evanescent field couplers that are typically used. The nuller itself is made of cascaded MMIs, taking 4 input channels and creating both a null output, between two input pairs, and a photometric tap. The resulting nulled ports are routed to a second tier MMI that can recover the fringes, or provide a second null, with the bright port used for calibration.

This new approach to fabricating MIR photonic devices, specifically nulling interferometers, will provide astronomers with another option when

implementing the next generation of astronomical photonics in the mid-IR wavelengths.

All-in-one 4-telescope beam combination with a zig-zag array of waveguides

Romina Diener, Stefano Minardi, Friedrich Schiller Univ. Jena (Germany); Jan Tepper, Univ. of Cologne (Germany); Stefan Nolte, Friedrich Schiller Univ. Jena (Germany); Lucas Labadie, Univ. of Cologne (Germany)

Multi-telescope beam combination with integrated optics (IO) bear several advantages over bulk optics instruments, such as miniaturized packaging, considerable reduction of alignment procedures and stable interferometric transfer function. To date, IO beam combiners have been mainly manufactured for near-infrared wavelengths, exploiting the maturity of silica-based photolithographic technologies.

The desirable extension of the operation bandwidth of IO beam combiners to mid-infrared (MIR) wavelengths has been so far been prevented by the low maturity level of IO manufacturing technologies for MIR-transparent materials.

A very promising avenue for IO manufacturing at MIR wavelengths is ultrafast laser inscription in chalcogenide glasses. Additionally to being suitable for the processing of a large variety of substrate materials, this technique offers three-dimensional (3D) structuring capabilities. The latter feature is very interesting because it permits the simplification of the IO beam combiner design, e.g. by removing the need for waveguide crossings in pair-wise beam-combiners [1]. Further, the 3D geometry allows the simplification of the beam combiner down to a regular array of straight waveguides arranged on a square lattice (the so called discrete beam combiners or DBC [2,3]).

In the context of the DBC we have recently achieved a major breakthrough by designing a 4-telescopes, all-in-one beam combiner designed for a central wavelength of 3.4 microns.

The beam combiner features an array of 23 evanescently coupled waveguides arranged on a zig-zag lattice. The array configuration allows the dispersion of light in one dimension without the limits imposed by the previously investigated square array geometry [2,3]. This enables the use of DBC in high-resolution spectral interferometric instruments. Notice that a fully linear array of waveguides cannot be used as an interferometric beam combiner due to the absence of second order coupling between the waveguides [4], thus making the zig-zag geometry the only beam-combining waveguide array compatible with high-dispersion spectro-interferometry. The design of the array has been optimized to ensure a well conditioned V2PM transfer matrix (condition number 3.8), which is similar to that of the 4-telescope IO beam combiner of PIONIER (condition number 3.6, [5]).

Additionally, we have manufactured several samples of the array by direct laser writing in Gallium Lanthanum Sulfide glass, a highly transmissive material in the mid-infrared. The single waveguides were written by means of a laser multi-pass procedure which enables the precise tailoring of the waveguide core cross-section geometry. Writing parameters were optimized to achieve nearly circular mode fields.

Initial near-field characterization of the fabricated samples at a wavelength of 3.4 microns are encouraging, but require a better control of the polarization dispersion of the single waveguides and a significant suppression of stray light originating from poor coupling efficiency at the input waveguides.

Work is currently in progress to improve the manufacturing parameters and characterize experimentally the the V2PM matrix of the beam combiner.

ALOHA @3.39μm: implementation of the up-conversion interferometer in the L band

Ludovic Szemendera, Pascaline Darré, Romain Baudoin, Ludovic Grossard, Laurent Delage, XLIM Institut de Recherche (France); Harold Herrmann, Christine Silberhorn, Integrated Quantum Optics (Germany); François Reynaud, XLIM Institut de Recherche (France)

In the general framework of thermal infrared astronomical imaging, the mid infrared (MIR) domain addresses several prominent scientific areas like protoplanetary disc, brown dwarf or nebula studies. A few instruments such as Matisse, Visir or Midi, are able to provide data in the L, M and N band working with very low flux. In all these instruments, each interferometric arm can involve more than twenty mirrors. At room temperature, the thermal radiation of the mirror train can easily exceed the astronomical signal, significantly reducing the limiting magnitude to be observed. The related current experimental configuration requires the use of a chopped and nodded detection modes and their related data processing to enhance the Signal to Noise Ratio.

In order to limit the impact of this predominant noise contribution, the ALOHA (Astronomical Light Optical Hybrid Analysis) instrument promotes a hybrid interferometer concept where the astronomical light is frequency shifted into the near infrared domain through a sum frequency generation process. The MIR signal has to be converted out of the thermal infrared domain as close as possible to the telescope focus. This way, the main part of the instrumental chain would not be subject to any thermal noise disturbance.

A previous work among our team, led by P. Darré (ALOHA/CHARA at 1.5μm: sensitivity improvement and on-sky ability to detect astronomical sources in H band), has also investigated the joint use of sum frequency generation (SFG) and high resolution imaging by spatial coherence analysis at 1550 nm down to the photon counting regime. This work is performed in order to extend performances of ALOHA from the H band to the L band. Our inlab setup is conducted with a 3.39μm HeNe laser as a signal source. In each interferometric arm, the optical field is converted in a periodically polled niobate lithum (PPLN crystals) powered by a 1.06μm pump to generate a converted signal at 810nm. The shifted signal is injected in a single-mode fiber. Our converted signals from each arm of the interferometer are mixed by a fibre coupler. All our guided components are single-mode and polarisation maintaining. As a consequence we control the spatial overlapping, performing the spatial filtering problems. One can notice these elements have very low losses, opening the field of hectometric to kilometric interferometers.

A preliminary experiment has been conducted in the high flux regime (3mW signal power) and confirms the possibility to use a non linear stage on each arm of an interferometer dedicated to high resolution imaging in the L band. We aquired fringes with an average contrast of 98±2% over 1500 measurements.

We got a very high fringe contrast thanks to the use of polarisation maintaining single mode fibres. This first step validates our setup experimental calibration. Our current investigations are focused on the photon counting regime by attenuating the input signal monochromatic flux and addressing faint broadband sources to fit the astronomical requirements.

9907-112, Session PSTh

6- and 8-telescope discrete beam combiners

Ronny Errmann, Stefano Minardi, Friedrich Schiller Univ. Jena (Germany)

Imaging optical interferometry requires the evaluation of the complex visibilities over a large number of baselines. Current facilities can handle the combination of up to 6-telescopes but planned and future interferometric facilities (such as the MROI [1] or the Planet Formation Imager [2]) could require the combination of up to 20 telescopes.

While an all-in-one combiner for such a large number of telescopes may be impractical due to sensitivity and construction issues, a web of instruments combining partially redundant sub-sets of the telescope array could improve sensitivity at the expense of delivering visibilities over a smaller number of baselines.

Candidate devices for the single beam combination units are integrated optics (IO) circuits which can deliver highly stable transfer functions, miniaturization and simple maintenance procedures.

In this context, we evaluated the optimal waveguide configuration for the beam combination of 6 telescopes by means of an IO discrete beam combiner (DBC), that is a regular array of evanescently coupled waveguides disposed at the nodes of a two dimensional lattice [3].

Advantages of the DBC are potentially the minimal number of pixels per spectral channel required to reconstruct the whole coherence information of the telescope array, and the simplicity of the construction of the combiner, which allows a straightforward scaling of the device to a large number of telescopes.

Here we propose the use of a new figure-of-merit (FoM) for the theoretical evaluation of the performance of a multi-telescope all-in-one beam combiner, namely the condition number (CN) of the visibility to pixel matrix (V2PM [4]) by the square root of the number of output channels of the combiner. We show that by definition this FoM is proportional to the maximal relative error of the quadratures of the retrieved visibilities.

To evaluate the expected V2PM, we modeled the DBC in the frame of the coupled mode approximation of a rectangular lattice of waveguides. The model assumes that the modes of each waveguide of the array are only slightly perturbed by the neighboring waveguides. The model includes the first order coupling between waveguides (in the horizontal and vertical direction) and the second order coupling (in the diagonal direction). The existence of the diagonal coupling has been recently found to be a necessary condition for the retrieval of the complex visibilities from the output excitation pattern of the array [5].

We found that the chosen figure of merit calculated as a function of the number of waveguides has a flat minimum corresponding to about 50 waveguides, equivalent to a 7x7 array. As a further optimization procedure, we studied the impact of the diagonal coupling strength of a 7x7 array of waveguides. Numerical simulations show that for a diagonal coupling strength larger than 10% of the vertical/horizontal one, the FoM remains basically constant.

We further report on the possible input waveguide configuration of an 8-telescope combiner featuring 8x8 or 9x9 waveguides.

Model-based calculations of fiber output fields for fiber-based spectroscopy

Eloy Hernandez, Daniel Bodenmüller, Leibniz Institute for Astrophysics Potsdam (Germany)

The accurate characterization of the field at the output of optical fibers is of relevance for precision spectroscopy in Astronomy. The modal effects in the far field angular distribution of the fiber translate to the illumination of the pupil in the spectrograph and impact on the resulting point spread function (PSF).

A model is presented that is based on the Eigenmode Expansion Method that calculates the output field from a given fiber for different manipulations of the input field. Results are shown for different configuration parameters, such as: spatial and angular displacements of the input field, spot size variations, propagation length, different transverse fiber geometries and different wavelengths.

This work is in context with the phase A study of the fibre-system for MOSAIC, a proposed multi-object spectrograph for the European-Extremely Large Telescope (E-ELT-MOS).

9907-114, Session PSTh

Use of a photonic lantern into a fiber beam combiner

Ettore Pedretti, Heriot-Watt Univ. (United Kingdom) and Queen's Medical Research Institute (United Kingdom); Alan H. Greenaway, Robert R. Thomson, Paul A. Dalgarno, Heriot-Watt Univ. (United Kingdom)

We investigate the use of photonic lanterns in a fibre beam-combiner. One of the problems of fibre combiners is that the single-mode fibres coupling is affected by the atmospheric seeing. This effect could be potentially mitigated using a "photonic lantern". A photonic lantern converts the multi-mode input at the focal plane of a telescope to N single mode outputs. In presence of atmospheric seeing the light of the telescope will couple with one or more of the single-mode outputs unlike the current interferometers where coupling can be sporadic in bad seeing conditions. In a stellar interferometer each telescope focal plane could be coupled with a photonic lantern. After beam combination each single-mode outputs of the lantern will interfere with all the others. N single mode outputs from each lantern will make N non independent closure phases that can be averaged. Using this method the noise on the closure phase on independent baseline triangles could in principle be reduced by the square root of N.

Fringe tracking at longer wavelengths using near- and mid-IR integrated optics devices

Balaji Muthusubramanian, Lucas Labadie, I. Physikalisches Institut (Germany); Jörg-Uwe Pott, Max-Planck-Institut für Astronomie (Germany); Stefano Minardi, Friedrich-Schiller-Univ. Jena (Germany); Jan Tepper, I. Physikalisches Institut (Germany); Romina Diener, Friedrich-Schiller-Univ. Jena (Germany)

The availability of a reliable fringe tracking system is essential for optimal operation of a stellar interferometer to access fainter objects through long integration time. A typical fringe tracker compensates for the differential optical path differences (OPDs) due to the turbulent atmosphere and instrumental vibrations through additional delay lines. The influence of atmospheric turbulence and instrumental vibrations are weaker at longer wavelengths than the shorter wavelengths. On the other hand, ground based observations at longer wavelengths suffer from higher thermal background. Despite this, fringe tracking in the L-band could be advantageous when observing young stellar objects which emit more radiation at longer wavelengths in the infrared.

In this paper we investigate the possibilities to perform fringe tracking in the K and L bands at VLTi taking advantage of integrated optics beam combiner based on near and mid-infrared transparent GLS Chalcogenide glass. For this Purpose, we developed an atmospheric OPD simulator based on Von Karman turbulence statistics including the instrumental vibrations measured at the VLTi. We analyze the efficiency in performing group and phase delay tracking in the L band and address the case of dual-band fringe tracking by measuring the broadband fringes in K and L bands simultaneously. The general objectives are to estimate L-band fringe tracking sensitivity limit and check if the K+L group delay tracking associated to a "Blind mode" for the estimations of the science visibility and phase could be more sensitive than conventional K-band only phase+group delay fringe tracking.

Near-IR active beam-combiner for multi-telescope spectro-interferometry based on surface waveguide gratings and lithium niobate waveguides

Joran Loridat, Institut de Planétologie et d'Astrophysique de Grenoble (France); Gwenn Ulliac, Femto-ST (France); Alain Moran, IMEP-LACH (France); Nadège Courjal, Femto-ST (France); Guillermo Martin, Institut de Planétologie et d'Astrophysique de Grenoble (France)

Integrated optics spectro-interferometers, thanks their compacity and robustness, are well adapted for reducing size and weight of spatial spectrometers. One of the main type of integrated optics spectrometers is based on the dispersed mode. Following the principle of Grating Waveguide Structures, we extract the optical signal from a channel waveguide using a diffraction grating, made by Focused Ion Beam, that records nano-grooves periodically along the waveguide. Then an optical relay allows us to obtain the wavelength spectrum on the Fourier plane of a first cylindrical lens, two others cylindrical lens permit to get an achromatic system.

Using this approach, we have developed a 3T and 4T spectro-interferometer than can be used to combine and spectrally study signal coming from several telescopes. Indeed it's possible to extract the signal of two close waveguides and defocus the first cylindrical lens. This allows to get a wide area on the detector and in the area of overlapping of this two (or multiple) spots the light coming from the two (or multiple) waveguides will generate interference fringes.

The waveguides are realised using X-cut, Y-propagating Lithium Niobate. This allows us to get a strong angular separation of the TE and TM diffracted modes (due to the different effective index of the two modes), and using the electro-optic properties we are able to integrate a delay line in our chip by adding electrodes near the waveguides. We can thus scan and center the zero-optical path delay between the different entries and obtain in the detector the non-redundant fringes as a function of wavelength. This permit us to get a very compact system (the chips is 4cm long).

The device allows to obtain non-redundant interference fringes up to 4 Telescopes by extracting light from channel waveguides using surface gratings, which spectrally disperse the signal. The interference pattern is obtained on the detector by overlapping the light extracted from above the waveguide using a cylindrical relay optics. The whole system is contained in a volume <1L.

We will present the 3T and 4T results of our system, in the near IR (centered at 1.55um): grating extraction efficiency, spectral domain and resolution trade-off, related to the detector characteristics.

Novel multi-telescope beam combiners for next generation instruments (FIRST/SUBARU)

Guillermo Martin, Institut de Planétologie et d'Astrophysique de Grenoble (France); Florent Gardillou, Cedric Cassagnettes, Denis Barbier, Teem Photonics S.A. (France); Clement Guyot, Jérôme Hauden, iXBlue SAS (France); Elsa Huby, Univ. de Liège (France); Sylvestre Lacour, Observatoire de Paris (France) and Lab. d'Etudes Spatiales et d'Instrumentation en Astrophysique (France)

Integrated optic devices are nowadays achieving extremely good performances in the field of astronomical interferometry, as shown by PIONIER or GRAVITY silica/silicon-based instruments, already installed at VLTI. In order to address other wavelengths, increase the number of apertures to be combined and eventually ensure on-chip phase modulation, we are working on a novel generation of beam combiners, based on the hybridization of glass waveguides, that can ensure very sharp bend radius, high confinement and low propagation losses, together with lithium niobate phase modulators and channel waveguides that can achieve on-chip, fast (>100kHz) phase modulation. The work presented here has been realized in collaboration with our technological partners TeemPhotonics for glass waveguides and iXBlue-PSD for lithium niobate phase modulators. We will present our results on a hybrid glass/niobate (passive/active) beam combiner, that has been developed in the context of FIRST/SUBARU 9T beam combiner (See Huby et al.). The combiner is structured in three parts: a) the first stage (passive glass) achieves beam splitting from one input to eight outputs, and that for nine input fibers coming from the sub-apertures of the Subaru telescope ; b) the second stage consists on a 72 channel waveguides lithium niobate phase modulator in a push-pull configuration that allows to modify on-chip the relative phase between the 36 pairs of waveguides ; c) a final recombination system of Y-junctions (passive glass) that allows to obtain combination of each input to every other one. The aim of this presentation is to discuss different issues of the combiners, such as transmission, birefringence, half-wave voltage modulation and spectral range.

9907-118, Session PSTh

Recent results on photonic devices made by laser writing: 3D 3T near IR waveguides, mid-IR spectrometers, and electro-optic beam combiners

Guillermo Martin, Institut de Planétologie et d'Astrophysique de Grenoble (France); Javier Rodríguez Vázquez de Aldana, Univ. de Salamanca (Spain); Airán Ródenas, Univ. Rovira i Virgili (Spain); Ciro d'Amico, Razvan Stoian, Lab. Hubert Curien (France)

Direct laser writing is a powerful technique for the development of astrophotonic devices, namely by allowing 3D structuring of waveguides and structures. One of the main interests is the possibility to avoid in-plane crossings of waveguides, that can induce losses and crosstalk in future multi-telescope beam combiners. We will present our results in 3D three

telescope beam combiners in the near infrared, that allow for phase closure studies. Besides, laser writing can be used to inscribe a grating over long distances along the waveguide direction. This can be used as an on-chip diffraction grating or as a way to sample a stationary wave that can be obtained in the waveguide. Thus, integrated optics spectrometers based on the SWIFTS concept (stationary wave integrated Fourier transform spectrometer) have been realized and characterized in the mid infrared using commercial chalcogenide glasses. Finally, we will also present our results on laser writing on electro-optic materials, that allow to obtain waveguides and beam combiners that can be phase-modulated using electrodes. We have focused our work on two well known materials: Lithium Niobate, that allows for TM waveguides and has a high electro-optical coefficient, and BGO, that has a lower coefficient, but presents the advantage of being isotropic, guiding both TE & TM polarizations identically.

9907-119, Session PSTh

An integrated-optic single-mode photonic nuller: development and on-sky testing

Barnaby R. Norris, The Univ. of Sydney (Australia); Nick Cvetojevic, The Univ. of Sydney (Australia) and Australian Astronomical Observatory (Australia) and Ctr. for Ultrahigh bandwidth Devices for Optical Systems (Australia); Simon Gross, Alexander Arriola Martiarena, Macquarie Univ. (Australia) and Ctr. for Ultrahigh bandwidth Devices for Optical Systems (Australia); Peter G. Tuthill, The Univ. of Sydney (Australia); Jonathan S. Lawrence, Australian Astronomical Observatory (Australia); Michael J. Withford, Macquarie Univ. (Australia) and Ctr. for Astronomy, Astrophysics & Astrophotonics (Australia) and Ctr. for Ultrahigh bandwidth Devices for Optical Systems (Australia); Samuel N. Richards, The Univ. of Sydney (Australia) and Australian Astronomical Observatory (Australia) and ARC Ctr. of Excellence for All-sky Astrophysics (Australia); Michael Goodwin, Jessica R. Zheng, Australian Astronomical Observatory (Australia)

Ultra-high angular resolution, high-contrast imaging is crucial to many key areas of astronomy, including direct imaging of exoplanets and protoplanetary disks. However achieving high-contrast observations at or beyond the telescope diffraction-limit from ground-based telescopes - even with advanced AO systems - is extremely challenging. Pupil-segmenting interferometry and coronagraphy both have their limitations. Coronagraphy is limited by the inner-working angle of the device, and while interferometry has no strict inner-working angle it struggles to reach the needed contrasts due to mixing of the faint planet/disk light with the bright starlight.

Nulling interferometry addresses both these problems. Like a conventional interferometer it can perform super-diffraction limited imaging, but like a coronagraph it rejects the unwanted starlight in favour of the fainter science signal (from the disk or planet). This is achieved by destructively interfering the starlight with itself. Conventional nulling interferometry is an established technique, but a new generation of photonic nullers is poised to revolutionise the field.

Here we present a photonic nulling interferometer based upon an integrated photonic device manufactured using ultrafast laser inscription. Two sub-apertures on opposite sides of the telescope pupil are optimally injected - via steerable segments of a MEMS segmented deformable mirror and microlens array - into two single-mode waveguides of the photonic device. Each waveguide first encounters a Y-splitter inscribed within the chip, which splits off some of the light for simultaneous photometric measurements. The majority of the light continues to propagate along two (path-length matched) waveguides, which are then interfered via a (directly inscribed) evanescent coupler. The two outputs of the coupler are then routed to the output face. These four outputs are butt-coupled into single-mode fibres and sent to sensitive photodetectors.

By adding a pi phase shift to one input waveguide (via the MEMS mirror), destructive interference takes place in the coupler, and the null appears at one output waveguide (and the constructive interference at the other). By measuring the null depth and the coupling efficiency (using the photometric channels) as a function of time, the astrophysical null can be determined via a statistical analysis, revealing spatial information on the astrophysical object.

Performing nulling using a single mode fibre or waveguide offers greatly improved precision over bulk optics due to their spatial filtering properties. The instrument described here offers further advantages over optical-fibre based designs. It offers increased stability over bulk fibres, with critically optical-path-length matched routes taking place within waveguides inscribed within a solid glass chip. Photonic Y-splitters allow photometric measurements to be made simultaneously with the null measurements, avoiding the time-lag between null and photometry experienced when using a chopper wheel. Both the nulled (destructive) and the bright (constructive) channels are measured, providing extra data to constrain the astrophysical null. Critically, this design is easily scalable, with multiple nulling channels - and subsequent recombination to perform closure-phase nulling - able to all be fabricated in a single photonic chip.

Here, we will describe the instrument and present the results of laboratory characterisation and on-sky tests made at the 3.9m Anglo-Australian Telescope.

Interferometric field-of-view measurements at the VLTI

Christian Hummel, European Southern Observatory (Germany); Antoine Mérand, European Southern Observatory (Chile); Jean-Baptiste Le Bouquin, Institut de Planétologie et d'Astrophysique de Grenoble (France) and Univ. Joseph Fourier (France)

In August 2014 we performed technical observations at the VLTI with the AMBER and PIONIER beam combiners to measure the interferometric field of view (FOV). As targets we included binaries with component separations between 100 and 300 mas, for which orbits and/or interferometric speckle measurements are available from the Washington Double Star databases or from the literature. The analysis included effects such as bandwidth and time smearing of the interferograms, and photometric attenuation due to the seeing and image quality based on a new formalism of the ESO Exposure Time Calculators. We also consulted the literature for results of interferometric surveys such as the SMASH survey by H. Sana et al. 2014 to estimate the effective FOV for these instruments. Based on our analysis, we conclude that emission outside a FOV diameter of 160 mas will be significantly supressed if not completely invisible. These results provide important information as to the size of the source structure to be included when modeling interferometric data obtained with these instruments.

High-spectral resolution for all! Recovering full spectral 3D images from observations at uniform correlated magnitude

Férréol Soulez, Ecole Polytechnique Fédérale de

Lausanne (Switzerland); Eric Thiébaut, Michel Tallon, Isabelle Tallon-Bosc, Paul Berlioz-Arthaud, Observatoire de Lyon (France)

Sensitivity is one of the major issue of optical interferometry as it prevents interferometers access to a broader community (eg: AGN, exoplanets…). This prevents the observation not only of faint targets but also of well resolved object (like giant stars) star with large baselines. This curse plagues many objects as bright enough targets are often well resolved.

It is a major challenge especially for any future interferometer with long baselines like PFI.

Reducing the spectral dispersion is a way to mitigate the problem by increasing the number of incident photons per pixels. Unfortunately, this is at the cost of a precious astrophysical spectral information. Furthermore, inside such broad spectral channels, the variation of flux ratio between structures (e.g. star, shell…) implies a strong chromatic effect in the visibilities that may forbid astrophysical interpretations (Kluska, 2014). To address this problem, we propose a new observation mode for interferometric imaging: varying the spectral resolution with the baseline in order to keep similar fringe SNR whatever are the object visibilities and then making image reconstruction at the full spectral resolution using adapted priors.

In the present work, we demonstrate that it is not necessary to make all measurements with same spectral dispersion to recover image at the full spectral resolution. In this observation mode, the low frequencies are measured at full spectral resolution whereas the high frequencies are measured on broader bands. The estimation of the missing high frequency spectral information is done by the image reconstruction algorithm using regularization functions enforcing adapted spatio-spectral priors. These regularization tend to correlate high frequencies across the bandwidth. This is justified by the fact that, in most cases, spatial variations of spectrum are correlated with a variation of surface brightness in a broader band. As a consequence, a precise estimation of high spatial frequencies in broadband can be used as priors to determine high frequencies in each spectral channel.

Such joint reconstructions are already done in other fields (color imaging, remote sensing, microscopy,…) and we are convinced this will give the possibility to use large baselines even for well resolved objects and will be a step toward future kilometer long baselines interferometers like PFI.

Effective a posteriori co-phasing of interferometric fringe data

Antony Schutz, Ctr. de Recherche Astronomique de Lyon (France) and Lab. J.L. Lagrange (France); Éric M. Thiébaut, Ctr. de Recherche Astronomique de Lyon (France); Férréol Soulez, Ecole Polytechnique Fédérale de Lausanne (Switzerland); Michel Tallon, Ctr. de Recherche Astrophysique de Lyon (France) and Obvservatoire de Lyon (France); Gilles Duvert, Institut de Planétologie et d'Astrophysique de Grenoble (France); Isabelle Tallon-Bosc, Ctr. de Recherche Astronomique de Lyon (France)

We have recently shown that a posteriori co-phasing of multi-spectral interferograms was possible (Soulez et al., 2014). In this contribution, we develop the means to extend our approach so that it can be applied to actual data as provided by AMBER or MATISSE instruments. The main advantage of the proposed post-processing technique is that it requires no modifications of the instruments and yield interferometric observables with higher SNR and much fewer unknowns (in particular for the Fourier phase) than conventional measurements. In order to perform the co-phasing of a complete sequence of interferograms, we jointly estimate a global phase template and the frame dependent optical path errors due to the turbulence.

While the chromatic aspect of the analysis (or data) helps to fit the chromatic turbulence phase shift model, the adaptive behavior of the template update allow to recover the phase up to the initial reference.

We show that this strategy is effective for very low SNR data. After this initial co-phasing stage, we derive the amplitude and the phase of a chromatic complex visibility accounting for all the photometric and interferometric frames of a sequence. This complex visibility is the maximum likelihood estimator of the uncalibrated complex visibility of the object up to a low rank phase aberration and carries more information than conventional interferometric observables. We assess the effectiveness of our method on simulated and actual AMBER data. We also compare the lowest SNR that can be achieved to the theoretical bounds and estimate the gain in sensitivity compared to usual interferometric data.

Real-time piston variation reconstruction with wavefront sensor data

Qiang Fu, Max-Planck-Institut für Astronomie (Germany) and Institute of Optics and Electronics (China); Jörg-Uwe Pott, Diethard Peter, Max-Planck-Institut für Astronomie (Germany)

Atmospheric piston variation as observed by AO: The scientific goal is to increase the sensitivity of an adaptive optics (AO) supported optical interferometer (like the VLTI) to observe larger, statistically relevant samples of rare objects, like massive young stars, and AGN as well as to reach new target classes like brown dwarfs and microquasars, currently out of reach for optical interferometry. To do so, we propose to increase the sensitivity by deriving the time-variable atmospheric piston drift from AO-data, and therefore increasing the coherence time by up to two orders of magnitude over the currently implemented approach of direct fringe tracking. This in turn allows for much longer coherent integration times on the beamcombining camera. This new approach uses the time series of AO wavefront information to reconstruct the atmospheric piston variation.

The core of the algorithm derives the dominating wind speed and direction, using the frozen atmosphere approximation, and has been demonstrated to work with multi?layer atmospheric simulations. Combining wind and atmospheric tilt information then gives the piston drift. A key advantage is that no additional hardware is needed, if the interferometer is already equipped with a piston?neutral AO system and with fast delay line fringe tracker actuators as is the case for the VLTI. The initial goal is to apply the algorithm to MATISSE operation and to address GRAVITY in a second stage, since the longer operating wavelengths of MATISSE (3-10micron) pose lower requirements on the fringe tracking precision. Ideally this technique is combined with advanced accelerometer-based telescope vibration sensing (see contributions by M. Glück et al. and M. Böhm et al. to this SPIE), since telescope vibrations are the second dominant fringe motion disturbance, besides the atmosphere.

9907-124, Session PSTh

Image restoration for a hypertelescope

Yuto Nakai, Hokkaido Univ. (Japan); Naoshi Baba, Hokkaido Univ. (Japan) and Muroran Institute of Technology (Japan); Naoshi Murakami, Hokkaido Univ. (Japan); Noriaki Miura, Kitami Institute of Technology (Japan); Motohide Tamura, The Univ. of Tokyo (Japan) and National Astronomical Observatory of Japan (Japan)

In order to resolve exoplanets an effective aperture with several tens or more kilometers is needed. A hypertelescope consists of many elemental telescopes like an interferometric array. The beams from the elemental telescopes are enlarged and arranged compactly on the imaging lens to

form the snap-shot image. This procedure is referred to densification. This densification works to concentrate energy to form the image, otherwise the energy is distributed to periodically formed images. When quite a large number of elemental telescopes are available, a high-quality image is obtained. However, in practice, a limited number of elemental telescopes will be employed for the sake of the cost reduction. In this respect non-redundant arrays are preferable.

Snap-shot images formed with a limited number of elemental telescopes, however, do not exhibit high quality features, because the spatial frequency sampling is not dense enough to image properly exoplanets. Some image restoration should be implemented to reveal the surface structures of exoplanets.

A non-redundant array with 20 telescopes is postulated as a model of hypertelescope and an image of Jupitar as an object in our computer simulation. The pupil densification is conducted as a full spectrum densification (FSD) mode (Aime et al. (2012) A&A 543, A42). It is supposed that the object cannot be resolved with each elemental telescope. One of annoying problems in hypertelescope image restoration is shift-variant characteristic of PSF that is caused by the pupil densification. The CLEAN algorithm manages to restore images formed with shift-variant PSF. On the other hand pre-processing to a raw image can transform the shift-variant characteristic into the shift-invariant one. In such a case we can employ commonly used Wiener filtering and Richardson-Lucy algorithm.

We evaluate the quality of a restored image with root-mean-square-error (RMSE) . The CLEAN algorithm works well for the noise-less image. For noisy images the pseudo

Wiener filtering seems to restore better the pre-processed ones. We show the image restoration results and the effectiveness of the image restoration.

9907-125, Session PSTh

Rotation and translation registration of bandlimited interferometric images using a chirp z-transform

Alexander S. Iacchetta, James R. Fienup, Univ. of Rochester (United States); David T. Leisawitz, NASA Goddard Space Flight Ctr. (United States)

Sparse aperture, interferometric imaging techniques often rely on rotations of the interferometer (or the object) in order to sufficiently sample the spatial frequencies of the object such that an artifact-free image of the source can be computed from the measurements. For the case of spatio-spectral imaging interferometry, image reconstruction algorithms require that all rotations and translations are known well enough to register the measured low-resolution images to within the resolution of the desired high-resolution image to be recovered. Despite measurements of the rotation angles between the source and the interferometer, experimental effects, including image motion from temperature fluctuations, will prevent precise knowledge of the registration parameters, including image translations between measurements and errors in rotation angles. Other factors associated with an experimental testbed, such as NASA's wide-field imaging interferometry testbed (WIIT), cause the image on the detector to shift as a function of the interferometer's baseline length. In order to obtain precise estimates of the registration parameters without prior information of objects within the field-of-view, the image rotation must be simulated accurately. Because the measured images are bandlimited by the interferometer's imaging system, Fourier-domain image rotation algorithms can be applied to the images without introducing aliasing artifacts. As a result, a chirp z-transform can be applied to the image to simultaneously perform arbitrary rotation, translation, and down-sampling. We combine the chirp z-transform and nonlinear optimization to create an image registration algorithm, incorporating a multi-step procedure to improve the accuracy of the retrieved registration parameters. Included is the result of image registration of simulated images that are representative of scenes measured by WIIT. This image registration procedure will ultimately improve the high-resolution hyperspectral output of image synthesis algorithms for wide-field interferometric imaging.

Image reconstruction method IRBis for optical/infrared long-baseline interferometry

Karl-Heinz Hofmann, Matthias Heininger, Dieter Schertl, Gerd Weigelt, Max-Planck-Institut für Radioastronomie (Germany); Florentin Millour, Philippe Bério, Observatoire de la Côte d'Azur (France)

We will present IRBis, an image reconstruction method for optical/infrared long-baseline interferometry. IRBis is part of the MATISSE pipeline. IRBis can reconstruct images from a) measured visibilities and closure phases, or from b) measured complex visibilities (i.e. the Fourier phases and visibilities). The applied optimization routine ASA_CG is based on conjugate gradients. The method allows the user to implement different regularizers, as for example, maximum entropy, smoothness, total variation, etc., and apply residual ratios as an additional metric for goodness-of-fit. In addition, IRBis allows the user to change the following reconstruction parameters: (a) FOV of the area to be reconstructed, (b) the size of the pixel-grid used, (c) size of a binary mask in image space allowing reconstructed intensities > 0 within the binary mask only, (d) the strength of the regularization, etc.. The two main reconstruction parameters are the size of the binary mask in image space (c) and the strength of the regularization (d). Several values of these two parameters are tested within the algorithm. The quality of the different reconstructions obtained is roughly estimated by evaluation of the differences between the measured data and the reconstructed image (using the reduced chi^2 values and the residual ratios). The best-quality reconstruction and a few reconstructions sorted according to their quality are provided to the user as resulting reconstructions. We will describe the theory of IRBis and will present several applications to simulated interferometric data and data of real astronomical objects observed with the VLTI-AMBER instrument. We investigate, for example, image reconstruction of MATISSE target candidates by computer simulations. We have modeled gaps in a disk of a young stellar object and have simulated interferometric data (squared visibilities and closure phases) with a signal-to-noise ratio as expected for MATISSE observations. We have performed image reconstruction experiments with this model for different flux levels of the target and different amount of observing time, that is, with different uv coverages. As expected, the quality of the reconstructions clearly depends on the flux of the source and the completeness of the uv coverage. We will show also reconstructions obtained from observations of real astronomical targets. We will present reconstructions of the Luminous Blue Variable Eta Carinae obtained from AMBER observations in the high spectral resolution mode in the K band. We obtained diffraction-limited reconstructions of Eta Car in all spectral channels (~64 channels) of the high spectral resolution (R~12000) observation of the Brackett Gamma line.

9907-127, Session PSTh

High fidelity imaging of geosynchronous satellites with MROI

John S. Young, Christopher A. Haniff, David Buscher, Univ. of Cambridge (United Kingdom); Michelle J. Creech-Eakman, Ifan Payne, Magdalena Ridge Observatory (United States)

Interferometry provides the only practicable way to image satellites in Geosynchronous Earth Orbit (GEO) with sub-meter spatial resolution.

The Magdalena Ridge Observatory Interferometer (MROI) is being funded by the US Air Force Research Laboratory to demonstrate the 9.5 magnitude sensitivity (at 2.2 micron wavelength) and baseline-bootstrapping capability that will be needed to realise a useful turn-key GEO imaging capability. This program will utilise the central three telescopes of the MROI and will aim to validate routine acquisition of fringe data on faint well-resolved targets.

In parallel with this effort, the University of Cambridge are investigating the spatial resolution and imaging fidelity that can be achieved with different numbers of array elements. We present preliminary simulations of snapshot GEO satellite imaging with 4-, 7-, and 10-telescope deployments of MROI, and show the improvements in the recovered image obtained by combining contemporaneous low-spatial frequency measurements from a filled aperture telescope with the MROI data.

Our results indicate that faithful imaging of the main satellite components can be obtained with as few as 7 unit telescopes, and that increasing the number of telescopes to 10 improves the effective spatial resolution from 0.75 metre to 0.5 metre and enables imaging of more complex targets.

9907-128, Session PSTh

Kernel phase and kernel amplitude in optical imaging

Benjamin J. S. Pope, Univ. of Oxford (United Kingdom)

Kernel phase interferometry is a technique for high angular resolution in Fizeau interferometry, extending the idea of closure phases to redundant pupils to obtain the high signal-to-noise needed to detect faint companions close to their host stars. I will discuss recent work demonstrating kernel phase from the ground with the P3K AO system on the Palomar Hale 200-Inch Telescope, producing results comparable to aperture masking. I will present a generalization of the idea of kernel phases to calibrating amplitude errors, including atmospheric scintillation, residual amplitude aberrations from advanced AO techniques, and differential throughput across the optical path. This is a stepping stone towards extending the theory of optical self-calibration to more advanced optical systems, potentially even including coronagraphs. I will also discuss simulations of kernel phase, kernel amplitude and their application to JWST and WFIRST-AFTA.

9907-129, Session PSTh

Interbands phase models for polychromatic image reconstruction in optical interferometry

Antony Schutz, André Ferrari, Observatoire de la Côte d'Azur (France) and Lab. J.L. Lagrange (France); Éric M. Thiébaut, Ctr. de Recherche Astronomique de Lyon (France); Férréol Soulez, Ecole Polytechnique Fédérale de Lausanne (Switzerland); Martin Vannier, David Mary, Observatoire de la Côte d'Azur (France) and Lab. J.L. Lagrange (France)

Astronomical optical interferometers (OI) sample the Fourier transform of the intensity distribution of a source at the observation wavelength. Because of rapid atmospheric perturbations, the phases of the complex Fourier samples (visibilities) cannot be directly exploited, and instead linear relationships between the phases are used (phase closures and differential phases). Consequently, specific image reconstruction methods have been devised in the last few decades. Modern polychromatic OI instruments are now paving the way to multi-wavelength imaging. This paper presents a variation of a spatio-spectral ("3D") image reconstruction algorithm called PAINTER (Polychromatic opticAl INTErferometric Reconstruction software). In its later form, the algorithm is able to solve large scale problems. It relies on an iterative process, which alternates estimation of polychromatic images and of complex visibilities. The complex visibilities are not only estimated from squared moduli and closure phases, but also from differential phases, which help to better constrain the polychromatic reconstruction:

• the closure phases are estimated by the mean of three bases phases estimation which are "closed" at a given wavelength. As a results, a closure phases helps to constrain the phases estimation of three bases at a given wavelength.

• The differential phases, difference of phase between wavelength for a given base, helps to constrain the problem of phases estimation between wavelengths. ?The objective of this communication is to improve the phase estimation step taking into account more realistic constraint in the phases estimation process. ?In the first version of PAINTER, the differential phases are computed using a single reference per spectral channel. In this case, the differential phases corresponding to two distant spectral channels may be affected by the atmospheric turbulence.

We propose in this communication to define new turbulent independent differential phases. This is achieved using multiple phase references across all the bandwidth.

Two solutions are proposed and the condition numbers related to the inverse problem that needs to be solved are studied in both cases. The benefits of the proposed modifications are illustrated by image reconstruction results

A method to assess the quality of reconstructed interferometric images

Nuno Gomes, Univ. do Porto (Portugal) and Univ. de Lisboa (Portugal); Paulo J. V. Garcia, Univ. do Porto (Portugal); Éric M. Thiébaut, Observatoire de Lyon (France)

We present a method to assess the quality of restored interferometric images, in which we take into account the resolution of the interferometer prior to image comparison.

Three type of astronomical objects (stellar cluster, young stellar object and stellar photosphere) are mock observed with VLTI configurations, and their images are reconstructed using MiRA.

We consider the most common merit functions to quantify the quality of the images, including the interferometry imaging beauty function and the ALMA fidelity function.

The major difference for other methods is that the reference image is convolved with a Gaussian effective PSF before quality assessment with the aforementioned metrics. By taking into account the resolution of the interferometer, this method prevents wrong classifications of images when compared with each other.

Following the work by Gomes et al 2014, we use this methodology to infer in which conditions phase referencing and phase closure techniques yield similar restored images, when the observations are spanned during a fixed number of nights but using a different number of telescopes in each scenario. We demonstrate that when the (u, v)-space is judiciously chosen, phase referencing and phase closure techniques yield similar results.

Imaging methods for PFI

Fabien Baron, Georgia State Univ. (United States); John D. Monnier, Univ. of Michigan (United States)

Unlike the current generation of interferometers, the Planet Formation Imager (PFI) shall often work in a regime where a very large number of (u,v) points of relatively low SNR will be collected. Current image reconstruction codes are ill-adapted to such a reconstruction task. As the number of terms in likelihood is at least an order of magnitude larger than current data sets (especially if essential data correlations are taken into account), all software suffer from slow performance. Moreover, the reconstruction fidelity offered by conventional regularizers (e.g. total variation) also appears to be poor for typical PFI targets. We explore here possible solutions to both the likelihood and regularization issues.

User-friendly imaging algorithms for interferometry

John S. Young, Univ. of Cambridge (United Kingdom); Éric M. Thiébaut, Ctr. de Recherche Astronomique de Lyon (France); Gilles Duvert, Institut de Planétologie et d'Astrophysique de Grenoble (France); Martin Vannier, Observatoire de la Côte d'Azur (France); Paulo J. V. Garcia, Univ. do Porto (Portugal)

The scientific exploitation of the current and planned generations of interferometric instruments clearly depends on their imaging capabilities. Hardware developments such as combining more telescopes and developing phase referenced acquisition of the fringes will yield significant improvements. On the software side, many successful image reconstruction algorithms have been developed for optical/IR interferometry. However, successfully using these algorithms requires a high level of expertise, strongly restricting the number of potential users. OPTICON currently supports a Joint Research Activity (JRA) dedicated to providing easy to use image reconstruction algorithms for optical/IR interferometric data. The objectives of this JRA are to provide to the community a number of state-of-the-art image reconstruction methods with a common interface and with comprehensive documentation. We will present the tools developed by the JRA and make a demonstration of their usage. Our idea is to encourage users to consider image reconstruction as a data processing task. This implies that they will require the capability to compare the results of using different settings and algorithms in a consistent and unified way. The JRA has therefore designed a common framework for image reconstruction in order to unify the formats of the input and output data, and also the settings and control of the various algorithms. Exploiting this framework a common graphical user interface has been built. Currently BSMEM, MiRA and WISARD have been updated to use this framework and have been made available to the community. The proposed infrastructure is flexible and can accommodate the later addition of other existing and future imaging algorithms. The JRA is also providing tutorials and data samples to introduce the principles of image reconstruction and illustrate how to use the software products.

Cross verification of 450+ stellar calibrators observed with VLTI/PIONIER

Antoine Mérand, Steve Ertel, Henri M. J. Boffin, Alexandre Gallenne, European Southern Observatory (Chile); Lindsay Marion, Olivier Absil, Univ. de Liège (Belgium)

We have analysed 450+ stellar calibrators taken on several observing programs of VLTI/PIONIER. The goal of the present work is to identify calibrators with stellar companion and/or resolved flux which can bias the final calibrated visibilities. To do so, we used an iterative process using cross-calibration and the companion detection tool CANDID. We present the method and the first results. This work can be the basis of a verified database of calibrators for optical interferometry.

9907-135, Session PSTh

An interferometric view of binary stars

Henri M. J. Boffin, European Southern Observatory (Germany)

Stars tend to form and live in binaries, with the fraction of binary stars being higher for more massive stars: the binary fraction increases from 25–30 % for M dwarfs and about 50% for solar-like stars, to more than 70% for B and O stars. Moreover, a significant fraction of these binary stars will interact in one way or another during their evolution. Mass transfer will affect the chemical composi?tion of the companion, which can for example become polluted in processed elements like in Algols or in Barium stars. It also leads to a mass increase of the companion, with sometimes strong consequences, such as blue straggler stars or Type Ia supernovae. Finally, mass transfer has also an impact of the evolution of the orbital separation. The study of binary stars is therefore critical to apprehend many of the most interesting classes of stars. Moreover, quite often, the study of stars in binary systems is our only mean to constrain stellar properties, such as masses and radii. Unfortunately, a great fraction of the most interesting binaries are so compact that they can be apprehended by high-resolution techniques only, and most recently by interferometry. I will present some results highlighting how interferometry is used in the study of binary stars, from finding companions and deriving orbits, determining the mass and radius of stars, to studying mass transfer in symbiotic stars, and tackling luminous blue variables. In particular, I will show how interferometric studies have allowed us to confirm a dichotomy within symbiotic stars, obtain masses of stars with a precision better than 1% and thereby serve as benchmark for future GAIA results, and help us find a new eta Carinae-like system. I will also illustrate the benefits for the study of binary stars one would get from upgrading the VLT Interferometer so as to be able to observe in the visible range.

9907-136, Session PSTh

Stellar physics in the mid-infrared with MATISSE

Florentin Millour, Observatoire de la Côte d'Azur (France); Josef Hron, Univ. of Vienna (Austria); Gerd Weigelt, Max-Planck-Institut für Radioastronomie (Germany); Andrea Chiavassa, Philippe Bendjoya, Pierre Cruzalebes, Observatoire de la Côte d'Azur (France); William C. Danchi, NASA Goddard Space Flight Ctr. (United States); Armando Domiciano de Souza, Thierry Lanz, Observatoire de la Côte d'Azur (France); Karl-Heinz Hofmann, Max-Planck-Institut für Radioastronomie (Germany); Bruno Lopez, Alexis Matter, Anthony Meilland, Nicolas Nardetto, Gilles Niccolini, Observatoire de la Côte d'Azur (France); Claudia Paladini, Univ. Libre de Bruxelles (Belgium); Romain G. Petrov, Observatoire de la Côte d'Azur (France); Anthony Soulain, Philippe Stee, Frédéric Thévenin, Farrokh Vakili, Observatoire de la Côte d'Azur (France); Dieter Schertl, Max-Planck-Institut für Radioastronomie (Germany)

We will present science projects that can be performed in the field of stellar physics with the MATISSE instrument. MATISSE is the second-generation mid-infrared instrument of the VLTI. MATISSE, with its milli-arcsecond resolution imaging capabilities, its spectral resolution of up to 5000, and the opening of the L and M bands (3.5-5.5 microns), will give access to unprecedented angular resolution spectro-interferometric-images of a variety of stellar objects. We will show detailed aperture-synthesis image reconstruction experiments performed with realistic

simulations of MATISSE data (e.g., uv coverage, target brightness, field-of-view) to illustrate the expected performance of MATISSE.

The strength of MATISSE is its capability to locate where the dust, molecular layers, and gas reside close to the stars. Studies of these regions are of great importance to improve our understanding of the mass-loss process, which is not yet well understood. Infrared spectro-interferometry provides a unique opportunity to probe the region in which mass outflows are initiated. The high spectral resolution mode will allow us to study the physics and kinematics of outflow regions with high spectral and high spatial resolution simultaneously (e.g., super-granulation, the kinematics of large-scale clouds in the atmosphere of supergiants, stellar winds from hot stars, wind collision regions in hot binaries). Examples of targets include Cepheids, AGB stars, red and blue supergiant stars, Luminous Variable stars, Be stars, and dusty Wolf-Rayet stars.

9907-137, Session PSTh

Model fitting of dusty pinwheel nebulae WR104: probing inner part with interferometry

Anthony Soulain, Florentin Millour, Bruno Lopez, Observatoire de la côte d'azur (France)

Wolf-Rayet stars are luminous massive blue star with strong and optically thick stellar wind. They are the immediate precursor of the supernovae type II. This strong wind exerts a major influence on their immediate surroundings, and play a dominant role in the evolution of their host galaxies. As a consequence, these stars show many lines of nitrogen and helium for WN stars and of carbon, oxygen and helium for WC stars. WC8 and WC9 exhibit a strong infrared excess triggered by hot and warm dust (Allen et al. 1972), produced by the central source while this is not the case in WN stars. These WR dust makers are few but remarkable in terms of the absolute dust-formation rate they exhibit. The wind-wind collisions in WR+O in such system offer ideal condition to reach critical densities to produce dust pattern observe around some Pinwheel nebulae (WR104, WR98a or WR118). The prototype star WR104 is the most studied pinwheel nebula to date (Tuthill et al. 2006). It was discovered as a "pinwheel" dusty nebula by Tuthill (1999) and subsequently observed in a follow-up series of observations (Tuthill et al. 2008), confirming its binarity and refining most of its parameters. These atypical dust shell are a remarquable problem for modeling and theory of dust production, some hydrodynamical and radiative transfer model was made to explain the Pinwheel pattern around the prototype WR104 (Harries et al. 2004; Lamberts et al. 2012). In lines of these studies, we used new interferometric data available in VLTI to study WR104 with the highest resolution. We used AMBER, the near-infrared focal instrument of the VLTI, which operates in the bands J, H, and, K (1.0 to 2.4 μm). AMBER can take profite of spectral information to probe an importante part of (u-v) plan. We will present the fitting software used which exploits a geometrical model of Pinwheel made of a succession of rings. We add an unresolved central point to explain increase of visibility observed in H band. This unresolved source could well be the central binary star. Furthermore, the AMBER data reveal that the pinwheel is diluted by diffuse emission in the system. The different model's parameters are difficult to constrain due to the relatively sparse (u-v) coverage available. Nevertheless, we developed different model and fitting method to interpret futur interferometry data. We present also the future possibilities of the next generation of interferometer MATISSE, curently developed in Nice, France. This new instrument will be able to observe in L and N band. For the first time, we will produce images in thermal infrared. Wolf-Rayet star and dusty producers are one of the scientific objective of this instrument.

9907-138, Session PSTh

Direct temperature map estimation in optical long baseline interferometry

Férréol Soulez, Ecole Polytechnique Fédérale de Lausanne (France); Eric M. Thiébaut, Ctr. de Recherche Astronomique de Lyon (France) and Observatoire de Lyon (France); Jacques Kluska, Univ. of Exeter (United Kingdom); Michel Tallon, Ctr. de Recherche Astrophysique de Lyon (France) and Observatoire de Lyon (France); Anthony Schutz, Observatoire de la Cote d'Azur (France) and Univ. Nice Sophia Antipolis (France); André Ferrari, Univ. de Nice Sophia Antipolis (France) and Observatoire de la Côte d'Azur (France) and Lab. J.L. Lagrange (France)

The arrival of 2nd generation beam combiners GRAVITY and MATISSE at the VLTI shed the light on the need of multispectral image reconstruction algorithm. Indeed, as they combine four telescopes with medium and high spectral resolution, it is now conceivable to use them as high spatial resolution integral field spectrograph by mean of image reconstruction. Image reconstruction is a very challenging problem. Recently, as part of the effort of the community to develop the research on multispectral image reconstruction the POLCA project gave birth to three methods : MiRA3D (Soulez et al, 2013), PAINTER (Schutz et al., 2014) and SPARCO (Kluska et al., 2014).

The reconstructed spatio-spectral data cubes give very valuable astrophysical information such as velocity, abundance or temperature map. It is important to notice that this astrophysical information represents often few estimated parameters per pixel (e.g. dispersion and mean velocity, temperature, relative abundance of few chemical elements,...) and lies only on a complex but small subspace (i.e. a manifold) of each spectra. Using this fact as priors to better contraint the reconstruction, our algorithm thus will provides directly a 2D map of parameters of astrophysical interest. Such an idea was already behind the principle SPARCO method that only estimates from polychromatic interferometric data a 2D image and a parametric model with different spectral index

In the presented work, we proposed the first method for reconstructing an objective temperature map from the interferometric polychromatic measurements. This approach is based on the MiRA3D algorithm in which we add the hypothesis that the spectrum of each pixel is described as a black body (or a combination of black bodies to take into account the variation of temperature within a pixel. This prior is enforced by constraining each spectra to be described by only few atoms of a dictionary using sparse coding technique (Mairal et al., 2010). This dictionary is built from a set of spectra of black bodies at different temperatures. This method has been successfully applied on the Herbig Be star HD98922. On the reconstructed temperature map, the temperature difference between the star and the surrounding environment is clear and the mean temperature of the disk is estimated to be 1670 K, very close to the one estimated from photometry.

9907-139, Session PSTh

Science with MATISSE

Sebastian Wolf, Univ. Kiel (Germany); Bruno Lopez, Observatoire de la Côte d'Azur (France); Jean-Charles Augereau, Institut de Planétologie et d'Astrophysique de Grenoble (France); Marco Delbo, Observatoire de la Côte d'Azur (France); Carsten Dominik, Univ. van Amsterdam (Netherlands); Thomas Henning, Max-Planck-Institut für Astronomie (Germany); Karl-Heinz Hofmann, Max-

Planck-Institut für Radioastronomie (Germany); Michiel Hogerheijde, Leiden Univ. (Netherlands); Josef Hron, Univ. Wien (Austria); Walter J. Jaffe, Leiden Observatory (Netherlands); Thierry Lanz, Observatoire de la Côte d'Azur (France); Klaus Meisenheimer, Max-Planck-Institut für Astronomie (Germany); Florentin Millour, Observatoire de la Côte d'Azur (France); Eric J. Pantin, CEA-Ctr. de SACLAY (France); Romain G. Petrov, Observatoire de la Côte d'Azur (France); Dieter Schertl, Max-Planck-Institut für Radioastronomie (Germany); Roy van Boekel, Max-Planck-Institut für Astronomie (Germany); Gerd P. Weigelt, Max-Planck-Institut für Radioastronomie (Germany)

MATISSE, the Multi Aperture Mid-Infrared SpectroScopic Experiment (Lopez et al. 2014), is foreseen as a mid-infrared spectro-interferometer combining the beams of up to four UTs/ATs of the Very Large Telescope Interferometer (VLTI). MATISSE will measure closure phase relations and thus offer an efficient capability for image reconstruction. In addition to this, MATISSE will open two new observing windows at the VLTI: the L and M band in addition to the N band. Furthermore, the instrument will offer the possibility to perform simultaneous observations in separate bands. MATISSE will also provide several spectroscopic modes with spectral resolutions up to 5000. These modes will provide unique insight in the physical properties and kinematics of line emitting gas regions, for example in the environment of YSOs and hot stars.

MATISSE will extend the astrophysical potential of the VLTI by overcoming the ambiguities often existing in the interpretation of simple visibility measurements. The existence of the four large apertures of the VLTI will permit to push the sensitivity limits up to values required by selected astrophysical programs such as the study of Active Galactic Nuclei and protoplanetary disks around low-mass stars. Moreover, the existence of ATs which are relocatable in position will allow the exploration of the Fourier plane with up to 200 meters baseline length. Key science programs using the ATs cover for example the formation and evolution of planetary systems, the birth of massive stars as well as the observation of the high-contrast environment of hot and evolved stars.

In most astrophysical domains which require a multi-wavelength approach, MATISSE will be a perfect complement of high angular resolution facilities. MATISSE covers the mid-infrared spectral domain, between the near-infrared domain, for which various high-angular resolution instruments are available (e.g., SPHERE/VLTI, PIONIER/VLTI) and submillimeter/millimeter wavelengths at which ALMA, the Atacama Large Millimeter Array, operates. With the extended wavelength coverage from the L to the N band, MATISSE will not only allow one to trace different spatial regions of the targeted objects, but also different physical processes and thus provide insights into previously unexplored areas, such as the investigation of the distribution of volatiles in addition to that of the dust.

Based on the general characteristics of MATISSE, we will present a general overview of the scientific potential of this instrument as well as selected case studies from various areas, such as star and planet formation, active galactic nuclei, evolved stars, extrasolar planets, and solar system minor bodies. We will discuss strategies for the planning and analysis of future MATISSE observations. Moreover, the impact of MATISSE observations in combination with complementary high-angular resolution observations at near-infrared and submillimeter/millimeter wavelengths will be highlighted.

9907-140, Session PSTh

Observing the PTPS sample of evolved exoplanet host candidates using the NPOI

Ellyn K. Baines, J. Thomas Armstrong, Henrique R. Schmitt, U.S. Naval Research Lab. (United States); Andrzej Niedzielski, Pawel Zielinski, Nicolaus Copernicus Univ. (Poland); Martin Vanko, Slovak Academy of Sciences (Slovakia); Alexander Wolszczan, The Pennsylvania State Univ. (United States)

We plan to measure the angular diameters of a sample of Penn State-Torun Planet Search (PTPS) giant exoplanet host star candidates using the Navy Precision Optical Interferometer. The radii of evolved giant stars obtained using spectroscopy are usually ill-defined because of the method's indirect nature and evolutionary model dependency. The star's radius is a critical parameter used to calculate luminosity and mass, which are often not well known for giant stars. Therefore, this problem also affects the orbital period, mass, and surface temperature of the planet. Our interferometric observations will significantly decrease the errors in these parameters.

9907-141, Session PSTh

Unveiling new stellar companions from the PIONIER exozodi survey: follow up

Lindsay Marion, Olivier Absil, Univ. de Liège (Belgium); Steve Ertel, European Southern Observatory (Chile); Jean-Baptiste Le Bouquin, Institut de Planétologie et d'Astrophysique de Grenoble (France); Denis Defrère, The Univ. of Arizona (United States); Tim Pearce, Institute of Astronomy (United Kingdom)

In 2012, we have conducted a survey of nearby main sequence stars with VLTI/PIONIER to search for the presence of circumstellar dust. This survey, carried out during 12 nights, comprised about 100 stars. For each star, we obtained typically three OBs and we searched for circumstellar emission based on the measurement of squared visibilities at short baselines. A drop in the measured visibilities with respect to the expected photospheric visibility indicated the presence of resolved emission around the target star. It was however generally not possible to conclude on the morphology of the detected emission based solely on the squared visibilities. This is why we focused on closure phases to search systematically for faint companions around the whole sample. In our method, we used the closure phases and the square visibilities in a combined way to provide a better systematic rejection of false positive detection.

We reached the conclusion that 4 out of our 13 candidate infrared excesses were actually binaries, which allowed us to identify a clean sample of 9 real excesses.This information also helped us to refine statistics about binaries in our neighborhood. Indeed, since the four binaries were A type stars, we came to the conclusion that 47% of A type stars are binaries in our neighborhood.In 2014, we carried out follow up observations of those targets to confirm that the four stars are bound binaries.Three of them were confirmed, and we found another previously unknown binary. Preliminary constraints on the orbits can be derived on the three companions imaged in 2012 and 2014. Only HD202730 remains ambiguous, as the companion detected in 2012 was not recovered in 2014. Kinematic constraints suggest that HD202730B could still be a bound companion to HD202730, but that it should have a semi-major axis of at least 0.93 AU. We cannot conclude about the eccentricity of this binary based on the existing data.

9907-142, Session PSTh

The optical interferometry data base: how to make the best use of reduced data

Xavier Haubois, European Southern Observatory (Chile); Guillaume Mella, Laurent Bourgès, Gilles Duvert, Jean-Baptiste Le Bouquin, Institut de Planétologie et d'Astrophysique de Grenoble (France); Denis Mourard, Observatoire de la Cote d'Azur (France)

The Optical interferometry DataBase (OiDB) aims at facilitating the access to science-ready data provided by various existing or decommissioned interferometers.

The first version of OiDB has been released in June 2015. Today it contains more than 5000 OIFITS datafiles including the full collection of PIONIER data since 2011. All these reduced data are made publicly available and easily downloadable by OiDB.

The OiDB conditions of use were designed so that the data user collaborates with the team that obtained the data. Fast metadata forms allow an efficient upload of data, making OiDB an ideal platform to diffuse interferometric data from any observatory. Moreover, OiDB also provides regularly updated observation logs from some CHARA instruments.

After presenting the characteristics of OiDB, we analyse how the community made use of it during this first year of operation. We will also show how new features make this tool more interactive, more connected to other virtual observatory tools and to article citations.

9907-143, Session PSTh

Searching for exozodiacal light around main sequence stars with JouFLU/CHARA

Paul D. Nunez, Jet Propulsion Lab. (United States) and California Institute of Technology (United States); Nicholas J. Scott, Georgia State Univ. (United States) and CHARA (United States); Bertrand P. Mennesson, Jet Propulsion Lab. (United States) and California Institute of Technology (United States); Theo A. ten Brummelaar, CHARA (United States) and Georgia State Univ. (United States)

JouFLU is the upgraded Fiber-Linked Unit for Optical Recombination, located at the CHARA array. The use of single-mode optical fibers of JouFLU allows removing atmospherically induced wave-front distortions (except for atmospheric piston), which results in more precise (~1%) visibility measurements. FLUOR was used by Absil et al. (2013) to search for near-infrared exozodiacal light in the vicinity (0.1 AU - 10 AU) of 42 main-sequence stars, and found 11 stars that display a K-band excess that is consistent with uniform extended emission. The circumstellar excess is likely attributed to hot circumstellar-dust, whose origin is still poorly understood.

Since 2013, JouFLU has been extending the survey and performing follow-up observations of previously observed targets. These studies aim to search for correlations between near-infrared excesses and basic stellar parameters, as well as the detection of a mid/far-infrared excess. So far we have added 30+ main-sequence stars to the survey, and 14 follow-up observations. We have also developed a new data analysis pipeline which has been tested by performing angular diameter measurements as well as an independent analysis of the data obtained by Absil et. al (2013), which agrees with published results. Our preliminary analysis of the recent data reveals 4 new detections of extended circumstellar emission and 2 excesses that are likely due to binarity. Our preliminary analysis of follow-up observations indicates that the circumstellar emission may be variable for at least 2 targets.

9907-144, Session PSTh

Co-phasing the planet formation imager

Romain G. Petrov, Observatoire de la Côte d'Azur (France) and Lab. J.L. Lagrange (France); Abdelkarim Boskri, Univ. Cadi Ayyad (Morocco); Theo A. ten Brummelaar, CHARA (United States) and Georgia State Univ. (United States); Christopher A. Haniff, Univ. of Cambridge (United Kingdom); Michael J. Ireland, The Australian National Univ. (Australia); Stefan Kraus, Univ. of Exeter (United Kingdom); John D. Monnier, Univ. of Michigan (United States); Karine Perraut, Institut de Planétologie et d'Astrophysique de Grenoble (France)

The Planet Formation Imager (PFI) is a projected very large post-VLTI infrared interferometer intended to obtain images of the planet formation process, down to the Hill sphere of a Jupiter mass giant exoplanet in some of the closest star forming regions. This resolution requires baselines up to 10 Km and the need for high contrast imaging implies the use of at least 20 apertures. The science windows of PFI are in the thermal infrared but the array must be cophased in the near infrared K or, more likely, H bands. The limiting sensitivity of PFI will be set by the capacity to cophase the array, i.e. to measure and actively correct the optical path variations introduced by the atmosphere down to a fraction of wavelength. This sensitivity depends on the size of the individual apertures and the performance of the fringe tracker. Observing typical solar mass young stellar objects in nearby (100 to 250 pc) star forming regions implies cophasing on objects with correlated magnitudes of H>9 (e.g. an inner-disk free H~9, or H~8 with a ~50% disk contribution) Observing the full range of targets (including e.g. HL Tau) needs a correlated magnitude limit of H>10 with critical baselines of typically 1 Km. In the currently used fringe trackers, the sensitivity decreases with the number nT of apertures and reaching H>10 with nT>20 would require individual diameters larger than 10 m. This would quite certainly make the PFI project far too expensive. In this paper we evaluate alternative FT architectures in order to achieve the desired sensitivity with much smaller apertures. In the Chain FT (CFT), each telescope is cophased with only two other apertures and each flux is divided only by two, whatever nT. In the Hierarchical Fringe Tracker (HFT), we cophase pairs of apertures, then pairs of pairs and then pairs of groups and the limiting sensitivity is this of a two-telescope interferometer independently of nT. If PFI can be cophased with an HFT, it could use 2-3 m individual apertures. We also investigate arrays that are only coherenced within a few wavelengths and the possibilities of off-axis cophasing and coherencing in special sites to try either to show that PFI can be done with telescopes smaller than 2 m or that a PFI with 3 m apertures could also be used for observations of AGNs with magnitudes K>13.

9907-145, Session PSTh

Practical beam transport for PFI

David Mozurkewich, Seabrook Engineering (United States); John S. Young, Univ. of Cambridge (United Kingdom); Michael J. Ireland, The Australian National Univ. (Australia)

The Planet Formation Imager (PFI) is a future facility to image the process of planetary formation. The key science driver is the resolution of sub-Hill sphere structures around giant proto-planets orbiting solar-type stars in nearby star forming regions. Operating at wavelengths around 10 micron, PFI will require at least 20 telescopes separated by maximum baselines of 5 to 10 km. Heterodyne and homodyne (direct detection) interferometer designs are being studied for PFI. Both options will require near-IR homodyne fringe tracking. Technologies that could be used to transport starlight from the telescopes to a beam-combining laboratory include free-space propagation in air (with adaptive optics to mitigate atmospheric turbulence effects) or in vacuum, and optical fibres. Free-space propagation (usually in vacuum) is the solution typically adopted at more modest scale infrared interferometers, and this paper addresses the design and cost issues associated with following such an approach for PFI. We present straw-man beam-relay designs for pseudo-circular and Y-shaped telescope arrays, and discuss their advantages and disadvantages. The results of Fresnel diffraction calculations predicting the worst-case coherence losses are presented, and used to determine optimum beam diameters for the two types of array layout.

9907-146, Session PSTh

A high-precision thermal near-infrared instrument for the VLTI

Denis Defrère, The Univ. of Arizona (United States); Olivier Absil, Univ. de Liège (Belgium); Sylvestre Lacour, Observatoire de Paris à Meudon (France); Steve Ertel, European Southern Observatory (Chile); Philip M. Hinz, The Univ. of Arizona (United States); Jean-Baptiste Le Bouquin, Guillermo Martin, Institut de Planétologie et d'Astrophysique de Grenoble (France); Bertrand P. Mennesson, Jet Propulsion Lab. (United States); Rafael Millan-Gabet, California Institute of Technology (United States); Jean Surdej, Univ. de Liège (Belgium); Konrad Tristram, European Southern Observatory (Chile)

The development of high dynamic range capabilities has long been recognized as one of the top priorities for the VLTI. In the era of extremely large telescopes, the VLTI will remain a major observational tool as the only southern instrument able to probe the smallest spatial scales of nearby planetary systems. As of today, the VLTI can achieve a dynamic range of a few 100:1 in the near-infrared and second-generation instruments are not designed to improve that limit. Other interferometers in the northern hemisphere have however demonstrated that a dynamic range of 1000:1, or even higher, is within reach. In this paper, we first review the state of the art regarding high-precision infrared interferometry and then present a preliminary instrumental concept of a possible high-precision four-telescope VLTI instrument. The instrumental concept combines several features that made the success of other high-precision interferometric instruments such as integrated optics, closure phase, nulling, and statistical data reduction. In particular, recent advent in lithium niobate technology now opens the possibility to manufacture integrated optics components that operate in the thermal near-infrared (3-5 microns), a sweet spot to image and characterize young extra-solar planetary systems. We describe the expected performance of a high-precision thermal near-infrared instrument and briefly address its science cases, which mainly consist of extrasolar planetary science (exoplanets, exozodiacal disks, and planet-forming regions) but also include stellar physics and active galactic nuclei.

9907-147, Session PSTh

Cost models for the Planet Formation Imager

Gerard T. van Belle, Lowell Observatory (United States); John D. Monnier, Univ. of Michigan (United States); Stefan Kraus, Univ. of Exeter (United Kingdom); Michael J. Ireland, The Australian National Univ. (Australia)

We examine cost drivers for the Planet Formation Imager (PFI) project. This includes the following major infrastructure elements: telescopes, adaptive optics, beam transport, beam delay, fringe tracking instrumentation, scientific beam recombination, on-sky operations control, and data infrastructure (including data reduction pipelines). In part, the economics of these items - including economies of scale - will drive architecture decisions for PFI. Reconciling the intersection of optimimum cost with highest scientific return will be a key design goal of the facility.

9907-148, Session PSTh

The Wide-field Imaging Interferometry Testbed (WIIT): analysis and synthesis of measured and simulated data

Roser Juanola-Parramon, David T. Leisawitz, Matthew R. Bolcar, Stephen F. Maher, Stephen A. Rinehart, NASA Goddard Space Flight Ctr. (United States); Giorgio Savini, Univ. College London (United Kingdom)

The Wide-field Imaging Interferometry Testbed (WIIT) is a double Fourier interferometer (DFM) operating at optical wavelengths, and provides data that are highly representative of those from a space-based far-infrared interferometer like SPIRIT. This testbed has been used to measure both a spatial and spectrally simple test scene and a more complex and astronomically representative test scene. Here we present the simulation of recent WIIT measurements using FIInS (the Far-infrared Interferometer Instrument Simulator), which main goal is to simulate both the input and the output of a DFM system, and compare the input map with the synthesized one after data processing. The results from FIInS are compared with the results obtained from recent measurements with WIIT.

9907-149, Session PSTh

Stray light evaluation for the astrometric gravitation probe mission

Federico Landini, INAF - Osservatorio Astrofisico di Arcetri (Italy); Alberto Riva, Mario Gai, INAF - Osservatorio Astrofisico di Torino (Italy); Cristian Baccani, Univ. degli Studi di Firenze (Italy); Mauro Focardi, Maurizio Pancrazzi, INAF - Osservatorio Astrofisico di Arcetri (Italy)

The main goal of the Astrometric Gravitation Probe (AGP) mission is the verification of General Relativity (GR) and competing gravitation theories by precise astrometric determination of light deflection, and of orbital parameters (e.g., the effect of pericentre excess shift) of selected Solar System objects. The bending of the light path due to the gravitational pull of massive bodies is in fact one of the best known effects introduced by GR. One of the earliest confirmations of Einstein's GR theory was obtained by Dyson, Eddington and Davidson during the May 29th, 1919 solar eclipse.

Their experiment, as well as subsequent attempts during the XX century, was strongly constrained to 10% precision by the eclipse short duration and location (imposing usage of small portable instruments), and by atmospheric turbulence.

More recent measurements, mainly from space, currently achieve the \$10^{-5}\$ level on the \$gamma\$ and \$beta\$ parameters of the Parametrized Post-Newtonian (PPN) formulation of gravitation theories.

The AGP mission is conceived to achieve a precision level corresponding to \$10^{-8}\$ on \$gamma\$ and \$10^{-6}\$ on \$beta\$, much better than any other astronomical experiment planned for the forthcoming years.

The telescope optical design is an evolution of the GAME (Gai et al., Proc. SPIE 9150, 2014) and ISAS (Gai et al., Proc. SPIE 8446, 2012) concepts, and it is based on a classical Korsch Three Mirror Anastigmatic telescope configuration.

The key element is the coherent combination of a set of 92 circular entrance apertures, each feeding an elementary inverted occulter similar to the one developed for Solar Orbiter/METIS and described in Landini et al., Proc. SPIE 8862, 2013.

This provides coronagraphic functions over a relevant field of view, in which all stars are observed for astrometric purposes with the full resolution of a 1 m diameter telescope.

The telescope primary mirror acts as a beam combiner, feeding the 92 pupils, through the internal optics, toward a single focal plane.

The primary mirror is characterized by 92 output apertures, sized according to the entrance pupil and telescope geometry, in order to reject the solar disk light by dumping it beyond the instrument.

The astronomical objects are much fainter than the solar disk, which is angularly close to the inner field of view of the telescope.

The stray light as generated by the diffraction of the solar disk at the edges of the 92 apertures defines the limiting magnitude of observable stars.

In particular, the stray light due to the diffraction from the pupil apertures is scattered by the telescope optics and follows the same optical path of the astronomical objects; it is a contribution that cannot be eliminated and must therefore be carefully evaluated.

This paper describes the preliminary evaluation of this stray light contribution.

The whole solar disk is considered as a source and a limb darkening model is included as well.

9907-150, Session PSTh

Opto-mechanical design of AGP (Astrometric Gravitation Probe)

Alberto Riva, Mario Gai, INAF - Osservatorio Astrofisico di Torino (Italy); Federico Landini, INAF - Osservatorio Astrofisico di Arcetri (Italy); Deborah Busonero, Mario G. Lattanzi, Alberto Vecchiato, INAF - Osservatorio Astrofisico di Torino (Italy)

This paper describes the current opto-mechanical design of AGP (Astrometric Gravitation Probe).

The Astrometric Gravitation Probe (AGP) mission is designed for astrometric verification of General Relativity (GR) and competing gravitation theories by means of precise determination of light deflection on field stars, and of orbital parameters (e.g., pericentre excess shift) of selected Solar System objects.

The bending of the light path due to the gravitational pull of massive bodies provided one of the earliest confirmations of Einstein's GR theory, by the measurements of Dyson, Eddington and Davidson during the May 29th, 1919, solar eclipse.

Recent measurements, mainly from space, currently achieve the 10^{-5} level on the $gamma$ and $beta$ parameters of the Parametrized Post-Newtonian (PPN) formulation of gravitation theories.

The AGP mission is conceived to achieve a precision level corresponding to 10^{-8} on $gamma$ and 10^{-6} on $beta$, much better than any other astronomical experiment planned for the forthcoming years.

We briefly review the mission concept to derive the instrument and operation requirements, then proceeding to the design definition based on the guideline of mitigation of systematic errors.

The most innovative aspect of the instrument is the combination of Fizeau Interferometry and coronagraphy for high precision astrometry close to the Sun. The coronagraphic concept and performance is discussed in the paper by Landini et al. [this conference].

Furthermore, the optical concept includes a planar rear-view mirror for simultaneous imaging on the CCD mosaic detector of fields of view (FOV) also from the direction opposite to the Sun, affected by negligible deflection, for the sake of real time calibration.

Other relevant issues are nearly constant Sun/Earth pointing, instrument stability at the milli-arcsec (mas) level and imaging quality. Reversal of the lines of sight over each orbit is used to ensure that instrumental characteristics are introduced mostly as common mode.

The precision of astrometric measurements on individual stars will be of order of 1 mas, over two fields separated by few degrees around the Sun and observed simultaneously. The proposed design retains the angular resolution of a 1 m telescope, in spite of the trade-offs imposed by adoption of a coronagraphic system and multiple lines of sight.

We describe the optical design characteristics, with particular reference to manufacturing and tolerancing aspects, evidencing the preservation of very good imaging performance over the range of expected operating conditions.

We also present the proposed mechanical solution, discussing the implications of thermo-elastic disturbances and evidencing their efficient cancellation in the measurement combination.

Finally, we report on the current error budget and discuss the technological development plan.

9907-49, Session 23

Hierarchical fringe tracker to co-phase and coherence very large optical interferometers

Romain G. Petrov, Observatoire de la Côte d'Azur (France); Abdelkarim Boskri, Thami El Halkouj, Univ. Cadi Ayyad (Morocco); Stéphane Lagarde, Observatoire de la Côte d'Azur (France); Jean-Pierre Folcher, Univ. Côte d'Azur (France); Zouhair Benkhaldoun, Mohammed Lazrek, Univ. Cadi Ayyad (Morocco)

The limiting sensitivity and often the accuracy and dynamical range of optical interferometers is set by the architecture of the Fringe Tracker (FT) used to cophase or to coherence the array. With conventional fringe tracking concepts, such as the pairwise approach of the 2nd generation VLTI instrument GRAVITY, the cophasing sensitivity decreases with the number of apertures, which is a growing problem from the current 4 telescopes instruments to the planned 6 apertures combination of CHARA. This problem will be dramatic for a large interferometer such as the Planet Formation Imager (PFI) with more than 20 apertures. In addition, the necessity to measure in real time the group delay of the fringe packet implies the dispersion of the light on several spectral channels, with a cost in limiting sensitivity in the detector noise dominated near-infrared domain that must be used for fringe tracking. These conceptual constraints set a sensitivity limit for the GRAVITY/PIONIER pairwise approach near K~10.5 with the UTs and K~7.5 with the ATs. In comparison, the full scientific potential of the VLTI requires cophasing the UTs up to K>14 for the AGN program and the ATs up to K>9 for the Young Stellar Objects and K>10 for the AGN program. PFI has similar requirements about sensitivity and would need individual apertures larger than 10 m with a pairwise approach.

Here we describe our concept study of an alternative Hierarchical Fringe Tracker (HFT) architecture based on a broad band achromatic 2 beams spatial filter (SF2B) that transmits most of the incoming flux if the two inputs beams are cophased, as produced by a single aperture cophased telescope. When the inputs beams are not cophased, about 50% of the flux is deflected toward a pair of single pixel detectors that measure the piston necessary to cophase the pair. A combination of SF2B allows to cophase pairs of apertures, then pairs of pairs, then pairs of groups with a sensitivity set only by the performance of the broad-band, two telescopes, single channel fringe tracker. The coherencing of the array is obtained by an optimized fluted spectrum dispersed fringe device, derived from the 2D Fourier Transform group delay processing that we have used to boost the limiting sensitivity of the VLTI instrument AMBER. This paper describes the numerical simulations and the experiments to validate the SF2B and discusses the optimization of its performances. It evaluates the global HFT performance and discusses its control architecture. We show that an HFT would allow operating the VLTI beyond K~15 with the UTs and K~11 with the ATs. It would also allow building a "more than 20 apertures" PFI with individual telescopes in the 2-3 m diameter range. We discuss also the use and optimization of the HFT for bootstrapping an interferometer with very low fringe contrast on its longer baselines.

9907-50, Session 23

Simultaneous water vapor and dry air optical path length measurements and compensation with the Large Binocular Telescope Interferometer

Denis Defrère, Philip M. Hinz, Elwood C. Downey, The Univ. of Arizona (United States); William C. Danchi, NASA Goddard Space Flight Ctr. (United States); Olivier Durney, The Univ. of Arizona (United States); Steve Ertel, European Southern Observatory (Chile); John M. Hill, William F. Hoffmann, The Univ. of Arizona (United States); Bertrand Mennesson, Jet Propulsion Lab. (United States); Rafael Milan-Gabet, California Institute of Technology (United States); Oscar Montoya, Andrew J. Skemer, Eckhart Spalding, Jordan Stone, Amali Vaz, The Univ. of Arizona (United States)

The Large Binocular Telescope Interferometer uses a near-infrared camera to measure the optical path length variations between the two AO-corrected apertures and provide high-angular resolution observations for all science channels (1.5-13 microns). There is however a wavelength dependent component to the atmospheric turbulence, which can introduce optical path length errors when observing at a wavelength different from that of the fringe sensing camera. While generally a small contributor to the atmospheric refractive index at infrared wavelengths, the water vapor component of the atmospheric seeing must nevertheless be taken into account for high-precision infrared interferometric observations as described previously in the context of the Keck Interferometer Nuller. In this paper, we present the new sensing approach that has been developed at the LBT to measure the optical path length fluctuations due to dry air and water vapor separately. We describe both the new optical setup and the computation of the N-band feedforward quantities from the K-band measurements. Simultaneous H, K and N-band sky data are presented to illustrate both the good correspondence with the underlying atmospheric models and the improvement in the co-phasing stability in the mid-infrared. Finally, we review the current performance and limitations of the system and discuss briefly their implications for the LBTI exozodiacal dust survey (i.e., getting stellar nulls to accuracy levels of 10-4 in the mid-infrared).

9907-51, Session 24

Long baseline interferometry in the visible: first results of the FRIEND project

Marc-Antoine Martinod, Philippe Bério, Observatoire de la Côte d'Azur (France); Karine Perraut, Institut de Planétologie et d'Astrophysique de Grenoble (France); Anthony Meilland, Florentin Millour, Jean-Michel Clausse, Alain Spang, Yves Bresson, Julien Dejonghe, Christophe Bailet, Observatoire de la Côte d'Azur (France); Isabelle Tallon-Bosc, Univ. de Lyon (France) and Ctr. de Recherche Astronomique de Lyon (France); Michel Tallon, Univ. Claude Bernard Lyon 1 (France)

In the coming year, the CHARA 1-meter telescopes will be equipped with Adaptive Optics (AO) systems. This improvement opens the possibility to apply, in the visible domain, the principle of spatial filtering with single mode fibers well demonstrated in the near-infrared. It will clearly open new astrophysical fields by taking benefit of an improved sensitivity and state-of-the-art precision and accuracy on interferometric observables. A demonstrator called FRIEND (Fibered and spectrally Resolved Interferometric Experiment - New Design) has been developed. FRIEND combines the beams coming from 3 telescopes after injection in single mode optical fibers and provides some spectral capabilities for characterization purposes as well as photometric channels. It operates in the R spectral band (from 600nm to 750nm) and uses the fast and sensitive analogic detector OCAM2. On sky tests at the focus of the CHARA interferometer have been performed during the last year. Complementary lab tests have permitted to characterize the polarization behavior of the prototype, including detector characteristics. In this paper, we present the results of these tests and our conclusion for the development of the science instrument.

9907-52, Session 24

Towards a new generation 6T visible instrument for the CHARA array and VLTI perspectives

Denis Mourard, Observatoire de la Côte d'Azur (France); Jean-Philippe Berger, European Southern Observatory (Germany); Philippe Bério, Observatoire de la Côte d'Azur (France); Theo A. ten Brummelaar, CHARA (United States); Jean-Michel Clausse, Julien Dejonghe, Observatoire de la Côte d'Azur (France); Michael J. Ireland, The Australian National Univ. (Australia); Guillermo Martin, Univ. Grenoble Alpes (France); Frantz Martinache, Marc-Antoine Martinod, Anthony Meilland, Florentin Millour, Observatoire de la Côte d'Azur (France); John D. Monnier, Univ. of Michigan (United States); Nicolas Nardetto, Observatoire de la Côte d'Azur (France); Karine Perraut, Univ. Grenoble Alpes (France); Romain G. Petrov, Alain Spang, Philippe Stee, Observatoire de la Côte d'Azur (France); Isabelle Tallon-Bosc, Michel Tallon, Univ. Claude Bernard Lyon 1 (France); Peter G. Tuthill, The Australian National Univ. (Australia)

The recent progresses made on the FRIEND prototype, the planning of the AO development on CHARA and the increased performance required for the enhancement of important scientific programs in the visible have led to the start of a system analysis of a new generation 6T visible beam combiner for CHARA with potential perspectives for the VLTI Array. Its specification will be based on potential large programs of general interest like massive stellar parameters determination.

In this paper we present the current status of the various activities from the science specifications, the detector and beam combiner principles, up to the detailed analysis of injection optimization, polarization control and fringe tracking requirements. A conceptual design will be presented with the main important specifications and a study of the potential performance will be presented.

9907-53, Session 24

Building a hypertelescope: prototype testing and perspective toward kilometric versions

Antoine Labeyrie, Collège de France (France); Maxime Ballouard, Univ. d'Angers (France); Erick Bondoux, Observatoire de la Côte d'Azur (France); Sandra Bosio, Lab. Ondes et Matière d'Aquitaine (France) and Univ. Bordeaux 1 (France) and Ctr. National de la Recherche

Scientifique (France); Rijuparna Chakraborty, Univ. of Calcutta (India); Wassila Dali-Ali, Bruno Lacamp, Association Hypertelescope L.I.S.E. (France); Thierry Lépine, Institut d'Optique Graduate School (France); Jerome Maillot, Association Hypertelescope L.I.S.E. (France); Denis Mourard, Institut National des Sciences de l'Univers (France) and Ctr. National de la Recherche Scientifique (France); Paul D. Nunez, Jet Propulsion Lab. (United States); Jordi Pijoan, Rémi Prud'homme, Pierre Riaud, Martine Roussel, Arun Surya, Association Hypertelescope L.I.S.E. (France); Bernard Tregon, Lab. Ondes et Matière d'Aquitaine (France) and Univ. Bordeaux 1 (France) and Ctr. National de la Recherche Scientifique (France)

The spherical Arecibo geometry, and the nearly spherical active paraboloïd adopted for the FAST radiotelescope, are of interest for a large dilute optical aperture with hundreds of small mirrors. It requires no delay lines, just actuators for adaptive co-phasing toward direct high-resolution images. These are obtainable at the combined focus in the Fizeau mode, with field extent limited by the field aberrations of the large meta-mirror, or in the "hypertelescope" mode, using a small pupil-densifier element added downstream for a more efficient light concentration in images of compact sources. The latter mode divides the Fizeau field into an array of narrow sub-fields with gaps between them, which can match multiple sources such as globular clusters, galaxies, etc... Also, several focal gondolas, equipped with different visible or infra-red detectors, coronagraphs, etc... and independantly tracking different sources, can be operated at the same time. The basic architecture is suitable both for terrestrial versions, at suitable concave mountain sites, and for space versions employing a dilute flotilla of mirrors, eventually as large as 100,000km.

Among the initial science targets are exoplanets in near-transit position, for which direct images showing the crescent of grazing starlight refracted by their atmosphere can be recorded in a coronagraphic mode, together with spectra containing planet's atmospheric information.

We have verified, at the scale of a 200m meta-aperture, the feasibility and operability of terrestrial hypertelescopes. A smoothly curved high valley of the southern Alps has been equipped with a few initial tripods, anchored and adjusted to carry small (15cm) mirrors on the spherical locus. A focal gondola is suspended, 101m above them, from a traversing cable, and driven, for tracking the star image, by six oblique wires tensioned by computerized winches. The specified tracking accuracy of the gondola, one millimeter, proved achievable with manual feedback in low-wind conditions, frequent during anticyclonic weather. In the absence yet of a camera aboard the focal gondola, a small mirror has relayed a coudé focus at ground level. An image of Vega could be observed there, but from a single sub-aperture and thus not yet containing fringes.

Plans are made for the adaptive cophasing and tip-tilt correction, using a modified wave sensor. For early science, non-cophased exposures can be initially recorded in a Speckle Imaging mode to generate reconstructed images (Surya et al., 2011). Also to be tested is a "Hypertelescope Laser Guide Star", already explored in the laboratory by Labeyrie (2013) and Nunez et al. (2014), which differs from the versions serving for conventional telescopes and ELTs. Although requiring appreciable laser power, it may extend high-resolution Earth-based observing to very faint sources, pending space hypertelescopes.

Tests of a "flying gondola", using a small balloon-assisted electric drone, are also foreseen for further simplifying the hypertelescope's architecture, which is already much simplified with respect to conventional interferometers featuring complex optical trains, and costly optical delay lines which have drastically limited the number of their subapertures. If validated, the "flying gondola" scheme may provide kilometric meta-apertures.

9907-54, Session 25

Planet Formation Imager: science vision and key requirements

Stefan Kraus, Univ. of Exeter (United Kingdom); John D. Monnier, Univ. of Michigan (United States); Michael J. Ireland, The Australian National Univ. (Australia); Gaspard Duchêne, Univ. of California, Berkeley (United States); Catherine Espaillat, Boston Univ. Haniff, Univ. of Cambridge (United Kingdom); Sylvestre Lacour, Observatoire de Paris à Meudon (France); Romain G. Petrov, Observatoire de la Côte d'Azur (France); Stephen T. Ridgway, National Optical Astronomy Observatory (United States); Peter G. Tuthill, The Univ. of Sydney (Australia); Gerard T. van Belle, Lowell Observatory (United States)

Despite recent advancements, many fundamental questions still surround the processes that are involved in planetary birth: Where in the protoplanetary disk do the planets form and how do they grow? What factors determine the final architecture of planetary systems? How are water and other volatiles delivered to the protoplanets and how does this affect the potential habitability of these worlds? The aim of the Planet Formation Imager (PFI) project is to answer these questions by witnessing the planetary formation process on the natural spatial scales where the material is assembled, which is the Hill sphere of the forming planets. PFI will detect giant protoplanets on all stellocentric radii, image their interaction with the ambient disk material, and trace their dynamical evolution during the first 100 million years, thereby reveal the processes that determine the architecture of planetary systems.

Starting from the initial thoughts outlined in a 2014 SPIE paper, the PFI science working group has worked on refining and quantifying the science drivers for PFI. Our 70+ contributors investigated the observational characteristics of young planets, the migration mechanisms that alter the system architecture, and the imprints that the planets leave in the disk from the pre-main-sequence to the debris disk phase. We also studied intriguing secondary science cases in exoplanet science, stellar astrophysics, and extragalactic astronomy. Our aim is to publish a comprehensive science whitebook in the second half of 2016.

This talk will present our main findings and discuss the key science requirements that will guide the technology choices, the site selection, as well as potential science/technology tradeoffs. The associated proceedings paper will serve as an executive summary of the comprehensive (200+ pages) whitebook.

9907-55, Session 25

Status of the Planet Formation Imager (PFI) concept *(Invited Paper)*

Michael J. Ireland, The Australian National Univ. (Australia); Andrea Isella, Rice Univ. (United States); Stefano Minardi, Friedrich-Schiller-Univ. Jena (Germany); Stefan Kraus, Univ. of Exeter (United Kingdom); David Mozurkewich, Seabrook Engineering (United States); Romain G. Petrov, Observatoire de la Côte d'Azur (France); Theo A. ten Brummelaar, Georgia State Univ. (United States); John D. Monnier, Univ. of Michigan (United States); John S. Young, Univ. of Cambridge (United Kingdom)

More than 2 decades ago, the first accepted detection of an extrasolar planet greatly broadened and accelerated our understanding of planet formation. Today, after more than a thousand of radial velocity detections, some direct imaging detections and a treasure trove of data from Kepler, many of the key elements of the planet formation process are now understood to a limited extent. At the heart of our current uncertainties is the period of giant planet assembly where processes of grain growth, protoplanet assembly, magnetic fields, disk/planet dynamical interactions and complex radiative transfer all come together to both form the last giant planets in a solar system and determine the conditions for habitable terrestrial planet formation. The Planet Formation Imager (PFI) project aims to image this period of planet assembly directly, resolving structures as small as a giant planet's Hill sphere. This capability will also enable many auxilliary science cases. We will present the overall vision for the PFI concept, focusing on the key facility requirements that are needed to achieve the science goals. For example, we will show that only the direct detection concept can probe gas tracers in the 3-5 micron window, which may be critical for directly measuring exoplanet masses. For the direct detection design, we will outline key elements with known costs and key cost uncertainties for a baseline design. Important details (for example on the technology roadmap, detailed design and subsystems) will be given other presentations in this conference.

9907-56, Session 26

Imaging planet formation: heterodyning with mid-IR frequency combs

Gautam Vasisht, Stephanie Leifer, Jet Propulsion Lab. (United States); Kerry J. Vahala, California Institute of Technology (United States); John D. Monnier, Univ. of Michigan (United States); Michael J. Ireland, The Australian National Univ. (Australia); Stefan Kraus, Univ. of Exeter (United Kingdom)

We discuss our efforts to build a broadband heterodyne receiver for 10-micron applications using a laser frequency comb local oscillator (LFC-LO). LFC generation (and applications) has thus far been focused in the visible and near-IR. However, mid-IR (MIR) frequency combs are of growing interest in astrophysics because they enable dispersed, wide-band, multi-telescope heterodyne interferometry over long baselines, providing imaging for complex scenes and also phase information as compared to traditional direct detection interferometers; A heterodyne receiver based on a comb local oscillator (LO) can enable astronomical observations with spectral bandwidths similar to or exceeding direct detection. This enables observations of planet-formation in the nearest star-forming regions (~150 pc away) on sub-AU scales with conceptual instruments such as the Planet Formation Imager (PFI). The physical scales of interest are the planetary Hill spheres, targeting protoplanetary accretion and fine structure in protoplanetary disks, and catching planets in the act of formation.

For the Earth and planetary sciences, frequency comb spectroscopy is revolutionizing spectroscopic sensing through the simultaneous combination of broad spectral coverage, fast acquisition, and high spectral resolution. Extension of frequency comb technology into the MIR will greatly enhance sensitivity for molecular detection, leading to substantial scientific capabilities and/or cost savings for future missions that monitor greenhouse gases and atmospheric pollution on Earth, as well as those searching for life and biomarkers on solar system bodies.

9907-57, Session 26

Beam combination schemes and technologies for the Planet Formation Imager

Stefano Minardi, Friedrich Schiller Univ. Jena (Germany); Sylvestre Lacour, Observatoire de Paris à Meudon (France); Jean-Philippe Berger, European Southern Observatory (Germany); Lucas Labadie, Univ. of Cologne (Germany); Robert R. Thomson, Harriot-Watt Univ. (United Kingdom); Michael J. Ireland, The Australian National Univ. (Australia)

The Planet Formation Imager (PFI) initiative [1] is aiming at developing the next generation large scale facility for imaging astronomical optical interferometry operating in the mid-infrared.

A conceptual technical study is currently underway to identify suitable key technologies for the realization of the facility.

Here we report on the progress of the Technical Working Group on the beam-combination instruments.

Our working baseline scenario considers an array of 20 telescopes and two alternative options for the science beam combination, namely a dispersed heterodyne or a dispersed homodyne scheme. In both cases, fringe tracking at near-infrared wavelengths will be necessary to access faint targets, thus requiring an additional beam-combiner instrument.

Regarding the science beam-combiner(s), we will discuss the various available options for the homodyne scheme ranging from direct imaging [2], to non-redundant fiber arrays [3], to integrated optics (IO) solutions [4,5]. We will consider instrumental aspects such as the throughput, per-baseline sensitivity, numerical stability of the visibility retrieval method, with an eye to the overall SNR of the reconstructed image.

In this context, a strategy to boost per-baseline sensitivity is to combine entangled sub-sets of at least 3 telescopes to obtain visibilities and closure phases over a selected sub-network of baselines. This task could be achieved easily with integrated optics circuits, as recently demonstrated at the Observatory of Paris with an IO 18-telescope, 32-baselines beam combiner operating in H-band.

While a compromise between sensitivity and image reconstruction fidelity should be found, we mention that further technological development is still required to achieve the reliability and throughput of near-infrared IO at longer wavelengths, as required by PFI. In this respect, a promising technology platform for mid-infrared IO is represented by ultrafast laser inscription [6], which can be used to manufacture waveguides with losses as low as 0.2 dB/cm in the L-band.

Concerning the fringe tracker beam combination scheme, near-infrared fringe measurement on a selection of short/intermediate baselines is required. Some level of redundancy in the combination scheme will be necessary to limit the impact of failure of fringe tracking on individual baselines. As for the fringe tracker instrument, we believe that near-infrared IO will play a central role in delivering a stable and compact device with high throughput. As mentioned before, planar IO in near-infrared is already technologically mature to deliver such baselines-selective beam combiners. Additionally, ultrafast laser inscription could be used to avoid cross-overs in the beam combination scheme [6] and thus limit the cross-talk between the combined channels.

9907-58, Session 26

Architecture design study and technology road map for the Planet Formation Imager (PFI)

John D. Monnier, Univ. of Michigan (United States); Michael J. Ireland, The Australian National Univ. (Australia); Stefan Kraus, Univ. of Exeter (United Kingdom); Fabien Baron, Georgia State Univ. (United States); Michelle J. Creech-Eakman, New Mexico Institute of Mining and Technology (United States); Andrea Isella, Rice Univ. (United States); Antoine Mérand, European Southern Observatory (Chile); Stefano Minardi, Friedrich-Schiller-Univ. Jena (Germany); David Mozurkewich, Seabrook Engineering (United States); Romain G. Petrov, Univ. de Nice Sophia Antipolis (France); Stephen A. Rinehart, NASA Goddard Space Flight Ctr. (United States); Theo A. ten Brummelaar, Georgia State Univ. (United States); Gautam Vasisht, Jet Propulsion Lab. (United States); Edward Wishnow, Univ. of California, Berkeley (United States); John S. Young, Univ. of Cambridge (United Kingdom)

The Planet Formation Imager (PFI) Project has formed a Technical Working Group (TWG) to explore possible facility architectures to meet the primary PFI science goal of imaging planet formation in situ in nearby star-forming regions. The goals of being sensitive to dust emission on solar system scales and resolving the Hill-sphere around forming giant planets can best be accomplished through sub-milliarcsecond imaging in the thermal infrared. Exploiting the 8-13 micron atmospheric window, a ground-based long-baseline interferometer with approximately 20 apertures including 10km baselines will have the necessary resolution to image structure down 0.1 milliarcseconds (0.014 AU) for T Tauri disks in Taurus. Even with large telescopes, this array will not have the sensitivity to directly track fringes in the mid-infrared for our prime targets and a fringe tracking system will be necessary in the near-infrared. Here, we describe feasible designs for both a “direct detection” and a heterodyne facility, emphasizing their common elements as well as the distinct dis/advantages of each variant. Guided by imaging simulations with realistic signal-to-noise ratios as well as a simple cost model, we will discuss the architecture trade offs in terms of number of telescopes, telescope diameter and efficiency metrics. The required sensitivity metrics for PFI include adaptive optics guide star sensitivity, fringe tracking sensitivity and thermal infrared sensitivity. For the direct detection design, the high thermal infrared sensitivity required means that a high degree of care has to be taken in appropriate cold stops and diffractive effects. We will advocate for a specific technology road map in areas including telescopes, adaptive optics, beam train, fringe sensor and imaging software that will allow PFI to reach its scientific goals with a feasible facility plan. This work will pull together results from multiple sub-groups within the PFI-TWG, some of which will be explored in more detail in other presentations at this meeting (e.g., mid-IR laser combs, beam combiners).

9907-59, Session 27

Interferometry community discussion session *(Invited Paper)*

Stefan Kraus, Univ. of Exeter (United Kingdom)

The international interferometry community is bursting with activity, as it works to deliver a new suite of instruments and major facility infrastructure upgrades (CHARA, NPOI, and VLTI) and to bring a new facility on the sky (MROI). A close coordination & collaboration between facility

representatives, instrument builders, and potential users will be essential in order to implement these advancements successfully and to maximize their scientific return. At the same time, we need to plan the next steps and develop a coherent roadmap for the future development of our field.

SPIE offers an unique forum to discuss these topics, as it brings interferometrists from all facilities and all continents together. In this discussion session, the panelists and attendants will discuss a broad range of topics that are of interest for all communities & facilities or that could benefit from coordination.

Sunday - Thursday 26–30 June 2016

Part of Proceedings of SPIE Vol. 9908 Ground-based and Airborne Instrumentation for Astronomy VI

9908-1, Session 1

The Paranal instrumentation program *(Invited Paper)*

Luca Pasquini, European Southern Observatory (Germany)

The Paranal Instrumentation Programme is responsible for designing and procuring, in collaboration with consortia in the ESO community, all the instruments for the Paranal and La Silla observatories, their upgrades and the upgrade of the infrastructures to host them. I will report about the latest progresses and the future plans to keep the Paranal and La Silla observatories competitive in the E-ELT era.

9908-2, Session 1

Overview of the instrumentation programme of the 10.4m GTC Telescope *(Invited Paper)*

Antonio L. Cabrera-Lavers, Romano L. M. Corradi, GRANTECAN S.A. (Spain)

We will present the instrumentation plan until 2019 of the 10.4m Gran Telescopio Canarias (GTC), located in the island of La Palma.

It includes a suite of instruments covering different wavelength domains (from 350 to 2000 nm), with imaging, multiplexed (MOS, IFUs, and Fabry-Perot) spectroscopy at a resolution R<=30000 and polarimetric capabilities, and adaptive optics correction.

Up to six instruments will be available at the same time, taking advantage of the five, full-equipped and interchangeable focal configurations of GTC, which include one Cassegrain, two Nasmyth, and two Folded-Cassegrain foci.

9908-3, Session 1

Instrumentation at Gemini Observatory *(Invited Paper)*

Scot J. Kleinman, Stephen J. Goodsell, Chadwick A. Trujillo, Gemini Observatory (United States)

I will provide an update of Gemini's new instrument and adaptive optics capabilities. The new Gemini high-resolution optical spectrograph is now in its build phase and will be available to Gemini users in 2018. We have also started our next new instrument, designed to provide valuable support and follow-up for coming new facilities and capabilities in astronomy. Meanwhile, our current instrument upgrade program continues with plans to expand it this year. We continue to improve and stabilize our multi-conjugate adaptive optics system at Gemini South and are making additional upgrades to our Gemini North AO system, Altair.

9908-4, Session 1

New developments in instrumentation at the W. M. Keck Observatory *(Invited Paper)*

Sean M. Adkins, W. M. Keck Observatory (United States); Michael P. Fitzgerald, James E. Larkin, Univ. of California, Los Angeles (United States); Hilton A. Lewis, W. M. Keck Observatory (United States); D. Christopher Martin, Dimitri Mawet, California Institute of Technology (United States); Jason X. Prochaska, Univ. of California, Santa Cruz (United States); Peter L. Wizinowich, W. M. Keck Observatory (United States)

The W. M. Keck Observatory is committed to maintaining the scientific leadership of our observing community by matching our observers' skills and passions in their fields of astronomical science with a continuing dedication by the Observatory and its collaborators to the development of state of the art instrumentation and systems. Our science driven strategic plan guides these developments and informs our plans for the future. In this paper we describe the performance of recently completed new instruments, instrument upgrades, and infrastructure upgrade projects. We also describe the expected performance of projects currently in the development or construction phases. Projects recently completed include the blue channel of the Keck Cosmic Web Imager, a new laser for the Keck II AO system, the upgrade of the spectrograph detector in the OSIRIS instrument, and the upgrade to the telescope control systems on both Keck telescopes. Projects in development include a deployable tertiary mirror for the Keck I telescope, the red channel of the Keck Cosmic Web Imager, an upgrade to the imager of OSIRIS, a major upgrade to the NIRSPEC instrument, and a fiber feed from the Keck II AO system to NIRSPEC.

9908-5, Session 2

An overview of the current and future instrumentation at the Subaru Telescope *(Invited Paper)*

Yosuke Minowa, Naruhisa Takato, Ikuru Iwata, Takashi Hattori, Subaru Telescope, National Astronomical Observatory of Japan (United States)

Subaru telescope has a suite of 7 facility instruments and 2 visitor instruments, which provide imaging and spectroscopic capabilities over the wide range of wavelengths from optical to mid-infared. Recently, a new prime focus optical wide-field imager Hyper Suprime-Cam (HSC), which has 1.5 deg field-of-view (FoV), is commissioned and started its science operation including a large survey program by using 300 nigths over 5 years. A new facility instrument, Prime-Focus Spectrograph (PFS), which is an optical to near-infrared multiplexed spectrograph over 1.3 deg FoV, is currently being developed by an international collaboration led by Kavli IPMU, University of Tokyo. PFS is planning to have an engineering first light for the part of the system in 2018 and to start science operation in 2019. As a next facility instrument in near-infrared, we are investigating the feasibility of wide-field near-infrared imagers and multi-object spectrograph (or IFUs) with ground layer adaptive optics system, which is expected to provide a great seeing improvement (less than 0.2 arcsec in K-band) over a wide field coverage (13x16 square arcmin). Our strategy toward 2020s is to fully utilize the Subaru's wide-field capability using

these three facility instruments. As well as the development for the future wide-field instruments, we are upgrading the existing facility instruments to extend the current capabilities. New infrared detectors H2RG and IFU system will be installed to MOIRCS (multi-objet near-infrared camera and spectrograph), and a fiber-fed multi-object spectrograph module will be installed to HDS (optical high-dispersion spectrograph). In addition to the facility instrument, we are accepting several visitor instruments to perform the science that is not covered by the suite of the facility instruments, especially for exoplanet science, and to test a new technology for future instrumentation. In this talk, we will present an overview of the current status of instrumentation and future development plan at the Subaru telescope.

9908-6, Session 2

The JCMT future instrumentation project *(Invited Paper)*

Jessica T. Dempsey, Paul T. P. Ho, Per Friberg, East Asian Observatory (United States); Dan Bintley, James Clerk Maxwell Telescope (United States); Craig A. Walther, East Asian Observatory (United States); Ming-Tang Chen, Institute of Astronomy and Astrophysics - Academia Sinica (United States)

Under the new operational purview of the East Asian Observatory, the JCMT continues to produce premier wide-field submillimetre science. Now the Observatory looks to embark on an ambitious series of instrumentation upgrades and opportunities to keep the telescope at the bleeding edge of its performance capabilities, whilst harnessing the collaborative expertise of the participating EAO regions and its JCMT partners. New heterodyne instruments include a new receiver at 230GHz, a super array (100+ pixels) at 345GHz (SHARP) and the upgrade possibilities for the continuum camera SCUBA-2. In addition, the opportunities for PI and visiting instruments, including TimePilot and Gismo/Gismo2 will be described.

9908-7, Session 2

LBTO's post-first generation instrumentation

Christian Veillet, Julian C. Christou, Large Binocular Telescope Observatory (United States)

The first generation of facility instruments, i.e. instruments to be proposed to users at first light (or soon after), were developed in parallel with the telescope. There are three pairs of such instruments devoted to (1) wide-field imaging (LBC), (2) visible (MODS), and (3) near infrared (LUCI) imaging and spectroscopy. The commissioning of MODS2 and LUCI2 were completed by the end of the first semester of 2016 and all instruments can now be used in binocular mode. With two adaptive secondaries, LBTO provides exquisite diffraction-limited performances, and a GLAO system, ARGOS, should be commissioned by early 2017.

In parallel, two interferometers were developed: LBTI, which produced its first scientific publications in 2015, and LINC-NIRVANA, which arrived at the observatory in the fall of 2015 and will be installed on the telescope as "Lean-MCAO", a limited field MCAO near-infrared imager (fist light by the end of 2016) without interferometric capabilities.

LBTO is now contemplating the expansion of its instrument suite to better benefit from the excellent performance of its Adaptive Optics. Four projects using the LBT at its 8.4m mirrors diffraction limit are contemplated: a near-infrared imager/coronagraph with IFU capabilities (SHARK-NIR) and its analogue in the visible (V-SHARK), iLocater, an ultra-precise near-infrared diffraction-limited spectrometer, and an upgrade of Lean-MCAO, a wide-field multi-conjugate imager.

However, the uniqueness of the telescope resides in its interferometric imaging capabilities, which would be strengthened by the further development of LBTI and the evolution of Lean-MCAO to an interferometric instrument, thus reinforcing the role of LBTO as the first of the ELTs.

These options and their challenges at a time of limited funding and operational limitations will be presented.

9908-8, Session 2

The European Solar Telescope *(Invited Paper)*

Sarah A. Matthews, Mullard Space Science Lab. (United Kingdom) and Univ. College London (United Kingdom); Manuel Collados Vera, Instituto de Astrofísica de Canarias (Spain)

The European Solar Telescope (EST) is a planned 4-metre class solar telescope that is being designed to optimize studies of the magnetic coupling between the lower layers of the solar atmosphere (the photosphere and chromosphere) in order to investigate the origins and evolution of the solar magnetic field and its role in driving solar activity. In order to achieve this, the thermal, dynamic and magnetic properties of the solar plasma must be probed over many scale heights, requiring the use of multi-wavelength spectroscopy and spectropolarimetry at high spatial, spectral and temporal resolution, and the EST project will specialize in the development of cutting edge instrumentation to address these questions. This presentation will present an overview of the main science drivers for EST, the current status and challenges, as well as complementarity with current and future ground and space-based solar instrumentation.

9908-9, Session 3

SITELLE: CFHT's new imaging FTS, early science results

Laurent Drissen, Univ. Laval (Canada); The Sitelle Team, Univ Laval (Canada)

We present the first science results obtained with SITELLE at the Canada-France-Hawaii telescope, during the commissioning run (August 2015) and the Science Verification phase (January 2016). SITELLE is an imaging Fourier transform spectrometer (iFTS), designed to obtain the spectrum of extended emission-line sources in a 11x11 arcminute field of view, with a spatial sampling of 0.32 arcsecond/pixel, in selected bandpasses of the visible range (350 - 850 nm). Hyperspectral data cubes of various objects (Milky Way nebulae and star clusters , nearby galaxies, distant galaxy clusters, Lyman-alpha galaxies) have been obtained at spectral resolutions R ~ 400 - 4000 in order to demonstrate SITELLE's capabilities and potential for discoveries. SITELLE's on-sky performance is as expected, in terms of sensitivity and line spread function. It allows to study of the very important diagnostic [OII] 3727 diagnostic line in HII regions, to map the velocity field of the ionized gas in interacting galaxies with very high accuracy, and to detect dozens of star-forming galaxies in z = 0.15 - 0.25 clusters. Although iFTS are not optimized for continuum and absorption line work because of their well-known distributed noise disadvantage, we also show that SITELLE can provide high-quality spectra of stars in the Milky Way and stellar populations in galaxies.

9908-10, Session 3

FLITECAM: delivery and performance on SOFIA

Sarah E. Logsdon, Ian S. McLean, Univ. of California, Los Angeles (United States); Eric E. Becklin, Ryan T. Hamilton, William D. Vacca, SOFIA / USRA (United States)

We present a performance report for FLITECAM, a 1-5 micron imager and spectrograph, upon its acceptance and delivery to SOFIA (Stratospheric Observatory for Infrared Astronomy). FLITECAM has two observing configurations: solo configuration and 'FLIPO' configuration, which is the co-mounting of FLITECAM with the optical instrument HIPO (PI Edward Dunham, Lowell Observatory). FLITECAM was commissioned in the FLIPO configuration in 2014 and flew in the solo configuration for the first time in Fall 2015, shortly after its official delivery to SOFIA. Here we quantify FLITECAM's imaging and spectral performance in both configurations and discuss the science capabilities of each configuration, with examples from in-flight commissioning and early science data. As expected, the solo configuration (which comprises fewer warm optics) has better sensitivity at longer wavelengths. We also discuss the causes of excess background detected in the in-flight FLITECAM images at low elevations and propose possible solutions.

9908-11, Session 3

300 nights of science with IGRINS at McDonald Observatory

Gregory Mace, The Univ. of Texas at Austin (United States); Hwihyun Kim, The Univ. of Texas at Austin (United States) and Korea Astronomy and Space Science Institute (Korea, Republic of); Daniel T. Jaffe, The Univ. of Texas at Austin (United States); Chan Park, Jae-Joon Lee, Korea Astronomy and Space Science Institute (Korea, Republic of); Kyle Kaplan, The Univ. of Texas at Austin (United States); In-Soo Yuk, Moo-Young Chun, Korea Astronomy and Space Science Institute (Korea, Republic of); Soojong Pak, Kyung Hee Univ. (Korea, Republic of); Kang-Min Kim, Korea Astronomy and Space Science Institute (Korea, Republic of); Jeong-Eun Lee, Kyung Hee Univ. (Korea, Republic of); Christopher A. Sneden, The Univ. of Texas at Austin (United States); Melike Afsar, Ege Üniv. (Turkey); Michael D. Pavel, MIT Lincoln Lab. (United States); Hanshin Lee, The Univ. of Texas at Austin (United States); Heeyoung Oh, Ueejeong Jeong, Korea Astronomy and Space Science Institute (Korea, Republic of); Sunkyung Park, Kyung Hee Univ. (Korea, Republic of); Benjamin T. Kidder, The Univ. of Texas at Austin (United States); Hye-In Lee, Huynh Anh Nguyen Le, Kyung Hee Univ. (Korea, Republic of); Kevin Gullikson, The Univ. of Texas at Austin (United States); Michael Gully-Santiago, Kavli Institute for Astronomy and Astrophysics (China); Jae Sok Oh, Sungho Lee, Young Sam Yu, Narae Hwang, Byeong-Gon Park, Korea Astronomy and Space Science Institute (Korea, Republic of)
