The Advance Mirror Technology Development (AMTD) project is a multi-year effort initiated in FY12 to mature technologies required to enable 4 to 8 meter (or larger) UVOIR space telescope primary mirror assemblies for both general astrophysics and ultra-high contrast observations of exoplanets. AMTD Phase 1 completed all of its goals and accomplished all of its milestones. AMTD Phase 2 started in 2014. Key accomplishments include deriving primary mirror engineering specifications from science requirements; developing integrated modeling tools and using those tools to perform parametric design trades; and demonstrating new mirror technologies via sub-scale fabrication and test. AMTD-1 demonstrated the stacked core technique by making a 43-cm diameter 400 mm thick 'biscuit-cut' of a 4-m class mirror. AMTD-2 is demonstrating lateral scalability of the stacked core method by making a 1.5 meter 1/3rd scale model of a 4-m class mirror.

9912-28, Session 5

Large Synoptic Survey Telescope camera design and construction

Nadine Kurita, Steven Kahn, SLAC National Accelerator Lab. (United States); Christopher W. Stubbs, Harvard Univ. (United States); Steven Ritz, Univ. of California, Santa Cruz (United States); Martin E. Nordby, SLAC National Accelerator Lab. (United States); Vincent J. Riot, Lawrence Livermore National Lab. (United States)

The Large Synoptic Survey Telescope (LSST) Camera is being constructed for the large-aperture, wide-field, optical imaging facility designed to address some of the most pressing questions about the structure and evolution of the universe and the objects in it. The LSST Camera with three refractive lenses and a 9.6 square degree field-of-view will take pairs of 15-second exposures of the southern hemisphere. The Camera has a 3.2-gigapixel flat focal plane array with 4K x 4K CCD sensors. The sensors are deep-depleted, back-illuminated devices with a highly segmented architecture that enables the entire array to be read out within 2 seconds. Sensors are mounted on a silicon carbide grid inside a vacuum cryostat, and will operate at -100ºC. There are three refractive lenses, L3 is the entrance window to the cryostat and L1 and L2 are mounted in an optics structure at the front of the camera body, which also contains a mechanical shutter and a carousel assembly that holds all the large optical filters. The LSST Camera received approval to start fabrication of the sensors in 2014 and approval all other components in 2015. A summary of the design and construction progress will be presented, as well as the technical challenges.

9912-29, Session 5

Thin glass shells for AO: from plano to off-axis aspheric

Eric Ruch, Emmanuelle Harel, Roland Geyl, REOSC (France)

Reosc is working on thin glass shells for many years and was recently selected by ESO for the E-ELT M4 mirror thin glass shells up to 2.5-m diameter. Previously Reosc also produced the aspheric thin shell for the VLT-M2 AO Facility. Based on this experience we will discuss how off axis thin glass shells can be made for the nex generation AO systems like the GMT one.

9912-30, Session 5

Status of mirror segment production for the Giant Magellan Telescope

Hubert M. Martin, The Univ. of Arizona (United States); James H. Burge, College of Optical Sciences, The Univ. of Arizona (United States); Jonathan M. Davis, The Univ. of Arizona (United States); Daewook Kim, College of Optical Sciences, The Univ. of Arizona (United States); Jeffrey S. Kingsley, Kevin Law, The Univ. of Arizona (United States); Adrian R. Loeff, College of Optical Sciences, The Univ. of Arizona (United States); Randy D. Lutz, Catherine D. Merrill, Peter A. Strittmatter, Michael T. Tuell, Stuart Weinberger, Steve C. West, The Univ. of Arizona (United States)

The Richard F. Caris Mirror Lab at the University of Arizona is responsible for production of the 8.4 m segments for the primary mirror of the Giant Magellan Telescope. Since our last report in 2014, the most significant progress is the successful casting of Segment 4, the center segment. We are currently building the mold for casting Segment 5, the next off-axis segment, in June 2017. On the polishing side, we completed the combined 8.4 m primary and 5.1 m tertiary mirrors for the Large Synoptic Survey Telescope and made progress on a 6.5 m primary mirror; both projects are prior commitments that precede GMT Segments 2-8 in the Mirror Lab queue.

Prior to generating Segments 2 and 3, we carried out a major upgrade of our 8.4 m Large Optical Generator (LOG). The upgrade includes replacement of worn or obsolete mechanics and electronics, and a

completely new set of software with features to improve accuracy, safety, reliability and ease of use. An automated calibration procedure uses a laser tracker to measure and compensate for tool position errors over a 5 m horizontal x 1 m vertical envelope. The generated surface is measured in situ with a laser tracker, allowing rapid turnaround without disturbing the alignment of the mirror on the turntable. An occasional surface measurement using an enhanced laser tracker system in the optical test tower serves to calibrate the in situ measurements and provide measurement accuracy of about 5 ?m. The tool path is adjusted to correct for the measured surface error using a LOG-specific module in SAGUARO, a MATLAB-based data processing platform that provides standard manipulation and analysis of optical data from multiple sources.

We are currently designing a similar upgrade of our 8.4 m polishing machine. The first component of the upgrade is an orbital capability for the primary polishing tool, a 1.2 m stressed lap. With GMT Segment 1 and the LSST mirrors, we were able to achieve very predictable removal and good figure convergence using an orbital polishing system with control of dwell as a function of position. The original system was designed for small compliant tools, and was very effective for mid-scale figure errors. Combining this system with a large, stiff stressed lap should lead to more efficient correction of large-scale errors and better passive smoothing of small-scale errors.

A set of optical tests measures the mirror figure on scales from 8.4 m down to about 1 cm. The overlapping capabilities of the tests provide redundant measurements of critical parameters, in particular the radius of curvature and low-order aberrations. We added and modified several components of the tests during the manufacture of Segment 1, and we have continued to improve the systems in preparation for Segments 2-8. We will have a new interferometer with improved spatial resolution, and improved alignment references for the large, asymmetric null corrector. We have also implemented and refined two test systems based on deflectometry that provide better spatial resolution than the interferometer and can guide figuring on all necessary scales.

9912-31, Session 5

LSST camera lens manufacture

Mark A. Smith, Arizona Optical Systems, LLC (United States); Andrew Fox, Corning Incorporated (United States); William Raggio, Rayotek Scientific, Inc. (United States); Justin P. Hoover, Benjamin Lewis, James H. Burge, Martin J. Valente, Arizona Optical Systems, LLC (United States)

The Large Synoptic Survey Telescope (LSST) is a three-mirror 8.4-m telescope that achieves 3.5° field of view with 0.2 arcsecond sampling. Field lenses made from Corning fused silica are used to provide high quality images over the 64-cm diameter 3.2 gigapixal focal plane. This paper discussed the fabrication of the large field corrector lenses. The largest, L1, is 1.57 meters in diameter and only 32 mm thick at the edge. The second lens (L2) is 1.17 meters in diameter, 30 mm thick, and incorporates an aspheric surface. The manufacture and test of the fused silica glass blanks is described. An overview of subsequent processing including diamond generating, grinding, and polishing is provided with special emphasis on solutions to the unique challenges presented by these lenses.

9912-32, Session 5

Manufacture and final tests of the LSST monolithic primary/tertiary mirror

Hubert M. Martin, The Univ. of Arizona (United States); J. Roger P. Angel, College of Optical Sciences, The Univ. of Arizona (United States); George Z. Angeli, William J. Gressler, LSST (United States); Daewook Kim, College of Optical Sciences, The Univ. of Arizona (United States); Jeffrey S. Kingsley, Kevin Law, The Univ. of Arizona (United States); Ming Liang, Douglas Neill, Jacques Sebag, LSST (United States); Peter A. Strittmatter, Michael T. Tuell, Steve C. West, Neville J. Woolf, The Univ. of Arizona (United States); Bo Xin, LSST (United States)

The LSST M1/M3 combines an 8.4 m primary mirror and a 5.1 m secondary mirror on one glass substrate. The combined mirror was completed in October 2014. Interferometric measurements show that both mirrors have surface accuracy better than 20 nm rms over their clear apertures, in near-simultaneous tests, and that both mirrors meet their stringent structure function specifications. The optical axes of the two mirrors coincide to better than 0.5 mm at the surface of M3 and are parallel to better than 4 ?rad. The parameters of the optical prescriptions and all mechanical dimensions have been measured to be within their specified tolerances.

The LSST M1/M3 mirror was spin-cast in March 2008. The rear surface was ground and polished over the period January - September 2009, followed by bonding of loadspreaders, hardpoint wedges and thermocouples from September to December 2009. The front surfaces were generated from January to October 2010, followed by successful repair of a region that was damaged at the end of the generating process. Loose-abrasive grinding was carried out on M1 from April to August 2011 and on M3 from September 2011 to March 2012. Polishing of both mirrors covered the period April 2012 - October 2014. M1 was finished first, in April 2014, and M3 was finished in October 2014. Acceptance tests were conducted from October 2014 to February 2015.

The mirror figures are obtained with a simulated active optics correction that uses the 156 support actuators to bend the glass substrate. Before the active optics correction is applied, corrections are made for small errors in support forces and small temperature gradients measured in the substrate. The active optics correction affects both mirror surfaces simultaneously. We used near-simultaneous tests of both surfaces, along with the simulated correction, to show that both mirrors have excellent figures and meet their specifications with a single set of correction forces. The magnitude of the forces is less than half the allowed amount.

The interferometers do not resolve some small surface features with high slope errors. We used a new instrument based on deflectometry to measure many of these features with sub-millimeter spatial resolution over 12.5 cm apertures. Working with LSST staff, we created synthetic models of both mirrors by combining the interferometric maps and the small high-resolution maps, and used these to calculate the impact of the small features on images. The impact was found to be acceptably small.

In this paper we summarize the fabrication process and tests, document the quality of the mirror, and present the results of the analysis of small-scale features.

9912-33, Session 6

Large aperture modular freeform VIS telescope with smart alignment approach

Matthias Beier, Fraunhofer-Institut für Angewandte Optik und Feinmechanik (Germany) and Friedrich-Schiller-Univ. Jena (Germany); Johannes Hartung, Andreas Gebhardt, Stefan Risse, Fraunhofer-Institut für Angewandte Optik und Feinmechanik (Germany); Wilko Fuhlrott, Fraunhofer Institut für Angewandte Optik und Feinmechanik (Germany)

Metal mirrors are key components for small and medium sized instruments used within space or ground based astronomical applications. Optical systems based on metallic substrates offer a high degree of integration, which belongs to a direct monolithic fabrication of datum and reference

planes, metrology fiducials, or decoupling mounting interfaces at the mirror substrate itself. Using servo assisted diamond machining techniques, optical surfaces and mechanical references are manufactured in the same machining operation, which results in an exact knowledge between the optical and mechanical coordinate systems. By applying ultra-precision diamond machining techniques to the mechanical telescope structure, all interfaces can be generated highly accurate in shape and position.

A strict application of this reference based machining and metrology approach enables a simplified assembly of the whole optical system. Individual parts of the telescope are snapped together at their ultra-precisely machined interfaces, while the integration is reduced to a few relative alignment steps. Further improvements are achieved, if the optical design allows for special fabrication approaches that make use of a modular arrangement of single surfaces on common mechanical carriers. Two mirrors can be simultaneously machined in a common toolpath to fix the relative position between the surfaces with uncertainties as low as the machine precision. The combined fabrication is coupled to a further reduction of the open degrees of freedom that have to be considered in the final telescope integration step.

Snap-together approaches were traditionally developed for infrared (IR) applications having relative loose tolerances on figure and position, where the required precision is achieved by diamond machining only. Using local figure correction and polishing techniques such as Magnetorheological Finishing (MRF) and computer controlled polishing (CCP), single surface deviations and remaining position errors can be compensated. The improvements allow for a transfer of the integration approach to applications in the near infrared (NIR) and visual (VIS) spectral range.

The article presents the development, fabrication, and testing of a large aperture, anamorphic imaging four mirror telescope exhibiting a smart alignment approach. Four biconic aspheres are used to transform an incoming 200 x 50 mm? rectangular field of view onto a 90 x 90 mm? square image plane. Optical and mechanical designs intend a simplified system integration by combining each two freeform surfaces on a common mechanical substrate. Using a combination of fast tool servo diamond machining and subsequent MRF figure correction, mirror modules having single surface deviations < 150 nm p.-v. and relative position errors < 1 μm are manufactured. Fabrication and metrology approaches proposed always relate to well defined fiducials that are machined in a combined diamond turning – diamond milling step. Local MRF polishing helps to reduce the final microroughness of the mirror to less than 0.5 nm rms.

System assembly is finally simplified to a snap-together mounting of both mirror modules into the overall telescope structure. The performance is measured over the field of view with the help of a parallel kinematic setup and results are reported.

9912-34, Session 6

Effects of thermal inhomogeneity on 4m class mirror substrates

Thomas Westerhoff, Ralf Jedamzik, Clemens Kunisch, SCHOTT AG (Germany)

The new ground based telescope generation is moving to a next stage of performance and resolution. Mirror substrate material properties tolerance and homogeneity are getting into focus. The coefficient of thermal expansion (CTE) homogeneity is even more important than the absolute CTE. The error in shape of a mirror, even one of ZERODUR®, is affected by changes in temperature, and by gradients in temperature. Front to back gradients will change the radius of curvature R that in turn will change the focus. Some systems rely on passive athermalization and do not have means to focus. Similarly changes in soak temperature will result in surface changes to the extent there is a non-zero coefficient of thermal expansion. When there are inhomogeneities in CTE, the mirror will react accordingly. Results of numerical experiments are presented discussing the impact of CTE inhomogeneites on the optical performance of 4 m class mirror substrates. Latest improvements in 4 m class ZERODUR® CTE homogeneity and the thermal expansion metrology are presented as well.

9912-35, Session 6

Unmanned aerial vehicles in astronomy

Federico Biondi, Demetrio Magrin, Roberto Ragazzoni, Jacopo Farinato, Davide Greggio, Marco Dima, Marco Gullieuszik, Maria Bergomi, Elena Carolo, Luca Marafatto, Elisa Portaluri, INAF - Osservatorio Astronomico di Padova (Italy)

Unmanned Aerial Vehicles (UAVs) are used in a wide range of activities both for civilian and military purposes, for scientific and commercial scopes. Involved fields of interest are getting broader as technological developments make UAVs affordable and reliable tools to position sensors in locations otherwise difficult or unsafe to access or expensive for other options. The ability of UAVs to pinpoint positions with increasing precision and automation goes along with the evolution of laser ranging sensors in term of compactness and lightness, allowing them to be employed in a number of metrological measurements for natural or artificial structures otherwise difficult to properly sense.

Considering all these benefits, the use of UAVs in astronomy is a step to be considered for valuable contributions in making some procedure easier and cheaper. Although applications of UAVs for strictly astrophysical objectives have not planned yet, we consider a wide spectrum of possibilities for them to be used as facilities for Ground Based Telescopes. Here we describe a non-exhaustive list of possible applications that we at least try to briefly discuss, emphasizing the applications in the field of alignment and maintenance of the telescopes and seeing measurements.

Nowadays, a dozen of 8 to 10 m diameter class telescopes are employed for astronomical purposes and the generation of Extremely Large Telescopes (diameter of 24 to 39 m) is in advanced phase of construction. Alignment of these telescopes, in order to achieve nominal performances, is an important asset, especially taking into account the relatively high operation costs of such devices. Primary mirrors can be tested in daylight condition placing a calibration device in their centre of curvature. Moreover, every time an intermediate real focus is identified, all the optical train following such a point can be easily adjusted with a simple calibration device to be inserted in the proper position. Since for 30 m telescopes with a very fast (F/1) optical primary, such a device should be located about 60 m away from the primary mirror to align it and for popular Cassegrain telescopes the autocollimation point is even more distant to align the secondary, it is clear that the use of a UAV to reach those locations would set aside the need for expensive and inconvenient static structures, employed only in few cases (McDonald telescope in Texas is a notable case).

Other examples of daylight activities of telescope maintenance, potentially performed by an adequately equipped UAV, are the measurement of the cophasing of adjacent surfaces, scattering and reflectivity of tiles of segmented mirrors. UAVs can be employed overnight in monitoring environmental parameters, like Cn2 and Ct2 that would be measured dynamically for an arbitrary thick ground layer and in exploring fine details in the dome seeing evolution.

In this work we discuss the prospects of use of UAVs for these mentioned activities, relating them to a small number of parameters, and tracing which could be the schemes, requirements, and benefits for employing them in the telescope alignment, both at the stages of erection and maintenance.

9912-36, Session 6

Coordinate metrology of a primary surface composite panel from the Large Millimeter Telescope

David M. Gale, Instituto Nacional de Astrofísica, Óptica y Electrónica (Mexico); Miguel Viliesid Alonso, Edgar

Arizmendi Reyes, Octavio Icasio-Hernandez, Ctr. Nacional de Metrología (Mexico); Andrea León-Huerta, Lizeth Cabrera Cuevas, David Castro Santos, Emilio Hernández Ríos, Maribel Lucero Álvarez, Esteban Tecuapetla Sosa, Carlos A. Tzile Torres, Instituto Nacional de Astrofísica, Óptica y Electrónica (Mexico)

The Large Millimeter Telescope (LMT) Alfonso Serrano is a fully steerable single-dish radio telescope presently operating with a 32.5 m parabolic primary reflector, soon to be extended to 50 m. The primary surface is composed of 180 segments arranged in five concentric rings. Each segment is formed by a set of 8 precision composite Nickel reflective panels. Five height-adjustable support points per panel allow surface adjustment to the local design parabola prior to segment installation. Since 2011 the project has used commercial laser trackers to measure the surface shape of the panels, not only for initial adjustment, but also for periodic checks after installation in the antenna. More recently, photogrammetry has been used to provide a sanity check of the tracker data.

The LMT project has invested much effort in developing and verifying surface fitting algorithms, used to transform data point clouds from the measuring instruments into RMS surface error. Conversely, relatively little effort has been spent on attempting to verify the data collection process itself, relying simply on periodic equipment calibration and occasional field checks with linear scale bars. Verification of the measurement process is important for two reasons; firstly, because a poor understanding of equipment–related measurement uncertainty may lead to unreliable results, and secondly because the LMT project routinely uses its metrology equipment at the limits of stated accuracy or beyond the manufacturer's environmental specifications.

Recently the LMT team has started a collaboration project with CENAM, the National Metrology Institute (NMI) of Mexico, to characterize the measurements performed on the curvature of the telescope primary panels, validate these measurement results and establish the measurement uncertainty. For this purpose, a panel was sent to CENAM to be measured horizontally on a high accuracy Coordinate Measuring Machine (CMM) with well-controlled temperature conditions. The panel was also measured using LMT and CENAM laser trackers, and LMT photogrammetry equipment. All measurements were performed by LMT and CENAM personnel, within the controlled laboratory environment at CENAM. This panel will be used hereafter by the LMT project as a reference artifact to make regular checks on our portable coordinate measuring systems and validate subsequent measurements at INAOE and on-site.

In this paper we present some results of the surface panel metrology exercise with an emphasis on the identification and estimation of measurement uncertainties that have relevance to the equipment and procedures used routinely by the LMT project as part of the surface qualification process. We also describe the steps taken to use the sample panel as a calibrated work-piece as described by ISO-15530-3. The creation of a calibrated work-piece is an experimental process that will allow the LMT metrology group to simplify the evaluation of measurement uncertainty when using coordinate metrology techniques such as a laser tracker and photogrammetry.

9912-37, Session 6

Error analysis of back focal length measurement technique for long focus larges-scaled lenses

Ivan N. Sudarikov, Magomed A. Abdulkadyrov, Aleksandr N. Ignatov, Vladimir E. Patrikeev, JSC Lytkarino Optical Glass Factory (Russian Federation)

The technique for positive long focus lenses allows to perform back focal length and transmitted wavefront measurements. Based on high-precision interferometric alignment and laser distance meter system (laser tracker) the technique allows measuring the back focal length with high precision. Testing of transmitted wavefront is done by means of an autocollimation optical system based on dynamic phase-shifting interferometer. The major contribution to the technique precision is the instrumental errors. The main instrumental error sources and their correlation with a measurement process were found. The main components of instrumental error are optical system alignment error, laser tracker measurement error, error of manufacturing additional accessories. Statistical modeling showed that this technique has a relatively measured precision value of less than 0.003%.

9912-38, Session 7

Evaluation of novel approach to deflectometry for high accuracy optics

Giorgia Sironi, INAF - Osservatorio Astronomico di Brera (Italy); Rodolfo Canestrai, INAF - Osservatorio Astronomico di Bologna (Italy); Giovanni Pareschi, INAF - Osservatorio Astronomico di Brera (Italy)

A deflectometrical facility was developed at Italian National Institute for Astrophysics-OAB to characterize free-form optics with shape errors within few microns rms.

Deflectometry is an interesting technique because it allows the fast characterization of free-form optics. The capabilities of deflectometry in measuring medium-high frequencies are well known, but the low frequencies error characterization is more challenging. Our facility design foresees an innovative approach based on the acquisition of multiple direct images to enhance the performance on the challenging low frequencies range.

This contribution presents the error-budget analysis of the measuring method and a study of the configuration tolerances required to allow the use of deflectometry in the realization of optical components suitable for astronomical projects with a requirement of high accuracy for the optics. Test examples are the primary mirrors for the E-ELT and the MAORY mirrors.

9912-39, Session 7

Laboratory and field testing results of the LMT/GTM primary surface actuators

David R. Smith, MERLAB, P.C. (United States); Kamal Souccar, Univ. of Massachusetts Amherst (United States); César E. Cuevas-Arteaga, José Luis Hernández Rebollar, Arak Olmos Tapia, Instituto Nacional de Astrofísica, Óptica y Electrónica (Mexico); Daniele Gallieni, Paolo Lazzarini, Pierluigi Fumi, Enzo Anaclerio, A.D.S. International S.r.l. (Italy)

With the final installation of the two outermost rings of the primary surface of the Large Millimeter Telescope/Gran Telescopio Milimetrico (LMT/GTM), the project is also upgrading the primary surface actuators. There are commercial actuators that can approach the required operational accuracy and stroke, but the combination of the size and load requirements ultimately required a customized design. The new actuators fit within the volume constraints imposed by the tighter interior angles in the outer rings and are designed to support the operational and survival loading conditions even for the largest surface segments. Laboratory testing confirmed that the actuators should meet the precision, repeatability, load, and lifetime requirements.

However, the LMT/GTM is at a particularly difficult site for electromechanical systems. The high altitude has the usual effect of reducing cooling effectiveness for the drives and motors, and the ambient temperature hovers near freezing. Since there is a significant amount of

precipitation during some times of the year, there are frequent freeze/thaw cycles. The constant formation and either sublimation or melting of ice, along with the associated high humidity, has been a challenge for the environmental protection of many devices at the LMT/GTM. Because there are a total of 720 primary surface actuators in the system, it is particularly important that the actuators, their local drive control boxes, and their cable connections be able to meet its specifications even under the site conditions.

To confirm the suitability of the actuators, the LMT/GTM procured an initial set of sixteen actuators for testing at the site. After laboratory testing, the actuators were installed into the outer two rings of the telescope and cycled during the early winter months of the 2015-2016 scientific observing season. Because of the continuing installation activities in these two rings, they are not illuminated by the receivers, so field testing under actual operational conditions could be conducted without affecting the ongoing scientific observations. This paper presents the characterized performance of the actuators before and after testing, as well as a report on their environmental robustness.

9912-41, Session 7

Optical tests of the Si immersed grating demonstrator for METIS

Tibor Agócs, ASTRON (Netherlands)

We present the optical tests of the silicon immersed grating (IG) demonstrator for the Mid-infrared E-ELT Imager and Spectrograph, METIS. IG-s offer several advantages over conventional front-surface gratings. Since diffraction takes place inside the high-index of refraction material, the optical path difference and angular dispersion are increased proportionally. Consequently, a smaller grating area and beam diameter is sufficient to obtain the same spectroscopic resolution, so a significant reduction of spectrometer volume becomes possible. Also, using the available expertise and techniques of the semiconductor industry, IG-s can achieve higher diffraction efficiency and lower stray light levels.

The METIS IG demonstrator is produced on a 150 mm industry standard for wafers. Similarly, standard semiconductor lithography techniques and anisotropic etching in silicon are used to define grating grooves with nanometer accuracy and sub-nanometer roughness. Optical bonding is used then to combine the wafer and silicon prism, followed by thermal fusion to strengthen the wafer-prism bond.

In the current paper we discuss the results of the IG tests that were performed in order to verify the optical requirements of the component. We detail the interferometric tests that were done to measure the wavefront error. A HeNe laser interferometer operated at 633nm was used to measure the entry/exit facet as well as the grating surface itself from air-side in various orders, in different grating orientations. We present the wavefront error budget of the complete IG and show how the wavefront error of various sources were deduced and calculated from the measurements. We present the optical arrangement and the results of the throughput measurements that were done with a modified infrared Fourier Transform Spectrometer (FTS). The measurement gave insight into the diffraction efficiency of the grating knowing the AR coating characteristics of the entrance/exit surface. Throughput was measured over the complete operational wavelength range of the METIS spectrograph, between 2.9?m and 5.3?m. We also show the dedicated mounting arrangement and results of the BRDF (Bidirectional Reflection Distribution Function) measurement that were performed with a Complete Angle Scatter Instrument (CASI) in spectral and spatial direction. Wafer defects observed after optical contacting and bonding (between the prism and wafer) were investigated as well. We present the lessons learnt during the IG demonstrator test campaign and elaborate on the challenges that we encountered, especially during the wavefront error measurements that led us to investigate further and improve the fabrication processes of the grating patterning on the silicon wafer.

9912-42, Session 8

Optical performance analysis and test results of the EUCLID near-infrared ?spectro-photometer

Csaba Gal, Hans D. Thiele, Elena Gubbini, Ahmad Mecsaci, Alexander Meister, Amir Mottaghibonab, Karina Gawlik, Maximilian Dubowy, OHB-System AG (Germany); Frank U. Grupp, Univ.-Sternwarte München (Germany); Andreas Bode, Carolin Wimmer, Max-Planck-Institut für extraterrestrische Physik (Germany); Ralf Bender, Univ. Sternwarte München (Germany)

The Near Infrared Spectrometer and Photometer (NISP) of the EUCLID satellite ?project encompasses high precision large lens mounts of 168 mm diameter that are ?operated at cryogenic temperatures down to 135K. The four lenses of the optical ?system are made of different materials: SUPRASIL 30001, CaF2, and S-FTM16, ?which are mounted in a separate lens mount design using glue connections. Each ?lens assembly has its individual mechanical interface to the structure, the so called ?lens barrel.

Exhaustive structural and thermal investigations ?have determined lens surface ?deformations and lens position ?changes that are introduced by ?various ?environmental loads, such as thermal-, mechanical-, ?interface-, and gravity ?loads, as well as ?mechanical stress of the lenses due to glue shrinkage ?during ?curing. All these impacts change the ?lens optical behaviours under real ?operational ?conditions of ?the optical assembly, which are thoroughly investigated in ?the optical performance assessment activity.?

Especially, great effort has been made for the simulation of interface tolerances. ?Due to the complexity of all mechanical interfaces (baffle, lens mounts, housing, ?telescope structure, etc.) statistical simulation is conducted applying ?Monte Carlo ?method. From the result of the statistical simulation 3 representative cases are ?selected for the optical performance assessment, which have 95% confidence level ?of the lens surface deformation.?

In the context of the evaluation procedure the surface form error of all EUCLID ?lenses as well as the RMS ?WFE at the ?focal plane is assessed, and results are ?compared with the nominal ?performance of the ?system, as well as with ?interferometrically measured results achieved during the interface– and gravity ?release test campaign.?

The performance of the lens holder design in terms of glue shrinkage effects, gravity ?release and interface tolerances is verified by an adapted test facility including an ?interferometer based optical metrology system. Finally, the measured values are ?compared with the analytical results, which show great confidence and hence ?proves validation of the analytical model.?

The paper presents the optical performance analysis results and the measured ?performance of the EUCLID high precision large cryogenic lens mounts. The ?achievements are presented on behalf of the EUCLID consortium.?

9912-43, Session 8

GMTIFS: the adaptive optics beam steering mirror for the GMT integral-field spectrograph

Brady Espeland, Gabriel J. Bloxham, Robert Boz, David Bundy, John Davies, Bartholomew Fordham, John Hart, Robert Sharp, Annino Vaccarella, Colin Vest, The Australian National Univ. (Australia)

To achieve the high adaptive optics sky coverage necessary to allow

the GMT Integral-Field Spectrograph (GMTIFS) to access key scientific targets, the on-instrument adaptive-optics wavefront-sensing (OIWFS) system must patrol the full 180 arcsecond diameter guide field passed to the instrument. The OIWFS uses a diffraction limited guide star as the fundamental pointing reference for the instrument. The science target must be held stationary with respect to the guide star. During an observation the offset between the science target and the guide star will change due to sources such as flexure, differential refraction and non-sidereal tracking rates. GMTIFS uses a beam steering mirror to set the initial offset between science target and guide star and also to correct for changes in offset. In order to reduce image motion from beam steering errors to those comparable to the AO system in the most stringent case, the beam steering mirror is set a requirement of less than 1 milliarcsecond RMS. This corresponds to a dynamic range for both actuators and sensors of better than 1/180,000. The GMTIFS beam steering mirror uses piezo walk actuators and a combination of eddy current sensors and interferometric sensors to achieve this dynamic range and control. While the sensors are rated for cryogenic operation, the actuators are not. We report on the results of prototype testing of single actuators, with the sensors, on the bench and in a cryogenic environment. Specific failures of the system are explained and suspected reasons for them. A modified test jig is used to investigate the option of heating the actuator and we report the improved results. In addition to individual component testing, we built and tested a complete beam steering mirror assembly. Testing was conducted with a point source microscope, however controlling environmental conditions to less than 1 micron was challenging. The assembly testing investigated acquisition accuracy and if there was any un-sensed hysteresis in the system. Finally we present the revised beam steering mirror design based on the outcomes and lessons learnt from this prototyping.

9912-44, Session 8

Development of superconducting voice coil motor of a cold chopper for MICHI

Kiyoshi Mori, Takashi Miyata, The Univ. of Tokyo (Japan); Mitsuhiko Honda, Kurume Univ. (Japan); Takafumi Kamizuka, Hidenori Takahashi, Shigeyuki Sako, Ryou Ohsawa, Kazushi Okada, Masahito S. Uchiyama, The Univ. of Tokyo (Japan); Hirokazu Kataza, Japan Aerospace Exploration Agency (Japan); Hiroyuki Ohsaki, Takashi Hiroe, The Univ. of Tokyo (Japan); Christopher Packham, The Univ. of Texas at San Antonio (United States)

A collaborating group based dominantly in Japan and the USA is investigating the science enabled and instrument design for a Mid-Infrared Camera, High disperser, and Integral field unit, called MICHI for the 30 m TMT. We hope that MICHI could become a strong candidate for the second generation of TMT instruments.

A cold chopper is one of the key elements of MICHI. For ground-based mid-infrared observations, time variations of atmospheric radiation are often many times greater than the radiation from target. Cold chopping is a technique to account for these background variations. 8 m class telescopes have chopped their secondary mirror, but this is impractical for the 30 m class of telescopes due to their much larger secondary mirror. For MICHI, we plan to use a movable mirror in the instrument at 30 K which will enable us to capture two slightly spatially and temporally different images to accurately remove the sky and account for the sky variations.

A cold chopper mirror (35mm diameter) for MICHI/TMT requires a stroke of 2.5 mm, a response time ≤ 10 ms. To prevent a significant power dissipation of the actuator, we require a power dissipation of ≤ 0.1 W.

In order to satisfy these requirements, we focused on Voice Coil Motor (VCM). VCM is a linear and electromagnetic actuator, and can be easily designed and have high responsibility.

Additionally, we use a superconducting wire made from MgB2 which has the highest transition temperature, 39 K, among metal superconductors. Thus VCM using MgB2 wire should work in the superconducting state at 30 K.

The force applied by a VCM is proportional to the applied current and magnetic field. In order to reduce joule heat from wire other than superconducting wire of a VCM, the current of electric circuit which includes a VCM is required to be ≤ 1 Ampere, so the magnetic field strength is a very important element for designing the VCM.

Generally, a neodymium magnet is known as the strongest magnet at room temperatures. But under about 135 K, the magnetic field becomes weak due to the spin reorientation transition. Therefore we use a praseodymium magnet, which produces a stronger magnetic field than the neodymium magnet at 30 K.

The magnet field easily permeates the vacuum. We should design the magnetic circuit to prevent the leakage flux. We select two fundamental designs of VCM and have completed a parameter search to find best design of the actuator for the MICHI cold chopper. We note that even a superconducting VCM produces energy dissipation when there is a variation in the current. This is caused by the magnetic hysteresis. However, it is difficult to estimate the power dissipation of the superconducting wire analytically, thus we use a numerical simulation to estimate the dissipation, and the result showed that the power dissipation is within 0.1 W.

Using these considerations, we made a prototype VCM. We are currently evaluating this VCM and plan to install it in MIMIZUKU, a mid-infrared instrument for the University of Tokyo Atacama Observatory 6.5 m Telescope.

9912-45, Session 8

Characterizing the performance of cryogenic lens mounts for the HARMONI spectrograph

Jamie R. Allen, Kieran O’Brien, James D. Lynn, Niranjan A. Thatte, Univ. of Oxford (United Kingdom); Ian A. J. Tosh, STFC Rutherford Appleton Lab. (United Kingdom); Mike Tacon, Univ. of Oxford (United Kingdom)

HARMONI is an optical and near infrared spectrograph that will be the first-light spectrograph on the E-ELT. To minimize the thermal background in the infrared, it will be a cryogenic instrument with an operating temperature of 130K. Cooling down the instrument causes differential thermal contraction, which should be compensated for in the lens mount designs, to allow alignment of the optics at room temperature. The lenses in the current camera design have a diameter of 200mm and need to be centred to an accuracy of around 20?m at the operating temperature.

We have designed 4 different self centring lens mounts and have also developed an alignment procedure based on the idea of avoiding any contact with the lens where possible, to reduce any risk of damage. The position of the lens is measured once with a CMM, with the mount then moved into alignment with it so that it can be used as a mechanical reference for the lens when assembling the camera barrel.

We have performed cryogenic tests on the different lens mount designs and here we present the development of the alignment and bonding procedures as well as the optomechanical performance of mounts.

9912-46, Session 8

Characterization of the actuator of EMIR configurable slit unit

Angel Mato, Miguel Núñez Cagigal, Maria Barreto, Jesús Patrón Recio, Francisco Garzón López, Instituto de Astrofísica de Canarias (Spain)

EMIR (Espectrógrafo Multiobjeto Infra-Rojo) is a wide field multi-object spectrograph for the Nasmyth focus of GTC (Gran Telescopio Canarias). It will operate in the near-infrared (NIR) wavelengths 0.9–2.5μm and it will include several mechanism working at cryogenic conditions.

A key component of EMIR is the CSU (Configurable Slit Unit), which is a cryogenic mechanism used to generate a multi-slit configuration and a long slit on EMIR focal plane when working in spectroscopic mode. The system have 110 sliding bars which can be configured at cryogenic working temperature to create 55 slits with a high position accuracy and repeatability. The movement of the bars is obtained by an actuator which allows to reach a relatively high speed for coarse movement and controllable steps up to 2 microns for fine positioning. This subsystem has been designed and manufactured by Janssen Precision Engineering (JPE) and thoughtfully verified at the IAC (Instituto de Astrofísica de Canarias) facilities.

One of the most critical parts of the CSU are the actuators, which have a design based on a piezo stick-slip effect. In each step there is a first phase in which the bar is dragged in the movement direction (stick) and a second phase in which it should not move (slip), although it really produces a small movement in reverse direction; therefore, the total movement in each step depends on these two effects. The balance between these two phases is strongly affected by other factors such as: the electrical wave used for exciting the piezo, the orientation of movement with respect to gravity and the friction between the bar and the actuator. In this paper we present the results of the tests performed in order to characterize these effects on the two phase movement of the bar.

9912-47, Session 8

A cryogenic “set-and-forget” deformable mirror

Robin Trines, Huub Janssen, Sander L. Paalvast, Maurice Teuwen, Janssen Precision Engineering B.V. (Netherlands); Bernhard R. Brandl, Leiden Observatory (Netherlands); Michiel Rodenhuis, Netherlands Research School for Astronomy (Netherlands)

This paper discusses the development, realization and initial characterization of a demonstrator for a cryogenic “set-and-forget” deformable mirror. Many high-end optical instruments on modern large telescopes like METIS (The Mid-Infrared E-ELT Imager and Spectrograph) use either a large number of spherical mirrors or several complex free-form mirrors to manipulate the wavefront to the desired shape. Due to manufacturing and alignment tolerances, each mirror contributes static aberrations to the wavefront. Many of these aberrations are not known in the design phase and can only be measured once the system has been assembled. A “set-and-forget” deformable mirror can be used to compensate for these aberrations, making it especially interesting for systems with complex free-form mirrors or cryogenic systems where access to iterative re-alignment is very difficult.

The mirror with an optical diameter of 200 mm is designed to correct wavefront aberrations of up to 2 μm RMS. The shape of the wavefront is approximated by the first 15 Zernike modes. Analysis of the mirror shows a theoretically possible reduction of the wavefront error from 2 μm to 50 nm RMS (3?). To produce the desired shapes, the mirror surface is supported by 19 identical actuator modules at the back of the mirror. Additional actuators are used to control tip/tilt and piston, providing a larger stroke. This allows for correction of alignment tolerances of the deformable mirror. These additional actuators also introduce redundancy to the system, maintaining optimal performance in case of an actuator malfunction.

The actuator modules have a bidirectional stroke of ±10 μm and sub-nanometer resolution. Elastic flexures are used to eliminate friction and backlash and increase the stability of the mirror shape. To minimize parasitic forces acting on the mirror, the actuator modules are coupled to the mirror using flexible struts. The mirror’s in-plane degrees of freedom are constrained by three folded leaf springs, providing a symmetrical, hysteresis-free connection to the frame.

The actuator modules use commercially available PiezoKnob actuators with a high technology readiness level (TRL). These provide nanometer resolution at cryogenic temperatures combined with high positional stability, and allow for the system to be powered off once the desired shape is obtained. The stiff design provides a high resonance frequency (>200 Hz) to suppress external disturbances.

9912-48, Session 9

Local seeing determination by thermal-CFD analysis to optimize the European Solar Telescope image quality

Nauzet Vega Reyes, Instituto de Astrofísica de Canarias (Spain); Lluis Cavaller, GRANTECAN S.A. (Spain); José Marco de la Rosa, Instituto de Astrofísica de Canarias (Spain); Joan Baiges, Daniel Pérez-Sánchez, International Ctr. for Numerical Methods in Engineering (Spain); Christine Grivel, Manuel Collados, Instituto de Astrofísica de Canarias (Spain); Arnau Pont, Ramon Codina, International Ctr. for Numerical Methods in Engineering (Spain)

The design of telescope facilities which minimize the amount of aerodynamic turbulence flow around them is a key for getting the best possible performance out of a telescope. This is especially true in the case of solar telescopes such as the European Solar Telescope (EST), a large aperture solar telescope (4 meters) that will be located in the Canary Islands. Solar radiation has a critical impact onto the image quality because of the turbulence generated by large temperature gradients at ground level. Therefore, an analysis of the optical distortion due to turbulent effects and the influence of facilities on these parameters is required.

The purpose of this paper is to present the results of thermal and computational fluid dynamics (CFD) analyses of the telescope environment (dome, pier, building, ground, etc.), in order to evaluate the local seeing effect caused. The objective is to keep the temperature of the surfaces of the facility as close as possible to the ambient temperature and minimize the local seeing effect. Two major configurations have been analyzed for the telescope facilities in different environmental conditions, open configuration (without conventional dome) and closed configuration (with conventional dome).

The work flow consists in a thermal analysis followed by CFD analysis. The first stage provides temperature maps for the second, once the model is established (day-night cycles comprising two consecutive days – transient analysis). CFD simulations provides accurate convection models for the analysis (LES turbulence model) which have been used to calculate the refractive index structure constant (Cn2) integrated along the telescope optical beam, at three moments of the day: morning, noon and afternoon.

This contribution starts by reviewing the cases of study analyzed during phase III of the EST project, mainly focused on the study of the “open configuration”. Building orientation, materials, coatings and cooling systems are some of the parameters evaluated. The “closed configuration” analysis is divided in four sections:

- Dome without thermal control
- Dome with thermal control
- Heat rejecter effect inside dome
- Observations out of the sun

Finally, the conclusions of the study are presented together with the advantages and disadvantages of both configurations.

9912-49, Session 9

Initial development of high-accuracy CFRP panel for DATE5 antenna

Yuan Qian, Zheng Lou, Purple Mountain Observatory (China); Xufeng Hao, Jing Zhu, Shanghai Composites Science & Technology Co.,Ltd (China); Jingquan Cheng, Hairen Wang, Yingxi Zuo, Ji Yang, Purple Mountain Observatory (China)

DATE5 antenna, which is a 5m telescope for terahertz exploration, will be sited at Dome A, Antarctica. It is necessary to keep high surface accuracy of the primary reflector panels so that high observing efficiency can be achieved. In antenna field, carbon fiber reinforced composite (CFRP) sandwich panels are widely used as these panels are light in weight, high in strength, low in thermal expansion, and cheap in mass fabrication.
In DATE5 project, CFRP panels are important panel candidates. In the design study phase, a CFRP prototype panel of 1-meter size is initially developed for the verification purpose. This paper introduces the material arrangement in the sandwich panel, measured performance of this testing sandwich structure samples, and together with the panel forming process. For deicing in the South Pole region, a special CFRP heating film is embedded in the front skin of sandwich panel. The properties of some types of basic building materials are tested. Base on the results, the deformation of prototype panel with different sandwich structures and skin layers are simulated and several types of sandwich structure samples are tested in the conditions of Antarctic weather, a best structural concept is selected. The panel mold used is a high accuracy one with a surface rms error of 1.4 ?m. Prototype panels are replicated from the mold. Room temperature curing resin is used to reduce the thermal deformation in the resin transfer process. In the curing, vacuum negative pressure technology is also used to increase the volume content of carbon fiber. After the measurement of the three coordinate measure machine (CMM), a prototype CFRP panel of 5.1 ?m rms surface error is developed finally.

9912-50, Session 9

Completely open-foldable domes remaining cool in sunshine

Robert H. Hammerschlag, Leiden Univ. (Netherlands) and Utrecht Univ. (Netherlands); Sander Deelen, Utrecht Univ. (Netherlands); Pieter W. Hoogendoorn, Utrecht Univ. (Netherlands) and Leiden Univ. (Netherlands); Johannes N. M. Kommers, Leiden Univ. (Netherlands); Thomas Sonner, Roberto Simoes, Olivier Grassin, Andreas Fischer, Kiepenheuer-Institut für Sonnenphysik (Germany)

These open-foldable domes are designed for bad-weather protection and maintenance of instruments for astronomical, meteorological and civil-engineering measurements. It is important that all parts of the opened domes remain cool in sunshine for daytime observations: (i) high-resolution observations of the Sun and other astronomical objects visible during daytime and the first part of the night; (ii) meteorological scintillation measurements in a horizontal path between two towers above ice fields, agriculture fields and nature regions giving information about air-temperature and humidity fluctuations; (iii) precision civil-engineering measurements of ground shape and buildings with theodolites and laser scanners.

The open-foldable domes are designed to withstand extreme weather situations of storm and ice formation, as occur on mountains and in arctic regions. The construction is based on very strong textile membranes highly tensioned between steel bows when the dome is closed. The result is a very light-weight dome despite its extremely high wind stability. Consequently, these domes are also very suitable for light-weight open-construction towers. The domes of the GREGOR telescope and the Dutch Open Telescope are the two existing prototypes. Improvements were developed with all parts light-colored to remain cool in solar light.

New textile parts were developed for the GREGOR dome. The connection parts (eyes) between the textile parts now are made from white-colored PETP, a very strong and UV-stable synthetic, instead of the black-colored standard available PVC eyes used before. In addition, the new specially made eyes have a better geometrical shape giving higher stability. The new eyes are not glued to the textile membranes, but locked in textile pockets attached on the membranes. Consequently, it is easy to replace the eyes when necessary.

The rubber seal tubes on top of the dome were of black-colored chloride rubber CR (neoprene). Reason for use of this black rubber was its strength and UV stability; however, disadvantage was heating in sunshine. Nowadays, light-colored UV-stable rubbers are available. Sheet pieces of several rubber types were tested for their temperature rise in sunshine. Values varied from 21.5 to 45 degree Celsius when exposed longer time to solar light. Clearly the best was an EPDM rubber in natural light color. From this EPDM rubber, new rubber tubes were produced and mounted on the GREGOR and DOT domes. Unfortunately, this rubber was not stiff enough to give good sealing and water leakage occurred. It was found that the addition of the black carbon to the rubber compound is essential to get the EPDM rubber stiff enough to get a reliable closing. The solution was found in a special construction, where inside the light-colored EPDM rubber tube a black-colored stiff EPDM rubber is put. The forces necessary for compression of the rubber tubes were measured in several tests. An inside black tube with a circa 1.5 times larger compression force than the original black tubes was applied. The assembling of the black tubes into the light-colored tubes was successfully applied at the DOT and GREGOR domes.

The presentation will give description, drawings and photos of the constructions applied for the newly developed fastenings of the textile membranes and of the sealing rubber tubes.

9912-51, Session 9

New isostatic mounting concept for a space born Three Mirror Anastigmat (TMA) ?on the Meteosat Third Generation Infrared Sounder Instrument (MTG-IRS)?

Maximilian Freudling, Jesko Klammer, Christian Körner, OHB-System AG (Germany); Grégory P. Lousberg, Jean-Marc Schumacher, AMOS Ltd. (Belgium)

The Meteosat Third Generation (MTG) Programme is being realised through the well-established ?cooperation between EUMETSAT and ESA. It will ensure the future continuity with and enhancement ?of operational meteorological (and climate) data from geostationary orbit as currently provided by the ?Meteosat Second Generation (MSG) system. ?

The industrial prime contractor for the space segment is Thales Alenia Space (France) with a core team ?consortium including OHB-Bremen (Germany) and OHB-Munich (Germany). This contract includes ?the provision of six satellites, four Imaging satellites (MTG-I) and two sounding satellites (MTG-S), ?which will ensure a total operational life of the MTG system in excess of 20 years.?

MTG-S carries the Fourier transform interferometry based Infrared Sounder (IRS), the design of which ?contains a Back Telescope Assembly (BTA) which will relay the interferogram beam into the cold ?optics and then to the focal planes. This BTA is based on a new isostatic mounting concept that has ?been developed, in collaboration between OHB and AMOS, for a space born Three Mirror Anastigmat ??(TMA) light-weighted for the MTG IRS. The TMA with additional folding mirror is based on a light-?weighted all-aluminium design. This developed isostatic mounting concept accommodates the TMA ?onto a CFRP structure (Carbon-Fiber-Reinforced-Polymer). The concept is able to cope with an CTE ?mismatch

of about 20 ?m/m between aluminium and CFRP introducing only very limited stresses into ?the sensitive TMA structure. In ?addition the operational temperature of the TMA is below 0°C, which is ?more than ??20K below the ?integration and alignnment temperature, as well as also 20K between ?temperature of the rest of the ?instrument.? Besides the capability to introduce low stresses into the TMA ?structure, ?the design allows to withstand launch loads of up to 47g. ?

The mounting principle is based on six interface ?element made of titanium, each blocking one degree ?of freedom but providing high flexibility for ?the other degrees of freedom. As three different materials ?are used (aluminium TMA, ?titanium I/F Elements, CFRP structure), one of the main challenge was to ?maintain the optical ?interfaces during the transition to 0°C. A ?very stable Line of Sight (LoS) of a few ?microrads could be achieved. ?

Another important aspect was ?to guarantee the pointing performance in the geostationary orbit of ?MTG with changing thermal conditions for the instrument. In addition the gravity release effect as well ?as the shrinkage of the CFRP structure due to the moisture expansion effect had to be considered by ?the development of the mounting system. The analysis results of the preliminary design confirm that ?these ambitious performance requirement can be met with margin. ?

This paper will provide the design of the BTA isostatic mounting and will summarise the consolidated ?technical baseline reached following a successful PDR. Further it will provide the predicted BTA ?performances, including the way forward to be carried out, and will highlight some of the numerous ?challenges and design solutions required to implement this complex relay telescope.?

The authors acknowledge that this work is supported by an ESA funding through the MTG satellites development.?

9912-52, Session 9

Analytical optimization and test validation of the submicron dimensional stability of the CHEOPS space telescope's CFRP structure

Luc Blecha, Daniel Zindel, Herve Cottard, Almatech Sàrl (Switzerland); Thomas Beck, Virginie Cessa, Christopher Broeg, Univ. Bern (Switzerland)

The CHEOPS mission (CHaracterising ExOPlanet Satellite), an ESA PRODEX founded misson, is the first one dedicated to search for transits by means of ultrahigh precision photometry on bright stars already known to host planets. The optical design is based on a Ritchey-Chretien style telescope to provide a de-focussed image of the target stars.

The telescope's mirrors M1, M2 as well as the focal plane detectors are supported by a thermally controlled CFRP structure suspended on isostatic mounts. The dimensional stability of the structural system supporting the optics is a key requirement as it directly impacts the instrument's accuracy. The M1 and M2 mirrors are supported by a tubular CFRP telescope design which has been optimized by analyses down to carbon fiber layer level with the support of extensive sample test results for model correlation and accurate dimensional stability predictions. This sample characterization test campaign has been conducted on samples with different carbon fibre layup (orientation and stack sequence) to measure accurately the Coefficient of Thermal Expansion (CTE) over a wide temperature range extending from -80°C to +80°C. Using the correlated Finite Element model, the fiber orientation combination that minimized the relative displacement between the M1 and M2 mirrors, including the consideration of the thermo-elastic contributions of the isostatic mounts on the overall stability of this optical system, has been identified and selected for the baseline design of the CHEOPS Structure.

A dedicated Structural and Thermal Model (STM) was manufactured and tested with an ad hoc setup to verify the overall structural stability of the optical train assembly. The relative distance between M1 and M2 was measured under thermal vacuum conditions using laser interferometry techniques. Thermal cycling tests were initially conducted to eliminate and characterize settling effects. Then, the structure stability was measured at three stable operational temperatures: -5, -10 and -15°C. The thermally induced M1-M2 misalignment was measured to be between 0.156 and 0.22 micron/°C in the focus direction. Relative mirror tilt and lateral centre shift were also measured. The obtained focus, tilt and centre shift stability were all compliant with the system level requirements and a CHEOPS Structure was successfully delivered for integration on the spacecraft only 1.5 years after project initiation.

This paper describes the novel technique used by Almatech for the analytical optimization of the Cheops CFRP Optical Train Assembly design based on extensive CFRP layout sample characterizations as well as the sub-micron dimensional stability test results performed under thermal vacuum conditions demonstrating its successful validation.

9912-53, Session 10

Developments in active optics for space instruments: an ESA perspective

Pascal Hallibert, Atul Deep, Alessandro Zuccaro Marchi, European Space Agency (Netherlands)

The increasing need for higher image resolution for space applications is driving the entrance aperture of optical systems, requiring the use of large primary mirrors either monolithic or deployable (cf ESA's Future Technology Advisory Panel First cycle report lists large monolithic mirrors as one of the 7 enabling technologies). This trend calls for the study of crucial technologies aimed at improving the imaging performance beyond what is currently achievable by classical optical systems.

Active Optics is a very promising example of such enabling technologies, based on the combination of three key technological components:

1. Corrective element (e.g. deformable mirror),

2. Wave front sensor (in order to characterize the aberrated wave front),

3. Algorithms determining the required correction to be applied, based on the wave front sensing results.

Active optics allows correcting for in-flight effects which impact the optical quality of space instruments. In particular, in the case of large mirrors, extreme lightweighting will need to be applied, leading to increased effects due to e.g. thermo-elastic deformations, radiation effects on optical materials, gravity release, etc. that need to be identified and corrected.

Active optics can also decrease the stringent requirements on the manufacturing quality for large optical components (e.g. compensating residual surface figuring errors), reduce structural and thermal design complexity (e.g. relaxing requirements on structure stability) and reduce the outage period of missions caused e.g. by Sun baffle intrusions or eclipses altering the thermal conditions within the instrument.

As such, active optics constitutes a key building block for the improvement of high-resolution imaging capabilities of future missions (namely for optical systems involving large mirrors, either monolithic or segmented) and constitutes a crucial generic technology able to find applications in all classes of optical instruments.

In terms of technological developments, concepts and demonstrators for corrective components (e.g. deformable mirrors) for space applications have already been initiated at ESA, e.g.:

- GSTP R&D activity "adaptive deformable mirror for space instruments" recently completed by Prof. Dr Wittrock's group at the Muenster University.

- TRP R&D activity "Large Aperture Telescope Technology" performed by Microgate, ADS, CNR-INO, INAF-Florence and CGS.

However, the other essential parts of the complete Active Optics correction chain have so far remained relatively untouched in the context of European space applications, namely: the technology performing the sensing of the aberrated wave front, and the strategy to pilot the corrective elements based on the wave front sensing results.

Furthermore, novel concepts for deformable components need to be explored further in order to anticipate the next generation of active optics specifically tailored for the compensation of large optics (e.g. deformable primary, multiple corrective elements, etc.).

This has led to the launch of a new TRP R&D activity "Active Optics Correction Chain for large monolithic mirrors", which is run in the frame of 2 parallel contracts (TNO-RUAG-Airbus DS- CFAO, Durham-NOVA and University of Galway-IoF), aiming at a complete concept for a correction chain for space applications.

9912-54, Session 10

FAME: freeform active mirror experiment

Felix C. M. Bettonvil, ASTRON (Netherlands) and NOVA Optical Infrared Instrumentation Group (Netherlands); Chris Miller, Martin Black, UK Astronomy Technology Ctr. (United Kingdom); Szigfrid Farkas, Konkoly Observatory (Hungary); Tibor Agócs, Gabby Aitink-Kroes, ASTRON (Netherlands) and NOVA Optical Infrared Instrumentation Group (Netherlands); David M. Montgomery, UK Astronomy Technology Ctr. (United Kingdom); Emmanuel Hugot, Lab. d'Astrophysique de Marseille (France); Hermine Schnetler, UK Astronomy Technology Ctr. (United Kingdom); Lars Venema, ASTRON/NOVA (Netherlands) and NOVA Optical Infrared Instrumentation Group (Netherlands)

FAME stands for Freeform Active Mirror experiment. It is a four-year project and part of the OPTICON/FP7 programme. It aims at providing a breakthrough component for future compact, wide field, high resolution imagers or spectrographs, based on both freeform technology and the flexibility and versatility of active systems.

Due to the opening of a new parameter space in optical design, Freeform Optics are a revolution in imaging systems for a broad range of applications ranging from high tech cameras to astronomy, via earth observation systems, drones, defense.

Freeform mirrors are defined by a non-rotational symmetry of the surface shape, and the fact that the surface shape cannot be simply described by conicoids extensions, neither off axis conicoids. An extreme freeform surface is a significantly challenging optical surface, especially for UV/VIS/NIR diffraction limited instruments. Some of these exotic surfaces are already proposed and used on-sky, such as the recombination surfaces of the PIAA apodiser.

The aim of the FAME effort is to use an extreme freeform mirror with standard optics in order to propose an integrated system solution for use in future instruments. The work done so far concentrated on identification of compact, fast, wide field optical designs working in the visible, with a diffraction limited performance; optimization of the number of required actuators and their layout; the design of an active array to manipulate the face sheet, as well as the actuator design.

In this paper we present the status of the demonstrator development, with focus on the different building blocks: an extreme freeform thin face sheet, the active array, a highly controllable thermal actuator array and the metrology and control system.

9912-55, Session 10

Novel and efficient ADC concept for BlackGEM telescope

Rik ter Horst, Jan W. Kragt, ASTRON (Netherlands); Dirk Lesman, NOVA Optical Infrared Instrumentation Group (Netherlands)

Earth base telescopes suffer from atmospheric dispersion caused by refraction of light through the atmosphere. For high quality astronomical observations dispersion should be corrected to a level where the spectral shift is virtually eliminated. A common practical solution is a combination of two counter rotating wedge shaped lens combinations for a step-less correction of all Zenith angles in the desired range. Drawbacks of this solution are high complexity of the optical elements, the required extra space and added mass and a mechanism with control electronics.

A novel solution has been found where the ADC function is integrated in the three-lens corrector by optimizing radii and offsets. The result is a highly effective system where, without adding any extra optical component or sacrificing on image quality, atmospheric dispersion can be corrected for Zenith angles down to 70 degrees. The correction is done by lateral displacement of only one field corrector lens such that the introduced dispersion compensates the dispersion of the atmosphere. The concept is applicable for other optical systems having at least three lens elements used as a field corrector. This concept will be applied in the BlackGEM telescope array. The basic design of the BlackGEM telescope consists of a parabolic primary mirror, a spherical secondary and a three-lens field corrector (Harmer-Wynne configuration).

BlackGEM is a planned array of optical telescopes located at the La Silla astronomical observatory in Chile. The system is specifically designed to detect the optical counterparts from gravitational wave sources detected with Virgo and LIGO. The BlackGEM array will comprise at least 3 remotely controlled telescopes with primary mirrors of 650 mm diameter. Each telescope will be equipped with a 10500 x 10500 pixel detector of 9 micron pixel size. The 3300 mm focal length of the telescope leads to a sky sampling of 0.56"/pixel, well matched to the seeing on La Silla. BlackGEM's precursor and prototype, the Meerlicht telescope, will be located in South Africa.

The paper describes the optical trade-offs, design and optimization and the mechanical design and implementation of this novel ADC solution.

9912-56, Session 10

Multilayer active shell mirrors for space telescopes

John Steeves, Jet Propulsion Lab. (United States); Sergio Pellegrino, Kathryn Jackson, California Institute of Technology (United States); David C. Redding, James K. Wallace, Samuel C. Bradford, Jet Propulsion Lab. (United States); Troy Barbee II, Lawrence Livermore National Lab. (United States)

A novel active mirror technology based on carbon fiber reinforced polymer (CFRP) substrates and replication techniques has been developed. Multiple additional layers are implemented into the design serving various functions. Nanolaminate metal films are used to provide a high quality reflective front surface on the mirror. A backing layer of thin active material (piezoelectric/electrostrictive) is implemented to provide the surface-parallel actuation scheme. Printed electronics are used to create a custom electrode pattern and flexible routing layer. Mirrors of this design are thin (< 1.0 mm), lightweight (2.7 kg/m2), and have large actuation capabilities (> 100 ?m defocus amplitude). These capabilities, along with the associated manufacturing processes, represent a significant change in design compared to traditional optics. Such mirrors could be used as lightweight primaries for small CubeSat-based telescopes or as meter-class segments for future large aperture observatories. Multiple mirrors can be produced under identical conditions enabling a substantial reduction in manufacturing cost and complexity.

An overview of the design decisions and manufacturing processes will be presented here. Specifically, considerations related to material selection, sizing of the active layer, and accommodating multiple active channels will be presented here. Methods to reduce the as-manufactured figure error of thin composite shells will also be presented. Additionally, predictions on

the actuation performance of the Carbon Shell Mirrors have been made through finite element simulations. An optimized electrode pattern has been developed in order to generate astigmatic modes of deformation. Results show that correctabilities on the order of 250-300x can be achieved with only 41 independent actuators. Actuation strokes of 10-100 ?m PV are also achievable over low-order modes – a product of the ultra-thin design.

Characterizing thin, highly active mirrors presents a significant challenge due to 1) the relatively high magnitude initial figure error, and 2) the extremely large actuation capabilities. Traditional optical techniques have proven insufficient due to a lack of dynamic range. An outline of the custom metrology system used to characterize the Carbon Shell Mirrors will be presented. The system is based on a Reverse Hartmann test and can accommodate extremely large deviations in mirror figure (> 100 ?m PV) down to nanometer precision. The system has been validated against several traditional techniques including photogrammetry and interferometry. Closed-loop figure correction experiments have been performed with this apparatus on 150 mm dia. prototypes. The mirrors have demonstrated post-correction figure accuracies of 250 nm RMS (one dead actuator limiting performance). Current efforts are focused on reducing the initial figure error leading to diffraction-limited performance over visible wavelengths.

9912-57, Session 10

Advances in silicon carbide active and passive telescopes

John Vayda, Northrop Grumman Xinetics (United States)

Recent advances in the fabrication processes of silicon carbide optics have resulted in the ability to produce lightweight mirrors and structures allowing for truly athermalized systems. Increased understanding of processing parameters and interactions have enabled these reaction bonded silicon carbide structures to be manufactured with less internal stress allowing for a reduction in generation times and improved yields. These improvements have been used to successfully manufacture the passive 0.5m primary used in the recent PICTURE-B payload on a NASA Black Brant IX sounding rocket. Assembly techniques are being incorporated that allow for individual components to be bonded together using similar, near identical compositional formulations thus eliminating the need to compensate for bond differences as one would observe in brazed components. Developing technologies in additive manufacturing of silicon carbide with "in family" properties relative to fugitive core cast materials have provided a new vehicle for manufacture of unique geometries which can be combined with more traditional parts through bonding to give the designer a wider range of practical options.

9912-58, Session 10

Orbiting rainbows: a granular imager

Scott A. Basinger, Marco B. Quadrelli, Jet Propulsion Lab. (United States); Grover A. Swartzlander Jr., Rochester Institute of Technology (United States); David M. Palacios, Jet Propulsion Lab. (United States)

"Orbiting Rainbows" is a Phase II NASA Innovative Advanced Concepts (NIAC) study that is looking twenty years into the future of creating a space-based observatory from granular media. "Granular matter" is considered to be the fifth state of matter; this investigation draws from recent research on disordered lenses and turbid lens imaging. The investigators are performing fundamental research and developing the technology roadmap to construct an optical system in space using nonlinear optical properties of a cloud of micron-sized particles, shaped into a specific surface by light pressure, to form a very large and lightweight aperture of an optical system. This "cloud optic" will be relatively simple to package, transport, and deploy. It is reconfigurable and can be re-targeted; the focal length is variable and it will be self-healing and ultimately disposable. The concept, in which the aperture does not need to be continuous and monolithic, will allow the aperture size to be several times larger than currently envisioned observatories such as ATLAST and a fraction of the mass and cost. The ultimate cloud optic could be several tens of meters in diameter, and multiple clouds can be combined to create kilometer-class apertures. The concept also relies heavily on computational optics to deconvolve objects from non-deal imagery. Simulations and experiments have been positive using speckle interferometry techniques together with blind image deconvolution using a sparse, specular media for a primary mirror of an optical system. This talk with give a brief overview of the Orbiting Rainbows concept and presents ground-based subscale experimental results.

9912-59, Session 10

Long-term stable active mount for reflective optics

Claudia Reinlein, Christoph Damm, Matthias Mohaupt, Andreas Kamm, Nicolas Lange, Fraunhofer-Institut für Angewandte Optik und Feinmechanik (Germany)

We report on the development of an active device/mount with orthogonal actuator matrix offering a stable shape optimization for gratings or mirrors. The design of the device is following a set-and-forget idea, meaning that it should remain constant after optimizing the position of the actuators and the shape of the optical element. We introduce the actuator distribution and show its capability to compensate for wavefront aberrations. Therefore, we calculate the accessible Zernike polynomials from the actuator influence function. Further, we will give results on the mechanical implementation. We use manual actuators to build a device with a reasonable price. In order to translate the stroke of the manual actuators, we introduce hinges that simultaneously pre-load the actuators. Therewith, we enable up-and downward movement of the optical element by the actuators.

Experimental tests show the capability of the device to compensate for aberration in two grating substrates. Thus we report on the interferometric measurements of the achievable best flat surface of 110x105 mm device and 220x210 mm device. The smaller device is used to take measurements of the position depending aberrations. Here we optimize the position in a vertically installed interferometer and repetitively measure the devices shape over several weeks. Then we bring the device to a horizontally installed interferometer and repeat these long-term measurements showing no position depending aberrations. Long-term measurements of the large device show similar results. We will particularly stress that the rms-shape remains constant within +/-3 nm rms during three month and for both devices.

Further, we will adress temperature-induced shape variations in order to update the thermo-mechanical model. Therewith we will discuss potential applications in space telescopes such as active mirrors, and Earth-based facilities where long-term stability is mandatory.

9912-60, Session 11

Multi-core fibers: the road to multimode photonics

Joss Bland-Hawthorn, Sergio G. Leon-Saval, Seong-Sik Min, Emma Y. Lindley, The Univ. of Sydney (Australia)

Photonic devices are finding increasing use in astronomical instruments: these include fibre bundles, laser combs, waveguides, fibre Bragg gratings, photonic lanterns, circulators and splitters. A major problem is that most devices developed for telecom operate only with single-mode fibres which are notoriously difficult to couple light into. We show that multi-core fibre technology can be used in place of multimode fibres and incorporate many photonic functions. The challenge here is to imprint uniform functions across all cores. We have built a Sagnac interferometer in order to mass produce the first high throughput multi-core devices, an essential step on the road to multimode photonics.

9912-61, Session 11

A micro-lens array based pupil slicer and double scrambler for MAROON-X

Andreas Seifahrt, Julian Stürmer, Jacob L. Bean, The Univ. of Chicago (United States)

We report on the design and construction of a micro-lens array (MLA)-based pupil slicer and double scrambler for MAROON-X, a new fiber-fed, red-optical, high-precision radial-velocity spectrograph for the 6.5m Magellan Telescope in Chile. We compare various design concepts and alignment strategies and show test data for different types of MLAs. Our final device uses two MLAs to slice the pupil projected from a f/3 100um octagonal fiber in three parts and feeds them at f/5 into three 50x150um rectangular fibers, effectively combining a pupil slicer with a double scrambler design.

9912-62, Session 11

Fiber mode scrambler experiments for the Subaru Infrared Doppler Instrument (IRD)

Masato Ishizuka, The Univ. of Tokyo (Japan); Takayuki Kotani, Jun Nishikawa, National Astronomical Observatory of Japan (Japan); Takashi Kurokawa, Takahiro Mori, Tsukasa Kokubo, Tokyo Univ. of Agriculture and Technology (Japan); Motohide Tamura, The Univ. of Tokyo (Japan); IRD Team, National Astronomical Observatory of Japan (Japan)

We report the results of fiber mode scrambler experiments for the high-precision radial-velocity (RV) instrument for the Subaru telescope. The instrument, IRD, is a fiber-fed, near-infrared spectrometer with an Echelle grating and combined with a laser frequency comb. IRD can get high-resolution (R~70000) spectra from 0.97 to 1.75 ?m and its main purpose is to search for habitable exoplanets around late-M dwarf stars. The flux distribution of late-M dwarfs has a peak at near-infrared wavelengths, so high-dispersion spectrometer working at near-infrared wavelengths is necessary. Searching for planets around low-mass stars has several advantages. (1) RV change of low-mass stars by planets orbiting around the star is larger than that of solar-like stars. (2) Habitable Zone (HZ) of low-mass stars is closer to the stars due to its low-luminosity. These make planets in HZ around low-mass stars easier to be detected. IRD's expected accuracy of the radial velocity measurement is ~1m/s and with this accuracy planets in HZ around late M-stars can be detected.

It is mandatory to reduce the modal noise in order to achieve ~1m/s accuracy.

The modal noise is an instability of phase and amplitude distributions of light emerging from a multi mode fiber and is caused by interference of many propagating modes of light. Multi-mode fiber has many propagating modes of light and interference of these modes makes speckle pattern. This pattern is very unstable and varies by change of optical fiber's stress, temperature, and so on. This speckle pattern change is called the modal noise and produces fake signals of RV change and reduces the accuracy of RV measurements. The modal noise is larger with narrow-bandwidth light source because narrow-bandwidth light produces small number of propagation modes. At near-infrared wavelengths the modal noise is larger than at visible because the number of propagating modes of light is smaller.

We have systematically tested many kinds of mode scramblers to reduce the modal noise by averaging energy distribution of propagation modes at near-infrared wavelengths. We need 2 mode-scramblers for star and for laser frequency comb. Mode-scrambler for comb needs greater scrambling effect because bandwidth of laser is narrower than that of absorption line of star, but low efficiency is permissible. On the contrary, scrambling for star is easier because bandwidth of absorption line is broad and atmospheric seeing works as a scrambler. However, it needs high efficiency. We mainly report effects of mode scrambler for star.

We have compared both static and dynamic scramblers with narrow and broad bandwidth light sources and deformable mirror to simulate seeing condition. The effect of the static scrambler includes the fiber-length dependence, double scrambler, octagonal fibers, and the fiber-twining. Dynamic scrambler is devised to move fibers dynamically and yields time averaged light without the modal noise.

9912-63, Session 11

12.5-GHz-spaced laser frequency comb covering Y, J, and H bands for infrared Doppler instrument

Tsukasa Kokubo, Takahiro Mori, Tokyo Univ. of Agriculture and Technology (Japan); Takashi Kurokawa, National Astronomical Observatory of Japan (Japan); Ken Kashiwagi, Yosuke Tanaka, Tokyo Univ. of Agriculture and Technology (Japan); Takayuki Kotani, National Institute of Natural Sciences (Japan); Jun Nishikawa, National Astronomical Observatory of Japan (Japan); Motohide Tamura, The Univ. of Tokyo (Japan)

In order to detect Earth-like planets around nearby red dwarfs (in particular late-M stars), it is crucial to conduct precise radial velocity (RV) measurements at near-infrared wavelengths where these stars emit most of the light. We have been developing the Infrared Doppler (IRD) spectrograph covering the wavelength from 0.97 to 1.75 ?m for the Subaru telescope. To achieve 1m/s RV measurement precision, we employ our original laser frequency comb (LFC) with a wide-wavelength coverage in the near-infrared as an extremely stable wavelength standard.

Our LFC has been developed based on a novel multi-gigahertz-spaced comb generation technology employing a frequency stabilized laser diode, an optical pulse synthesizer (OPS) and a highly nonlinear fiber (HNF). The seed comb generated from a hydrogen-cyanide stabilized laser at 1549 nm is input into the OPS consisting of an arrayed waveguide grating and 30 output channel waveguides each having intensity and phase modulators. A picosecond pulse train with a repetition frequency of 12.5 GHz synthesized by the OPS is amplified by an EDFA and is compressed to enhance the peak power up to more than 700 W. Finally, it is launched into the HNF to generate the 12.5-GHz-spaced LFC. Our LFC generator has some advantages including simple and easy frequency stabilization, all fiber-optic configuration, and broadband calibration by the frequency shift of all modes in the LFC. However, it was not easy to broaden the comb spectrum since the pulse peak power was not quite high due to the high repetition rate. We have found that a configuration of two kinds of spliced HNFs with different dispersion wavelengths is effective for broadening the comb spectrum toward shorter wavelength compared to a single HNF configuration.

We have successfully generated a 12.5-GHz-spaced comb ranging over 700 nm from 1040 to 1750 nm, almost covering Y, J, and H bands as the atmospheric windows. The frequency stability was measured by optically heterodyning the comb with an acetylene-stabilized laser at 1542 nm as a reference light. The LFC showed a frequency stability of less than 0.2 MHz and an almost constant spectrum profile for 6 days. The noise of the comb modes was evaluated by optically heterodyning the comb with another

continuous-wave laser. The comb showed a high contrast of about 35 dB.

The LFC has much stronger intensity than star light and its spectrum has full of ups and downs. Furthermore, it has a high degree of polarization and high coherence that induces speckle noise after the multimode-fiber propagation. Since these characteristics degrade the spectrograph performance, we have developed wavelength independent optical processing components including an optical power attenuator, a spectrum equalizer, a depolarizer, a speckle reducer and a mode scrambler for multimode fiber transmission.

We have also achieved a novel calibration system for astronomical spectrographs by introducing an optical frequency shifter in our LFC generator. The optical frequency shifter induces a precise frequency shift of around 40 MHz for all spectral comb lines, which is helpful for the spectrograph calibration over a wide wavelength region.

9912-64, Session 11

Design of real-time measurement for optical fiber positioning based on FPGA

Huajie Han, Yonggang Gu, Guocheng Liu, Chao Zhai, Univ. of Science and Technology of China (China)

In order to track the stellar objects in fiber spectroscopic telescopes, measuring the fiber positions is necessary, which is currently unsolved due to the large number of data. Field Programmable Gate Arrays (FPGA) is an integrated circuit designed to be configured by a customer or a designer after manufacturing, and it is convenient to achieve an image processing system based on parallelism and pipeline technology with FPGA, hence the FPGA based imaging processing method as a newly arisen technique owns unparalleled advantages in high-speed image processing system over the conventional ones based on Central Processing Unit (CPU), Graphics Processing Unit (GPU), Application Specific Integrated Circuit (ASIC) etc.. In this paper, we design a novel real-time fiber position measure system based on FPGA. The large-scale distributed parallel calculation is fulfilled in the embedded system, and the real-time threshold segmentation, the labeling of connected domain and the feature extraction for the high-speed data stream are completed during the data transmission, thus the large number of data can be transformed into less information of image feature. To be specific, the system consists of the data acquisition module, the image processing module and the image display module. At first, a high speed digital camera is employed for the image acquisition. Next, in particular, the spot detection, which is affected directly by the detection algorithm and realization mode, is the key part of the image processing module. In this system, data stream structure model based on feature transmission is utilized to extract the feature of connected domain with parallel data, and the distributed calculation based on the feature of the connected domain includes a hardware accelerating structure based on a multi-dimensional pyramid, which is designed for global searching and labeling of the connected domain. After the processing, the coordinate data calculated by a digital signal processor (DSP) and the processed images are output to peripheral devices for the display, moreover, a Microcontroller Unit (MCU) is an alternative for the system to implement additional process. As a result, with the test system, the fiber spot detection can be finished at 50 f/s for 4k 4k pixel images, and the detection error is within 1% pixel, which proves the system we design is feasible for the precise and real-time measurement of the optical fibers.

9912-65, Session 12

Modal noise suppression in the NIR region using multicore fibre and photonic lanterns

Dionne M. Haynes, Leibniz-Institut für Astrophysik Potsdam (Germany); Itandehui Gris-Sánchez, Tim A. Birks, Univ. of Bath (United Kingdom); Ernesto Oliva, Andrea Tozzi, Marcella Iuzzolino, Nicoletta Sanna, INAF - Osservatorio Astrofisico di Arcetri (Italy); Roger Haynes, Leibniz-Institut für Astrophysik Potsdam (United Kingdom) and Univ. of Bath (Germany)

Exoplanet detection is one of the fast-growing areas of astronomical research. A strong drive to detect habitable Earth size planets is underway, with a number of new instruments due to come on-line in 2016. Many of these instruments operate in the near-infrared (NIR) band and use the radial-velocity method (detection of host star absorption-line Doppler shifts), to measure radial velocity shifts of the order of 1 m/s or less. This requires a very stable NIR high-resolution spectrograph and, if fibre coupled, a very stable fibre feed. However light propagation in multimode optical fibres is not inherently stable and suffers from modal noise caused by quasi-random phase and amplitude variations in near- and far- field light distributions. This modal noise has been shown to critically limit the signal-to-noise ratio achievable in fibre-coupled, high-resolution spectrographs. Because modal noise becomes significantly worse with increasing wavelength and decreasing mode numbers, it presents a risk to the next generation of near-infrared precision radial velocity spectrographs being proposed for ELTs.

We are investigating new fibre technologies that can potentially solve the modal noise issues in the NIR region. The new technology that we present is a combination of a multicore fibre (MCF) and a photonic lantern (PL) specifically designed to provide highly efficient phase and amplitude scrambling in the NIR with a low mode count. We designed the multicore fibre to match the GIANO fibre core size and mode count when injected with an F/5 beam at a central wavelength of 1.64 ?m. The GIANO-laboratory spectrograph facility at Arcetri Observatory was used to measure the modal noise of the MCF-PL device and the GIANO test fibres for direct comparison of performance.

The preliminary results show that the MCF-PL device performs an order of magnitude better (in terms of modal noise reduction) than the equivalent circular multimode silica fibre. In this paper we give an overview of the specifications, design and manufacture of the multicore fibre and photonic lantern. We also present the initial modal noise test results for the MCF-PL and equivalent multimode circular fibre obtained with the GIANO laboratory spectrograph test facility.

9912-66, Session 12

Communication architecture for the fiber positioning system of the DESI fiber-fed spectrograph

Karim Kaci, Guillermo Gonzalez de-Rivera, Fernando Lopez-Colino, Univ. Autónoma de Madrid (Spain); M. Sofia Martinez, Univ Autónoma de Madrid (Spain); Jose L. Masa, Univ. Autónoma de Madrid (Spain); Justo Sánchez, Instituto de Astrofísica de Andalucía (Spain); Francisco Prada, Javier Garrido, Univ. Autónoma de Madrid (Spain)

This paper presents a design solution for controlling the five thousand fiber positioners within the sensing plate of the DESI telescope. Each of these positioners is a robot which allows positioning its optic fiber with a resolution within the range of few microns. The high number and density of these robots poses a challenge for handling the communication from a central control device to each of these five thousand. Furthermore, an additional restriction applies as the required time to inform every robot of its desired position must be lower than a second. Additionally, a low energy consumption profile is desired.

The complexity of standard internet-based protocols would imply that most of the computational resources of each robot should be applied to the communication protocol, instead of the positioning process itself. However, several embedded system oriented communication protocols

are still available and are evaluated in this paper. The study has considered both wired and wireless protocols.

Among the wireless solutions, ZigBee and CyFi have been considered. The wireless approach implies that the communication channel is shared among the five thousand robots. The shared channel along with the distribution of the robots and the sensing plate lead to high interferences and delays in the transmission of the information. Using simulation tools these wireless protocols have been discarded as they do not allow achieving the requirements previously presented.

The studied wired protocols comprise I2C, CAN and Ethernet. These three protocols, and different combinations of them, have been studied and evaluated to determine their hardware requirements, computational complexity, communication time and power consumption.

The best solution is a hybrid multilayer architecture combining both Ethernet and I2C. A 1 Gbps Ethernet based network is used to communicate the central control unit with ten management boards. Each of these boards is a low-cost, low-power embedded device that manages a thirty six degrees sector of the sensing plate. Each of these boards receives the positioning data for five hundred robots and communicate with each one through a two layer multiplexed I2C channel. This proposal allows to communicate the positioning information to each of the five thousand robots in 0.08 s. The whole communication architecture has a power consumption of 35.5 W.

9912-67, Session 12

Taipan instrument fibre positioner and starbug robots: engineering overview

Nicholas F. Staszak, David M. Brown, Rebecca A. Brown, Scott Case, Michael Goodwin, Kyler Kuehn, Jonathan S. Lawrence, Nuria P. F. Lorente, Vijay Nichani, Australian Astronomical Observatory (Australia)

TAIPAN, currently nearing completion, is a multi-object parallel-positioning fibre-optic spectrograph designed for the UK Schmidt Telescope at Siding Spring Observatory in northern New South Wales, Australia. The instrument will be used to perform galactic and stellar surveys across the whole Southern hemisphere sky, over a 5 year period. The fibre positioning portion of TAIPAN consists of a complete refurbishment of the UKST interior spider which replaces the 6DF serial positioning instrument used for the RAVE Survey. The TAIPAN Instrument Structure provides a stiff, low deflection, spider to interface the necessary support infrastructure to allow the Starbug Positioning Robots to operate, while maintaining a minimum obscuration of the incoming beam. The TAIPAN Spider Assembly, to support the Starbug Positioning Robot, requires a curved glass field plate, located on the telescope focal plane, on which they are adhered through pressure differential generated by a vacuum system. The glass field plate is a kinematically mounted optic providing the instrument with tip-tilt and focus capability. The TAIPAN Instrument contains a driven “bug catcher” assembly to allow adherence and removal of the Starbug to the glass field plate. The TAIPAN Fibre Positioner contains a uniquely designed connector plate consisting of a high density interface to the Starbug routing all electrical, optical, and vacuum services required for Starbug operation. The high density connector plate is motor driven to allow lift off and adherence of the Starbug Robot to the GFP. A metrology system consisting of video camera under closed loop control monitors the position of 900 metrology fibres. The metrology camera is located in the central hole within the UKST Primary mirror.

The Starbug Robot itself consists of concentric piezo-ceramic tubes fully integrated with all necessary electrical wiring, vacuum and external metrology. The TAIPAN Starbug design contains a single optical fibre for each astronomical source. The design has an on-board LED which illuminates three positional metrology fibres. The Starbug is a line replaceable unit, 300 mm in length, with a detailed assembly and quality control process.

To drive Starbugs TAIPAN involves significant design work in independent motion control software and electronics. Starbug motion is controlled by 60 processors managing four phases of a 400V, 100Hz waveform that are independently switched to the 2100 Starbug electrodes. Software determines the exact location of 300 observing fibres and simultaneously positions them on their respective targets with a tolerance of 5 ?m. A Starbug can move on its X and Y axes and can rotate on a point. This allows 300 Starbugs to move to their target position without collision.

In addition to undertaking the TAIPAN surveys, it will serve as a prototype for the MANIFEST fibre positioner system for the future Giant Magellan Telescope. The TAIPAN instrument is designed to use a complement of 300 Starbugs. The initial deployment of the instrument in 2016 will consist of 150 Starbugs.

9912-68, Session 12

High contrast imaging using a visible nulling coronagraph

Jagmit S. Sandhu, Michael Shao, Jet Propulsion Lab. (United States)

We present results of experiments undertaken with the visible nulling coronagraph testbed (APEP) at JPL to further development of high contrast coronagraphy using interferometric nulling and an array of spatial filters. This technology is especially suitable for implementing a coronagraph on centrally obscured and/or segmented telescopes. The advantage arises by use of a segmented deformable mirror (DM) in the interferometer and an array of spatial filters comprised of individual single mode fibers. This allows division of the telescope pupil into sub-apertures that can be nulled independently while a Lyot Stop can be used to reject parts of the pupil that are obscured. Thus segment gaps, spiders and central obscurations can be easily ignored for the purpose of nulling. The combination of the DM and spatial filters also leads to the formation of a 360 degree dark hole without the need of a second DM.

While nulling has been demonstrated in prior experiments, the use of a 2-D array of single mode fibers in combination with the nuller is unique and challenging. Early in our experiments we discovered that the fiber array installed in APEP was deficient in its role as a spatial filter. The lengths of the fibers were too short to enable sufficient filtering of cladding light. Single fiber experiments were conducted to measure the length of fiber necessary for extinction of cladding light to 10-4. The results indicated that fibers with length between 1 to 2 m would be needed. We therefore had to explore novel methods to fabricate a new fiber array with sufficiently long fibers while simultaneously ensuring that all the fibers were equal to within the criteria needed to produce a coherent wavefront for planet light (the nulling of starlight does not care about the coherence since nulling occurs independently in each fiber).

We adopted a dual-pronged approach of building a quick, incoherent fiber array to demonstrate and uncover issues with starlight nulling, while also building a coherent fiber array to be used for the final demonstration. Both arrays also presented the challenge of fabrication of microlenses. Each microlens had to be positioned to within +/- 0.5 um of the center of the corresponding fiber. Additionally, each fiber was potentially offset randomly from the ideal grid by +/- 10 um. We developed a measurement system that measured the fiber positions with the accuracy necessary for this purpose. We then had to develop a new microlens fabrication technique (thermal reflow of photoresist) because the traditional technique (etching of fused silica) could not meet the large microlens sag requirement. We fabricated, aligned and bonded microlenses to the incoherent array and conducted nulling experiments. The DM segments were used to match path lengths in the interferometer (necessary for phase control), while the fibers were used to match the amplitudes of the interfering beams. We were able to demonstrate mean contrast between 2x10-7 and 6x10-7. The contrast was limited mainly by instability of the intensity distribution of starlight in the pupil and possible polarization mis-match between the interfering beams.

9912-69, Session 12

Post-inscription tuning of multicore fibre Bragg gratings

Emma Y. Lindley, Seong-Sik Min, Sergio G. Leon-Saval, Joss Bland-Hawthorn, The Univ. of Sydney (Australia)

Fibre Bragg gratings are used in astronomy for their ability to suppress narrow atmospheric emission lines of temporally varying brightness before the light is dispersed. These gratings can only operate in a single-mode fibre as the suppressed wavelength depends on mode velocity in the core. Recent experiments with fibres containing multiple single-moded cores have demonstrated the potential for inscribing identical gratings across all cores in a single pass. We have already improved the uniformity of gratings in 7-core fibres via modifications to the writing process; further progress can be achieved by tuning the gratings of the outer and inner cores relative to one another. By coating the fibre in a heat-conductive material with a high expansion coefficient, we can harness the effects of temperature and strain on the spectral response of each core in order to make the entire fibre suppress one wavelength to a depth of 30 dB or greater.

In this paper we present methods and results from experiments concerning the post-write tuning of gratings in multicore fibres.

9912-70, Session 13

First results of tests on the WEAVE fibers

Frédéric N. Sayède, Youssef Younes, Gilles Fasola, Stéphane F. Dorent, Observatoire de Paris à Meudon (France); Don Carlos Abrrams, Isaac Newton Group of Telescopes (Spain); Jose Alfonso López Aguerri, Instituto de Astrofísica de Canarias (Spain); Piercarlo Bonifacio, Observatoire de Paris à Meudon (France); Gavin B. Dalton, Rutherford Appleton Lab. (United Kingdom) and Univ. of Oxford (United Kingdom); Kevin Dee, Isaac Newton Group of Telescopes (Spain); Philippe Laporte, Observatoire de Paris à Meudon (France); Ian Lewis, Univ. of Oxford (United Kingdom); Emilie Lhome, Isaac Newton Group of Telescopes (Spain); Kevin F. Middleton, STFC Rutherford Appleton Lab. (United Kingdom); Johan H. Pragt, NOVA Optical Infrared Instrumentation Group (Netherlands); Juerg Rey, Isaac Newton Group of Telescopes (Spain); Remko Stuik, NOVA Optical Infrared Instrumentation Group (Netherlands); Scott C. Trager, Univ. of Groningen (Netherlands)

WEAVE is a new wide-field spectroscopy facility proposed for the prime focus of the 4.2m William Herschel Telescope. The facility comprises a new 2-degree field of view prime focus corrector with a 1000-multiplex fibre positioner, a small number of individually deployable integral field units, and a large single integral field unit. The IFUs (Integral Field Units) and the MOS (Multi Object Spectrograph) fibres can be used to feed a dual-beam spectrograph that will provide full coverage of the majority of the visible spectrum in a single exposure at a spectral resolution of ~5000 or modest wavelength coverage in both arms at a resolution ~20000. The instrument is expected to be on-sky by 2017 to provide spectroscopic sampling of the fainter end of the Gaia astrometric catalogue, chemical labeling of stars to V~17, and dedicated follow up of substantial numbers of sources from the medium deep LOFAR surveys.

After a brief description of the Fibre System, we describe the fibre test bench, its calibration, and some test results. We have to verify 1920 fibres from the MOS bundles and 740 fibres from the mini-IFU bundles with the test bench. In particular, we present the Focal Ratio Degradation and throughput verification of some cables.

9912-71, Session 13

Echidna Mark II: one giant leap for 'tilting spine' fibre positioning technology

James Gilbert, Univ. of Oxford (United Kingdom) and Australian Astronomical Observatory (Australia); Gavin B. Dalton, Univ. of Oxford (United Kingdom); Jonathan S. Lawrence, Australian Astronomical Observatory (Australia)

The Australian Astronomical Observatory's 'tilting spine' fibre positioning technology has been redeveloped to provide superior performance in a smaller package. The new design offers demonstrated 2.8 micron RMS closed-loop positioning errors in ~10 s (excluding metrology overheads) and an improved capacity for open-loop tracking during observations. Throughput losses are shown to be reduced by lengthening spines while maintaining excellent accuracy. New low voltage piezo actuator technology has greatly simplified the control electronics design, allowing a highly modularised architecture and significantly reducing the relative size, mass and cost of the entire positioner system.

Tilting spine technology, also known as 'Echidna' technology, offers simultaneous positioning of hundreds to thousands of densely-packed optical fibres at a telescope's focal plane for the purpose of multi-object spectroscopy. A key benefit of the technology is a high target allocation yield, achievable due to each fibre's large and overlapped patrol area and small exclusion radius around its tip.

A redesigned spine motor has improved positioning performance while remaining true to Echidna's simple pivoting ball principle. The new design has a refined mechanism and uses miniature piezo elements that require signal amplitudes an order of magnitude smaller than before. Specialised electronics components can now be replaced with standard off-the-shelf devices that are readily available at a fraction of the cost. Each spine can now be given its own postage stamp sized drive circuit that is completely independent and able move the fibre in any direction at any time.

A closed-loop positioning accuracy of 2.8 microns RMS has been demonstrated over thousands of positioning cycles in the lab. Such small errors offer a chance to reduce fibre tilt losses by trading off positioning resolution with spine length. A representative example is presented where these losses are halved, while still achieving a positioning error better than 5 microns RMS and a target allocation yield of 94%.

This paper describes the concept, design and prototyping of this next generation Echidna technology, the exemplary results seen in a laboratory test system, and the many advantages on offer for future instruments. Prospects for further miniaturisation of the motor assembly are explored, along with ideas to utilise the same piezo actuators in the AAO's autonomous Starbug fibre positioner robots.

9912-72, Session 13

The Potsdam MRS spectrograph: heritage of MUSE and the impact of cross-innovation in the process of technology transfer

Martin M. Roth, Benito Moralejo, Leibniz-Institut für Astrophysik Potsdam (Germany); Philippe Godefroy, Winlight System S.A. (France); Thomas Fechner, Svend-Marian Bauer, Elmar Schmälzlin, Andreas Kelz, Roger Haynes, Leibniz-Institut für Astrophysik Potsdam (Germany)

After first tentative experiments to utilize astronomical instrumentation for the purpose of minimal invasive optical diagnostics in medicine we have been able to demonstrate that the technique of integral field

spectroscopy from Astronomy, applied to a microscope rather than to a telescope, is indeed capable to differentiate complex organic tissue on the basis of spatially resolved Raman spectroscopy. The new technique is orders of magnitude more efficient than the current state of the art in medical instrumentation, and it has great potential to revolutionize resection margin identification in cancer diagnostics and surgery. Based on these findings, we have launched a joint research program with clinical experts and industrial partners to develop an optimized fibre-coupled multi-channel spectrograph with a dedicated novel IFU for the purpose of a formal validation program in dermatology towards a future prototype for clinical applications. On the basis of the concept of modular and replicable spectrographs for MUSE, we have designed and built a modified spectrograph that, as opposed to its predecessor, is adapted to a telecentric fibre input and has an extended blue performance, but otherwise maintains the properties of high-throughput and excellent image quality over an octave of wavelength coverage with modest spectral resolution. We present the opto-mechanical layout and a new detector system. Owing to the immediate purpose of the experiment, the spectrograph is dubbed the Multiplex-Raman-Spectrograph (MRS). However, given the performance of the new system, and building on the successful concepts of replicable spectrographs and small series production, e.g. the MUSE and VIRUS instruments, we also envision to deploy copies for integral field and/or multi-object spectroscopy at astronomical telescopes. We stress the benefits of a partnership between Astronomy, other disciplines in academia, and industry as a win-win situation for the expensive development of instrumentation.

9912-73, Session 13

Taipan fiber feed and spectrograph: engineering overview

Nicholas F. Staszak, Robert Content, Ross Zhelem, Vladimir Churilov, Scott Case, Rebecca A. Brown, Jonathan S. Lawrence, Australian Astronomical Observatory (Australia)

TAIPAN, currently nearing completion, is a multi-object parallel-positioning fibre-optic spectrograph designed for the UK Schmidt Telescope at Siding Spring Observatory in northern New South Wales, Australia. The instrument will be used to perform galactic and stellar surveys across the whole Southern hemisphere sky, over a 5 year period. An AAO designed fibre optic cable is used to transmit light from each of the 150 Starbug Robots (with upgrade path to 300) to a custom designed slit as input to the TAIPAN Spectrograph. The TAIPAN Fibre cable is designed to minimize path length to the Spectrograph for maximum throughput while incorporating AAO's best practices for minimizing FRD within a fibre run. Presented is a discussion of the detailed design considerations of fibre cable and slit design.

The TAIPAN Spectrograph is a facility upgrade of the UKST 6DF Spectrograph used for the RAVE Survey. It completely replaces the 6DF spectrograph and is part of the complete TAIPAN Instrument package being delivered to the UKST in 2016. The TAIPAN Spectrograph is an AAO designed all-refractive 2-arm design. It delivers a spectral resolution of R>2000 over the wavelength range 370-870 nm. It contains completely custom optics and mechanical components starting with a 300 fibre slit assembly. The 300 fibre slit feeds a 5 element F1.75 collimator assembly with one aspheric surface. The collimator optics reside within individual lens cells that provide tip, tilt, and x, y alignment adjustment. Alignment is occurring on the AAO lens centering station. The beam from the collimator is split into two bands with the blue arm covering 370 to 592 nm and the red arm covering 580 to 870 nm. Two VPH gratings are provided by Kaiser Optical Systems. The beam splitter and VPH grating assemblies reside in kinematically mounted holder assemblies for alignment and the ability to accurately remove and replace from the spectrograph. Custom camera barrels and lenses feed semi-custom Spectral Instruments 1100s Dewar Detectors. The red and blue cameras are F1.5, each a five element design with three aspheric surfaces. The optical subassemblies interface to a monolithic spectrograph structure. All optics in the TAIPAN Spectrograph have been manufactured by Optimax. An overview the overall opto-mechanical design and assembly of the TAIPAN spectrograph will be presented.

In addition to undertaking the TAIPAN surveys, the TAIPAN Spectrograph is part of a suite of upgrades to the UKST that are serving as a prototype for the MANIFEST fibre positioner system for the future Giant Magellan Telescope. The TAIPAN instrument is designed to use a complement of 300 Starbugs. The initial deployment of the instrument in 2016 will consist of 150 Starbugs.

9912-74, Session 13

On-sky performance evaluation and calibration of a polarization-sensitive focal plane array

Dmitry Vorobiev, Zoran Ninkov, Rochester Institute of Technology (United States); Neal Brock, 4D Technology Corp. (United States); Ray West, MOXTEK, Inc. (United States)

The advent of pixelated micropolarizer arrays (MPAs) has facilitated the development of polarization-sensitive focal plane arrays (FPAs) based on charge-coupled devices (CCDs) and active pixel sensors (APSs), which are otherwise only able to measure the intensity of light. Polarization sensors based on MPAs are extremely compact, light-weight, mechanically robust devices with no moving parts, capable of measuring the degree and angle of polarization of light in a single snapshot. Furthermore, micropolarizer arrays based on wire grid polarizers (so called micro-grid polarizers) offer extremely broadband performance, across the optical and infrared regimes. These devices have potential for a wide array of commercial and research applications, where measurements of polarization can provide critical information, but where conventional polarimeters could be practically implemented. To date, the most successful commercial applications of these devices are 4D Technology's PhaseCam laser interferometers and PolarCam imaging polarimeters. Recently, MPA-based polarimeters have been identified as a potential solution for space-based telescopes, where the small size, snapshot capability and low power consumption (offered by these devices) are extremely desirable. In this work, we investigated the performance of MPA-based polarimeters designed for astronomical polarimetry using the Rochester Institute of Technology Polarization Imaging Camera (RITPIC). We deployed RITPIC on the 0.9 meter SMARTS telescope at the Cerro Tololo Inter-American Observatory and observed a variety of astronomical objects (calibration stars, variable stars, reflection nebulae and planetary nebulae). We use our observations to develop calibration procedures that are unique to these devices and provide an estimate for polarimetric precision that is achievable.

9912-75, Session 14

Fabrication of a wide-field NIR integral field unit for SWIMS using ultra-precision cutting

Yutaro Kitagawa, The Univ. of Tokyo (Japan); Shin-ya Morita, Tokyo Denki Univ. (Japan) and RIKEN Ctr. for Advanced Photonics (Japan) and RIKEN (Japan); Yutaka Yamagata, RIKEN Ctr. for Advanced Photonics (Japan); Kentaro Motohara, The Univ. of Tokyo (Japan); Shinobu Ozaki, National Astronomical Observatory of Japan (Japan); Hidenori Takahashi, Masahiro Konishi, Natsuko M. Kato, Yutaka Kobayakawa, Yasunori Terao, The Univ. of Tokyo (Japan)

Recently an observational technique called integral field spectroscopy (IFS) has been extensively used in astronomy. It enables us to obtain a three-dimensional data cube (x, y, ?), i.e. spatially resolved spectrum in a single exposure. In the context of increasing importance of IFS, we have been developing a new near-infrared integral field unit (IFU) for SWIMS (Simultaneous-color Wide-field Infrared Multi-object Spectrograph), which we call SWIMS-IFU. SWIMS will be mounted on University of Tokyo Atacama Observatory (TAO) 6.5-m telescope as one of the 1st generation instruments, and planned to be installed on Subaru 8.2-m telescope for verification and initial science observations in 2016.

Concept of SWIMS-IFU is simple: To realize IFS observation readily, we develop a compact and lightweight IFU and set it on a focal plane in a conventional multi-slit spectrograph, thus it can be remotely selected and exchanged like a slit mask. The IFU works as a connector between a telescope and the spectrograph by converting 2-D image of FoV into 1-D pseudo-long slits in the same way as so-called "Advanced Image Slicer" configuration. We apply this concept to SWIMS.

SWIMS-IFU appends a capability of IFS to SWIMS which was originally designed as an imager and multi-slit spectrograph. In the current design, we can switch observational modes (imaging, MOS and IFS) easily and quickly during an observing night.

SWIMS-IFU provides entire near-infrared spectrum from 0.9 to 2.5 micron simultaneously with wider field of view of 17.2" x 12.8" compared with current existing near-infrared IFUs. This capability allows us to carry out high-efficiency IFS observations with SWIMS. Its basic parameter and optical design were reported in the previous proceeding (Y. Kitagawa et al., 2012).

In this presentation we describe a method for fabrication and measurements of optical surfaces and support structures of SWIMS-IFU. We specially make consideration for designing support structures as the IFU has tight restriction on both size (< 60 mm x 170 mm x 220 mm) and weight (< 0.8 kg) to be installed and handled with the mask-exchanger unit of SWIMS. All the components of the IFU are made of special aluminum alloy which has the same thermal expansion coefficient as an electroless nickel-phosphorus. This enables us to achieve high-quality surface finish on the Ni-P coating easily without thermal strain between the alloy and the coat under cryogenic condition. We adopt an ultra-precision cutting technique to monolithically fabricate mirror arrays such as an image slicer, which have complicated shapes and many facets. Each facet is created by shaper cutting process with a single crystal diamond tool. The measurement results show that the surface roughness is less than 10 nm r.m.s. and satisfies our requirements. This method considerably reduces alignment procedure of optical elements. When increasing number of elements, monolithic fabrication has also an advantage to shorten processing time with keeping good repeatability. It will be useful for a multi-object IFS facility such as a 2nd generation instrument for TMT.

9912-76, Session 14

Stop-less Lyot coronagraph for exoplanet characterization: first on-sky validation in VLT/SPHERE

Arthur Vigan, Lab. d'Astrophysique de Marseille (France); Mamadou N'Diaye, Space Telescope Science Institute (United States); Kjetil Dohlen, Lab. d'Astrophysique de Marseille (France); Jean-Luc Beuzit, Institut de Planétologie et d'Astrophysique de Grenoble (France); Anne Costille, Amandine Caillat, Lab. d'Astrophysique de Marseille (France)

The VLT/SPHERE instrument includes a unique long-slit spectroscopy (LSS) mode coupled with Lyot coronagraphy dedicated to the spectral characterisation of directly imaged giant exoplanets. The performance of this mode is limited by its non-optimal coronagraph, but in a previous work we demonstrated that it could be significantly improved at small inner-working angles using the stop-less Lyot coronagraph (SLLC). A prototype of the SLLC was installed in VLT/SPHERE in 2014 during the reintegration of the instrument in Paranal, and it was extensively tested in 2015 to characterise its performance. The performance is tested in both imaging and spectroscopy using data acquired on the internal source of SPHERE. In imaging, we obtain a raw contrast gain of a factor 10 at 0.3" with the SLLC. We also demonstrate that no Lyot stop is required to reach the full performance, which validates the SLLC concept. Comparison with a realistic simulation model shows that we are currently limited by the internal phase aberrations of SPHERE. In spectroscopy, we obtain a gain of ~1 mag in a limited range of angular separations. Simulations show that although the main limitation comes from phase errors, the performance in the non-SLLC case is very close to the ultimate limit of the LSS mode. We present the very first on-sky data with the SLLC, which appear extremely promising for the future scientific exploitation of an apodized LSS mode in SPHERE. Finally, we explore a new possibility for the speckle subtraction in the LSS mode that could significantly improve the data analysis with respect to methods based on spectral differences.

9912-77, Session 14

Development of an efficient photonic device for the reformatting of celestial light

David G. MacLachlan, Heriot-Watt Univ. (United Kingdom); Robert J. Harris, Ruprecht-Karls-Univ. Heidelberg (Germany); Itandehui Gris-Sánchez, Univ. of Bath (United Kingdom); Debaditya Choudhury, Heriot-Watt Univ. (United Kingdom); Timothy J. Morris, Durham Univ. (United Kingdom); Éric Gendron, Observatoire de Paris (France); Alastair G. Basden, Durham Univ. (United Kingdom); Izabela J. Spaleniak, Heriot-Watt Univ. (United Kingdom); Alexander Arriola Martiarena, Macquarie Univ. (Australia); Tim A. Birks, Univ. of Bath (United Kingdom); Jeremy R. Allington-Smith, Durham Univ. (United Kingdom); Robert R. Thomson, Heriot-Watt Univ. (United Kingdom)

The advent of 30 m class Extremely Large Telescopes will require spectrographs of unprecedented spectral resolution in order to meet the ambitious science goals of such telescopes, for example the detection of Earth-like exoplanets via the radial velocity technique. The consequent increase in the size of the spectrographs makes it challenging to ensure their optimal environmental stabilisation and precise spectral calibration. Currently, multimode (MM) optical fibres transport light from the telescope focal plane to the spectrograph housed in a separate environmentally-stabilised facility. However, the use of MM fibres introduces "modal noise", which manifests as variations in the light pattern at the output of the fibre as the input coupling and/or fibre position changes. These variations degrade the spectrograph line profile, thereby reducing the precision of the instrument.

The "photonic lantern" is a guided-wave transition that efficiently couples a MM Point Spread Function (PSF) into an array of single modes (SM). Recent developments have shown that they can, in principle, generate a spectrograph input free of modal noise by reformatting the output SMs into a linear array. Placed at the input to a spectrograph, this pseudo-slit is diffraction-limited in the dispersion axis and hence free of modal noise, whilst also minimising the instrument size in the plane of dispersion.

In 2013 we developed the "photonic dicer", a monolithic device that seamlessly integrated the photonic lantern and reformatting functions to produce such a pseudo-slit. They were manufactured using the direct-write technique of Ultrafast Laser Inscription (ULI) to inscribe waveguides into a glass substrate. These devices exhibited an in-laboratory throughput of ~65 % and an on-sky throughput of ~20 % for H-band light from the

CANARY Adaptive Optics (AO) system on the William Herschel Telescope (WHT). While this proved the feasibility of using them on-sky, additional work was required to accurately mode-match the input with the telescope PSF and to integrate the device with a MM relay fibre. However, the interface between the MM fibre and the MM waveguide of an integrated device can cause additional modal noise when these components are not mode matched, which results in the coupling losses at the interface being strongly wavelength dependent.

In this paper we describe the fabrication and throughput performance of the "hybrid reformatter", which we propose as a solution to this problem. It combines the proven low-loss performance of a multicore fibre-based photonic lantern with a ULI manufactured three-dimensional waveguide interconnect that performs the reformatting function to a diffraction-limited pseudo-slit. We report on the in-laboratory throughput of the hybrid reformatter, and compare this to the throughput achieved on-sky at the WHT.

9912-78, Session 14

Modal noise characterisation of a hybrid reformatter

Izabela J. Spaleniak, David G. MacLachlan, Heriot-Watt Univ. (United Kingdom); Itandehui Gris-Sánchez, Univ. of Bath (United Kingdom); Debaditya Choudhury, Heriot-Watt Univ. (United Kingdom); Robert J. Harris, Durham Univ. (United Kingdom); Jeremy R. Allington-Smith, Durham Univ. (United Kingdom) and Univ. of Bath (United Kingdom); Timothy A. Birks, Univ. of Bath (United Kingdom); Robert R. Thomson, Heriot-Watt Univ. (United Kingdom)

The use of single-mode fibres in high-precision Doppler spectrographs has become very attractive: not only can they provide a stable point-spread-function and an absence of without modal noise, but they also allow for the use of a smaller spectrograph with the associated cost and complexity benefits. However, a major obstacle in using single-mode fibres on seeing-limited telescopes is inefficient coupling of light into the fibre.

Photonic lanterns can overcome this limitation, and enable the efficient coupling of incoherent multimode light to an array of single-modes. The most efficient types of photonic lantern demonstrated to date are made from multicore fibre, but they do not allow the output of the device to be arbitrarily reshaped. To address this shortcoming we made the hybrid reformatter -- a device which merges a multicore-fibre photonic lantern with a slit-reformatting device inscribed by an ultrafast laser. The reformatter reshapes the 2-D array of single-mode cores (the output of the multicore-fibre photonic lantern) into a 1-D array of single-mode waveguides, forming a slit-like structure suitable for input to a single-mode spectrograph. The device output is single-mode across the slit, i.e. in the spectrograph dispersion axis, and highly multimode along the slit.

Here we report the testing of a hybrid reformatter for modal noise by measuring device throughput at high spectral resolution and assessing the stability of the output point-spread-function under different injection conditions. This hybrid device operates around 1550 nm wavelength, supports 92 modes, and has a circular input 45 microns in diameter and a rectangular output measuring 6.2 microns x 570 microns. We demonstrate that the point-spread-function at the output of the hybrid device did indeed behave as a single mode across the slit and that no presence of modal noise was found.

9912-79, Session 14

A laser-locked white-light etalon calibrator for MAROON-X

Julian Stürmer, Andreas Seifahrt, The Univ. of Chicago (United States); Christian Schwab, Macquarie Univ. (Australia); Jacob L. Bean, The Univ. of Chicago (United States)

We report on the development, construction, and testing of a vacuum-gap Fabry-Perot etalon calibrator. Our etalon comb is based on a tightly temperature and pressure controlled bulk etalon with a finesse of 40 and a FSR of 15GHz, well suited for high-resolution astronomical spectrographs. White light from a fiber fed laser-driven light source is used to form a bright etalon comb spanning 500-900nm. A tunable laser scans the etalon and several transitions of atomic rubidium, providing a means to precisely align, trace and, if desired, lock the etalon to NIST traceable frequency standard. Our etalon crucially differs from other, similar systems. We use a single mode fiber to simultaneously feed laser and white light into the etalon, thereby removing any illumination-depended effects and guaranteeing the laser and white light to share the same mode volume in the etalon. We will discuss various implementations of how to separate white light and laser light with minimal loss of bandwidth for the etalon comb. We show a long-term stability of the etalon comb in the cm/s domain and discuss intrinsic limitations and future improvements. Where appropriate, we have used off-the- shelf, commercial components with proven long-term performance to accelerate the development timescale of this instrument. We demonstrate a turn-key system, ready to be installed at any astronomical observatory. The technology development shown here solves one of the key technical issues that stands in the way of constructing a radial velocity spectrograph capable of finding Earth-mass, habitable-zone exoplanets around Sun-like stars and low-mass M dwarfs.

9912-80, Session 15

New grating concepts in the NIR and SWIR spectral band for low and high resolution earth-observation spectrometers

Thomas Flügel-Paul, Uwe D. Zeitner, Gerhard Kalkowski, Tino Benkenstein, Torsten Harzendorf, André L. Matthes, Fraunhofer-Institut für Angewandte Optik und Feinmechanik (Germany)

The resolution of a spectral apparatus is directly proportional to the angular dispersion of the applied dispersive element, e.g. a grating, times its illuminated cross section L. Consequentially, typical applications demand for two different types of grating layouts depending on the required spectral resolution. On the one hand, there are low-resolution blazed gratings with a period significantly larger than the addressed operational wavelength and which work near normal incidence. On the contrary, high resolution spectrometers often operate using binary gratings with a period smaller than the addressed wavelength range and which work under Littrow conditions. Our contribution here is twofold and covers both scenarios. We will report about our latest achievements to realize the essential dispersive elements during the breadboard activities of FLEX and CarbonSat missions; both announced within the framework of ESA's earth observation program.

The CarbonSat instrument uses a fused-silica GRISM (grating-prism) element in the high resolution SWIR-1 spectral channel. In order to meet the system's specification (diffraction efficiency >70%, polarization sensitivity <10%) while simultaneously decreasing the risk for a technological realization, our approach is the following: First, we have successfully established a high refractive index conformal coating with a

purposely designed nanolaminate made of titanium dioxide and aluminum dioxide. This coating is applied by atomic layer deposition onto a backbone fused silica grating which was fabricated by electron beam lithography (EBL) and deep reactive ion etching (DRIE). The aspect ratio (structure height to width) of the final element approaches 1:10. This value is still significantly smaller as compared to a pure fused silica grating necessary to fulfill the same optical specifications. The measured diffraction efficiency of the best realized elements are well above 75% with a polarization sensitivity of at most 5%. Finally, the grating substrate of size 120mm x 66mm is combined with the prism by plasma activated direct bonding such that no adhesion layer remains between both specimens. A specific mechanics was constructed for this purpose and we were able to achieve alignment accuracies better than 1 mrad.

The low-resolution channel of the FLEX instrument operates in VIS-NIR region. Here the challenges for the realization of a dispersive grating mainly lie within the large spectral bandwidth of 300nm. In order to guarantee high diffraction efficiency throughout the entire bandwidth, our technological realization approach is based on a so-called binary blazed grating. Here, a grating of uniform depth with varying lateral features was designed and fabricated by EBL and DRIE in fused silica. In order to minimize the polarization sensitivity and to relax the technological realization difficulties, some of the grating trenches were transformed into rectangular pillars with a two-dimensional cross section. Thus, the smallest realized features within the grating are about 140nm in width and 1700nm in depth. The measured diffraction efficiency was larger than 75% throughout the entire spectral region between 500nm to 800nm.

Both concepts offer a significant extension of the available design freedom for the realization of a great variety of high-performance gratings for different spectroscopic instruments.

9912-81, Session 15

Characterizing the cross dispersion reflection gratings of CRIRES+

Roman Follert, Thüringer Landessternwarte Tautenburg (Germany); Jörg Hollandt, Dieter R. Taubert, Christian Monte, Physikalisch-Technische Bundesanstalt (Germany); Ernesto Oliva, INAF - Osservatorio Astrofisico di Arcetri (Italy); Ulf Seemann, Georg-August-Univ. Göttingen (Germany); Tom Löwinger, Thüringer Landessternwarte Tautenburg (Germany); Reinhold J. Dorn, Paul Bristow, European Southern Observatory (Germany); Artie P. Hatzes, Thüringer Landessternwarte Tautenburg (Germany); Ansgar Reiners, Georg-August-Univ. Göttingen (Germany); Nikolai A. Piskunov, Ulrike Heiter, Thomas Marquart, Eric Stempels, Alexis Lavail, Uppsala Univ. (Sweden); Claudio Cumani, Jason Grunhut, Andreas Haimerl, Renate Hinterschuster, Derek J. Ives, Yves Jung, Florian Kerber, Barbara Klein, Jean-Louis Lizon, Ignacio Molina-Conde, Belinda Nicholson, European Southern Observatory (Germany); Livia Origlia, INAF - Osservatorio Astronomico di Bologna (Italy); Luca Pasquini, Jérôme Paufique, Jörg Stegmeier, Sebastien Tordo, European Southern Observatory (Germany)

High resolution Infrared spectroscopy has many important applications in astrophysics from exoplanets to cosmology. Yet, almost all currently existing infrared spectrographs are limited by the rather small wavelength range which can be simultaneously covered.

The CRIRES+ project attempts to upgrade the CRIRES instrument which has been in operation at one of the VLT observatory (Cerro Paranal, Chile) 8 m Unit telescopes until July 2014. This will turn CRIRES+ into a fully operational cross dispersed echelle spectrograph with a simultaneous recording of 8-10 diffraction orders. CRIRES+ will provide a spectral resolving power of R = 100,000 over a usable wavelength range of (0.95 – 5.2) μm.

One of the main design goals of the upgrade project is to at least maintain or to increase the overall throughput of the instrument. To achieve this ambitious goal, all components will be optimized for their task and rigorously tested before integration.

In order to transform the CRIRES instrument into a multi-order cross-dispersed echelle spectrograph, a set of six reflection gratings, each one optimized for one of the wavelength bands CRIRES+ will operate in (YJHKLM), will be used as cross dispersion elements in CRIRES+. Due to the upgrade nature of the project, the choice of gratings depends on the fixed geometry of the instrument. Thus, custom made gratings would be required to achieve the ambitious design goals. Custom made gratings have the disadvantage, though, that they come at an extraordinary price and with lead times of more than 12 months. To mitigate this, a set of off-the-shelf gratings was obtained which had grating parameters very close to the ones being identified as optimal. To ensure that the rigorous specifications for CRIRES+ will be fulfilled, the CRIRES+ team started a collaboration with the national metrology institute of Germany PTB to characterize gratings under conditions similar to the operating conditions in CRIRES+ (angle of incidence, wavelength range).

The respective dedicated test setup was designed in collaboration between PTB and the CRIRES+ consortium. It consists mainly of bulk optics and is operated at room temperatures. The PTB provided light sources and detectors as well as a calibrated reference reflective sample for each wavelength range. With this setup, it is possible to measure the relative diffraction efficiency of the gratings both wavelength dependent (nine different wavelength equally distributed in each band) and polarization state dependent (the setup is equipped with a polarimetry unit based on wire-grid type polarizers) in a wavelength range from (0.9 to 6.0) μm.

We will present in this paper a description of the test setup, including a discussion of the lessons learned, and the test results on a set of off-the-shelf gratings. In addition to this paper, a summary paper giving a status update on the project and other more detailed papers on dedicated sub-systems of CRIRES+ will be presented by other members of the CRIRES+ consortium.

9912-82, Session 15

Final design and choices for EUCLID NISP grism

Anne Costille, Lab. d'Astrophysique de Marseille (France); Christelle Rossin, Observatoire de Physique du Globe de Clermont-Ferrand (France); Amandine Caillat, Sandrine Pascal, Patrice Sanchez, Benjamin Foulon, Sébastien Vives, Lab. d'Astrophysique de Marseille (France)

The ESA mission Euclid is designed to explore the dark side of the Universe and to understand the nature of the dark energy responsible of the accelerated expansion of the Universe. Its objective is to map the geometry of the dark Universe by investigating the distance-redshift relationship and the evolution of cosmic structures. The NISP (Near Infrared Spectro-Photometer) is one of the two Euclid instruments operating in the near-IR spectral region (0.9-2?m). The NISP instrument has two main observing modes: the photometric mode, for the acquisition of images with broad band filters, and the spectroscopic mode, for the acquisition of slitless dispersed images on the detectors. The spectroscopic Channel uses four low resolution grisms to cover two spectral ranges: three "red" grisms for 1250-1850nm range, with three different orientations, and one "blue" grism for 920-1300nm range. The NISP grisms are complex optical components that combine four main optical functions: a grism function (dispersion without beam deviation of the first diffracted order) done by the grating on the prism hypotenuse, a spectral filter done by a multilayer filter deposited on the first surface of the prism to select the wavelength bandpass, a focus function done by a curved surface where the filter is

deposited and a spectral wavefront correction done by the grating nor parallel, neither straight grooves. This specific grating is made thanks to a new technic developed with SILIOS Technologies company to manufacture a resin-free grating with curved groove paths. The optical component is glued onto a mechanical ring, designed to survive to 60g load DLL and to keep optical performance at 130K. The design and manufacturing of these components represent an important challenge in order to obtain the best performance possible with very constraining requirements in particular for transmitted wavefront error quality. We will present the performance obtained on scale one prototypes of the filter, the grating and the mount manufactured to validate the final design choice and used to make the necessary trade-off during the development phase. All the prototypes manufactured have shown very good optical performances and have withstand vibrations and vacuum cryogenic test that confirms the feasibility of NISP grisms and prepare the next phase of the project for the procurement and test of NISP grism flight models.

9912-83, Session 15

Carbon nanotube coated petal-shape masks to suppress reflections in space-based telescopes

Ron S. Shiri, Shannon R. Sankar, Jeffrey C. Livas, NASA Goddard Space Flight Ctr. (United States)

A broad class of on-axis telescopes, which simultaneously transmit and receive, require suppression of the reflected light from the secondary mirror. For instance, an on-axis design of the optical telescope for the evolved Laser Interferometric Space Antenna (eLISA), a re-scoped version of the baseline LISA mission concept, fits in this category. If operated for this application, the telescope requires suppression of the directly reflected laser source from the secondary mirror of the telescope assembly back onto the detector. A simple circular hole or black spot on the secondary mirror as a means of suppressing the reflected light produces a bright (Poisson) spot on the detector due to diffraction from the edges of the hole or spot, defeating the purpose. To eliminate this diffraction effect, earlier work has shown that petal-shape mask designs based on hypergaussian functions could suppress the retro-reflected light intensity by several orders of magnitude.

However, when applied to a reflective surface, a suitable level of 'darkness' and low surface roughness in addition to the shape of the petal-shaped mask is required for good suppression. In this work, we lithographically fabricated an assortment of petal-shaped masks on silicon wafers and investigated growing carbon nanotubes (CNT) on the surface of the masks. The CNTs have been shown to be exceptionally good absorbers. They also provide an order-of-magnitude improvement over current absorptive surface treatments. We report on the challenges and technical difficulties of growing multiwalled carbon nanotubes on the surfaces of petal-shape masks on thin reflective substrates. The CNT growing process involves exposure of the reflective wafer imprinted with the petal masks to a 750-degrees Celsius environment in a furnace. Common reflective metals such as aluminum and silver, used in mirror fabrication, could not sustain the furnace heat. We discuss the process used to create these highly absorptive petal shapes. The final product is a reflective wafer with carbon nanotubes coated on the petal-shape areas only. Furthermore, we investigated the suppression capability of the petal-shaped masks in optical test beds subjected to incident laser sources of 532-nm and 1064-nm. An initial optical analysis of CNT coated masks on reflective substrates show 3-4 orders of magnitude intensity suppression relative to the incident laser source. The future application of this technology could be applied to variety of space-based telescopes requiring coronagraphs.

9912-95, Session P1

Revisiting static modulation in pyramid wavefront sensing

Luca Marafatto, Roberto Ragazzoni, Jacopo Farinato, Valentina Viotto, Maria Bergomi, Federico Biondi, Demetrio Magrin, Davide Greggio, Carmelo Arcidiacono, INAF - Osservatorio Astronomico di Padova (Italy)

The Pyramid Sensor (PS) is based on the Focault knife-edge test, yielding then, in geometrical approximation, only the sign of the wavefront slope. To provide linear measurements of the wavefront slopes the PS relies on a technique known as modulation, which also plays a central role to improve the linear range of the pyramid WFS, very small in the non-modulated case. In the main PS using modulation so far, this task is achieved by moving optical components in the WFS, increasing the complexity of the system. An attractive idea to simplify the optical and mechanical design of a pyramid WFS is to work without any dynamic modulation.

This concept was only merely described and functionally tested in the framework of MAD, and subsequently, with a holographic diffuser. The latter produce a sort of random distribution of the light coming out from the pupil plane, leading to sort of inefficient modulation, as most of the rays are focused in the central region of the light diffused by such device. The bi-dimensional original grating is, in contrast, producing a well defined deterministic distribution of the light onto a specifically shaped pattern. A crude option has been already discussed as a possibility, and it is here generalized to holographic plates leading to various distribution of lights, including a circle whose diameter would match the required modulation pattern, or more cost effective approaches like the one of a square pattern. These holographic diffusers would exhibit also zero-th and high order patterns and the actual size of the equivalent modulation would be linearly wavelength dependent, leading to colour effects that requires a careful handling in order to properly choose the right amount of equivalent modulation.

9912-96, Session P1

Multifunctional coating for the PROBA3 ASPIICS coronograph internal occulter

Karl Fleury-Frenette, Ctr. Spatial de Liège (Belgium); Cédric Lenaerts, Univ. de Liège (Belgium); Olivier Dubreuil, Ctr. Spatial de Liège (Belgium); Frédéric Rabecki, Camille Galy, Cédric Thizy, Jean-Sébastien Servaye, Etienne Renotte, Univ. de Liège (Belgium)

We present the development status of a radially variable functional coating designed for the internal occulter of the ASPIICS (Association of Spacecraft for Polarimetric and Imaging Investigation of the Corona of the Sun) instrument. ASPIICS is the primary payload of the ESA PROBA-3 mission devoted to the in-orbit demonstration of precise formation flying for future European missions. The instrument is based on an externally occulted Lyot coronograph with the particularity of being distributed over two spacecrafts approximately 150 m apart. The internal occulter consists in a coating applied on the planar side of a plano-convex field lens; it features an opaque ring surrounded by a highly transparent outer ring and an inner clear aperture. The transmission is enhanced thanks to an antireflective coating stack whereas the occulting function over the ring is provided by a coating sharing layers with the former stack but absorbing light incoming from both sides of the lens-vacuum interface. The operational spectral range spans from 530 nm to 590 nm. The absorbing and antireflective coating stacks are metal-dielectric and dielectric-dielectric multilayers respectively all deposited using ion beam sputtering. They provide absorption higher or equal to 95% on both faces of the occulting ring and reflectivity lower or equal to 0.1% over the high transmission regions. Low reflectivity is required over the whole occulter

surface to minimize straylight.

One can divide the overall coating into four sub-stacks: the first one, in order of deposition, covers the whole lens planar surface and is at the same time constitutive of both antireflective and absorbing coatings. The second sub-stack is constrained to the occulting area and consists of additional layers that complete the absorbing coating for incidence from the lens material side. The third one, applied over the same area, forms the main part of the vacuum-side absorbing coating. Finally, the last stack, applied over the whole surface, completes both antireflective and vacuum-side absorbing coatings with its last layers providing protection against side corrosion for the metallic layers within the occulting ring. The optical designs of the different stacks are optimized simultaneously using a simulated annealing algorithm. The complex refractive indices for the design calculations were determined from the combination of variable angle spectral ellipsometric (VASE) and spectral transmittance measurements carried out on monolayers deposited on fused silica and silicon (100) substrates.

The proposed coating stack structure and the juxtaposition of antireflective and absorbing zones require a masking step during the application process in order to achieve the deposition of differentiating layers. UV projection photolithography involving a photoresist lift-off process is used to such purpose. The coating defects are characterized before and after the photolitographic process using scanning electron microscopy and digital optical microscopy. The vertical nano-roughness and lateral roughness of the interfaces between the occulting and transparent zones is characterized using phase-shift interferometry. Both spectral transmittance and reflectance of stack samples are measured and compared to simulations.

9912-97, Session P1

Progress on sol-gel antireflective coatings for astronomical optics

Yeru Wang, Jinfeng Wang, XinNan Li, Jie Tian, Nanjing Institute of Astronomical Optics & Technology (China)

Modern astronomical telescopes have a wide working wave band and large aperture. Multilayer, complex film structure would be needed for the demand of broadband antireflection with the method of vacuum evaporation which not has a high transmittance. Sol-gel coatings, on the contrary, have a better result only with several layers. In addition, there are many advantages of sol-gel coatings, such as simple technical control, better transmittance, large-area film formation. So a good application prospect of sol-gel coatings in the field of astronomical telescope is expected.

We have conducted some basic experiments about film formation, including the effects caused by various technology conditions on quality of film formation, for example, the proportion of each component, the aging time of sol, the speed of dip-coating, baking temperature etc. And the optimization and improvement on this basis. We also had the tests about environment endurance of the sol-gel coatings, including film hardness, friction resistance and hydrophobic property. Then we will concentrate on them and make improvement to gain a more steady performance film. We will continue to pay close attention on the relative optical properties such as optical constant, microstructure, contact angle, adhesive force and so on.

The technical test of small-aperture (about (100mm) lens have been finished, then we will increase the aperture of sample step by step to study the restriction on dip method and the possibility of replacement of film formation method. In the end. the double-side anti-reflective coatings for the meter-scale lenses, such as the Atmospheric Dispersion Corrector (ADC) for the KECK is expected. we have conducted some tentative verification tests and got an ideal result that the double-side transparency (300nm to 1100nm) is better than 97%.

9912-98, Session P1

J-Black: a stray light coating for optical and infrared systems

Patrick G. Waddell, David S. Black, Universities Space Research Association (United States)

Successful designs for scientific optical and infrared systems intended for wide dynamic range operation must include well defined stray light control to prevent noise contributions from unwanted radiation. Stray light control components, such as baffles, enclosures and structures require surface coatings that have minimum optical reflectivity and that are diffuse over the wavelengths for which the instrument is sensitive. Environmental conditions over the science mission life can provide similarly challenging physical requirements on stray light coatings.

A new stray light coating, called J-Black has been developed for NASA's Stratospheric Observatory for Infrared Astronomy (SOFIA). The J-Black formulation stems from a series of trial coating runs at Puget Sound Coatings in Seattle. Combinations of commercially available aerospace grade coatings with selected additives, such as silicon carbide and glass spheres, were tried followed by optical and environmental testing. In July 2014, SOFIA participants worked with Lufthansa Technik personnel in Hamburg to apply J-Black to large areas of the SOFIA airborne telescope. The telescope is currently operated within the open cavity environment of the Boeing 747 platform aircraft.

Comparisons between J-Black reflectivity and other coatings commonly used for large area coverage, including two formulations of Ball Infra-Red Black, composites of Aeroglaze Z306 and Desothane CA8271F37038, demonstrate the new coating is among the lowest achieved for the 0.4 to 21 micron wavelength range. The J-Black coating is comprised of a combination of Nextel 3101, Nextel Primer 5523 and silicon carbide. A simple process has been developed to achieve a homogeneous complex surface structure which is needed for long wavelength applications. And while the process has numerous detailed steps, they are of short duration with minimal requirements for preciseness. Overall, the coating is relatively easy to apply and has been used on aluminum and composite materials. Tests with J-Black coated substrates demonstrate robust strength properties over the temperature range of -200C to +100C, including thermal shock and icing conditions and physical abuse via stiff brushing. Specular and diffuse reflectance performance measurements of J-Black coated samples were acquired using Surface Optics InspectIR-Vis which includes 4 filtered bands between 400 to 1100 nm. Long wavelength measurements using six filter bands covering 1.5 to 21 microns were made with a Surface Optics ET-100 Emissometer.

9912-99, Session P1

Atomic Layer Deposited (ALD) coatings for future astronomical telescopes: recent developments

Christopher S Moore, Univ. of Colorado at Boulder (United States); John J. Henessy, April D. Jewell, Shouleh Nikzad, Jet Propulsion Lab. (United States) and California Institute for Technology (United States); Kevin C France, Univ of Colorado at Boulder (United States)

Atomic Layer Deposition (ALD) can create conformal, near stoichiometric and pinhole free transmissive metal fluoride coatings to protect reflective aluminum films. Spectral performance of astronomical mirror coatings strongly affect the science capabilities of future astronomical satellite missions. We are utilizing ALD to create a transmissive overcoat to protect aluminum film mirrors from oxidation. We desire high reflectance (> 80%) from the UV (~100 nm) to the IR (~2,000 nm). This paper summarizes the recent developments of ALD coatings on Al. Reflectance measurements, storage effects, film composition, film structure and future applications are discussed.

9912-100, Session P1

Astronomical large Ge immersion grating by CANON

Takashi Sukegawa, Takeshi Suzuki, Tsuyoshi Kitamura, Canon Inc. (Japan)

An immersion grating is a powerful optical device for the infrared high-resolution spectroscope.(Marsh et al.(2007),Kuzmenko et al.(2006)) Ge is the best material for a mid-infrared immersion grating because of Ge has very large reflective index (n=4.0). On the other hands, there is no practical Ge immersion grating under 5um use. It was very difficult for a fragile IR crystal to manufacture a diffraction grating precisely. Our original free-forming machine has accuracy of a few nano-meter in positioning and stability. We already fabricated the large CdZnTe immersion grating. (Sukegawa et al. (2012), Ikeda et al. (2015)) We are developing Ge immersion grating that can be a good solution for high-resolution infrared spectroscopy with the large ground-based / space telescopes. We succeeded practical Ge immersion grating with the grooved area of 75mm (ruled direction) x 19mm (groove width) and the blaze angle of 75 degrees. (CANON/Sukegawa et al. (2015)) The diffraction efficiency after HR and AR coating is over 70% at 4um which is almost same as theoretical value. A next generation large ground-based telescope will be required more large immersion grating. We are developing large Ge immersion grating for astronomy which has the grooved area of 155mm (ruled direction) x 40mm (groove width) and groove pitch of 91.74um. The typical performance are the spacing accuracy of <5nmRMS, the surface roughness of <2nmRMS and the surface irregularity of 80nm (PV) / 18nm (RMS). In this paper, we report performance of astronomical large Ge immersion grating, especially optical performance results. An apex angle of groove is very important to ideal efficient realization. Additionally, an optional apex angle can be achieved in Germanium by our process, we report on the theoretical efficiency of the apex angle and the actual efficiency compared with 85 degrees and 89 degrees.

9912-101, Session P1

The legacy of filter design and how that has extended into current choices for advanced astronomical filters

Steffen Reichel, SCHOTT AG (Germany) and Hochschule Darmstadt (Germany); Tony B. Hull, The Univ. of New Mexico (United States); Ulf Brauneck, Vincent Naulin, SCHOTT Suisse SA (Switzerland)

In 1935 the single layer anti-reflective (AR) coating was invented by Alexander Smakula and patented by Zeiss. During that time SCHOTT also worked on AR coatings and filters based on interference due to multi-layers. Dr. habil. Walter Geffcken from SCHOTT invented a series of different coatings: metal dielectric interference filters (1939), (broad band) coatings with reduced surface reflections (1940), all dielectric interference filters with alternating high and low refractive index coatings (1942), and small bandpass interference filters based on multi-cavities (1944). These fundamental principles were invented by SCHOTT between about 1935 and 1945 and are still used in modern interference filter designs.

After World-War II this know-how was transferred to Mainz, West-Germany and further developed. In 2010 SCHOTT's interference filter know-how was bundled with the processing, polishing, and assembly know-how in Switzerland (Yverdon) now with more than 6200 square meter of coating space. These capabilities enable the complete design and manufacturing of high-tech cutting edge interference filters bringing the technology to its edge. In 2007 a study was performed for bandpass and blocking coatings for use in satellites.

Bandpass coatings in visible and NIR range are produced since 2008 for several space projects. With their FWHM bandwidth between 60nm to over 130nm, their very tight tolerance and a low defect requirement, theses filters are real challenges. Beside the bandpass filters, a black chrome coating has been developed to drastically reduce crosstalk and ghost image.

The projects were led together with SODERN who managed the assembly of the filters and took care of the space qualification of the filters. Despite the highly demanding tests, no change was observed in the spectral performance. Some of the produced butcher filters are currently operating above our heads in space.

Besides space coatings and filters for satellites in the orbit, steep edge narrow bandpass filters for ground based telescope instrumentations were developed fro CEFCA. The demanding requirements in terms of steepness, broad blocking range, center wavelength uniformity, center wavelength homogeneity, and transmitted wavefront error of the filter assembly pushed the filter design and the technology to its limits. A special developed white-light Shack Hartmann sensor enables the possibility to measure and reach the transmitted wavefront of the narrow bandpass filter who typically block light at 633 nm (measurement wavelength of state-of-the art wavefront systems). Such demanding filter requirements could only be reach by a combination of color glass (absorption filters) and interference filters based on special designs. As an example an H? filter (center wavelength of 660 nm) was manufactured with blocking range from 250 nm to 1050 nm with T < 10-5 (on average), FWHM bandwidth of 14.5 nm, and Tmax > 95 %. The transmitted wavefront error (RMS) was 0.07 lambda and the center wavelength uniformity over 100 mm x 100 mm filter size was below ±0.16 %.

9912-102, Session P1

Mid-infrared transmission gratings in chalcogenide glass manufactured using ultrafast laser inscription

David Lee, UK Astronomy Technology Ctr. (United Kingdom); David G. MacLachlan, Heriot-Watt Univ. (United Kingdom); Helen L. Butcher, Damien Weidmann, STFC Rutherford Appleton Lab. (United Kingdom); Colin R. Cunningham, Hermine Schnetler, UK Astronomy Technology Ctr. (United Kingdom); Robert R. Thomson, Heriot-Watt Univ. (United Kingdom)

Ultrafast laser inscription is a versatile manufacturing technique which can be used to modify the refractive index of various glasses on a microscopic scale. This enables the production of a number of photonic devices such as waveguides, beam-splitters, photonic lanterns, and diffraction gratings. In this paper we report on the use of ultrafast laser inscription to fabricate volume phase transmission gratings in mid-infrared transmitting chalcogenide glass.

We describe the optimisation of the laser inscription process parameters to produce the best performing gratings and present theoretical models for expected grating performance. The first order diffraction efficiency of the gratings was measured, at mid-infrared wavelengths (3-5 ?m), and found to exceed 60% at the Littrow blaze wavelength, compared to a substrate external transmittance of 67%. This impressive result implies the diffraction efficiency should exceed 90% for a grating substrate treated with an anti-reflection coating. There is excellent agreement between the modelled grating efficiency and the measured data and from a least squares fit to the measured data we infer the refractive index modulation achieved during the inscription process. We also present preliminary K-band spectra of a laboratory light source obtained using one of the prototype gratings. These encouraging preliminary results demonstrate that ultrafast laser inscription of chalcogenide glass may provide a potential new and alternative technology for the manufacture of astronomical diffraction gratings for use at near-infrared and mid-infrared wavelengths.

9912-103, Session P1

Thin-film optical pass band filters based on new photo-lithographic process for CaSSIS FPA detector on Exomars TGO mission: development, integration, and test

Lisa Gambicorti, Daniele Piazza, Michael Gerber, Claudio Zimmermann, Antoine Pommerol, Victoria Ann Roloff, Ruth Ziethe, Univ. Bern (Switzerland); Vania Da Deppo, IFN-CNR LUXOR Lab. (Italy); Iacopo Ficai Veltroni, Emiliano Di Carmine, SELEX ES S.p.A. (Italy); Thomas E. Bauer, Petra Moebius, Optics Balzers Jena GmbH (Germany); Gabriele Cremonese, INAF - Osservatorio Astronomico di Padova (Italy); Nicolas Thomas, Univ. Bern (Switzerland)

A new technique based on photolithographic processes of thin-film optical pass band coatings on a monolithic substrate has been applied to the filters of the Focal Plane Assembly (FPA) of the Colour and Stereo Surface Imaging System (CaSSIS) that will fly onboard of the ExoMars Trace Gas Orbiter to be launched in 2016 by ESA.

The FPA including the detector, integrated by Selex ES under TAS-I responsibility, is one of the spare components of the Simbio-Sys instrument of the Italian Space Agency (ASI) that will fly on ESA's BepiColombo mission to Mercury. The detector, developed by Raytheon Vision Systems, is a 2kx2k hybrid Si-PIN array with a 10 ?m pixel. The detector is housed within a block and has filters deposited directly on the entrance window. The window is a 1 mm thick monolithic plate of fused silica. The Filter Strip Assembly (FSA) is based on dielectric multilayer interference coatings, 4 colour bands have been selected with average in-band transmission greater than 95 percent within the CaSSIS wavelength range (400-1100 nm). This manufacturing approach gives multispectral images on the same detector and thus allows CaSSIS to operate in push-frame mode.

The Field of View (FOV) of each colour band on the detector is surrounded by a mask of low reflective chromium (LRC), which also provides with the straylight suppression required (an out-of-band transmission of less than 10^-5/nm). The mask has been shown to deal effectively with cross-talk from multiple reflections between the detector surface and the filter.

This paper shows the manufacturing and optical properties of the FSA filters and the FPA preliminary on-ground calibration results.

9912-104, Session P1

Novel diffraction gratings for next generation spectrographs with high spectral dispersion

Noboru Ebizuka, Takuya Hosobata, Takayuki Okamoto, Yutaka Yamagata, RIKEN (Japan); Minoru Sasaki, Toyota Technological Institute (Japan); Shinya Sato, Ayano Tanabe, Nobuyuki Hashimoto, Citizen Holdings Co., Ltd. (Japan); Miyuki Uomoto, Takehito Shimatsu, Tohoku Univ. (Japan); Shin-ya Morita, Tokyo Denki Univ. (Japan); Shinobu Ozaki, Wako Aoki, Hideki Takami, National Astronomical Observatory of Japan (Japan)

We are developing birefringence volume phase holographic (birefringence VPH) grating, quasi-Bragg grating and immersion grating as novel high dispersion gratings for 8.2m Subaru telescope, Thirty Meter Telescope and a next generation huge space telescope. The birefringence VPH grating uses liquid crystal of visible light curable mixed with UV curable resin. The quasi-Bragg grating is fabricated by lamination of mirror plate with emboss and UV curable adhesive. We introduce Si immersion gratings (grism) fabricated by using a diamond endmill with 60 blades.

9912-105, Session P1

Manufacturing and coating of optical components for the EnMAP hyperspectral imager

Mark Schürmann, Dieter Gäbler, Ralph Schlegel, Stefan Schwinde, Thomas Peschel, Christoph Damm, Robert Jende, Jan Kinast, Sandra Müller, Stefan Risse, Fraunhofer-Institut für Angewandte Optik und Feinmechanik (Germany); Bernhard Sang, Markus Glier, Hermann Bittner, Markus Erhard, OHB-System AG (Germany)

The hyperspectral imager of the Environmental Mapping and Analysis Program (EnMAP) utilizes an optical system consisting of both mirrors and prisms in order to achieve the required imaging properties and spectral performance. The imager consists of a TMA and two independent spectrometers which measure the solar radiance reflected from the surface in a continuous spectrum.

The VNIR spectrometer contains five spherical and aspherical mirrors and four curved prisms. The ultraprecise mirrors were manufactured by diamond turning of electroless NiP plated Al6061 substrate. After polishing the surface the roughness of the mirrors was better than 1 nm rms. The applied coating was a high-reflective protected silver coating optimized for the spectral range 420 nm to 1000 nm. The reflectivity is higher than 95 % from 420 nm to 500 nm and higher than 96 % from 500 nm to 1000 nm. Two curved prisms (substrate material Fused Silica) were coated with a broadband antireflection coating optimized for small polarization sensitivity, especially in the spectral range from 600 nm to 900 nm. Two curved prisms (substrate material SF6) were coated with a broadband antireflection coating on one side and a high-reflective enhanced Ag-coating on the backside.

The SWIR spectrometer contains five plane and spherical mirrors and two curved prisms. As the mirrors for the VNIR spectrometer these ultraprecise mirrors were manufactured by diamond turning of Al6061 substrate materials coated with an electroless NiP polishing layer and have a comparable surface quality and surface shape deviation. These mirrors are coated with a gold-coating in order to achieve a reflectivity higher than 97.5 % in the spectral range 900 nm to 2450 nm. The two curved SWIR-prisms (substrate material Fused Silica) are coated with a broadband antireflection coating.

This contribution will report on the manufacturing of the mirrors and the coating of both mirrors and prisms. The most important technological steps and the achieved results will be discussed.

9912-106, Session P1

Novel fabrication methods of silicon and germanium gratings for infrared astronomy

Shin-ya Morita, Tokyo Denki Univ. (Japan); Noboru Ebizuka, Yutaka Yamagata, RIKEN (Japan); Hirofumi Suzuki, Chubu Univ. (Japan); Takafumi Kamizuka, Takashi Miyata, The Univ. of Tokyo (Japan)

Single crystal silicon and germanium is an excellent optical material in the infrared astronomical spectroscopy. We developed a ductile-mode micro

grooving process for fabricating diffraction gratings made of silicon and germanium. We report a trial of the new fabrication methods of silicon and germanium gratings for an infrared astronomical instrument, Mid-Infrared Multi-field Imager for gaZing at the UnKnown Universe (MIMIZUKU). The MIMIZUKU is the first generation instrument of the University of Tokyo Atacama Observatory (TAO) 6.5-m telescope. We developed new fabrication methods of a silicon grism designed for KL-band spectroscopy in MIMIZUKU.

In the past work, we had developed a ductile mode grinding in order to fabricate immersion gratings made of germanium substrate. Although the ground surface roughness is enough good for mid-infrared spectroscopy, tip radius of grinding wheel is limited to be larger than several microns because of tool ware in grinding process. In order to overcome this situation, single crystalline diamond (SCD) cutting tools have been developed for fabrication of the grism . We adopt an ultra-precision cutting technique to fabricate micro grooves for grisms. New shaper and milling SCD cutting tools have been developed for this purpose.

A shaper SCD tool is formed into v-shape with negative rake angle to fabricate v-grooves ductilely in brittle materials like silicon and germanium crystal. A milling SCD tool has 60 cutting edges fabricated 3-dimensionally on the edge of a cylindrical SCD by a laser beam.

In the preliminary cutting experiments, the workpiece of silicon was machined using ultrahigh precision machine tools and the developed SCD tools to evaluate machinability of silicon substrate in ductile regime and its tool wear.

9912-107, Session P1

Performance characteristics of advanced volume phase holographic gratings for operation in the near infrared

James Arns, Kaiser Optical Systems, Inc. (United States)

Volume phase holographic (VPH) gratings have proven useful as dispersing elements in astronomical spectrographs over the visible spectrum. VPH gratings have also been successfully deployed for use at cryogenic temperatures. Recent advances in production technology now permit the production of gratings for use in the H-band and K-band on optical materials needed for high throughput in the near infrared.

This paper discusses the limitations a common VPH grating material, dichromated gelatin, imposes on the production of near infrared grating elements as well as the practical limitations of testing.

The theoretical expectations generated by three RCWA optimized designs are presented. The H-band grating operates over the wavelengths of 1500 to 1800 nm and has a grating frequency of 290 lines/mm. The two K-band gratings operate over the wavelengths of 1950 to 2450 nm and have grating frequencies of 200 and 400 lines/mm. Measured results from production of the three grating designs are given.

9912-108, Session P1

Strategies for single-point diamond machining a large format germanium blazed immersion grating

Richard Montesanti, Steve L. Little, Paul J. Kuzmenko, Jay V. Bixler, John L. Jackson, Lawrence Livermore National Lab. (United States); Joseph G. Lown, Akima Infrastructure Services, Inc. (United States); Robert E. Priest, Brian E. Yoxall, Lawrence Livermore National Lab. (United States)

A large format germanium immersion grating was flycut with a single-point diamond tool on the Precision Engineering Research Lathe (PERL) at the Lawrence Livermore National Laboratory (LLNL) in November – December 2015. The grating, referred to as 002u, has an area of 59 mm x 67 mm (along-groove and cross-groove directions), line pitch of 88 line/mm, and blaze angle of 32 degree. Details on flycutting a grating with a single-point diamond tool are already reported in the literature. This paper presents new strategies for flycutting a grating, most notably pre-machining the grating substrate to produce a smooth, flat, damage-free surface into which the grooves are cut. We report on the key risks for the 002u grating, accelerated test program, trade-offs that drove decisions, and experimental results.

The 002u grating has a total groove length of 350 m which required twenty-eight contiguous days to cut. The previous largest grating produced by flycutting on PERL, based on total groove length, is a zinc-selenide grating having a total groove length of 63 m which took nine days to cut. The previous largest germanium gratings cut on PERL are grisms for LMIRcam, which have a total groove length of 7.8 m. Comparing gratings by total groove length instead of area accounts for line density and provides a comparison basis for issues like tool wear and cutting days required. By this measure, the 002u grating is five times larger than the previous largest grating (Zn-Se) cut on PERL, and forty-five times larger than the previous largest germanium grating cut on PERL. The strategies described in this paper were developed to mitigate the risks associated with the uncertainties of tool wear and keeping the PERL running for such a long grating cut, and can be applied to other gratings produced by single-point diamond machining.

The immersed grating approach, especially when using a high index of refraction substrate, provides a more compact grating diffraction geometry than is obtainable when approaching the grooves from air or vacuum. In addition the entry and exit faces of the grating substrate provide refracting surfaces for controlling optical performance. With the appropriate blaze angle, the flat-faceted, saw?tooth shaped groove profile of a blazed grating provides the highest diffraction efficiency at the wavelength of interest. The grating geometry depends on the design of the overall optical system the grating is used in, and can be optimized during trade-offs among all the optical components. Grating grooves can be produced by chemical etching – if the substrate lends itself to etching – or by single-point diamond machining. Chemical etching can produce a flat blaze face if the groove geometry is aligned to the substrate crystallographic axes. Single-point diamond machining can produce flat blaze faces even when the groove geometry is not aligned to the substrate crystallographic axes, and therefore provides increased design freedom for the overall optical system.

9912-109, Session P1

Programmable CGH on photochromic material using DMD

Romain Alata, Lab. d'Astrophysique de Marseille (France); Giorgio Pariani, INAF - Osservatorio Astronomico di Brera (Italy); Frédéric Zamkotsian, Patrick Lanzoni, Lab. d'Astrophysique de Marseille (France); Andrea Bianco, INAF - Osservatorio Astronomico di Brera (Italy); Chiara Bertarelli, Politecnico di Milano (Italy)

Computer Generated Holograms (CGHs) are useful for wavefront shaping and complex optics testing, including aspherical and free-form optics. Today, CGHs are recorded directly with a laser or intermediates masks. We propose to use a Digital Micro-mirror Device (DMD) for writing directly the CGHs. DMD is actually studied at LAM, for generating programmable slit masks in multi-object spectrographs. It is composed of 2048x1080 individually controllable micro-mirrors, with a pitch of 13.68 μm. This is a real-time reconfigurable mask, perfect for recording CGHs. We developed a first setup dedicated to hologram recording: the DMD is enlightened with a collimated beam and illuminates the CGH plate through an Offner relay, with a magnification of 1:1. In order to follow in-situ and in real

time CGH writing, the plate is imaged through the CGH substrate on a camera. It implies that the CGH's maximum size is directly limited by the DMD's size, the size of a DMD's micro-mirror corresponding to the size of a CGH's pixel. In order to write and erase CGHs during test procedure or according to different requests, we will use a photochromic plate as a sensitive material. This material, called PUR-GD71-50-ST, is opaque at rest, and becomes transparent when it is illuminated with visible light, between 400 and 700 nm; then it can be erased by a UV flash. For our preliminary tests, we recorded up to 1000x1000 pixels CGHs with a contrast greater than 10, knowing that the material is able to reach an ultimate contrast of 1000. The optical resolution of our system being around 3 μm, each pixel written is perfectly defined. We developed a second bench, dedicated to the reconstruction of the recorded images. We can calculate, write and reconstruct 2 types of CGHs, Fresnel and Fourier holograms. In both cases, the CGH is enlightened with a collimated He-Ne laser beam. Fresnel's CGH are obtained by calculating the inverse Fresnel transform of the original image at a given focus, ranging from 50cm to 2m, so it doesn't require any additional lens to reconstruct the image. For Fourier CGH, calculated with Lee's algorithm, where the magnitude and the phase of each pixel of the inverse Fourier transform of the image is encoded into a macro-pixel (a cell of 4x4 pixels), a lens has to be inserted in the beam for getting the reconstructed image. Thanks to our writing and reconstruction set-ups, we have been able to successfully record CGHs of different types, and reconstruct them with a high fidelity, revealing the potential of this method for generating programmable/rewritable CGHs on photochromic materials.

9912-110, Session P1

Cooled optical filters for Q-band infrared astronomy (15-40 μm)

Gary J. Hawkins, Richard E. Sherwood, Karim Djotni, Timothy M. Threadgold, The Univ. of Reading (United Kingdom)

With an evolving interest in observational astronomy across the mid- and far-infrared regions that is currently being motivated by technical advances and performance envisioned from the JWST-MIRI instrument and prospective next-generation telescopes, it is clear that improvements to the spectral and mechanical performance of optical filters to measure emission features in wavebands across the 15-40 ?m Q-band region is becoming increasingly important to provide a broader spectral wavelength coverage. This infrared region contains many signatures from astrophysical objects of which measurements are derived to determine the temperature, abundance of minerals, chemical composition, and grain size distribution from circumstellar dust and gas disks, crucial to theories on the formation of planetary systems. It is further vitally important for filters to be cooled to progressively lower temperatures to reduce noise, improve measurement sensitivity and avoid overwhelming signals originating from low energy astronomical sources by minimising the self-emission from heat sources within the instrument and telescope.

The desire to extend the range of interference filtering in order to separate and isolate wavebands in these infrared wavelengths is an area of challenging thin-film research, with goals to achieve high spectral positional accuracy, environmental durability and aging stability at cryogenic temperatures whilst maximising high transparency throughput. The major difficulties to realising this are through a balance of opposing constraints in the coating multilayer which include; accommodating large increases in the number of layers, deposition processing of high layer thicknesses, accumulation of material stress, maintaining transparency of layer materials, physical thin-film quality, and structural morphology of the condensed multilayer. The technical difficulties in achieving these demanding performance requirements has hindered characterisation of the cold and dust-filled Universe by low sensitivity and poor spatial resolution comparative to other wavelength ranges, even with the latest improvements in detector sensitivity across the infrared waveband.

Substrate and film materials exhibiting transparency across the Q-band wavelength range must utilise heavy molecular compounds with low lattice absorption properties, these include alkali-halides, thallium based mixed halides, Group II-VI compounds and Group IV elements. Many of the halide materials can possess a variety of undesired properties comprising high stress, hygroscopy, colour centres and toxicity that limit their usefulness. Deposition of cadmium-based dielectrics and lead (Pb) chalcogenide thin-films on cadmium telluride, silicon and diamond substrates, while not of outstandingly high mechanical strength have been manufactured and cooled whilst maintaining good transparency performance and durability at wavelengths across the 25-40 ?m range. Further, narrow bandpass filters for the 25 ?m region have been manufactured that exhibit temperature-invariant properties with negligible wavelength shift on cooling. The unique negative temperature coefficient (dn/dT<0) of Pb-based chalcogenide salts, in combination with the positive temperature coefficient of II-VI wideband dielectric materials enable multi-cavity bandpass filters to be designed with exclusive immunity to wavelength shifts with temperature.

In this paper we review and examine the interdependence between multilayer design, optical materials and fabrication properties of interference filters for the Q-band region, together with the rationale for the selection and characterisation of infrared materials, deposition method, spectral measurements and assessment of environmental durability.

9912-111, Session P1

Study on broadband reflective coating for astronomy

Jinfeng Wang, Yeru Wang, Jie Tian, Nanjing Institute of Astronomical Optics & Technology (China)

Spectral reflectance and reflective bandwidth are the key parameters of the mirror. The astronomical mirror is usually required to have both wide bandwidth and high reflection efficiency, but actually there are some defects in the coating material of mirror. Aluminum is the most commonly used material for astronomical mirror, and its average reflection efficiency is only about 90%, which is about 8% lower than silver; silver in the visible and infrared has the highest reflection efficiency, but its reflection is rapidly dropped to zero in the ultraviolet band shorter than 400nm; gold has a high reflection efficiency only in the infrared band longer than 600nm; because of the relationship between the stress and the total thickness of the all-dielectric mirror, high reflectance is only within a certain wavelength range. We have carried out the design and experiment of the wide band reflection mirror for the astronomical requirements, and have achieved some practical results: the ultraviolet enhanced silver mirror has the lowest reflectivity of 95% in the 300nm to the infrared band; the enhanced gold mirror is designed, which has better environmental stability compared with silver; all-dielectric mirrors are designed and fabricated, and successfully used in the LAMOST telescope spectrometers, the film stress is controlled properly, and surface shape has no change.

9912-112, Session P1

A local attenuation filter for accurate photometry of near-infrared bright stars

Takahiro Nagayama, Kagoshima Univ. (Japan)

In recent astronomical observation in the near-infrared wavelength, it is very difficult to observe bright stars because modern infrared array detectors are too sensitive and they are easily saturated. However, it is still important to observe bright stars. There are some methods which enable us to observe bright stars, for example, defocus, ND (neutral density) filters, or reducing the effective area of primary mirror and so on. These methods can attenuate the flux of bright stars and avoid the saturation but flux of other stars seen in the same image is also attenuated. Therefore, we cannot perform the relative photometry, which is crucial for the excellent photometric accuracy.

So, I have developed a special ND filter for observing bright near-infrared stars. This filter is a 60mm diameter with a 4mm thickness, on which an attenuation (1/5000 transparency) patch with an 8mm diameter is coated. This filter is expected to be installed near the focal plane of telescope. Only the flux through this patch is attenuated and the flux through outside this patch is not attenuated at all. Therefore, we can observe the attenuated bright star together with the not attenuated field stars as the reference stars for the relative photometry.

This filter has been installed to the Nagoya University IRSF 1.4m telescope at Sutherland observatory, South African Astronomical Observatory since 2013, and the test observations were carried out with the simultaneous JHKs camera SIRIUS. When we use this filter together with SIRIUS, the completely attenuated field of view is ~60" diameter and the area outer than 200" from the center of attenuation is attenuation free.

I observed 11 bright (K~1-3 mag) standard stars listed in Carter (1990) and have obtained that the averaged attenuation rates of patch are 1/5546, 1/6486, and 1/6427 for the J, H, and Ks bands, respectively. These values correspond to 9.36, 9.53, and 9.52 mag. I also examined the uniformity of transparency by pointing the standard star for 30 positions all over the attenuated area and comparing the instrument magnitude of standard star. The scatterings (rms) of instrument magnitude are 0.014, 0.015, and 0.020 mag for the J, H, and Ks bands, respectively. These values include the instability of sky transparency and so the uniformity should be better than them. This filter has been now used for the monitoring of NIR bright stars, for example, Eta Carina.

I also prepared the local attenuation filters with an attenuation patch of 1/200000(13.25 mag) for much brighter stars, including Betelgeuse, the brightest star in the Ks band, or 1/100 (5.0 mag) for less bright stars ranging 4-8 mag. Galactic or Magellanic super novae are very bright for almost all infrared camera but we are ready for them.

9912-113, Session P1

Characterization of an integrally wound tungsten and aluminum filament for use in the MMTO 6.5m primary mirror aluminization chamber

William Goble, Ricardo Ortiz, MMT Observatory (United States)

As part of the effort to increase the reliability of the MMT Observatory (MMTO) 6.5m Primary Mirror Coating System, the specified filament has changed from a configuration in which the aluminum charge is hand wound around a tungsten filament to a configuration in which the aluminum is integrally wound with the tungsten at the time of filament manufacture. In the MMTO configuration, this filament consists of the three strands of tungsten wire and one strand of aluminum wire. In preparation of a full system test utilizing two hundred filaments fired simultaneously, an extensive testing program was undertaken to characterize these filaments using a four filament configuration in the MMTO small coating chamber (0.5m) and then a forty filament configuration in the University of Arizona Steward Observatory coating chamber (2m). The testing using the smaller coating chambers has shown these filaments provide very consistent coatings from run to run, and with the proper heating profile, these filaments greatly reduce the chance of aluminum drips. The initial filament design was modified during the course of testing by shortening the unwound filament length to match the aluminum load required in the MMTO Coating Chamber. This change increased the aluminum deposition rates without increasing the capability of the filament power supplies (commercial DC welders). A summary of the filament power, current, resistance, and deposition rate for multiple test cases is presented.

9912-114, Session P1

Improved silver mirror coating for ground and space-based astronomy

David A. Sheikh, ZeCoat Corp. (United States)

A highly durable, UV-enhanced, silver mirror coating has been developed by ZeCoat Corporation. The coating is highly reflective (~ 97% average and 95% minimum) from 350-nm through the long IR and is relatively unaffected by exposure to warm-humid environments on earth, as well as, space radiation exposure at GEO. This paper presents polarized-angular reflectance data, as well as, the results of humidity tests and space radiation exposure tests.

9912-252, Session P1

First results on narrow bandpass steep edge optical filters for the JST/T250 telescope instrumentation

Steffen Reichel, SCHOTT AG (Germany) and Hochschule Darmstadt (Germany); Ulf Brauneck, Sébastien Bourquin, SCHOTT Suisse SA (Switzerland); Antonio Marín-Franch, Ctr. de Estudios de Física del Cosmos de Aragón (Spain)

The Observatorio Astrofísico de Javalambre in Spain (OAJ) is a new astronomical facility located at the Sierra de Javalambre (Teruel, Spain) whose primary role will be to conduct all-sky astronomical surveys. The OAJ facility has a wide-field telescope, the JST/T250; a 2.55-m telescope with a 3º diameter field of view (FoV) designed to perform the Javalambre Physics of the Accelerating Universe Astrophysical Survey (JPAS), an innovative photometric survey of more than 8000 square degrees of northern sky using 59 filters. Among them are 54 narrow bandpass (FWHM = 14.5 nm) filters continuously populating the spectrum between 370 to 920 nm with 10.0 nm steps.

The filters will operate close to, but up-stream from the dewar window in a fast converging optical beam (F# 3.64). This optical configuration imposes challenging requirements for the J-PAS filters, some of them requiring the development of new filter design solutions.

In this publication first results on 2 narrow bandpass steep edge filters with wide suppression will be shown. All filters have a physical size of 101.7 mm x 96.5 mm and 8.0 mm thickness. The thickness of the filter assembly had to be tightly controlled (< 40 µm) since the instrument works under fast convergence and observes with a mosaic of multiple filters simultaneously. The required center wavelength (cwl) uniformity was less than ±0.2 % over the whole clear aperture. This requires to push the coating design and technology to its technological limit. In addition the demanding image quality needed a strict requirement for the transmitted wavefront (RMS) to be less than lambda/2 over the whole clear aperture at 633 nm wavelength. The cwl of the 2 bandpass filters are 460 nm and 470 nm with a maximum transmission larger than 85 % in the passband. Both filters are part of the "filter comb" with a specified overlap for T > 0.7 Tmax to get continuity. The out of band blocking required a blocking of less than Tmax*10-5 on average from 250 nm and up to 1050 nm. In addition the spectral edges have to be steep for a small transition width from 5 % to 80 %. All these requirements have to be fulfilled for an operation temperature between -20°C and + 20°C.

The manufactured filters shown in this work consist of a coated substrate and an optical filter glass in order to reach the spectral requirements. The substrate is typically coated with layer systems from a plasma assisted reactive magnetron sputter process with typically more than 100 layers and a few micrometers total thickness. This coating process results in very dense and temperature stabile coatings. The inline control of the coating process was a combination of optical transmission monitoring and time/rate monitoring. Results and measurements of two steep edge narrow bandpass will be shown. The filters have a central wavelength and

a FWHM bandwidth of cwl = 460 nm and FWHM = 14.5 nm, cwl = 470 nm and FWHM = 14.5 nm fulfilling also all other demanding requirements mentioned before.

9912-253, Session P1

Photopolymer based VPHGs: from materials to sky results

Alessio Zanutta, Andrea Bianco, INAF - Osservatorio Astronomico di Brera (Italy); Enrico Orselli, Thomas P. Fäcke, Covestro AG (Germany)

Volume Phase Holographic Gratings (VPHGs) cover a relevant position as transmission dispersing elements in astronomical spectrographs with low and medium resolution. This is due to the unique properties especially in terms of diffraction efficiency.

These devices have to provide the dispersion, resolving power, bandwidth and diffraction efficiency according to the different astronomical scientific cases and sky targets to address. Indeed, each astronomical observation could take advantage of specific dispersive elements with features tailored for achieving the best performances.

The design and manufacturing of high efficiency and reliable VPHGs require photosensitive materials where it is possible to finely control the refractive index modulation, which is, together with the film thickness, the key property that determines the efficiency.

Photopolymers are a promising class of holographic materials since they can address precisely the refractive index modulation; moreover, they are self-developing, meaning that no chemical process is required after the light exposure.

We studied a specific family of photopolymers, Bayfol® HX by Covestro AG, which show a large tuning capabilities with a good transparency over the visible and NIR spectral range and a large refractive index modulation.

Based on such good properties of Bayfol® HX, we designed and manufactured six dispersing elements for astronomical instrumentation. Starting from the astronomical requirements, the features of the VPHGs have been determined, then the optimization of the writing conditions were carried out to achieve the desired refractive index modulation.

The six VPHGs were used in a GRISM configuration. Both the prism design and GRISM assembly was performed. Three GRISMs were integrated on ALFOSC (The Andalucia Faint Object Spectrograph and Camera) mounted on the Nordic Optical Telescope (2.56 meters, La Palma, Spain) and the other three on AFOSC (Asiago Faint Object Spectrograph and Camera) mounted onto Asiago's telescope in Italy.

The three elements for ALFOSC are characterized by a resolving power of approximately 1000 and they cover the 350-1000 nm spectral range.

The three elements for AFOSC have low dispersion covering the 350-1000 nm range. Interestingly, one GRISM shows a novel architecture based on slanted fringes VPHG and just one prism, with advantages such as less production costs and optical interfaces, that may form ghosts and decrease the overall efficiency.

All the six dispersing elements matched the astronomical requirements and overcome the performances of the already mounted devices with a system throughput gain that, in some cases, surpassed the 80%.

We demonstrated how the Bayfol® HX photopolymers are reliable for making VPHGs to be used in astronomical instrumentation and we defined a working range where the performances are similar or even better than those provided by DCG based VPHGs.

9912-271, Session P1

Ultra-narrow line VIS/NIR optical filters based on holographic volume Bragg gratings in PTR glass

Alexei L. Glebov, Vadim Smirnov, Oleksiy Mokhun, Leonid B. Glebov, OptiGrate Corp. (United States)

High-efficiency holographic volume Bragg gratings (VBGs) provide unmatched optical filtering capabilities with diffraction efficiencies as high as 99.999% and spectral linewidth as narrow as 15 pm (or <10 GHz). That enables splitting of individual optical bands spaced less than 100 pm apart and/or suppression of unwanted signals by 5-6 orders of magnitude. These holographic optical elements are formed in a photo-thermo-refractive (PTR) glass, the material that allows recording of phase Bragg gratings with high efficiency for visible and near IR spectral regions (350-2800 nm). The refractive index modulation in PTR glass is achieved by controlled precipitation of nano-crystalline phase in the whole volume of PTR glass exposed to UV radiation. Once recorded and developed, VBGs cannot be erased by illuminating to optical and ionizing radiation or by heating unless the temperature exceeds 400oC. Unlimited life time of PTR-VBG based filters combined with unique linewidth and suppression properties greatly benefit their usage for laser systems, spectroscopy, single photon counting, hyperspectral and Raman imaging, etc. In this work we present recent advances in the VBG technologies that led to development of next generation of Bragg notch and bandpass filters with enhanced transmittance and higher optical density.

9912-115, Session P2

Transmission and opto-mechanical performance of the liquid lens coupling in the Robert Stobie spectrograph

Ockert J. Strydom, Darragh E. O'Donoghue, The SALT Foundation (South Africa) and South African Astronomical Observatory (South Africa); Éric Depagne, Francois Strümpfer, Martin Wilkinson, Lisa A. Crause, Jonathan Love, South African Astronomical Observatory (South Africa) and The SALT Foundation (South Africa)

Fluid coupling provides good transmission efficiency over a wide bandwidth and in theory will outperform traditional multilayer coatings. However, the long term stability and reliability of the fluid coupling is very difficult to achieve in practise. This is due to chemical compatibility problems between the coupling liquids and plastics and elastomers used in the opto-mechanical design which caused degradation of the transmission of the liquid as constituent is leached out of the plastics as well as absorption of the coupling fluid by the elastomers causing swelling and compromising the opto-mechanical performance.

A recent service of the Robert Stobie Spectrograph (RSS) on SALT afforded the opportunity to inspect the performance of the liquid coupled groups within the spectrograph collimator, 6 years after assembly. The opto-mechanical design of RSS utilises Dow Corning Sylgard 184 to retain the lenses and seal in the coupling fluid. Two different coupling fluids are used in the different optical groups namely Laser Liquid 3421 and Index Matching Fluid 5610 both produced by the Cargille company.

During the service we disassembled the collimator into its main groups and measured the transmission through the groups in order to compare the transmission performance of the different coupling fluids. We also took the opportunity to measure the reflectivity of some of the coated lens surfaces which has to operate over a very wide band between 320 nm to 1750 nm. We also took transmission performance data for fluid removed from the optical assemblies.

In this paper we provide an overview of the materials exposed to coupling fluid in the RSS optical train, give a description of the experimental set-up and equipment used to measure the transmission performance utilising photometry. We report briefly on the difficulties of using Czerny–Turner monochromators as light sources causing red contamination in the blue part of the test spectrum.

We present results from transmission tests done on, the assembled groups, coupling fluid removed from the spectrograph and virgin fluid samples. We also present reflectivity test results taken from the coated surfaces. These results indicate performance degradation of the coatings to be similar in magnitude to absorption losses in the coupling fluids.

We further present laboratory data and analysis of the swelling effect of the coupling fluids on the Sylgard 184 elastomer and compare it to the performance in the spectrograph. Sylgard swells more when exposed to 5610 than with 3421, with 5610 causing swelling by 25% compared to 5% - 8% for 3421.

Finally, we summarise the lessons learned from the Instrument service and the test results, with analysis and comment on the features of the opto-mechanical design. We also provide some design guidelines for liquid coupling, including bezel design and equipment for fluid handling and filling.

9912-116, Session P2

Large optical glass blanks for the ELT generation

Ralf Jedamzik, Uwe Petzold, Olga Rexius, Volker Dietrich, SCHOTT AG (Germany)

The upcoming extremely large telescope projects like the E-ELT, TMT or GMT telescopes require not only large or large amount of mirror blank substrates but have also sophisticated instrument setups. On common instrument components are atmospheric dispersion correctors that compensate for the varying atmospheric path length depending on the telescope inclination angle. These elements consists usually of optical glass blanks that have to be large due to the increased size of the focal beam of the extremely large telescopes.

SCHOTT has a long experience in producing and delivering large optical glass blanks for astronomical applications up to 1 m and in homogeneity grades up to H3 quality in the past.

The most common optical glass available in large formats is N-BK7. But other glass types like F2 or LLF1 can also be produced in formats up to 1 m. The extremely large telescope projects partly demand atmospheric dispersion components even in sizes beyond 1m up to a range of 1.5 m diameter. The production of such large homogeneous optical glass banks require tight control of all process steps.

To cover this demand in the future SCHOTT initiated a research project to improve the large optical blank production process steps from melting to annealing and measurement. Large optical glass blanks are measured in several sub-apertures that cover the total clear aperture of the application. With SCHOTT's new stitching software it is now possible to combine individual sub-aperture measurements to a total homogeneity map of the blank. In this presentation first results will be demonstrated.

9912-117, Session P2

ULE design considerations for a 3m class light weighted mirror blank for EELT M5

Andrew Fox, Mary J. Edwards, Thomas W. Hobbs, Corning Incorporated (United States)

It is expected that the next generation of large ground based astronomical telescopes will have a need for large fast-steering / tip-tilt mirrors, made of ultra-lightweight construction. These fast-steering mirrors are used to continuously correct for atmospheric disturbances and telescope vibrations. An example of this is the EELT M5 lightweight mirror, which is part of the Tip-Tilt / Field-Stabilization Unit. The EELT Tip-Tilt Unit will be used to correct for low bandwidth tip-tilt errors arising from the effects of the wind on the telescope and larger amplitude errors from the atmosphere.

Corning has a long history of manufacturing lightweight mirror blanks using Corning ULE® in a closed-back construction. Corning's closed-back lightweight ULE® history goes back to the 1960's and includes the Hubble Space Telescope primary mirror, Subaru secondary and tertiary mirrors, Magellan tertiary mirror, and Kepler Space Telescope primary mirror, among many others. Corning can achieve lightweighting using abrasive waterjet (AWJ) cutting and CNC machining. These technologies can be leveraged for mirror design flexibility, enabling the manufacture of custom core structures to achieve an ideal design of light weight and high stiffness. Corning's capability to seal a continuous back plate to the core structure provides mirror rigidity, in a zero thermal expansion material, that meets or exceeds any other existing technology used in this space.

The baseline design for the EELT M5 mirror, as presented in the E-ELT Construction Proposal, is a closed-back ULE® mirror with a lightweight core using square core cells. This design provided exceptional mirror performance; with an aerial density below 70 kg/m2 and a first eigenfrequency above 290 Hz. Corning has investigated the performance of other lightweight designs leveraging elements of Corning's current manufacturing capabilities. Various mirror blank parameters were adjusted for different scenarios, including: mirror thickness, back face sheet shape, rib thickness, face sheet thickness, percentage of back face sheet coverage, core cell patterns (including triangular, hexagonal, and square), and core cell size. Finite Element Analysis was performed on the design scenarios to obtain: Weight, Aerial Density, First Eigenfrequency, and Gravity deformation at load cases pertinent to the EELT M5. In this paper, the performance of each design scenario will be reviewed and discussed, as well as the manufacturing advantages and disadvantages of each scenario.

9912-118, Session P2

High volume ULE segment production

Andrew Fox, Mary J. Edwards, Thomas W. Hobbs, Corning Incorporated (United States)

It is expected that many of the next generation of large ground based telescopes will utilize a segmented design for the primary mirror and, in some cases, the secondary mirror. The segmented mirrors are made of many hexagonal segments, each approximately 1.4 to 1.8 meters in size, and positioned in an array to emulate the parent optic. Many 10 meter class telescopes currently in operation utilize a segmented primary mirror, such as: Keck I and II, GTC – Gran Telescopio CANARIAS, HET – Hobby-Eberly Telescope, and SALT – South African Large Telescope. The number of mirror segments in these telescopes range from 36 to 91, based on the segment size. Next generation extremely large telescopes (ELTs) will contain many more segments. The Thirty Meter Telescope and European Extremely Large Telescope will contain 492 and 798 segments respectively. As the number of mirror segments increase, cost, capacity, and production speed of the mirror segment blank manufacture become increasingly critical. Corning has the capacity and capability to produce mirror segment blanks from Corning ULE® titania-silica glass in various segment sizes. Corning also has the ability to produce large monolithic mirrors for use in secondary, tertiary and other mirror blanks up to 4 meters in diameter.

Corning ULE® is manufactured in what is known as "boules." Typical boules are approximately 1.5 meters in diameter and 150 mm thick. The boules are fully characterized for room temperature coefficient of thermal expansion (CTE) using a non-destructive ultrasonic technique, which can be done without taking sacrificial samples. Segment manufacturing consists of cutting the boule into a hexagonal shape (a "hex"), slicing the hex with a gang wire saw to near net thickness, followed by final CNC grinding of the surfaces to achieve final specifications. Corning uses the same process to generate hexes that can be fused together to create large monolithic mirror blanks. Hundreds of these hexagonal segments have been produced by Corning in recent years for various projects. Thus, the fixed assets, resources, and expertise are established and remain in place to produce segments for future projects.

This paper will describe the facilities, equipment, resources, and processes employed by Corning to produce several hundred to several thousand mirror segment blanks, as well as large monolithic mirror blanks, for extremely large telescopes. Corning's manufacturing capacity will also be discussed. In 2006, a paper was published entitled "Review of Corning's Capabilities for ULE® Mirror Blank Manufacturing for an Extremely Large Telescope." Since 2006, as ELT programs have evolved, Corning's ULE® capacity and blank manufacturing capabilities have also evolved. This paper is intended to review and update the information and details previously presented.

9912-120, Session P2

Smart telescope for astronomy

Manuele Moschetti, Marco Riva, Matteo Aliverti, Giorgio Pariani, INAF - Osservatorio Astronomico di Brera (Italy)

In this paper, we present the preliminary design of a smart telescope, i.e. an optomechanical device whose structure is able to monitor external loads (gravity, wind, thermal gradients, displacements caused by earthquake) and actively adapt to them in order to correct misalignments. To obtain that, the proposed solution foresees the use of smart materials, or rather integrated smart structures containing sensors (such as fibre optics), and actuators (shape memory alloys or piezoelectric). Starting from the optical design, where the primary mirror is supposed to be in the class of 60cm diameter, with this work we illustrate the mechanical design philosophy. The basic idea is to conceive of a "low-performance" telescope from the stability point of view, in order to emphasize the environmental loads contributions, show that it is possible to correct them a posteriori, and generalize the results for more optimized structures (Serrurier-like). Therefore, it is shown the finite element model of a first naked version of the telescope (without smart structures), useful to know the displacements caused by predictable loads. Then, we describe the host material selection and the embedding technology of the smart materials, followed by the integrated modeling, to finally get the telescope upgrade.

9912-121, Session P2

Advanced structural design for precision radial velocity instruments

Daniel Baldwin, William A. Podgorski, Mark A. Mueller, Kenneth McCracken, Henry Bergner, Jeff Foster, Smithsonian Astrophysical Observatory (United States)

The GMT-Consortium Large Earth Finder (G-CLEF) is a fiber fed, optical echelle spectrograph that has been selected as a first light instrument for the Giant Magellan Telescope (GMT) being constructed at the Las Campanas Observatory in Chile's Atacama Desert region. G-CLEF has been designed to be a general-purpose echelle spectrograph with precision radial velocity (PRV) capability used for exoplanet detection. The radial velocity (RV) precision goal of G-CLEF is 10 cm/sec, which will enable it to detect Earth-like exoplanets in the habitable zones of sun-like stars. This goal imposes challenging stability requirements on the instrument's optical bench structure, optical mounts, and spectrograph support structures. Stability of the instrument and PRV accuracy will be affected by changes in temperature, air pressure, orientation relative to gravity, and vibrations caused by telescope movement. Extremely small image motions at the red and blue CCD detectors can degrade RV precision. Extreme stability requirements are required to minimize image motion. These requirements drove the selection of a carbon fiber/cyanate monocoque design for the primary optical bench structure to ensure that 10 cm/s PRV capability is maintained under the range of observational environments. Low CTE and high stiffness-to-weight are key features of the composite optical bench design. Manufacturability and serviceability of the instrument are also drivers of the structural bench design.

Maximum expected environmental loads during an observation include:

• Milli-Kelvin (0.001 °C) thermal soaks and gradients

• 10 m-bar ambient pressure change applied to the vacuum vessel which print through to the bench via quasi-kinematic flexure supports

• Changing gravity vector at instrument during slewing due to 116 ?-radian GMT azimuth axis misalignment with gravity over 360° azimuth, local azimuth track height variability, and flexure of the azimuth platform.

In this paper, we discuss the design of G-CLEF's optical bench and support structures including technical choices made to minimize the system's sensitivity to changing thermal gradients, acceleration environments, and print-through of atmospheric pressure variations into optical bench flexure mounts. The results of Finite Element Analysis (FEA) and sensitivity studies indicate the PRV performance ramifications of a variety of bench materials including mild steel, stainless steel, Invar-36, and carbon fiber composite. We discuss the design of the optical bench structure to optimize stiffness-to-weight and minimize deformations due to inertial effects. We also consider fiber and matrix materials options to ensure near-zero CTE, low moisture uptake, minimized CME effects, and minimal outgassing. Design of titanium mounting flexures for stable quasi-kinematic support of the instrument is discussed. We also discuss quasi-kinematic mounting of optical elements and assemblies, and optimization of these to ensure minimal image motion under thermal, pressure, and inertial loads expected during PRV observations.

9912-122, Session P2

Complex structures with extreme stability requirements for opto-mechanical applications

Matthias Krödel, ECM Engineered Ceramic Materials GmbH (Germany); Christoph Zauner, KRP-Mechatec Engineering GbR (Germany)

During a current project under OHB, Germany contract ECM is designing, fabricating and testing an extreme stable structure to demonstrate that HB-Cesic® properties at various temperatures are fully appropriate to the manufacturing of complex highly stable optical structures.

ECM together with its industrial partners designed, manufactured and tested several complex light weighted structures of its proprietary ceramic material "HB-Cesic ". The opto-mechanical structures have fulfilled extreme stability requirements under typical non stabilized space Environment. In this paper we report about fabrication, integration and testing of a recent example of such extremely thermal stable structure.

9912-123, Session P2

ESPRESSO optical bench: from mind to reality

Fabio Tenegi, Samuel Santana Tschudi, Instituto de Astrofísica de Canarias (Spain); José Gómez, Elena Rodilla, The Vacuum Projects SLU (Spain); Ian Hughes, Denis Mégevand, Observatoire de Genève (Switzerland); Marco Riva, INAF - Osservatorio Astronomico di Brera (Italy)

ESPRESSO is a high-resolution spectrograph under development for the VLT telescope. One challenge of the instrument opto-mechanical design is

to obtain the highest dimensional stability.

The Optical Bench allows the opto-mechanical mounts, and therefore the optical elements, to be supported and placed relatively among them, tracing out in an approximate way the optical layout. The design of an optical bench in order to optimize dimensional stability is indeed conditioned by selected materials and manufacturing process especially if the target is to keep dimensional stability about 1 ?m or even lower. At this level of accuracy all material properties and manufacturing process must be considered in order to assess their influence over the optical bench and optimize the design of structure in order to minimize their influence upon dimensional instability. In general, the OB structure can be considered as a 3D one, conformed by welding thin plates of Structural Steel (St-52) with a nickel-plated surface treatment, combined for getting maximum stiffness and minimum weight, that will be finally re-machined to get stringent geometrical and dimensional tolerances at I/Fs positions. TIG conventional welding procedure have been selected to minimize the cost and facilitate the own welding process. This solution follows the inheritance from HARPS due to its success to achieve the required performance for the bench.

Key features and performances:

• Upper and Lower base plates, and longitudinal and transverse lower stiffeners with a thickness of 20 mm

• Upper and lower side plates, and interface plates with the cameras with a thickness of 15 mm

• Rest of stiffeners with a thickness of 12 mm

• 3 support points, one in the lower part of the collimator mirror, and two in the joining of the upper base plate and the side stiffeners

• Enough stiffeners, including internal ones

• Enough pockets to facilitate the accessibility to the subsystems

• Overall dimensions: 3400x1400x1450 mm

• Approximate weight: 2970 Kg

• Maximum deformation: 65,3 microns

• Maximum Von-Misses stress: 34,5 MPa

• First Eigen-frequency: 91,1 Hz

This poster contains an overview of the whole process of designing and manufacturing the Optical Bench of ESPRESSO, from the very first beginning with the specifications to the current status of the bench with its integration on the Spectrograph (including the Finite Element Models and the delivery of the final structure by the supplier).

Some remarks are done, mainly in the manufacturing process to assure the stringent stability performances.

9912-124, Session P3

Approaching perfection in the manufacturing of silicon immersion gratings

Benjamin T. Kidder, Cynthia B. Brooks, Michelle Grigas, Daniel T. Jaffe, The Univ. of Texas at Austin (United States)

Silicon immersion gratings make near-IR spectrographs compact and allow them to have continuous wavelength coverage over a large bandwidth. We have produced a silicon immersion grating (hereafter ES2) that is, for all intents and purposes, optically perfect. An optimally flat immersion grating operating at the diffraction limit has peak-to-valley (PV) surface error of less than ?/4 where ? is the operating wavelength in immersion. Silicon is opaque to wavelengths shorter than 1.15?m, so a grating that is optically perfect down to this limiting wavelength will have a PV surface error of less than 85nm. ES2 approaches this ideal limit and has a PV surface error of 102nm over a 25mm beam.

Achieving this level of precision is difficult given that large-scale and periodic errors can be introduced in a number of the silicon processing steps. Our ability to reduce large-scale imperfections is essential for instruments operating near the diffraction limit. However, when the slit is significantly wider than the diffraction limit, large-scale errors will affect neither resolving power nor efficiency. We produce silicon immersion gratings using a contact printing method in which we coat the polished surface of a cut of silicon with a passivation layer (silicon nitride) and subsequently a UV-sensitive photoresist layer. We then pattern lines onto the surface using contact photolithography, etch the passivation layer in a reactive ion etch process and then etch grooves into the silicon substrate in a potassium hydroxide solution. We have linked the introduction of large-scale errors to non-uniformity in the illumination of the substrate by the UV exposure system during the patterning step. In order to reduce the level of these errors we have honed our contact printing method by optimizing our UV exposure system, introducing additional process checks and inspections and carefully evaluating large-scale and periodic errors in the gratings produced. These improvements to our standard process have allowed us to consistently produce instrument quality gratings including ES2, which will be used for the K-band channel of the Giant Magellan Telescope Near Infrared Spectrograph (GMTNIRS). Silicon immersion gratings will allow GMTNIRS to achieve continuous wavelength coverage over the J, H, K, L and M photometric bands in a single exposure. With their ability to produce spectral formats that permit continuous wavelength coverage, their high efficiency, and with the compactness that they enable, immersion gratings are now the dispersive devices of choice for high-resolution spectroscopy in the near-IR.

9912-125, Session P3

Towards freeform curved blazed gratings using diamond machining

Cyril J. Bourgenot, David J. Robertson, Durham Univ. (United Kingdom); Stephen S. Eikenberry, Richard Deno Stelter, Univ. of Florida (United States)

Concave blazed gratings greatly simplify the architecture of spectrographs by reducing the number of optical components. The production of these gratings using diamond-machining offers practically no limits in the design of the grating substrate shape, with the possibility of making large sag freeform surfaces unlike the alternative and traditional method of election beam lithography. In this paper, we report on the technological challenges and progress in the making of these curved blazed gratings using an ultra-high precision 5 axes Moore-Nanotech machine. The goal is to develop the technologies for the production of the next generation of low-cost, compact, high performance spectrometers.

9912-126, Session P3

Nonconventional ultra-precision manufacturing of ULE mirror surfaces using atmospheric reactive plasma jets

Thomas Arnold, Georg Böhm, Hendrik Paetzelt, Leibniz-Institut für Oberflächenmodifizierung e.V. (Germany)

Most designs of next generation of extremely large astronomical telescopes (ELTs) employ segmented primary mirrors. These are made up of hexagonal segments a bit larger than 1 meter in size, each manufactured with appropriate optical figure for their position in an array emulating the parent optic. Extremely large future telescopes each need of order 1000 segments that constitute a significant challenge in cost and schedule. The projects working to construct these telescopes have chosen approaches such as direct fabrication and warped segment polishing in pursuit of the lowest cost, highest fabrication rates, and acceptable optical figure. Since optical figuring is usually disproportionately expensive and time consuming, an alternate process is proposed to demonstrate

the manufacture of segments more rapidly and at lower cost via these approaches than those which constitute the current baseline for the ELTs under development. IOM has developed a process for Plasma Jet Machining (PJM) of optical surfaces. PJM is based on an atmospheric chemically reactive plasma jet tool that locally interacts with the optical surface in order to remove material by chemical reactions forming volatile species. Corning's proprietary near zero CTE material, ULE®, has been proven particularly suited to be processed by PJM. The process has been shown to achieve high material removal rates up to 50 mm?/min, that can be leveraged to shorten the time required to attain the desired optical figure. The plasma jet tool exhibits special features from its working principles such as sub-surface damage free material removal or insensitivity to machine vibration. Furthermore, the tool function is nearly independent on local radius of curvature thus being appropriate for freeform generation or error structure correction. The tool width (typically the full width at half maximum of a Gaussian function) can be scaled down to 1mm to address mid-spatial frequency surface structures. A proof-of-principle experiment has been performed on ULE® roundels of 200mm diameter and 30mm center thickness with a 650mm ROC concave spherical surface supplied by Corning that have been conventionally ground and polished. Spherical shape has been chosen to simplify testing.

Two different tool function widths have been consecutively applied in the dwell-time based figuring process achieving residual form errors of 5 nm RMS.

The paper summarizes the optimization of the PJM process to be effective on ULE® and providing high efficiency and reproducibility. It discusses the results of form error corrections and shows the potentials of PJM for fast fabrication of large optical surfaces.

9912-127, Session P3

Vibrating mirror concept for adaptive optics

Mousa Hadipour, Murat Tahtali, Andrew J. Lambert, The Univ. of New South Wales (Australia)

A new Vibrating Membrane Mirror (VMM) based on the vibration modes of membranes is proposed as a simple and inexpensive alternative to the traditional adaptive optics mirrors to mitigate wavefront aberrations. Elimination of the large number of complex micro-actuators present in traditional Deformable Mirrors (DM) used to control the reflective surface is the main advantage of this proposed VMM. It leads to a simpler control system, lower weight, higher control speed, lower fitting error, and lower overall manufacturing cost. It is suitable for systems where pulsed light or strobed exposure can be synchronized to the desired phase and excursion of the membrane.

Zernike Circular polynomials (ZCP) are used traditionally to approximate the aberrations caused by atmospheric turbulence. Using the orthogonality property of these polynomials it is possible to combine many different ZCP on a surface, and combine numerous surfaces, as needed to express the shape of arbitrary wavefront deviation with desired fitting accuracy. Bessel polynomials, which form the solution for the partial differential equation of motion of a vibrating membrane, and hence describe the vibrational modeshapes of circular membranes under tension, are orthogonal functions with similarity to ZCP. The general behavior of a vibrating membrane can be expressed using the principle of superposition of modeshapes. These similarities are exploited to find the degree of resemblance between the modeshapes of vibrating membrane and the surface changes of a DM to compensate for wavefront aberrations.

In this study, which follows from [1], first a finite element model of a piezoelectric PVDF (PolyVinylidene Fluoride) circular membrane is developed and its dynamic characteristics extracted. Its natural frequencies are compared with its analytical solution. The extracted modeshapes are compared with the ZCP to determine the corresponding modeshapes that bear the highest resemblance to the main wavefront aberrations. The similarities between the radial function of ZCP and the first kind Bessel functions are investigated and the degree of similarity is quantified using the root mean square error (RMSE) metric. Results show that the mean RMSE values between normalized modeshapes and the corresponding Zernike descriptions of seven common aberrations were below 0.2. An optimum diameter and a scaling factor for each modeshape are obtained to minimize this metric, and which form the effective aperture. As the vicinity of the excitation may become the site of undesired vibrations, the idea of using higher order modeshapes is proposed, and an excitation area, called the excitation ring is introduced. To achieve this, the excitation frequency is increased to create an extra circular node in modeshapes, while the desired modes are maintained within the effective aperture. A transient dynamic finite element analysis is performed to track the mode transitions and to compare them to previous experimental results [1], for which good agreement is observed.

In summary, the possibility of using vibrating membrane mirrors instead of the expensive traditional DM is investigated using numerical and analytical analysis. Fundamental concepts are discussed and practical solutions to avoid problems in empirical experiments are proposed. Future work will entail the experimental implementation of these concepts.

A segmented subreflector with electroformed Nickel laminated panels for the Large Millimeter Telescope

Giuseppe Valsecchi, Giovanni Bianucci, Josef Eder, Riccardo Ghislanzoni, Marco Terraneo, Fabio E. Zocchi, Media Lario Technologies S.r.l. (Italy); David R. Smith, MERLAB, P.C. (United States); David M. Gale, David H. Hughes, Instituto Nacional de Astrofísica, Óptica y Electrónica (Mexico)

The Large Millimeter Telescope (LMT) Alfonso Serrano is a 50 m diameter single-dish radio telescope optimized for astronomical observations at wavelengths of about a millimeter. Built and operated by the Instituto Nacional de Astrofísica, Óptica y Electrónica (INAOE) in collaboration with the University of Massachusetts (UMASS), the telescope is located at the 4600 m summit of volcano Sierra Negra, Mexico. The principal scientific goal of the telescope is the investigation of the physical processes underlying cosmic structure formation and its evolutionary history throughout the Universe.

Anticipating the completion of the 50 m main reflector, currently operating over a 32 m sub-aperture and expected to be aligned to an overall residual surface shape error of less than 50 μm RMS, INAOE has also scheduled the replacement of the 2.6 m monolithic Aluminum subreflector with a new higher-precision unit that will enable higher efficiency astronomical observations with the entire main reflector surface. In this project, INAOE has contracted Media Lario for the design and manufacturing of the subreflector, continuing a consolidated collaboration started in 2004 for the supply of the Nickel laminated panels for the main reflector.

The new 2.6 m M2 subreflector is segmented in 9 smaller reflector panels, one 1.2 m central dome and eight identical petals, assembled and precisely aligned on a steel truss structure that will be connected to the tetrapod head via a hexapod (supplied from separate contract). Each reflector panel is fabricated with Media Lario's unique laminated technology consisting of front and backside Nickel skins, produced by electroforming replication from a precise mold, that are bonded to a lightweight Aluminum core. The result is an extremely light and rigid laminated panel with a shape precision better than 7.5 μm RMS, expecting a total operational shape accuracy performance better than 20 μm RMS over the 2.6 m subreflector, which is well within the telescope error budget. The reflecting surface of each panel is given a thin galvanic Rhodium coating that ensures that the reflector survives the harsh environmental conditions at the summit of Sierra Negra without the need of any specific maintenance during the 30 year lifetime of the telescope. The segmented design carries the additional benefit that in the event of accidental damage, individual panels can be replaced and realigned separately, achieving a significant cost saving with respect to the current design. The total mass of the subreflector is about 210 kg, well within the 280 kg requirement set by INAOE.

After having completed the final design review in October 2015, Media Lario is now into the manufacturing tasks, and approaching completion of integration, assembly, and qualification of the subreflector. In this work, we will explain the design approach, illustrate the simulated operational performance in relevant astronomical observation conditions, report the shape measurements of the reflector segments and truss structure, describe the metrology and integration procedure implemented to reach the 20 μm RMS target for the entire subreflector surface, and finally report the qualification results on the fully assembled and aligned 2.6 m subreflector.

9912-129, Session P3

Optimisation of grolishing freeform surfaces with rigid and semi-rigid tools

Guoyu Yu, Glyndwr Innovations Ltd. (United Kingdom); David D. Walker, Zeeko Research Ltd. (United Kingdom) and Univ. College London (United Kingdom) and Glyndwr Innovations Ltd. (United Kingdom); Christina R. Dunn, Univ. College London (United Kingdom); Xiao Zheng, Glyndwr Innovations Ltd. (United Kingdom); Hsing Yu Wu, Univ. College London (United Kingdom); Hongyu Li, Caroline Gray, Glyndwr Innovations Ltd. (United Kingdom)

With success at the National Facility for Ultra Precision Surfaces in completing formal acceptance of prototype mirror-segments for the E-ELT, we are investigating further solutions to improve process steps that can accelerate segment mass production. Developments based on Zeeko's Precession technology have been proven to be effective for meeting form, mid-spatial, edge and texture specifications. However, an intermediate smoothing/grolishing will be highly beneficial to remove mid-spatial features before segments reach the polishing stage. To save valuable machine time on the CNC polishers, we aim to deliver the grolishing tasks on lower-cost industrial robots.

We have previously reported on areas such as tool design and toolpath generation, implemented on both Fanuc and ABB robots in our Facility. However, all of that work was conducted on flat or spherical parts. In this paper, we present new results evaluating the processes on aspheres for the first time, and in particular, report on studies of the effects of mismatch between a rotating tool and a work-piece for different abrasive types. In order to progress this, we have developed a bending rig which is capable of bending a flat glass sample to varied cylindrical radii of curvature. We report on the effectiveness of this test setup, and then present results for different combinations of aspheric mis-fit, bound or loose abrasive grit size, and type of tool-path used. We also explore flexible tooling including Non-Newtonian tools.

9912-130, Session P3

Polarization properties of ultra-fast laser inscribed waveguide array

Haosheng Lin, Univ. of Hawai'i (United States); Robert R. Thomson, Heriot-Watt Univ. (United Kingdom)

Recent development of ultra-fast laser inscription technology for the fabrication of waveguides offers a new possibility for astronomical spectroscopy to bypass many undesirable properties and limitations intrinsic to conventional optical fibers. The ability of ultra-fast laser inscription to construct complex distribution of waveguides in three dimension further provide a new integral field units (IFUs) fabrication method that allows us to build very large format high performance IFUs free of modal noise associated with fiber-optic IFUs. Without bending induced stress birefringence, these new photonics IFUs may also have important benefits for the field of astronomical spectropolarimetry. In this paper we will present measurements of polarization maintenance and in-waveguide polarization crosstalk of a 121-waveguide fan-out device that reformats a 2D spatial field into a 1D linear array for coupling into diffraction grating spectrograph. These measurements will be used to examine how polarized waves propagate through ultra-fast laser inscribed waveguides for evaluation of their suitability for astronomical spectropolarimetric applications.

9912-131, Session P3

Manufacturing of a new aluminium back-up secondary mirror for SOFIA

André M. Hoogstrate, TNO (Netherlands); Michael Lachenmann, Jürgen Wolf, Deutsches SOFIA Institut (Germany)

The Stratospheric Observatory for Infrared Astronomy - SOFIA - is an air-borne observatory designed to operate at wavelengths from 0.3 ?m to 1.6 mm. The 2.5-m effective diameter telescope has been built to cover this entire range. The telescope itself is a Cassegrain design with a convex, hyperbolic secondary mirror (M2). To enable efficient chopping, which is needed to suppress variable sky-noise via synchronous demodulation of signals from astronomical sources, the secondary mirror needs to be light in weight and low in inertia.

The M2, having a diameter of 352 mm, was made from silicon carbide and weighs only 1.9 kg. As this material is brittle, and the secondary mirror is indispensable to observations with SOFIA, a back-up mirror with the same mass and moments of inertia is required.

A first back-up mirror was made of Al 6061 aluminium in 2004. This mirror, however, allows diffraction-limited observations only above 20 μm and it produces double peaked images as seen in ground-based measurements using this mirror in 2004. In 2012, the work on a new, improved Aluminium backup secondary mirror began.

At first RSA6061 has been selected as base material for the mirror. This material is chemical identical to regular Al6061. However, a specific, rapid solidification process is used to produce the raw material. This material has a much more refined structure, enabling a lower surface roughness after the Single Point Diamond Turning Process (SPDT), typical Rq values of 1 to 2 nm RMS compared to 10 to 15 nm RMS in regular 6061.

A dedicated interface was designed to obtain a stress-free mounting of the mirror during SPDT-processing. Despite all these precautions it turned out that the mirror did deform unacceptable after dismounting from the interface. An in depth analysis pointed towards internal material stresses introduced during the quenching step of the heat treatment of the material.

After a re-evaluation of potential mirror materials RSA 905 was selected. The manufacturing was executed according to planning and the mirror has been delivered to the Deutsches SOFIA Institute. The final mirror has a surface roughness Rq <3.5 nm RMS a form-error of 121 nm RMS over the full aperture and a PV-error of 700 nm. This is an approximately 10 times lower form error and a 7 times lower surface roughness, compared to the first Aluminium mirror from 2004. In the paper details on the material selection and final results will be discussed.

Manufacturing methods of testing the large-size optics at the stage of grinding, aspherical surface centering, and positioning the interface elements before gluing

Aleksandr P. Semenov, Lytkarino Optical Glass Factory JSC (Russian Federation); Magomed A. Abdulkadyrov, JSC Lytkarino Optical Glass Factory (Russian Federation); Vladimir E. Patrikeev, Lytkarino Optical Glass Factory JSC (Russian Federation)

Technology with the use of programmable computer-controlled system and a set of special instruments, which makes possible aspherization of off-axis large-size optical elements of astronomical and space telescopes with deviation from the nearest sphere of more than 1 mm, was developed.

9912-133, Session P3

Studying the stability of Astrositall thermal and mechanical properties while manufacturing the astronomical and space mirrors

Aleksandr P. Semenov, Magomed A. Abdulkadyrov, Alexey P. Patrikeev, Sergey P. Belousov, Aleksandr N. Ignatov, Vladimir E. Patrikeev, JSC Lytkarino Optical Glass Factory (Russian Federation)

The technology of producing the astronomical and space mirrors from Astrositall? material, including its properties and stability of these properties in the course of time, is described. The results of long-term material tests are presented. In particular, the method of grinding and polishing the off-axis segment of the mirror of very large telescope in the stress-strain state is considered.

9912-134, Session P3

Diamond fly cutting of aluminum thermal infrared flat mirrors for the OSIRIS-REx Thermal Emission Spectrometer (OTES) instrument

Christopher E. Groppi, Matthew Underhill, Zoltan Farkas, Arizona State Univ. (United States)

We present the fabrication and measurement of monolithic aluminum flat mirrors designed to operate in the thermal infrared for the OSIRIS-Rex Thermal Emission Spectrometer (OTES) space instrument. The mirrors were cut using a conventional fly cutter with a large radius diamond cutting tool on a high precision Kern Evo 3-axis CNC milling machine. The milling machine's cutting spindle thermal growth compensation system was disabled, and the cooling fluid loop re-routed through a flat plate heat exchanger cooled with a process chilled water system rather than the machine's internal spindle cooling fluid chiller. This reduced the amplitude of disturbances in the finished flat mirror from ~0.5 micron down to less than 150 angstroms RMS. This represents a novel use of a conventional (albeit very high precision) conventional milling machine to diamond cut flat mirrors rather than use a specialized optical diamond turning machine. The ~20mm diameter flat mirrors were cut with a single pass of the diamond fly cutter, then measured with an optical laser interferometer. The full complement of flight mirrors and spares, along with test articles were cut with this technique. The delivered components were accepted by the OTES team and will fly on the instrument when launched in 2016.

9912-135, Session P3

Combined fabrication technique for high-precision aspheric optical windows

Hao Hu, Ci Song, Xuhui Xie, National Univ. of Defense Technology (China)

Specifications of optical components are becoming more and more stringent with the performance improvement of modern optical systems. These strict requirements not only involve the low spatial frequency surface accuracy, but also the mid-and-high spatial frequency surface errors, surface smoothness and so on. Nowadays, deterministic figuring technologies are developed to meet the growing demands of such high-precision optical components. This munuscript will report the fabrication process of a square aspheric optical window in our laboratory, which combines accurate grinding, magnetorheological finishing (MRF) and smoothing polishing (SP). We will highlight the applications for full spatial frequency errors control in different stages based on their inherent capability.

Accurate grinding can form the shape of optics quickly. However, series of issues would exist after grinding of high precision surfaces, such as the limit of accuracy, defects on subsurface and marks on surface. Fortunately, MRF is a deterministic polishing method with high convergence and high removal rates. It is an advanced technology which can remove the low spatial frequency surface errors and subsurface defects effectively. SP also exhibits excellent performance in eliminating mid-and-high spatial frequency surface ripples and high slope errors. Consequently, the combined fabrication technique is developed to fabricate the high-precision optical windows with high efficiency. Additionally, exact measurements are also vitally important for the high-performance optical component. The effective association of coordinate measuring method and interferometer metrology in the process are both investigated. The experiment validates the high-efficiency of this combined fabrication technique for high-precision optical windows.

9912-136, Session P3

Process optimization of laser-based solderjet bumping for mounting of optical components

Thomas Burkhardt, Marcel Hornaff, Andreas Kamm, Fraunhofer-Institut für Angewandte Optik und Feinmechanik (Germany); Diana Burkhardt, Numerik Jena GmbH (Germany); Erik Beckert, Ramona Eberhardt, Andreas Tünnermann, Fraunhofer-Institut für Angewandte Optik und Feinmechanik (Germany)

Advanced optical systems of telescopes and scientific instrumentation require high accuracy mounting and joining of components. Applications for deep UV, under high energetic radiation, for vacuum operation, or assemblies subjected to environmental loads (e.g. humidity and temperature) require a replacement of organic adhesives or optical cement by a more robust bonding agent. Soldering allows the bonding of different materials with an inorganic filler material.

We present the optimization of the laser-based Solder Bumping for the mounting of optical components and the parameters of the bonding process for fused silica and LAK9G15 (radiation resistant glass) with thermally matched metal mounts. The investigation covers the

experimental determination and optimization of solder wetting to the respective base materials and the achieved bond strengths. Photoelasticity measurements are used to evaluate the change in optical path difference during soldering and for different use cases. A final change in optical path difference of 3 to 5 nm is observed. The paper will conclude with a case study of lenses soldered to metal mounts with low surface deformation (less than 100 nm) suitable to high quality telescopes.

9912-137, Session P3

Every photon counts: improving low-, mid-, and high-spatial frequency errors on astronomical optics and materials with MRF

Chris Maloney, QED Technologies, Inc. (United States); Jean-Pierre Lormeau, QED Technologies, Inc (United States); Paul Dumas, QED Technologies, Inc. (United States)

Many astronomical sensing applications operate in low-light conditions; for these applications every photon counts. Controlling mid-spatial frequencies and surface roughness on astronomical optics are critical for mitigating scattering effects such as flare and energy loss. By improving these two frequency regimes higher contrast images can be collected with improved efficiency. Classically, Magnetorheological Finishing (MRF) has offered an optical fabrication technique to correct low order errors as well has quilting/print-through errors left over in light-weighted optics from conventional polishing techniques. MRF is a deterministic, sub-aperture polishing process that has been used to improve figure on an ever expanding assortment of optical geometries, such as planos, spheres, on and off axis aspheres, primary mirrors and freeform optics. Precision optics are routinely manufactured by this technology with sizes ranging from 5-2,000mm in diameter. MRF can be used for form corrections; turning a sphere into an asphere or free form, but more commonly for figure corrections achieving figure errors as low as 1nm RMS while using careful metrology setups.

Recent advancements in MRF technology have improved the polishing performance expected for astronomical optics in low, mid and high spatial frequency regimes. Deterministic figure correction with MRF is compatible with most materials, including some recent examples on Silicon Carbide and RSA905 Aluminum. MRF also has the ability to produce 'perfectly-bad' compensating surfaces, which may be used to compensate for measured or modeled optical deformation from sources such as gravity or mounting. In addition, recent advances in MRF technology allow for corrections of mid-spatial wavelengths as small as ~1mm simultaneously with form error correction. Efficient mid-spatial frequency corrections make use of optimized process conditions including raster polishing in combination with a small tool size. Furthermore, a novel MRF fluid, called C30, has been developed to finish surfaces to ultra-low roughness (ULR) and has been used as the low removal rate fluid required for fine figure correction of mid-spatial frequency errors. This novel MRF fluid is able to achieve <4Å RMS on Nickel-plated Aluminum and even <1.5Å RMS roughness on Silicon, Fused Silica and other materials. C30 fluid is best utilized within a fine figure correction process to target mid-spatial frequency errors as well as smooth surface roughness 'for free' all in one step.

In this paper we will discuss recent advancements in MRF technology and the ability to meet requirements for precision optics in low, mid and high spatial frequency regimes and how improved MRF performance addresses the need for achieving tight specifications required for astronomical optics.

9912-138, Session P3

Process improvements in the production of silicon immersion gratings

Cynthia B. Brooks, Benjamin T. Kidder, Michelle Grigas, Daniel T. Jaffe, The Univ. of Texas at Austin (United States); Ulf Griesmann, National Institute of Standards and Technology (United States); Daniel W. Wilson, Richard E. Muller, Jet Propulsion Lab. (United States)

Silicon immersion gratings improve performance and reduce spectrograph size by taking advantage of the high index of refraction (3.4) of silicon to increase dispersion and allow extensive wavelength coverage at high resolution in a single exposure. Silicon immersion gratings produced at the University of Texas at Austin provide the primary dispersive elements in the IGRINS instrument at the McDonald Observatory and the iShell instrument being built for the Infrared Telescope Facility on Mauna Kea, Hawaii, and will be used in the planned Giant Magellan Telescope Near-Infrared Spectrograph (GMTNIRS). To manufacture immersion gratings, we produce grooves in silicon using photolithography followed by plasma etching and wet etching. Our current process uses contact photolithography to pattern UV sensitive photoresist as the initial processing step. We then transfer this pattern into a layer of silicon nitride that, in turn, serves as a hard mask during the potassium hydroxide etching of V-grooves into silicon. The initial patterning of the grooves in resist is the dominant step in determining the quality of the immersion grating, and contact lithography can introduce global uniformity errors from non-uniformity in the light source and periodic errors caused by fringes in the contacting of the photomask to the substrate surface.

We have explored a number of lithographic techniques and improvements to produce the resist lines that then produce the grating groove edges. Electron beam patterning allows us to manufacture gratings that can be used in first order, with groove spacing down to 0.5 micron or smaller (2,000 grooves/mm), but could require significant e-beam write times of up to one week to pattern a full-sized grating. We are working with Jet Propulsion Laboratory to develop an alternate e-beam method that employs chromium liftoff to reduce the write time by a factor of 10. We are working with the National Institute of Standards and Technology using laser writing to explore the possibility of creating very high quality gratings without the errors introduced during the contact-printing step. Both e-beam and laser patterning bypass the contact photolithography step and directly write the lines in photoresist on our silicon substrates, but require increased cost, time, and process complexity. Finally, we have investigated anti-reflection (AR) coatings during our contact-printing lithography method to reduce the effect of fringes produced by the contact of the photomask on the photoresist surface. This AR coating reduces the amplitude of the repetitive errors by a factor of two.

9912-139, Session P3

Thermal issues related to the ion beam figuring technique when used as final step in the manufacturing of the mirror segments for the EELT

Mauro Ghigo, Gabriele Vecchi, Stefano Basso, Giovanni Pareschi, INAF - Osservatorio Astronomico di Brera (Italy)

The INAF-Astronomical Observatory of Brera (INAF-OAB) has developed a large IBF facility that is being used to investigate the problems related to the ion figuring of large Zerodur hexagonal reflecting segments, similar to those (almost 900) 1.4 m large to be realized for the assembly of the 39 m E-ELT primary mirror. It is already foreseen that the final profile correction of those segments will be done by the Ion Figuring technique. In the case of Zerodur substrates, this process has to be run quite slowly

since this material much suffer the thermal heating induced by the ion beam hitting on the mirror surface. The stresses caused in the material when heated above 120 °C can deform the final optical shape up to an unacceptable level and hence the electrical power of the ion source must be kept at a low level, with a consequent slowing down of the process that can bring to a longer than necessary time for the correction runs. The issue of the figuring time is therefore important also from the scheduling and economical point of view, especially when the number of mirrors to be processed is so large like in EELT. In INAF-OAB is under study an innovative approach to the thermal problem that has the potential to reduce substantially the figuring time of the E-ELT hexagonal segments. The results and conclusions obtained are discussed in this paper.

9912-140, Session P3

Aspherical metallic lightweight mirrors for the GCT: a prototype for the future Cherenkov Telescope Array

Jean-Laurent René Dournaux, Observatoire de Paris à Meudon (France) and Observatoire de Paris, CNRS (France); Philippe Laporte, Delphine Dumas, Observatoire de Paris à Meudon (France) and Ctr. National de la Recherche Scientifique (France); Johann Gironnet, Ctr. National de la Recherche Scientifique (France); Jean-Michel Huet, Observatoire de Paris à Meudon (France) and Ctr. National de la Recherche Scientifique (France); Paula M. Chadwick, Durham Univ. (United Kingdom); Miroslav Pech, Palack? Univ. Olomouc (Czech Republic); Bernard Peyaud, Commissariat à l'Énergie Atomique (France) and CEA-IRFU (France) and CEA-Ctr de SACLAY (France); Yves Piret, Commissariat à l'Énergie Atomique (France) and CEA-IRFU (France) and CEA-Ctr. de SACLAY (France); Cameron Rulten, Univ. of Minnesota (United States); Frédéric N. Sayède, Observatoire de Paris à Meudon (France) and Ctr. National de la Recherche Scientifique (France); Jurgen Schmoll, Durham Univ. (United Kingdom); Hélène Sol, Observatoire de Paris à Meudon (France) and Ctr. National de la Recherche Scientifique (France)

The GCT (Gamma-ray Cherenkov Telescope) is a dual-mirror prototype of a Small-Size-Telescope based on a Schwarzschild-Couder optical design and proposed for the Cherenkov Telescope Array (CTA). Metallic lightweight mirrors were designed and manufactured for this prototype. The choice of this manufacturing process was made possible thanks to the relaxing optical requirements compared to those ones used for the optical telescopes. This paper describes the manufacturing process of these mirrors as well as first the results of characterisation tests.

9912-141, Session P3

Development of the fast steering secondary mirror assembly of GMT

Myung K. Cho, National Optical Astronomy Observatory (United States); Christoph Dribusch, The Univ. of Arizona (United States); Won Hyun Park, College of Optical Sciences, The Univ. of Arizona (United States); Youra Jun, The Univ. of Arizona (United States); Robert Bernier, Andrew P. Rakich, Chris Alongi, Paul Gardner, Lee R. Dettmann, GMTO Corp. (United States); Sungho Lee, Namsoo Myung, Jihun Kim, Chan Park, Je Heon Song, Byeong-Gon Park, Korea Astronomy and Space Science Institute (Korea, Republic of)

The Giant Magellan Telescope (GMT) will be featured with two Gregorian secondary mirrors, an adaptive secondary mirror (ASM) and a fast-steering secondary mirror (FSM). The FSM is 3.2 m in diameter and built as seven 1.1 m diameter circular segments, which are conjugated 1:1 to the seven 8.4m segments of the primary. Each FSM segment contains a tip-tilt capability for fine co-alignment of the telescope subapertures and fast guiding to attenuate telescope wind shake and mount control jitter. This tip-tilt capability thus enhances the performance of the telescope in the seeing limited mode. The design and development of the FSM mirror configuration was fully optimized and the optical performances were fully evaluated. The performance evaluation includes the optical surface deformations, image qualities, and structure functions for the gravity print-through cases, thermal gradient effects, and dynamic performances. The design and development of the FSM mirror assembly was conducted by using finite element analyses and the optical analyses. The results of the FSM mirror assembly will be compare with the optical performance goals and the dynamic performance goal of tip-tilt operation.

9912-142, Session P3

Segmentation method study for large astronomical telescope

Yi Zheng, Xiaofei Li, Nanjing Institute of Astronomical Optics & Technology (China)

The primary of large ground telescopes like Thirty Meter Telescope (TMT) and European Extremely Large Telescope (E-ELT) are composed of hundreds of hexagonal segments. Because primary mirror is used to collect light, generally it has concave surface (i.e. not flat). The segments outline on this curved surface cannot be identical. There are several aspects should be considered for segmentation. They are irregularity, segment area variations, and circumscribed diameter and so on. Traditionally segmentation is ruled by a formula and solved by parameter optimization. This paper tries to present an alternative method basing on force equilibrium. By establish the connections between segmentation specifications with different forces, we can obtain a natural solution for this problem. Finally we use the new method basing TMT configuration and achieved acceptable results.

9912-143, Session P3

Stressed mirror polishing: calculation of bending forces for the successive stages of polishing

Vineeth Valsan, S. Sriram, J. P. Lancelot, G. C. Anupama, Naveen K. Mishra, Indian Institute of Astrophysics (India)

Stressed Mirror Polishing (SMP) is a method to fabricate large aspheric mirrors in a short time. In SMP, stresses are applied to the mirror blank in order to elastically deform the desired surface into a sphere. Once the required surface accuracy is obtained upon polishing the surface to a spherical profile, the stresses are released to deform the spherical surface to the desired one.

In certain cases, if the required surface is not achieved after the release of the stresses, the process has to be repeated by calculating new values for the stress to be applied. It is found that application of new values of stress to correct certain coefficients will induce error in other coefficients during the SMP process. This paper deals with the dependencies of monomial coefficients over each other while calculating the stresses for the

successive stages of SMP. The methodology to correct these dependencies and other cross coupling between these coefficients are also discussed.

9912-144, Session P3

Mechanical technology used for bonding of the SALT edge sensors

Ockert J. Strydom, Hitesh Gajjar, Jonathan Love, The SALT Foundation (South Africa) and South African Astronomical Observatory (South Africa)

SALT is in the process of installing a new edge sensor system for its 91 segment Primary Mirror. Each of the 91 segment requires 6 sensor pairs. Each sensor pair utilises a receiver and transmitter printed on flexible PCB, called flexes, each of which is glued to a low Clear Ceram L-Bracket. A total of 960 flexes have to be bonded to complete the system, not counting the spare units. To meet the production schedule all sensor had to be bonded in a two month period.

The flexes have to be aligned and bonded with respect to a reference axis to within +/- 100 arc seconds and be positioned to within +/- 30 micron shear direction and +/- 100 micron in the piston direction.

The paper gives a description of the mechanical components of the edge sensor system and the bonding system design at SALT to allow us to meet the tight production goals and quality goals. It describes the quality control system used to ensure compliance with the requirement and offers recommendations for further improvements.

We also report on the actual performance of the sensors bonded in this manner. Which will be of interest to uses and developers of similar systems.

9912-254, Session P3

Manufacturing process of the WEAVE prime focus corrector optics for the 4.2m William Hershel Telescope

Émilie Lhomé, Isaac Newton Group of Telescopes (Spain); Tibor Agócs, ASTRON (Netherlands); Don Carlos Abrams, Kevin Dee, Isaac Newton Group of Telescopes (Spain); Kevin F. Middleton, Ian A. J. Tosh, STFC Rutherford Appleton Lab. (United Kingdom); Attila Jaskó, Hungarian Academy of Sciences (Hungary); Peter J. Connor, Dave M. Cochrane, Luke Gers, KiwiStar Optics (New Zealand); Chris R. Benn, Marc Balcells, Isaac Newton Group of Telescopes (Spain); Scott C. Trager, Univ. of Groningen (Netherlands); Gavin B. Dalton, STFC Rutherford Appleton Lab. (United Kingdom) and Univ. of Oxford (United Kingdom); Esperanza E. Carrasco Licea, Instituto Nacional de Astrofísica, Óptica y Electrónica (Mexico); Antonella Vallenari, INAF - Osservatorio Astronomico di Padova (Italy); Piercarlo Bonifacio, Observatoire de Paris à Meudon (France); Jose Alfonso López Aguerri, Instituto de Astrofísica de Canarias (Spain)

In this paper, we detail the manufacturing process of the lenses that will constitute the new two-degree field-of-view Prime Focus Corrector for the William Herschel Telescope (WHT) optimised for the upcoming WEAVE Multi-Object Spectroscopy (MOS) instrument. The Prime Focus Corrector (PFC), including an Atmospheric Dispersion Corrector (ADC), is made of six large lenses, the largest being 1.1 meter diameter. We describe how the prescriptions of the optical design were translated into manufacturing specifications for the blanks and lenses. We explain how the as-built glass blank parameters were fed back into the optical design and how the specifications for the lenses were subsequently modified. We review the critical issues for the challenging manufacturing and discuss the trade-offs that were necessary to deliver the lenses while maintaining the optimal optical performance. A short description of the lens optical testing is also presented. Finally, the following manufacturing steps, including assembly, integration and alignment, are outlined.

9912-255, Session P3

Aspherization of off-axis high-asphericity mirrors with arbitrary external circuit by means of CNC machines

Aleksandr P. Semenov, Magomed A. Abdulkadyrov, Vladimir E. Patrikeev, Sergey P. Belousov, Aleksandr N. Ignatov, JSC Lytkarino Optical Glass Factory (Russian Federation)

Technology with the use of programmable computer-controlled system and a set of special instruments, which makes possible aspherization of off-axis large-size optical elements of astronomical and space telescopes with deviation from the nearest sphere of more than 1 mm, was developed.

9912-256, Session P3

Euclid mirrors and test collimator: AMOS developments

Pierre Gloesener, Fabrice Wolfs, Marcel Cola, Olivier Pirnay, Carlo Flebus, AMOS Ltd. (Belgium)

EUCLID is an optical/near-infrared survey mission to be launched in 2020 towards the L2 Lagrange point. It will aim at studying the dark universe and providing a better understanding of the origin of the accelerating expansion of the universe. Through the use of cosmological sounding, it will investigate the nature of dark energy, dark matter and gravity by tracking their observational signatures on the geometry of the universe and on the cosmic history of large structures formation.

The EUCLID payload module (PLM) consists of a 1.2 m-class telescope and will accommodate two instruments.

As a subcontractor of AIRBUS Defence & Space, AMOS is responsible for the manufacturing of the secondary and the third mirrors of the telescope as well as for the flat folding mirror set within the focal plane arrangement of EUCLID telescope, which incorporates dedicated filtering functions. AMOS produces in addition the 1.3 m-class test collimator for the on-ground validation of the EUCLID instrument.

The secondary and tertiary mirrors of EUCLID telescope are arranged in a Korsch configuration and are made from sintered silicon carbide from Boostec.

The presentation will detail the mirror manufacturing sequences, involving the CVD-SiC cladding initial step, the lapping and polishing work and the ion beam figuring operation. It will emphasize the specific constraints linked to the production of this kind of mirrors and related to the peculiar aspects of the EUCLID mission.

The corresponding mirror metrology with the accuracy budget will be outlined.

An overview of the folding mirror qualification and development will be provided with an insight into the specific spectral filtering functions brought by each mirror of the set and the associated thin film coatings developed by Schott Yverdon.

For the purpose of thermal vacuum testing and validation of the EUCLID payload, AMOS is developing a 1.3 m-class collimator.

The collimator will feature a Ritchey-Chrétien optical configuration.

The original aspect of this collimator is that it will work under a cryogenic vacuum environment at 100 K while being kept at a near-ambient temperature through an accurate thermal control involving thermal insulation, material selection and heater regulation, which will carefully be arranged to preserve the overall optical quality of the collimator.

Dedicated features of the collimator will be presented and discussed and related to the overall performance target from the EUCLID requirements.

9912-273, Session P3

Investigation of four typical groove types for use in the smoothing process

Hsing-Yu Wu, Univ. College London (United Kingdom); Kai Meng, Fan Wu, Yongjian Wan, Institute of Optics and Electronics (China)

When a surface experiencing smoothing to improve its optical performance (such as removing mid-spatial frequencies, localized grinding errors, and regional surface scratches), spindle speed, tool travel speed, pressure, slurry density as well as groove patterns are main factors to influence surface finishes. Based on the desired material removal rate, the Preston equation can effectively resolute optimized pressures and velocities between the tool and processed surface. Various groove patterns, however, can cause unique tool deformation and pressure distribution, leading to produce different slurry mobility to determine a surface finish. In this paper, four typical groove patterns are studied in this paper: non-groove, grid grove, annular groove and radial groove by using Finite Element Method (FEM) and statistical analysis. The four patterns with their optimized conditions have presented at the end of this paper.

9912-40, Session P4

Estimation of global transmitted wavefront error of the EUCLID/NISP grisms from intermediate measurements

Sandrine Pascal, Anne Costille, Amandine Caillat, Sébastien Vives, Lab. d'Astrophysique de Marseille (France)

The Euclid mission selected by ESA in the Cosmic Vision program is a massive spectroscopic survey based on a Near Infrared Spectro-Photometer (NISP). This instrument achieves a spectroscopic mode using four grisms (standing for "grating prisms") in slitless mode. The Euclid grisms are challenging and innovative optical components based on a prism with a spherical convex face. A diffractive optical element lays on one face (mainly for the grating function) and a multilayer filter is deposited on the second face. The manufacturing process is based on three different steps: the DOE manufacturing on a parallel plate by etching process, the curved prism manufacturing and polishing, and finally, the filter deposition. At each step of this process, visible interferometric measurements are performed in order to verify the manufacturing specifications. But, the measurement of the transmitted wavefront error on the final component at operational wavelength and cryogenic environment with an appropriate accuracy is difficult to achieve. Indeed, the filter only transmits in the near infrared waveband [1250 nm-1850 nm] and the cryogenic operational temperature needed (140K) is difficult to implement during such optical tests. Therefore, the global wavefront error induces by the grism is obtained using a chain of intermediate wavefront measurements (mainly in reflection on each face). This paper presents the reconstruction of the global transmitted wavefront performance of the NISP grism, based on calculations, visible interferometric measurement and comparison to a grism optical model. This includes: the grism wavefront error budget and allocation for each manufacturing part; the zemax model of the grism made in order to compare with measurements results (especially for the DOE optical behavior); and the chosen approach to estimate the global component wavefront error (based on a sequence of relative and absolute wavefront measurements).

9912-146, Session P4

Research on error analysis of phase-retrieval holography at the Tian Ma Telescope

Jian Dong, Qinghui Liu, Zhiqiang Shen, Li Fu, Wei Gou, Shanghai Astronomical Observatory (China) and Chinese Academy of Sciences (China)

The Tian Ma Telescope (TM) is the largest fully steerable radio telescope in China. It has a primary reflector of 65-m in diameter with a shaped Cassegrain configuration. It operates in a wide frequency range from 1.4 GHz to 43 GHz. The TM adopts active surface to correct the dynamic deformation due to gravity and thermal. The phase-retrieval holography will be used to measure the deformation. This paper introduces the phase-retrieval holography system at the TM, and a simulation system is implemented to find the relationship between the signal-noise ratios, defocus value, pointing errors and the measurement results.

9912-147, Session P4

Experimental verification of moment-based modal wavefront sensing

Hanshin Lee, The Univ. of Texas at Austin (United States)

Over the past few years, I have been investigating the moment-based modal wavefront sensing method. The focus of this investigation has been mainly on developing its basic theoretical components including the error propagation models and numerical simulation studies to understand the behavior of the method in certain measurement conditions. It has been demonstrated that this technique can be a powerful tool in various image quality / optical alignment test, especially for wide field systems and the real example has been shown where the technique was applied to the real task of assessing/driving the optical alignment of the massively replicated (i.e. 150+ identical copies) state-of-the-art astronomical spectroscopic systems called the VIRUS instrument (Visible Integral-field Replicated Unit Spectrograph). Therefore, it is fair to say that the technique is field-proven. However, the application was done in a setting where the goal was to get the job done, rather than to dig into the behavior of the technique under various (real) experimental conditions. As a result, many of the aspects and parameter spaces of the method could not be thoroughly tested or investigated. Also, there have been some not-insignificant amounts of interests among optical scientists/engineers about this particular technique. These served as my main motivation to undertake a controlled experiment to rigorously investigate the moment-based technique. This paper discusses the results of such experiment.

9912-148, Session P4

The influence of technological mounting of lightweight large size space astronomical mirrors into the shape of its reflecting surface during interferometric control

Oleg Vlasenko, Mikhail Sachkov, Institute of Astronomy (Russian Federation)

For the shape control of the reflecting surface lightweight large-size space astronomical mirrors the unweighting mirror unit is used for the neutralization of the effect of gravity on the deformation of the mirror. During the works on WSO-UV mission telescope primary mirror it was found that such a mounting has a strong influence on the mirror shape. We present the method that allows to take into account this effect. The proposed method is based on the optical surface interferometric control implementation with rotation of the mirror studied. Astigmatism and 3-point coma are main factors of mounting influence on the optical surface. The proposed method was tested on the WSO-UV primary mirror.

9912-149, Session P4

The large MEGARA pupil elements: assembly, tests, and performance

Ismael Martínez-Delgado, Ernesto Sánchez-Blanco Mancera, Ana Pérez-Calpena, María Luisa García Vargas, Manuel Maldonado Medina, FRACTAL S.L.N.E (Spain); Armando Gil de Paz, Univ. Complutense de Madrid (Spain); Esperanza E. Carrasco Licea, Instituto Nacional de Astrofísica, Óptica y Electrónica (Mexico); Jesús Gallego Maestro, Univ. Complutense de Madrid (Spain); Jorge Iglesias-Páramo, Instituto de Astrofísica de Andalucía (Spain); Francisco Manuel Sánchez-Moreno, Univ. Politécnica de Madrid (Spain)

MEGARA is a third generation spectrograph for the Spanish 10.4m telescope (GTC) providing two observing modes: a large central Integral Field Unit (IFU), called the Large Compact Bundle (LCB), and a Multi-Object Spectrograph (MOS). The instrument will be fiber-fed from the GTC Folded-Cassegrain F station to the Nasmyth-A platform of the telescope, through a collection ~44.5m length fibers of 100?m core coupled to a set of microlenses arrays arranged in two systems of 623 and 644 fiber bundles for the LCB and MOS modes respectively. Each bundle ends in a pseudo-slit at the instrument entrance. The spaxel scale is 0.62?? and the plate scale at the detector focal plane is 0.186?? per pixel (equivalent to 4-pixel resolution).

MEGARA shall work in the visible range (from 3650A to 10000A) allowing low (LR), medium (MR), and high resolution (HR) (with spectral resolving power of R = 6000, 11000 and 18000 for LR, MR and HR respectively) by means of different dispersion elements. MEGARA will provide 6 LR gratings, 10 MR and 2 HR, with the aid of a set of Volume Phase Hologram gratings (VPHs) sandwiched between two flat fused silica windows in all cases and coupled in addition to two prisms in the case of MR and HR units. The dispersive elements will be placed at the spectrograph pupil position in the path of the collimated beam.

Before the AIV and alignment, each grating unit will be subjected to several tests in order to check the requirements fulfilment. We have developed and designed several setups that will allow us to check the lines density on the grating, the diffraction efficiency and the image quality for each pupil element.

We describe the alignment procedure to be followed in the AIV process, the set of final tests and setups that will be carried out at the level of MEGARA verification (once finally assembled), and the performance results. These tests will check the top level requirements: LCB and MOS fiber links uniformity, focus position, spectral line identification, CWL and spectral coverage, FWHM and EER80, spectral resolution, instrument transmission and ghost analysis.

9912-150, Session P4

Thermal testing results of an electroformed nickel secondary (M2) mirror

David R. Smith, MERLAB, P.C. (United States); David M. Gale, Lizeth Cabrera Cuevas, Maribel Lucero Alvarez, David Castro Santos, Arak Olmos Tapia, Instituto Nacional de Astrofísica, Óptica y Electrónica (Mexico)

To support higher-frequency operation, the Large Millimeter Telescope/Gran Telescopio Milimetrico (LMT/GTM) is replacing its existing monolithic aluminum secondary mirror (M2). The new mirror is a segmented design based on the same electroformed nickel reflector panel technology that is already in use for the primary reflector segments. While the new M2 is lighter and has better surface accuracy than the original mirror, the electroformed panels are more sensitive to high temperatures. During the design phase, concerns were raised over the level of temperature increase that could occur at M2 during daytime observations. Although the panel surface is designed to scatter visible light, the LMT primary mirror is large enough to cause substantial solar heating, even at significant angular separation from the Sun.

To address these concerns, the project conducted a series of field tests, within the constraint of having minimum impact on night time observations. The supplier sent two coupon samples of a reflector panel prepared identically to their proposed M2 surface. Temperature sensors were mounted on the samples and they were temporarily secured to the existing M2 mirror at different distances from the center. The goal was to obtain direct monitoring of the surface temperature under site thermal conditions and the concentration effects from the primary reflector.

With the sensors installed, the telescope was then commanded to track the Sun with an elevation offset. Initially, elevation offsets from as far as 40 degrees to as close as 6 degrees were tested. The 6 degree separation test quickly passed the target maximum temperature and the telescope was returned to a safer separation. Based on these initial results, a second set of tests was performed using elevation separations from 30 degrees to 8 degrees.

To account for the variability of site conditions, the temperature data were analyzed using multiple metrics. These metrics included maximum temperature, final time average temperature, and an curve fit for heating/cooling. The results indicate that a solar separation angle of 20 degrees should be suitable for full performance operation of the LMT/GTM. This separation not only is sufficient to avoid high temperatures at the mirror, but also provides time to respond to any emergency conditions that could occur (e.g., switching to a generator after a power failure) for observations that are ahead of the motion of the Sun. Additionally, even approaches of 10 to 15 degrees of angular separation on the sky may be achievable for longer wavelength observations, though these would likely be limited to positions that are behind the position of the Sun along its motion.

9912-151, Session P4

Mapping the Large Millimeter Telescope primary reflector using photogrammetry: a first comparison with 12 GHz holography

David M. Gale, Andrea León-Huerta, Lizeth Cabrera Cuevas, David Castro Santos, Emilio Hernández Ríos, Maribel Lucero Álvarez, Esteban Tecuapetla Sosa, Carlos A. Tzile Torres, David Sánchez-Argüelles, Instituto Nacional de Astrofísica, Óptica y Electrónica (Mexico); Gopal Narayanan, F. Peter Schloerb, Grant W. Wilson, Univ. of Massachusetts Amherst (United States); David R. Smith, MERLAB, P.C. (United States)

The Large Millimeter Telescope (LMT) Alfonso Serrano is a fully steerable single-dish radio telescope presently operating with a 32.5 m parabolic primary reflector. Active surface control allows for programmed correction of gravity and thermal distortions, through electro-mechanical adjustment of 84 surface segments arranged in three concentric rings. Each segment comprises 8 precision composite Nickel laminate surface panels. Panels are adjusted to the local design parabola prior to segment installation using a laser tracker. Following installation in the back-structure, initial adjustment of segments to the global parabola is accomplished using a total station and laser tracker.

The LMT project makes extensive use of holography at 12 GHz during the annual maintenance period to check and adjust the alignment of segments against the best-fit design parabola. A main drawback of the technique is the need to remove the subreflector for installation of the holography receivers at the prime focus, however this has been compatible with a desire to remove the subreflector and positioner for annual preventative maintenance. Tracker measurements have also been used for this task, however our experience shows that the technique is severely limited by environmental noise and large data collection times, on the order of many hours for a single map. In 2015 we have begun to explore the use of photogrammetry as a complimentary measurement technique. Photogrammetry can offer mapping times similar to those used for holography, at potentially higher resolution and at arbitrary elevation angles.

Accurate photogrammetry requires a robust strategy for the selection of multiple camera stations, a task complicated by the size of the antenna, obstruction of the surface by the subreflector and tetrapod legs, and the practicability of using the site tower crane as a moving camera platform. Image scaling is also a major consideration, since photogrammetry lacks an in-built distance reference, hence appropriate scale bars must be fabricated and located within the camera field of view. Additional considerations relate to the size and placement of reflective targets, and the optimization of camera settings.

In this paper we present some early results using photogrammetry to measure the primary surface of the LMT, with emphasis on the key issues mentioned above. Our results are obtained using an unmodified INCA-3 camera from Geodetic Systems Inc., with proprietary V-Stars software producing surface coordinate data. RMS surface error maps are generated from the coordinate data using in-house fitting algorithms. Laser tracker measurements of the primary surface provide a sanity check for the general performance of the photogrammetry method; an important aspect of the comparative process is the inclusion of common reference points on the surface that are measured by both techniques.

We will compare our early photogrammetry data with results from the latest holography campaign, taken shortly afterwards. We discuss the differences between data processing strategies for each method, and consider the relevance of both measurement techniques for obtaining a meaningful quantitative evaluation of the surface in terms of optical performance.

9912-152, Session P4

Day-time local phasing of neighbouring segments of the E-ELT primary mirror, based simultaneous multiwavelength shearing interferometry

Samuel Leveque, European Southern Observatory (Germany); Claas Falldorf, Reiner Klattenhoff, Bremer Institut für angewandte Strahltechnik GmbH (Germany); Anne-Laure Cheffot, European Southern Observatory (Germany)

In the context of the segmented primary mirror of the E-ELT, the ability to measure the phasing state of neighbouring segments during day-time represents a way to mitigate the risk of potentially time consuming on-sky phasing after segment replacement. This paper presents the concept of a local phasing sensor based on simultaneous multiwavelength shearing interferometry, as well experimental results obtained on the ESO M1 test facility. A discussion about possible implementation scheme for the E-ELT is included.

9912-153, Session P4

Low-cost measurement and monitoring system for cryogenic applications

Óscar Tubío Araújo, Elvio Hernández Suárez, Félix Gracia Temich, Instituto de Astrofísica de Canarias (Spain)

Cryostats are closed chambers which maintain a high vacuum and low temperature inside, hindering the monitoring of materials, structures or systems installed therein.

This work presents webcam-based monitoring system, which can operate under vacuum and cryogenic conditions to be mainly used in astrophysical applications. The system can be configured in two different assemblies: wide field that can be used for mechanism monitoring and narrow field, especially useful in materials or structure deformation measurements with a resolution of 3 microns/pixel. Several thermal vacuum cycling tests have been performed on a prototype, showing a high reliability behavior at 80K and 10-5mbar.

A final system has been developed including some of the improvements detected in the prototype, such as: the use of a Full HD webcam to improve the resolution; an athermalized mechanical camera-cage design and an optical packed assembly, minimizing in this way the out-of-focus when the cryostat is been cooled down; an isostatic camera board holder that guaranties the perpendicularity between the detector an the lens during the whole thermal vacuum cycle and an improved fastening system and a better LED-based illumination.

A complete test campaign it is been designed to check the system performance. The paper will show the implementation of the final system, its performance and the tests results.

9912-154, Session P4

Three dimensional metrology inside a vacuum chamber

Anne Costille, Florent Beaumont, Eric Prieto, Michael Carle, Christophe Fabron, Lab. d'Astrophysique de Marseille (France)

Several three dimensional coordinates systems are proposed by companies to provide accurate measurement of mechanical parts in a volume. None of them are designed to perform the metrology of a system in a vacuum chamber. In the frame of the test of NISP instrument from ESA Euclid mission, the question was raised to perform a three dimensional measurement of different parts during the thermal test of NISP instrument into ERIOS chamber. EUCLID NISP will be tested at Laboratoire d'Astrophysique de Marseille (LAM) under vacuum and thermal conditions respectively in order to qualify the instrument in its operating environment and to perform the final acceptance test before delivery to the payload. One of the main objectives of the test campaign will be the measurement of the focus position of NISP image plane with respect to the EUCLID object plane to ensure a good focalisation of NISP instrument after integration on the payload. To simulate the EUCLID object plane, a telescope simulator will be installed in front of NISP into ERIOS chamber and focalised onto NISP detector. A metrology system shall be used to measure the position of the telescope simulator and NISP during the test campaign to determine the exact position of the NISP image plane with respect to the telescope simulator. A Metrology Verification System (MVS) has been proposed in this purpose: it is a set of metrological means

specially developed for the NISP thermal balance / thermal verification test into ERIOS vacuum chamber. The goal of the MVS is to provide at operational temperature the measurement of references frames set on the telescope simulator and NISP, the knowledge of the coordinates of the object point source provided by the telescope simulator and the measurement of the angle between the telescope simulator optical axis and NISP optical axis. The MVS concept is based on the use of a laser tracker, outside the vacuum chamber, that measures reflectors inside the vacuum chamber through a curved window. We will present preliminary results obtained during the design phase of the MVS and a preliminary test phase that shows the possibility to perform this type of measurements and the accuracy reached in this configuration. An analysis of the contributors to the measurement error budget of the MVS is proposed, based on the current knowledge of the MVS performance and constraints during the TB/TV tests. We will then propose a complete measurement error budget estimation for the MVS in the frame of NISP test campaign.

9912-155, Session P4

Measuring the elevation-dependent position of the Large Millimeter Telescope subreflector using a laser tracker

David M. Gale, Instituto Nacional de Astrofísica, Óptica y Electrónica (Mexico); David R. Smith, MERLAB, P.C. (United States); Andrea León-Huerta, Lizeth Cabrera Cuevas, David Castro Santos, Emilio Hernández Ríos, Maribel Lucero Álvarez, Esteban Tecuapetla Sosa, Carlos A. Tzile Torres, Instituto Nacional de Astrofísica, Óptica y Electrónica (Mexico)

The Large Millimeter Telescope (LMT) Alfonso Serrano is a fully steerable single-dish telescope for radio astronomy, operated jointly by the Instituto Nacional de Astrofísica, Óptica y Electrónica (INAOE) in Mexico, and the University of Massachusetts Amherst (UMASS) in the US. The telescope is located in the mountainous region to the East of the Mexican altiplano, at an altitude of 4,600 m (15,092 ft). It operates without any environmental enclosure.

The LMT uses a bent Cassegrain design, comprising a 50 m parabolic primary reflector and a 2.6 m hyperbolic subreflector. The subreflector is held at the 17.5 m primary focal distance by a tetrapod structure consisting of 1.12 m diameter tubular legs that reduce to a narrower profile to minimize aperture loss. Each leg is over 27 m in length. The subreflector is supported on a hexapod for controlling movement in focus, de-center, and tilt.

A planar tertiary mirror is located on the elevation axis, 6.25 m behind the vertex of the primary parabola. Light reaches the tertiary mirror by passing through the apex cabin, a conical chamber whose entrance diameter is 2.5 m. The tertiary mirror is located on a rigid platform, attached directly to the alidade structure that supports the elevation bearings. Whilst the antenna moves in elevation, this platform provides a stable location from where one can observe the subreflector continually.

Laser trackers are used routinely at the LMT for a variety of tasks, but mostly for measuring the surface shape of the telescope optics. In this paper we present a short study of the position of the subreflector relative to the tertiary mirror and apex cabin, with distance measurements provided by a laser tracker located at the tertiary platform. The tracker beam is reflected from four corner cube targets (SMRs) located around the perimeter of the subreflector. The location of the tracker allows an uninterrupted view of all targets during full movement of the antenna in elevation, and at the same time provides a stable point from which to take measurements. As the tracker is effectively located inside the receiver cabin, a high degree of protection is afforded against the elements. This consideration is important since the equipment is operating outside the manufacturer's environmental specifications.

The results are analyzed with the aim of checking for relative motion of the subreflector resulting from gravitational and/or thermal deformations of the antenna structure. We discuss the precision of this measurement technique, carried out using a high-accuracy commercial laser tracker and compare these experimental values with predictions from the structural model. While the exclusive use of a laser tracker may be considered overkill for a longer-term monitoring exercise, one might easily consider the employment of simpler, line-of-sight distance measuring devices.

9912-157, Session P4

Temperature measurement and thermal deformation analysis on the alidade of TM65m

Li Fu, Shanghai Astronomical Observatory (China); Xu Guang Geng, The 54th Research Institute of China Electronics Technology Group Corp. (China); Quanbao Ling, Shanghai Astronomical Observatory (China); Hong-liang Qian, Harbin Institute of Technology (China); Yong Bin Jiang, Shanghai Astronomical Observatory (China)

Aimed at the alidade of TM65m, 14 key joints were installed thermal sensors to map the distribution of temperature. The variation laws of the temperature with time of day and season were statistically analyzed. The largest temperature differences of the joints and four surfaces of each point were obtained. Furthermore, the measured joint temperatures were applied on the finite element model to analyze the thermal deformations of the alidade. At the same time, an inclinometer was installed on near one of the elevation axis to get thermal gradient information on the alidade deformation. The results of measurement and finite element analysis will provide basis for the pointing model modification.

9912-158, Session P4

Hollow-cathode lamps as optical frequency standards: the influence of optical imaging on the line ratios

Philipp Huke, Lev Tal-Or, Luis F. Sarmiento, Ansgar Reiners, Georg-August-Univ. Göttingen (Germany)

In recent years hollow cathode discharge lamps (HCLs) have been successfully used as a source for calibration of optical astronomical spectrographs. The numerous narrow metal lines are well suited for a m/s calibration accuracy of high-resolution spectrographs, while the gas lines are Doppler broadened and may not be used. Accordingly, one of the crucial issues is the strength ratio of metal to buffer-gas lines which is measured after the HCL is imaged onto the spectrograph entrance. However, the processes inside the lamp cause the light to be emitted from different regions between the cathode and anode. As a consequence different beams are emitted. We used four different HCLs to measure and characterize these beams with respect to their spatial distribution, their angle of propagation relative to the optical axis and their line-strength ratios. The model that we used to fit the measured beams allows us to predict the line-strength ratios available for different optical configurations. The lamps we used in this study were filled with either Argon or Neon as a buffer gas, and the cathode material consisted of either Uranium or Thorium embedded in a matrix material.

9912-159, Session P4

Alignment of the ESPRESSO Coudé train on the ESO VLT

Gerardo Ávila, European Southern Observatory (Germany); Alexandre Cabral, Manuel Abreu, João M. P. Coelho, Univ. de Lisboa (Portugal); Bernard-Alexis Delabre, European Southern Observatory (Germany); António Oliveira, Catarina J. Silva, Univ. de Lisboa (Portugal); Denis Mégevand, Observatoire de Genève (Switzerland); Marco Riva, INAF - Osservatorio Astronomico di Brera (Italy); Pedro Santos, Faculty of Sciences of the University of Lisbon, Physics Department (Portugal)

ESPRESSO (Echelle SPectrograph for Rocky Exoplanets and Stable Spectroscopic Observations) is a high resolution UV-Vis spectrograph that will be placed in the combined Coudé laboratory of the ESO VLT. The instrument is in its assembly phase and the Coudé optics will start to be mounted at the telescope in the first quarter of 2016. This paper describes the optics of the train and the strategies for its alignment taking into account the main constraints: accessibility, mechanical, as per built optics tolerances and tools.

9912-160, Session P4

Eliminating interferometric alignment error based on digital Moire technique

Qun Hao, Shaopu Wang, Yao Hu, Beijing Institute of Technology (China); Xuemin Cheng, Graduate School at Shenzhen, Tsinghua Univ. (China)

Large-aperture optical surfaces with very low figure error are adopted in astronomical telescopes. Interferometry is among the most accurate and popular methods for optical surface measurement. The accuracy of the interferometry relies on many key techniques, including frequency stabilization, violation isolation and also precise alignment of the optical system. If the elements inside the interferometer are not positioned at the designed places, measurement error will be introduced due to aberration.

Currently the alignment of interferometer is realized with high-accuracy mechanical stage, alignment symbol and laser ranger. Once the interference pattern reaches the sparsest or the peak-to-valley (PV) value of the measured wavefront reaches the minimum, the interferometer is well-aligned. That is because the fabrication error of the system (including the figure error of the measured surface) is determined for a specific optical system and will not change with the alignment. Only when the alignment error is 0 compared with the designed position, the PV value of the wavefront will be the smallest and only include the influence of fabrication error. We define the 0 alignment error position to be best alignment position. Generally the position and attitude of the measured surface is adjusted with complicated mechanical stages gradually and finally reaches the best alignment position.

In this paper, we propose an alignment error elimination method based on digital Moire technique. We create a virtual interferometer with simulation software. The virtual interferometer contains optical elements with nominal parameters and positions. Standard phase-shifting interferograms are generated with the simulation. For the actual interferometer, after coarse alignment, only one shot of the interferogram is taken. Then digital Moire technique is used to combine the virtual and actual interferograms. The corresponding Moire fringes carry the information of the difference between virtual and actual wavefront, which is affected by both fabrication and alignment error. In the next step, we do not adjust the actual interferometer any more, but gradually adjust the position and attitude of the measured surface in the virtual interferometer. We continue calculating the wavefront difference between actual and virtual interferometer. And when the PV value of the wavefront difference reaches the minimum, we consider the position and attitude of the measured surface in the virtual interferometer matches that in the actual interferometer. And the wavefront difference is free from alignment error and can be used directly for figure error solution.

The fine alignment of measured surface is done in the software and no accurate mechanical device or complicated alignment symbol is necessary. Moreover, only one shot of actual interferogram is taken, so the influence of vibration can be avoid.

The detailed principle of the alignment error elimination method will be proposed, followed by demonstration with simulation and real measurement experiments. The final influence of alignment error to figure error measurement can be reduced to less than 1/30 of the wavelength even when the coarse alignment only reaches accuracy of several millimeters.

9912-161, Session P4

Pyramid wavefront sensor for image quality evaluation of optical system

Dan Zhou, Shanghai Astronomical Observatory (China)

Based on the theory of the pyramid wavefront sensor, we are going to develop a simulation software and a wavefront detector which can be used to test the imaging quality of the telescope. In our system, the sub-pupil image intensity through the pyramid sensor is calculated to obtain the aberration of wavefront where the piston, tilt, defocus, spherical, coma, astigmatism and other high level aberrations are separately represented by Zernike polynomials. And the imaging quality of the optical system is then evaluated by the subsequent wavefront reconstruction. The performance of our system is to be checked by comparing to the measurements carried out using Puntino wavefront instrument (the method of SH wavefront sensor). Within this framework, the measurement precision of pyramid sensor will be discussed as well through detailed experiments. In general, this project would be very helpful both in our understanding of the principle of the wavefront reconstruction and its future technical applications.

9912-162, Session P4

VUV optical ground system equipment and its application to the ICON-FUV flight grating characterization and selection

Jérôme J. D. Loicq, Pascal Blain, Richard Desselle, Isabelle Domken, Christian Kintziger, Etienne Renotte, Yvan G. Stockman, Univ. de Liège (Belgium); Cathy Chou, Harald U. Frey, Kodi Rider, Stephen B. Mende, Univ. of California, Berkeley (United States)

ICON (Ionospheric Connection Explorer) is a NASA mission which aim is to understand how Earth's space environment is impacted by terrestrial climate. In the framework of this project, a facility for the characterization of the FUV (Far Ultra-Violet) instrument has been designed and developed at the Liège Space Center (CSL). FUV is a two channel spectrographic imager, that measures intensity and spatial distribution of oxygen (135.6 nm) and molecular nitrogen (157 nm). Those wavelengths are strongly absorbed by the atmosphere and the optical elements of the system have to be tested inside a vacuum chambers.

The facility is composed of a vacuum monochromator that can either be illuminated with a calibrated deuterium lamp source (with a wavelength range of 115 to 180 nm) or a fiber coupled visible light source for alignment, verification purposes and visible spectral analysis. Two selectable gratings

can be used to maximize throughput in each region of the spectrum (visible and UV). The second part of the installation is a vacuum collimator assembly based on an off-axis parabola which produces approximately a 10 cm diameter collimated beam. As the instrument is placed on a precise tip/tilt/rotation manipulator, each region of the instruments field of view can be addressed by the beam. The Optical Ground System Equipment has special useful features such as in situ control of the beam spatial homogeneity with calibrated detectors.

Prior to the instrument test, two 3600 ln/mm gratings were tested in order to check the diffraction efficiencies and select which one is the best and will become the flight instrument grating if there were any difference. The facility was adapted for this experiment. We used a well collimated beam and reduced its size to 1 cm diameter. For the purpose of the test, the plane of the grating is centered with the collinear rotation axes of two rotation stages. One rotation is dedicated to the detection, and gives the measured diffracted light intensity with respect to its angular position. The grating is fixed to a second rotation stage and thus allowed to modify the beam incidence angle on the grating. The grating was placed on two rotation stages in order to scan different locations of the grating. This adapted set up permitted to measure diffraction efficiencies and scattering properties at vacuum UV wavelength.

We present the simulation motivated design that lead us to build such a facility. Then we will give the results of the grating measurements. A discussion on the obtained result and their implication for the instrument will be given.

Singular values behaviour optimization in the diagnosis of feed misalignments in radioastronomical reflectors

Amedeo Capozzoli, Claudio Curcio, Angelo Liseno, Salvatore Savarese, Univ. degli Studi di Napoli Federico II (Italy); Pietro Schipani, INAF - Osservatorio Astronomico di Capodimonte (Italy)

The high performance required to modern radio telescopes as well as to large reflector antennas exploited to communicate with interplanetary probes asks for the monitoring of the antenna status, in terms of misalignments of the optical chain (primary reflecting surface, sub-reflector, if present, and feeding system) and/or of deviations from the nominal shape of the primary surface due to misplacements of the panels, in the case of panelled reflectors. The monitoring can be required at the installation stage as well as during the whole antenna lifetime, to guarantee the periodical reassessment of the instrument.

During the years, different approaches have been proposed to retrieve the antenna status. In particular, a convenient one is indirect, based on the measurement of the antenna Far-Field Pattern (in amplitude and phase, or in amplitude only) [1,2]. Indeed, those misalignments which are compatible with the measurements, i.e. those misalignments producing, according to the adopted electromagnetic model, a Far-Field Pattern (FFP) as close as possible to the measured one, can be assumed as the ones affecting the instrument. A full data set describing the FFP at the Nyquist rate is typically used in the diagnosis procedure, in both cases the amplitude only, and the amplitude and phase acquisitions. Unfortunately, for large electrical antennas, the number of FFP points, covering the whole visible range, is very large, resulting in very lengthy measurement processes, subjected to variations of environmental conditions, affecting the correlation among the collected data, and to an involved acquisition scheme determined by the complex tracking of the source.

The aim of the communication is to present an innovative method allowing the diagnosis in the case of amplitude and phase acquisitions, optimizing the number of FFP data by tailoring the number and the distribution of measured field samples to the desired monitoring goal. The approach is here referred to the feed misalignment reconstruction, and rephrases the antenna monitoring as the determination of the Aperture Field (AF) from the FFP, giving the result from AF thanks to Geometrical Optics considerations. The exploited AF model introduces the effects of the feed misplacement on the nominal AF in terms of an aberration function, expanded to the order compatible with the estimated maximum deviation of the feed position from the nominal one. The AF reconstruction from the FFP is formulated as an inverse problem, linearized thanks to a Principal Component Analysis on the perturbation factor of the nominal AF. The number and the positon of the field samples are then determined by optimizing the Singular Values behaviour of the relevant linear operator.

9912-164, Session P4

Rebuilding the spare Oxford SWIFT spectrograph camera

Jamie R. Allen, Matthias Tecza, Kieran O’Brien, James D. Lynn, Niranjan A. Thatte, Fraser Clarke, Mike Tacon, Univ. of Oxford (United Kingdom)

SWIFT is an I and z band integral field spectrograph on the 200 inch Hale Telescope at Palomar Observatory. The off-axis image quality is not as high as expected from the optical design, and it is not certain whether the lens mounting technique or optical misalignments are causing this problem.

To investigate this, the spare SWIFT spectrograph camera was rebuilt using new lens mount designs developed for the HARMONI spectrograph that are adhered to the edge of the lenses rather than clamped to the face, which should decrease any stress on the lens. These mounts also use the mount as a mechanical reference rather than the optic, which should minimize the risk of damaging the lens.

The camera was interferometrically tested at a range of field angles across the whole field of view with both the original and updated lens mounting schemes to measure the optical performance and determine whether the new lens mounting scheme should be used in future instruments.

9912-165, Session P4

High precision breadboard for integrations of the NISP/EUCLID focal plane

José Garcia, Florent Beaumont, Michel Marcos, Sébastien Vives, Christophe Fabron, Philippe Laurent, Lab. d’Astrophysique de Marseille (France)

The instrument NISP (standing for Near Infrared Spectro-Photometer) is one of the two instruments of the Euclid mission which was selected by ESA in the framework of the Cosmic Vision program. NISP will combine a photometer and a spectrometer working in the near-IR (0.9-2 microns). Its detection subsystem (called NI-DS) is based on a mosaic of 16 IR detectors cooled down to 95K while the front-end readout electronics will be kept at 140K. The detectors will be integrated on a mechanical focal plane made of Molybdenum and Aluminum while a panel in Silicon Carbide (SiC) allows to interface the NI-DS with the rest of NISP.

In this context, we have developed a specific and modular breadboard with a direct interface with the SiC panel aiming at supporting the NI-DS flight model FM during each step of its development from integration to validation at room temperature. Therefore, this tool has to cope with a large range of uses: in particular, it has to be stable during long period of time (for the integration phases), to allow the handling of the NI-DS (in various configurations and orientations), to be compatible with ISO5 and vacuum environments.

On top of that, the interface with the SiC panel of the instrument has imposed a very stringent specification on the flatness at the interface i.e. below 5 microns PV on a quarter square meter. This specification was verified by using a dedicated optical metrology which allowed us to reach the required accuracy (<0.5 microns) over the entire surface.

In this article, we will describe the functions and the design of this breadboard, the manufacturing process and the optical controls applied during its acceptance. We will also describe the validation campaign based on vibrations tests performed at the Laboratoire d'Astrophysique de Marseille (LAM) on a representative model of the NI-DS.

Alignment and metrology plans for the GESE telescope and instruments

Benjamin Lewis, Arizona Optical Systems, LLC (United States); Qian Gong, Sara R. Heap, NASA Goddard Space Flight Ctr. (United States); Tony B. Hull, The Univ. of New Mexico (United States); James H. Burge, Arizona Optical Systems, LLC (United States)

The Galaxy Evolution Spectroscopic Explorer (GESE) requires a 1.5-m class wide field space telescope coupled with a visible light imager and ultraviolet multi-object spectrograph.

This paper defines the technical challenges of the optical metrology and alignment for this system. A proposed solution that includes laser metrology and incorporates computer generated holograms is presented and discussed.

9912-167, Session P4

Fabrication and testing of large lenses for modern astronomical telescopes

James H. Burge, Justin P. Hoover, Benjamin J. Lewis, Mark A. Smith, Martin J. Valente, Arizona Optical Systems, LLC (United States)

Modern telescopes require increasing difficult optics. While the challenges and technical solutions for fabricating and testing the telescope mirrors are well known, the large field corrector lenses also require advances in technology. The lenses are larger, more highly aspheric, and have tighter performance requirements than ever. This paper defines the difficulty of manufacturing large lenses and discusses some technical advances, including support, grinding, polishing, and metrology that make it possible.

9912-257, Session P4

Errors analysis of dynamic stitching interferometry

Xin Wu, Department of Precision Mechanical Engineering, Shanghai University (China) and Centre for Precision Technologies, University of Huddersfield (United Kingdom); Te Qi, Yingjie Yu, Department of Precision Mechanical Engineering, Shanghai University (China)

Interferometry is the common method for measuring high precision optical elements. In order to extend the testing region and lateral resolution, an effective technology subaperture stitching is proposed to overcome the aperture size limitation of conventional interferometers. The combination of them is an efficient and economical way for measuring large optical flat, which is widely used in high-power laser system and astronomy. The large flat can be measured many times on different positions to get subaperture data, and then stitch them together to reconstruct full aperture surface.

In situ measurement is indispensable and effective for fabrication of large optical elements. It does not need moving and remounting the workpiece, which could reduce errors in testing and further guide the next manufacture. In situ means the workpiece stay in the fabricating position and measurement in workshop. The environmental disturbance is the most troublesome. Commonly commercial phase-shifting interferometers are not suitable for the vibrating environment. Thus some dynamic interferometers are invented and hoped to be employed in that condition gradually. We have built an experimental system to simulate in situ measurement for large plane mirror in workshop, which combine dynamic interferometer and multi-aperture stitching measurement technology. It includes dynamic interferometer, the interferometer support and a two-dimensional mobile platform and so on. Dynamic interferometer is placed on the interferometer support, and the measured component is placed on the two-dimensional mobile platform, which can achieve both horizontal and vertical directions of translation. In this dynamic interferometer, spatial carrier interferogram is taken and Fourier transformed to obtain the wavefront.

The moving uncertainly of this mobile platform has to be analysed in this paper. Straightness in different directions will introduce tip tilt or rotation in subaperture data, and positioning accuracy will decreased the stitching accuracy. We analysis the impact of these errors on the measurement results and proposed corresponding restrained method. The validity of this method is verified by an optical flat with size 200mm?300mm on above experimental system.

9912-168, Session P5

The integrated opto-mechanical FEA analysis for Large Space Telescope

Xin Wang, Shouwang Jiang, Jinlong Wan, Rong Shu, Shanghai Institute of Technical Physics of The Chinese Academy of Sciences (China)

The technology of integrating mechanical FEA analysis with optical estimation is essential to simulate the gravity deformation of large main mirror and the thermal deformation such as static or temperature gradient of optical structure. We present the simulation results during the process of FEA analysis, data processing, and image performance. Two kinds of supporting ways for large main mirror which has the center holding structure or the edge glue fixation, are designed and compared to get the optimal gravity deformation. Variable mirror materials Zerodure/SiC are chosen and combined with different structure materials titanium alloy/indium steel/silicon aluminum alloy, to obtain the small thermal gradient distortion. The simulation accuracy is dependent on the shape and number of FEA net nodes, the border definition of structure, the fitting error from discrete data to smooth surface. The relation between nodes number and fitting error is figured, and the suitable nodes number is proposed when making the FEA analysis. As a main mirror of 1m diameter as an example, the appropriate structure material to match mirror, the central supporting structure, and the key aspects of FEA simulation is achieved for space application.

9912-169, Session P5

Tolerancing of a carbon fiber reinforced polymer metering tube structure of a high-resolution space-borne telescope

Mustafa Ekinci, TÜBITAK UZAY (Turkey)

High resolution space borne telescopes require dimensionally stable structures to meet very stringent optical requirements. Furthermore, high resolution space borne telescope structures need to have high stiffness and be lightweight in order to survive launch loads. Carbon fiber reinforced polymers (CFRP) are lightweight and have tailorable mechanical properties like stiffness and coefficient of thermal expansion. However, mechanical properties are highly dependent on manufacturing processes and manufacturing precision. Moreover CFRP tend to absorb moisture which affects dimensional stability of the structure in the vacuum environment. In order to get specified properties out of manufacturing, tolerances need to be defined very accurately.

In this paper, behavior of CFRP metering tube structure of a high resolution space borne camera is investigated for ply orientation, fiber and void content deviations which may arise from manufacturing errors and limitations. A computer code is generated to determine laminate properties of stacked up uni-directional (UD) laminae using classical laminate theory with fiber and matrix properties obtained from suppliers and literature. After defining lamina stack up, many samples are virtually created with ply orientations, volumetric fiber and void content that randomly deviates in a tolerance range which will be used in manufacturing. Normal distribution, standard deviation and mean values are presented for elasticity modulus, coefficient of thermal expansion (CTE), coefficient of moisture expansion (CME) and thermal conductivity in axial and transverse directions of quasi-isotropic stack ups and other stack ups which have properties presented in literature.

9912-170, Session P5

TCS and peripherals robotization and upgrade on the ESO 1 meter telescope at La Silla Observatory

Samuel Ropert, Vincent Suc, Pontificia Univ. Católica de Chile (Chile); Marcelo Said Tala Pinto, Max-Planck-Gesellschaft (Germany); Philip Liedtke, Pontificia Univ. Católica de Chile (Chile); Santiago Royo, Univ. Politècnica de Catalunya (Spain); Andres Jordan, Pontificia Univ. Católica de Chile (Chile)

We describe in this work the robotization and upgrade of the ESO 1m telescope located at La Silla Observatory. The ESO 1m telescope was installed in La Silla in 1966. It will host FIDEOS, a high resolution spectrograph designed for precise RV measurement on bright stars. In order to meet this project's requirements, the TCS (Telescope Control System) and some of its mechanical peripherals needed to be upgraded. The old synchronous motors were replaced by steppers and DC motors with encoders added on. The Dome rotation and opening system was also integrated into the control system by modifying the old interface, encoders and limit switches. The telescope's shutter was modified changing its synchronous motors with modern stepper motors, but using the old mechanical interface. In order to improve the telescope's precision we added on-axes encoders to the system, which dynamically compensate within a PID control system the natural backlash and periodical errors inherent to these mechanical setups. The TCS was also upgraded into a modern and robust control system mounted on a group of Raspberry PI single board computers interacting together as a computer network with the CoolObs TCS board developed by Obstech. One of the particularities of the CoolObs TCS boards is the fact they allow to fuse the input signals of 2 encoders per axis in order to achieve a high precision and resolution with moderate cost encoders. The TCS also was integrated with the FIDEOS control system, so all the system can be controlled through the same remote user Interface. The modern TCS allows the user to run observations remotely through a secured internet web interface, minimizing the need of an onsite observer. We will show how this system improved the telescope's pointing and tracking on the FIDEOS commissioning. We also illustrate the main system's usability in detail.

9912-171, Session P5

Error compensation research on the focal plane attitude measurement instrument

Hongfei Zhou, Feifan Zhang, Chao Zhai, Zengxiang Zhou, Wei P. Zhang, Zhigang Liu, Jianping Wang, Univ. of Science and Technology of China (China)

The surface accuracy of astronomical telescope focal plate is a key indicator to precision stellar observation. Combined with the six DOF parallel focal plane attitude measurement instrument that had been already designed, space attitude error compensation of the attitude measurement instrument for the focal plane was studied in order to measure the deformation and surface shape of the focal plane in different space attitude accurately.

Position and attitude accuracy of the six DOF parallel focal plane attitude measurement instrument is one of the main factors which affect the quality of its work. In order to ensure the accuracy of attitude measurement and reduce the measurement error, first, zero calibration of each axis on the platform was done by a variety of methods. And the calibration stability was measured by dial indicator and magnetic table and the optimum calibration mode was obtained. Then the terminal attitude of the platform was measured by the high precision angle measurement instrument and the error data sample was analyzed. Based on the radial basis function (RBF) neural network compensation algorithm, a three layer RBF neural network model was established which took the actual attitude angle as input and the desired attitude angle as output. On the basis of the model, error compensation for the focal plane attitude measurement instrument through the experiment was carried out. The feasibility of the method to error compensation was verified.

9912-172, Session P5

Research and implementation of the integrated cooling system for focal plate

Jianping Wang, Lixuan Cheng, Jiaru Chu, Hongzhuan Hu, Zengxiang Zhou, Univ. of Science and Technology of China (China)

With the rapid development of multi-objective astronomical survey telescope technology, the heat of focal plate which high-density optical fiber positioners were mounted in has become the key factor of system precision. The new integrated cooling system designed multi curved composite grooves on the surface of focal plate for forced convection was proposed. Meanwhile, the manufacturing process, sealing structure and heat dissipation performance of the system were analyzed and tested with detail in the paper. The experimental results suggested that the new integrated cooling system of focal plate has a fast response speed and good heat dissipation performance.

The multi curved composite grooves are located in the gap on the focal plate surface with hole array, which should not only to meet the requirements of heat dissipation and space of high-density optical fiber positioners, but also to solve the problem of manufacturing and sealing in the narrow space of the focal plate, and to maintain mechanical properties of the whole system at the same time. The focal plate was modeled by

CAD software and its stiffness was analyzed by finite element software. The simulation of focal plate transient temperature field was carried out in different convection coefficient, different water mean temperture which flowed through the grooves and different number and distribution of grooves on the surface of focal plate. The model of focal plate cooling system was optimized after comparing and analyzing the simulation results and studying each variable effect on focal plate temperature field. At last, the model of the focal plate was fabricated and the experimental platform of cooling system was built. The pressure and sealing of the focal plate are tested, then the experiment was carried out the validate validity of simulation results. Experimental results suggested that the designed integrated cooling system is mainly in agreement with the simulation results. The cooling system can ensure the temperature field of whole focal plate stabled. The temperature in the experiment shows uniform distribution during the course of an observation. The temperature change of whole focal plane can be controlled in a constant range.

9912-173, Session P5

Mechanical performance of the GCT: a dual-mirror telescope prototype for the future Cherenkov Telescope Array

Jean-Laurent René Dournaux, Jean-Philippe Amans, Delphine Dumas, Observatoire de Paris à Meudon (France) and Ctr. National de la Recherche Scientifique (France); Jean-Michel Huet, Observatoire de Paris à Meudon (France) and Ctr. National de la Recherche Scientifique (France); Gilles Fasola, Observatoire de Paris à Meudon (France) and Ctr. National de la Recherche Scientifique (France); Johann Gironnet, Ctr. National de la Recherche Scientifique (France); Philippe Laporte, Observatoire de Paris à Meudon (France) and Ctr. National de la Recherche Scientifique (France); Abdel Abchiche, Ctr. National de la Recherche Scientifique (France); Jean-Jacques Bousquet, Observatoire de Paris à Meudon (France) and Ctr. National de la Recherche Scientifique (France); Gilles Buchholtz, Ctr. National de la Recherche Scientifique (France); Julien Gaudemard, Isabelle Jégouzo, Observatoire de Paris à Meudon (France) and Ctr. National de la Recherche Scientifique (France); Patrick Poinsignon, LATMOS (France) and Institut Pierre Simon Laplace (France); Hélène Sol, Observatoire de Paris à Meudon (France) and Ctr. National de la Recherche Scientifique (France)

The Cherenkov Telescope Array (CTA) project aims to create the next generation Very High Energy (VHE) gamma-ray telescope array. It will be devoted to the observation of gamma rays from 20 GeV to 300 TeV. Because of this wide energy band, three classes of telescopes, associated to different energy ranges and different mirror sizes, are defined. The Small Size Telescopes (SSTs) are associated to the highest energy range. About 70 of these telescopes are foreseen on the Southern site of the CTA. The large number of telescopes constrains their mechanical structure because easy maintenance and reduced cost per telescope are thus needed. Moreover, of course, the design shall fulfil the required performance and lifetime in the environment conditions of the site.

The Observatoire de Paris started in 2011 design studies of the mechanical structure of the GCT (Gamma-ray Cherenkov Telescope), a four-meter prototype telescope for the SSTs of CTA, from optical and preliminary mechanical designs made by the University of Durham. At the end of 2014 these studies finally resulted into a lightweight (~8 tons) and stiff design. This structure was based on the dual-mirror Schwarzschild-Couder (SC) optical design, which is an interesting and innovative alternative to the one-mirror Davies-Cotton design commonly used in ground-based Cherenkov astronomy. The benefits of such a design are many since it enables a compact structure, lightweight camera and a good angular resolution across the entire field-of-view. The mechanical structure was assembled on the Meudon site of the Observatoire de Paris in spring 2015 and the Telescope Control System was successfully implemented at the end of the year 2015 leading to a fully operational telescope.

This paper focuses on the mechanics of the telescope prototype. It describes the mechanical structure and presents its performance identified from computations or direct measurements. Upgrades of the design in the context of the pre-production and the large scale CTA production are also discussed.

9912-175, Session P5

Design of the telescope controller rejecting ground base disturbance

Yongmei Huang, Qiang Wang, Institute of Optics and Electronics (China)

In this paper, a telescope controller design method rejecting ground base disturbance is proposed. Telescope systems usually suffer some uncertain disturbances. One of these is the disturbance come from ground base. Unlike the other disturbances, such as wind load, friction etc. The ground base disturbance can hardly be rejected by improve the bandwidth of control system. This paper gives the measurement of the influence to the telescope coming from ground base disturbance. The property of ground base disturbance to the control system is concluded. Then, a control method is proposed. Finally the experiment result is proposed.

9912-176, Session P5

Detachable external telescope for mobile phone

Hongyang Yu, Jun Zhang, Zhe Chen, Zhihan Wang, Jinan Univ. (China); Shuaili Zou, Guangzhou Cyclops Optics Technology Co. (China)

Mobile phone has been a popular thing in life because of its many functions except making a call, such as camera, recorder, and so on. In fact, it has replaced normal digital camera gradually due to its high quality device, for example, CMOS and its lens. But it is difficult to catch a photo of a long distance object, comparing the normal digital camera as its lens is specially designed for conditional object instead of a long distance object. We have already designed and made an external wide angle lens for mobile phone successfully .This paper introduces a detachable external telescope for mobile phone. The external telescope system is designed to work with the mobile phone' own lens. It can be used to observe and take a photo of long distance object directly, even for the surface of the moon. The telescope drawtube is divided into two parts to connect easy and portable. Its objective lens uses doublet structure. Its strict spherochromatic aberration correction makes the image quality correction more excellent. The lens diameter is 60mm to ensure the light, bright image. The diameter of its ultra-wide-angle eyepiece lens is 22mmand the focal length is f=25 mm. Large eyepiece ergonomic design makes it more comfortable. The telescope system has a focal length of 700mm. It is not only enough to ensure high resolution imaging and but also to obtain higher multiples. Combining with the lens in mobile phone, image from a long distance, e.g. moon surface, can get clearly. In the mechanical structure, the length of the system along the axial is about 800mm. In order to facilitate carrying, the telescope tube is designed to be detachable structure of two part, which can be connected by a fastener immediately. The mechanical structure of eyepiece is designed reasonably to ensure that the system and mobile phone lens are coaxial and can be connect quickly.

It is an external accessary for the mobile phone to make the mobile phone more powerful. The system was designed for two kind of usage: one is the observation by human eye with a special lens in telescope, another is recording the image by the camera in the mobile phone simultaneously. After optimization of design, this moon telescope system has small size, light weight, easy to carry.

9912-258, Session P5

Advancements in strain matching of optical materials (glass and silicon carbide) with composite material metering structures

Kelly J. Dodson, Gregory V. Mehle, Orbital ATK (United States)

The historic approach for developing space borne optical systems has been to match the CTE of the optical components with the CTE of the metering structure. Polymer based composite materials are typically baselined as the structural material of choice when low CTE glass is selected as the optical material of choice as they offer benefits regarding minimizing mass and maximizing stiffness. Tailored composite material systems and near zero CTE glass materials such as ULETM and ZerodurTM achieve near zero CTE across temperatures near room temperature. However, for applications where there are larger operational temperature exposures, it becomes more desirable for the dL/L curves of the materials to match or track each other. Improvements in both composites and glasses are improving this matching of the dL/L behavior of the materials. Another very promising materials development is the CTE and dL/L matching of a new composite material system with Silicon Carbide (SiC) optical materials. When SiC optics have been selected, this new composite material system may be desirable to serve as the structure to meter the SiC optics. The use of this material avoids fracture mechanics concerns of using SiC as the metering structure, particularly in larger applications.

This paper summarizes some the work that has been done to address CTE and thermal strain matching of polymer composites to the more commonly used Glass optical materials and Silicon Carbide optical materials for satellite and aircraft applications.

9912-259, Session P5

Development of a 0.5m clear aperture cassegrain type collimator telescope

Mustafa Ekinci, Ozgur Selimoglu, TÜBITAK UZAY (Turkey)

Collimator is an optical instrument used to evaluate performance of high precision instruments, especially space-born high resolution telescopes. Optical quality of the collimator telescope needs to be better than the instrument to be measured. This requirement leads collimator telescope to be a very precise instrument with high quality mirrors and a stable structure to keep it operational under specified conditions. In order to achieve precision requirements and to ensure repeatability of the mounts for polishing and metrology, opto-mechanical principles are applied to mirror mounts. Finite Element Method is utilized to simulate gravity effects, integration errors and temperature variations. Finite element analyses results of deformed optical surfaces are imported to optical domain by using Zernike polynomials to evaluate the design against specified WFE requirements. Both mirrors are aspheric and made from Zerodur for its stability and near zero CTE, M1 is further light-weighted. Optical quality measurements of the mirrors are achieved by using custom made CGHs on an interferometric test setup. Spider of the cassegrain collimator telescope has a flexural adjustment mechanism driven by precise micrometers to overcome tilt errors originating from finite stiffness of the structure and integration errors. Collimator telescope is assembled and alignment methods are proposed.

9912-260, Session P5

Two approaches to thermal dimensional stability for spaceborne mirrors

Tony B. Hull, The Univ. of New Mexico (United States); Thomas Westerhoff, Guenter Weidmann, Rule Kirchhoff, SCHOTT AG (Germany)

Two material approaches to thermal stability are in practice today for spaceborne missions. A. The first uses materials with high thermal expansion and high thermal diffusivity. Since these materials respond to a transient rapidly and equalize, the thermal distortion on the optical surface is mitigated. B. The second uses materials with very low thermal expansion, inevitably accompanied by low thermal diffusivity. The small thermal expansion mitigates distortion even though the diffusion time is longer. Ideally the material would have low thermal expansion and high diffusivity. Unfortunately no such material is available. We will compare the thermal stability response of comparable systems in both a low and high earth orbit.

9912-177, Session P6

On the origin and removal of interference patterns in coated multimode fibres

Yazmin Padilla Michel, Technische Hochschule Wildau (Germany); Silvio Pulwer, Technische Hochschule Wildau (Germany) and Univ. degli Studi di Roma (Italy); Pouneh Saffari, European XFEL GmbH (Germany); Viachaslau Ksianzou, Sigurd K. Schrader, Technische Hochschule Wildau (Germany)

Integral Field Units (IFUs) are now widely used on large telescopes for three dimensional spectroscopy. These instruments have a complex design and, although their bulk properties are well known, there are subtle effects that need to be investigated to optimise their use and data reduction.

Such is the case for the VIMOS-IFUs, where variable interference patterns (fringing-like) have been reported and were not clearly explained until now. These interference patterns affects the spectra in the visible wavelengths.

At the focal plane of a telescope, the whole IFU, including the core, cladding and coating of each fibre, is illuminated. This coating is a polymer used not only to protect the glass of the fibre from the harsh environment, but it also has a higher refractive index to strip the cladding modes.

We present experimental results of interference patterns produced in multimode fibres coated with polyimide, the preferred coating material for the fibres used for IFUs. Our experiments show that, under some conditions, cladding modes are interacting with the polyimide coating producing interference in the output spectrum. Also we show that as the fibre is manipulated, the interference pattern changes, therefore the fibres should be carefully managed in order to minimize this potential problem for the instruments. Finally we also present a simple way of modelling this interference pattern, which can be included in the data reduction pipeline to remove this pattern from spectra ranging from the visible to the near infrared.

These results should be of interest for an optimisation of the data reduction pipelines. Moreover, understanding the effects of the different technologies will benefit innovations and developments of fibre systems.

9912-178, Session P6

Effects of fiber manipulation methods on optical fiber properties

Robert O. Reynolds, Large Binocular Telescope Observatory (United States)

Optical fibers are now routinely used to couple high-resolution spectrographs to modern telescopes, enabling important advantages in areas such as the search for extrasolar planets using spectroscopic radial velocity measurements of candidate stars. Optical fibers partially scramble the input illumination, and this phenomenon enables a fiber feed to provide more uniform illumination to the spectrograph optics, thereby reducing systematic errors in radial velocity measurements. Current instruments now achieve a precision of ~1m/s using fiber-feeds, but greater precision approaching 10cm/s is required to detect terrestrial planets orbiting sun-like stars. A primary limiting factor in multimode fiber coupling is modal noise, a measurement uncertainty caused by inherent properties of optical fibers, evident as a varying spatial intensity at the fiber exit plane. Many instruments utilize the strategy of agitating the fiber during an observation to reduce modal noise, and squeezing of the fiber and dynamical optical diffusers have been tested as alternatives to agitation. However, deformation of the fiber can lead to light loss, and diffusers may be suitable only for calibration sources due to significant known losses. The technique of stretching or varying the length of the fiber has been shown to offer advantages over other approaches, including potentially greater uniformity of the exit intensity distribution. But effects of stretching on fiber parameters such as total transmission and focal ratio degradation have not been adequately studied. In this paper we present results of measurement of transmission loss and focal ratio degradation in a stretched fiber, along with discussion of possible consequences.

9912-179, Session P6

Influence of misalignment on output of astronomical large-core fibers of multi-object fiber spectroscopic telescopes

Weimin Sun, Jing Wang, Yan Qi, Harbin Engineering Univ. (China) and Ministry of Education The People's Republic of China (China); Tao Geng, Harbin Engineering Univ. (China); Zhenyu Ma, Key Lab of In-fiber Integrated Optics, Ministry Education of China, Harbin Engineering University (China); Yongjun Liu, Harbin Engineering Univ. (China) and Ministry of Education The People's Republic of China (China); Xiangqun Cui, Nanjing Institute of Astronomical Optics & Technology (China) and Chinese Academy of Sciences (China)

Large-core fibers are wildly used in astronomical applications. For multi-object fiber spectroscopic telescopes, for example the Large Sky Area Multi-Object Fiber Spectroscopic Telescope (LAMOST), the aiming accuracy is important. The fibers in these telescopes have two ends; one input end is in the focal plane to collect the star image while another output end is inside a spectrometer.

If the input end doesn't exactly match the image of the star, the emitting spot from the output end could not be a central-peak circular spot. If the misalignment is serious, the output would be a ring. The ring spot would lead to wrong spectrum analysis result. To obtain the relationship of the input position and the output spot, we designed a scanning experiment. We chose a single-mode fiber for 650nm, which core diameter is 4 m, to scan a large-core astronomical fiber FBP320385415 of 320m core diameter, which is used in LAMOST. The light source was a laser diode, so the emitting spot from fiber had serious speckles. The strong speckles made it very difficult to fit the output spot to a certain shape. We introduced a fiber-vibration system to average the speckle patterns, then we can get much smoother output patterns.

The experimental results show that the output spot will be a ring spot instead of the supposed circular pattern, when the input point is 122m away the center of the fiber. The nearer of the input position is to the edge of fiber, the closer the output spot to a ring. A energy ratio function is proposed to describe the level from a circular spot to a ring. The peaks of energy ratio function correspond the dividing line between the circle spot and the ring spot. This experimental result is important for designing and optimizing the fiber-end adjusting devices of multi-object fiber spectroscopic telescopes.

9912-180, Session P6

Back-illuminate fiber system research for multi-object fiber spectroscopic telescope

Zengxiang Zhou, Zhigang Liu, Jianping Wang, Hongzhuan Hu, Wei P. Zhang, Jiaru Chu, Univ. of Science and Technology of China (China)

Using parallel controlled fiber positioner as the spectroscopic receiver is an efficiency observation system for spectra survey, has been used in LAMOST recently, and will be proposed in CFHT and rebuilt telescope Mayall. In the telescope observation, the position of fiber will highly influence the spectra efficient input in the fiber to the spectrograph. When the fibers were back illuminated on the spectra end, they would export light on the positioner end, so the CCD cameras could capture the photo of fiber tip position covered the focal plane, calculates the precise position information by light centroid method and feeds back to control system. After many years on these research, the back illuminated fiber measurement was the best method to acquire the precision position of fibers. A set of fiber back illuminated system was developed which combined to the low revolution spectro instruments in LAMOST. It could provide uniform light output to the fibers, meet the requirements for the CCD camera measurement and was controlled by high-level observation system which could shut down during the telescope observation. The paper was introduced the back illuminated system design and different test for the light resource. After optimization, the effect illuminated system could compare the integrating sphere, meet the conditions of fiber position measurement.

A compact optical fiber positioning device

Hongzhuan Hu, Jianping Wang, Zhigang Liu, Zengxiang Zhou, Chao Zhai, Jiaru Chu, Univ. of Science and Technology of China (China)

In this paper, a compact optical fiber positioning device is proposed, which is especially suitable for small scale and high density fiber positioning. Based on the positioning principle of double rotation, positioning device's center shaft depends on planetary gear drive principle, meshing with the fixed annular gear central motor gear drives device to rotate. The eccentric shaft is rotated by a coaxial eccentric motor. Both center and the eccentric shaft are supported by a rolling bearings. The center and eccentric shaft were designed with electrical zero as a reference point, all of them have position-limiting capability to ensure the safety of fiber positioning. The eliminating clearance with spring structure were combined in the eccentric and center shaft, which could eliminate the influence of gear gap. The driving circuit could be installed in the positioning device's body for two driving motor. Another excellent improvement design is the favorable heat sink, the heat bring by positioning operation can be effectively transmit to design a focal plane unit through the aluminum component. There are

cooling spiral airway integrate on positioner sleeve, when positioning, the cooling air flow is inlet into the unit hole on the focal plate, the cooling air flow can effectively take away the positioning's heat, which extremely eliminate the impact of the focus seeing. After experiment measured the prototype design of new fiber positioner, the results show that: the unit accuracy reached 0.01mm, which could meet the requirement of fiber positioning.

Research of subdivision driving technology for brushless DC motors in optical fiber positioning

Yi Kan, Yonggang Gu, Wenbo Xu, Chao Zhai, Univ. of Science and Technology of China (China)

In fiber spectroscopic telescopes, optical fiber positioning units are used to position thousands of fibers on the focal plane quickly and precisely. Stepper motors are used in existing units, however, it has some inherent deficiencies, such as serious heating and low efficiency. In this work, brushless DC motors without these disadvantages are employed instead of stepper motors in the developing optical fiber positioning units. Nevertheless, due to its own structure feature, brushless DC motor cannot meet the unit's demand of positioning accuracy and resolution in conventional driving methods. Therefore, the universally adopted subdivision driving technology for stepper motors, which can effectively improve the positioning accuracy and resolution, is transplanted to brushless DC motors. In brief, this research mainly focuses on develop a novel subdivision driving technology for brushless DC motor. Firstly, on-line brushless DC motor commissioning and configuration platform is set up based on FAULHABER drive systems with Motion Controllers, which is applied to realize subdivision simulation and to determine reasonable subdivision parameters. Secondly, experimental circuit for brushless DC motor driving and controlling is designed and printed. Lastly, the simulated subdivision parameters are verified by debugging the new driving board. Experiments indicate that the proposed brushless DC motor subdivision algorithm can achieve the expected functions, and moreover, power consumption and heating of the new driving board are observably decreased by the circuit layout optimization and the chip selection. Strikingly, the area of the new driving board is reduced by 36% than the former one. The brushless DC motors driven by subdivision technology keep the advantages of stepper motors such as high positioning precision and stability in low-frequency range, while overcome the disadvantages mentioned above. Thus, an innovational optical fiber positioning unit based on brushless DC motor is developed with high precision and reliability in this paper.

Pupil slicer design for the NASA-NSF extreme precision Doppler spectrograph concept "wisdom"

Mark D. Egan, Gábor Furész, Richard Foster, Robert A. Simcoe, MIT Kavli Institute for Astrophysics and Space Research (United States)

The formula describing the resolution (R) of a spectrograph clearly shows that maintaining a constant R value requires the collimated beam diameter, and thus the size of the instrument, to scale linearly with telescope diameter. This scaling relation becomes increasingly problematic for high-resolution echelle spectrographs, since the beam size is also proportional to R. Thus Precision Radial Velocity (PRV) instruments with R>100k require large gratings and optics, driving the cost and complexity of such spectrographs designed for large telescopes. Implementation of PRV instruments on the next generation of extremely large telescopes therefore calls for extreme budgets – or some clever solutions to keep the instrument size at bay, without sacrificing throughput.

Image or pupil slicing is one such solution, employed most recently in the G-CLEF design for the 25m aperture of the GMT. While a 3.5m telescope diameter allows for conventional approaches, as demonstrated by the HARPS instruments, the use of pupil slicing is still beneficial in reducing the overall size of the instrument. For our design of the "WISDOM" (WIYN Spectrograph for DOppler Monitoring) instrument concept, a response to the NASA-NSF call for a ground-based support facility of the Transiting Exoplanet Survey Satellite (TESS), we had to turn to this solution as the observatory could only offer a limited space for the installation of the instrument.

The primary of the telescope is conjugated to a small, 75mm diameter parabolic mirror, which is physically cut into six triangular segments that are slightly pushed in radially. These mirror segments feed light into six individual fibers, each with a core diameter of 32 microns. As this unit has to be mounted directly on the folded Cassegrain port of the WIYN telescope the challenge is not just to achieve but also to maintain the alignment of the optics in the changing gravitational and varying thermal environment. Since the fibers are very small and densely packed we chose to align the mirrors rather than the fibers. The "pizza-slice" shaped mirror segments are kinematically mounted by cantilevered tabs that are bonded to the outer edge of each segment. After initial alignment precision shims are ground to the measured thicknesses to permanently set the positioning. To mitigate the thermal changes we employ low thermal expansion materials: zerodur for the mirrors, invar and carbon fiber for the structure. To avoid misalignments induced by changing gravitational load the fibers are supported by a very stiff carbon fiber hexapod structure. FEA analysis aided the optimization of the support struts and spider vane structure to achieve <3 micron misalignment for the expected working conditions.

9912-184, Session P6

Slitmask based pupil scrambling integral field unit for the Robert Stobie spectrograph on SALT

Michael P. Smith, Marsha J. Wolf, Matthew A. Bershady, Guangwei Fu, Univ. of Wisconsin-Madison (United States); Longji Bing, Nanjing Univ. (China)

We propose to build an integral field unit (IFU) for the Robert Stobie Spectrograph (RSS) on the Southern African Large Telescope (SALT). The Pupil Scrambling IFU (PSI) will employ the scrambling properties of fibers to address fundamental problems in achieving photon-limited sky subtraction due to variations in pupil illumination during observations. PSI will be fully encapsulated with a compact folding scheme in a standard longslit mask—far thinner than any previous fiber-based implementation.

The IFU will cover 14 x 24 arcsec on sky, achieving spectral resolution R ? ?/?? up to 6200 and photon-limited sky subtraction for studies of faint extended gas around galaxies beyond the reach of current 4m-class instruments. It will incorporate new-technology octagonal shaped fiber cores coupled by telecentric, pupil-imaging lenslets to fully optimize pupil scrambling and provide 100% integral sky coverage. The PSI design consists of 300 microlens-coupled octagonal fibers, delivers fully integral-field coverage over a 14 arcsec x 24 arcsec field, performs well over the full bandpass from 350 nm to 900 nm, and achieves spectral resolution up to R=6200. The IFU contains 274 fibers in an elongated hexagon. There are 26 sky fibers in two mini-slits.

The PSI will require no modifications to the existing RSS instrument, as it is inserted like a longslit mask by the existing mechanism. Light from the telescope is picked off by fold prisms just before the telescope focal plane and sent through MLAs bonded to the prisms and mechanically aligned to the IFU head and sky fiber mini-slits. Fibers wrap around inside the cartridge with ample radius of curvature to V-groove blocks, output

microlens arrays, and fold prisms that are configured into a spectrograph entrance pseudo-slit. Sky fibers will be placed at the ends of every V-groove block in the spectrograph slit. The spectrograph slit, mini-slit (sky), and IFU are all folded by prisms that are optimized with AR coatings. Microlens arrays are bonded to the prisms and aligned as an assembly to the fibers via the flexure mounts.

This paper will show results of simulations and measurements done on the fiber scrambling properties of hexagonal fibers. It will also provide details of the optical and mechanical design of this Slitmask - based IFU.

9912-185, Session P6

Characterizing octagonal and rectangular fibers for MAROON-X

Adam Sutherland, Julian Stürmer, The Univ. of Chicago (United States); Katrina Miller, Duke Univ. (United States); Andreas Seifahrt, Jacob L. Bean, The Univ. of Chicago (United States)

We report on the scrambling performance and focal-ratio-degradation (FRD) of various octagonal, rectangular, and square fibers considered for MAROON-X, a new fiber-fed, red-optical, high-precision radial-velocity spectrograph for the 6.5m Magellan Telescope in Chile. Our report demonstrates the influence of different cladding types and shapes around rectangular fibers on their FRD behavior. We also discuss the difference in FRD between bare and connectorized fibers.

9912-186, Session P6

Modern fiber manufacturing and testing

Teodor Tichindelean, Polymicro Technologies, A Subsidiary of Molex Incorporated (United States); Gábor Furész, MIT Kavli Institute for Astrophysics and Space Research (United States)

Optical fibers have been widely used in astronomical instruments for decades. The basic properties of fibers and their manufacturing processes have not really changed much, although several recent applications have called for custom solutions. These include development of special core geometries, tailoring of refractive index values/profile, tight control of primary properties (e.g. core diameter, transmission) and understanding of secondary properties like focal ratio degradation (FRD). Customization and specification of tight tolerances come at a price, and without an insight into the manufacturing process it is hard for the end users to gauge what is feasible and where to draw the line in a trade study. Also, sensitive post-manufacturing tests (for FRD, transmission), or post-processing (tapering, splicing) requires expensive instruments and the results can highly vary from group to group. Therefore this paper provides details on current production, post-processing and recently developed testing capabilities, from the manufacturer point of view but with the astronomer in mind. With over 30 years of experience Polymicro Technologies has been in the forefront of the optical fiber industry, and even though astronomy is not a truly profitable application area, Polymicro has been taking pride in fulfilling the desires of the astronomical community.

9912-187, Session P6

A new miniaturized wireless driving system for LAMOST fiber positioning

Liang Guo, Yonggang Gu, Chao Zhai, Yuran Shen, Univ. of Science and Technology of China (China)

The fiber positioning system is one of the most important parts of LAMOST (The Large Sky Area Multi-Object Fiber Spectroscopic Telescope), which consists of 4,000 fiber positioning nodes and each of them can position a fiber. In addition, all of the fiber positioning nodes are distributed on the focal plate of 1.75m in diameter.

As the self-innovation and key technology of LAMOST, the fiber positioning system has been working steadily for more than 6 years. At present, a higher demand to install at least 5,000 fiber positioning nodes on focal plate of 1.75m in diameter is put forward and the most effective solution is to miniaturize the fiber positioning nodes. Every fiber positioning node consists of three parts: the wireless driving system, the mechanical device and the two stepper motors. The size of stepper motor has reduced from 10mm to 6mm in diameter, but the size of mechanical device depends on the wireless drive system. Therefore, to miniaturize the wireless driving system is of great importance and difficulties as well.

The previous wireless driving system board is 100 mm long and 15 mm wide and consists of the minimum system of wireless SOC based on technology of ZigBee wireless communication and the stepper motor driver module. In order to miniaturize the wireless driving system, two steps are proposed in the paper. The first step is to separate the whole wireless driving board into two parts of the minimum system board of wireless SOC (30mm x10mm) and the stepper motor driver module (8mm x 8mm). Compared with the pre-board installed at the end of the fiber positioning node, the new minimum system board of wireless SOC is installed at the end of fiber positioning node and the stepper motor driver module is installed at the end of the stepper motor. The second step is to adopt a smaller-size wireless SOC to replace the original one. The CC2530 used on new board is 6mm long and 6mm wide as a true system-on-chip solution for IEEE 802.15.4 and ZigBee applications launched by TI. The previous MC13213, with the size of 9mm x 9mm, possesses less performance of MCU and peripherals.

As a result, the size of the new wireless driving system reduces by above 60%. Meanwhile, the entire structure of every fiber positioning node can be designed smaller. Finally, more than 5,000 fiber positioning nodes with an alveolate distribution can be installed on the focal plate of 1.75m in diameter, of which the dense increases by 20%.

9912-188, Session P6

A new modular guidance system for the Southern African Large Telescope

Janus D. Brink, South African Astronomical Observatory (South Africa) and Southern African Large Telescope (South Africa); Ockert J. Strydom, Stephen N. Hulme, Southern African Large Telescope (South Africa); Anthony R. Koeslag, Deneys S. Maartens, South African Astronomical Observatory (South Africa) and Southern African Large Telescope (South Africa); Martin Wilkinson, Southern African Large Telescope (South Africa); Keith R. J. Browne, Eben P. Wiid, South African Astronomical Observatory (South Africa) and Southern African Large Telescope (South Africa); Raoul van den Berg, Southern African Large Telescope (South Africa)

Following successful commissioning of the guidance probe on the Southern African Large Telescope (SALT) Fiber Instrument Feed (FIF), the concept was developed further in a project to re-design the guidance system currently supporting Robert Stobie Spectrograph (RSS) observations. The features of the new system, its mechanical and optical designs and its control system architecture are presented. Improvements to the operational user interfaces and integration of the new RSS probe with the greater SALT software control system are also discussed.

The systems engineering approach was taken allowing the core science and operational requirements to drive the re-design from the ground up.

Lessons learnt from the first two years of FIF probe operations and how they influenced the new design are presented. Newly adopted project management and design processes were used to good effect to streamline and monitor all aspects of the project. Major features of the new system include a compact, modular and removable design, high optical efficiency, a double-probe positioning system enabling both translation and rotation guidance corrections as well as optional closed-loop focus feedback.

A strong requirement for maintainability and advances in technology allowed a new control system architecture to be employed, resulting in the first line-replaceable guidance subsystem at SALT. The electronic control system is housed in an easily accessible cooled enclosure, while the positioning mechanics, optics and detectors form a removable unit mounted directly to the instrument.

A double-probe rectilinear positioning mechanism using off-the-shelf linear translation stages was developed that allows accurate selection and simultaneous imaging of two guide stars enabling telescope de-rotation guidance corrections — especially important during long-exposure multi-object-spectroscopy (MOS) observations. The mechanical design provides significantly faster guide star acquisition times as well as accurate offsets while closed-loop guidance is active to precisely re-position science targets within the telescope field of view during an observation.

Compared to the existing RSS probe, the optical train and camera system employed on the FIF probe improved sensitivity by a factor of eight, allowing successful guidance on much fainter objects — up to 20th magnitude in the V band. This optical design was extended to include a deployable two-face pyramid wavefront sensor that enables focus-sensing functionality while retaining throughput efficiency. Some caveats and characteristics of this wavefront sensing method are discussed.

Motion control is accomplished via a compact re-configurable input/output (cRIO) embedded controller from National Instruments. Each motion stage is driven by a stepper motor and provides accurate position feedback via linear optical grating encoders. The embedded controller also hosts the guidance image processing functionality and high-level software control system that interfaces to the rest of the telescope control system (TCS) via middleware based on the Data Distribution Service (DDS) standard.

9912-189, Session P6

Design, development, and performance of the fibers of MOONS

Isabelle Guinouard, Observatoire de Paris à Meudon (France); Gerardo Ávila, European Southern Observatory (Germany); Jean-Philippe Amans, Observatoire de Paris à Meudon (France); David Lee, Philip Rees II, William D. Taylor, David M. Montgomery, UK Astronomy Technology Ctr. (United Kingdom); Ernesto Oliva, Istituto Nazionale di Astrofisica (Italy)

The Multi-Object Optical and near-Infrared Spectrograph (MOONS) will exploit the full 500 square arcmin field of view offered by the Nasmyth focus of the Very Large Telescope and will be equipped with two identical triple arm cryogenic spectrographs covering the wavelength range 0.64μm-1.8μm, with a multiplex capability of over 1000 fibres. Each spectrograph will produce spectra for 500 targets simultaneously, each with its own dedicated sky fibre for optimal sky subtraction. The system will have both a medium resolution (R~4000-6000) mode and a high resolution (R~20000) mode.

The fibres are used to pick off each sub field of 1" and are used to transport the light from the instrument focal plane to the two spectrographs. Each fibre has a microlens to focus the beam into the fibre at a relative fast focal ratio of F/3.7 to reduce the Focal Ratio Degradation (FRD).

This paper presents the design of the fibre management module and describes the specific developments required to optimise its performances.

9912-190, Session P6

PEPSI-feed: Linking PEPSI to the Vatican-Advanced-Technology Telescope using a 450m long fiber

Daniel P. Sablowski, Leibniz-Institute for Astrophysics Potsdam (Germany); Michael Weber, Manfred Woche, Ilya V. Ilyin, Klaus G. Strassmeier, Leibniz-Institut für Astrophysik Potsdam (Germany)

Limited observing time at large telescopes equipped with the most powerful spectrographs, makes it almost impossible to gain long and dense time-series of observations. Ditto, high-time-resolution observations of bright targets with high signal-to-noise are not always possible with large telescopes. By pulling an optical fibre of 450 m in length from the Vatican-Advanced-Technology-Telescope (VATT) to the Large-Binocular-Telescope (LBT) to connect the Potsdam-Echelle-Polarimetric and Spectroscopic Instrument (PEPSI), allows to gain from the advantages of ultra-high resolution measurements on bright targets. This article presents the fibre-link in detail from the technical point-of-view as well as future plans and will also demonstrate it's performance by first observations.

9912-191, Session P6

Design of multi-motor distributed control system for optical fibers positioning based on CAN bus

Tiancheng Li, Yonggang Gu, Liang Guo, Chao Zhai, Univ. of Science and Technology of China (China)

In fiber spectroscopic telescopes, the real-time precise position measurement of the optical fibers is the key to track the stellar objects .CAN bus is a bus-based serial communication network which can support distributed control or real-time control effectively. As a kind of industry fieldbus, it is widely used among industry circle because of its outstanding reliability, real time and flexibility.

In the fiber positioning system, every fiber positioning node is driven by two stepping motors. According to the general structure of distributed control system, an overall scenario for multi-motor distributed control system based on CAN bus is given. Taking the integration CAN control chip as main controller, the hardware of CAN intelligent node and adapter is designed to be the bottom hardware platform for the whole system. Following the performance features and the technical specifications of CAN bus, the application layer protocol of CAN bus is set down on the basis of soft model for the intelligent node, including the assignment of message identifiers, the design of frame format, the method of data exchange and the mechanism of message filter. Besides, some software interfaces are designed, such as message sending and receiving, motor control and so on; the main function flow charts for intelligent node and adapter are given and the software designed for intelligent node and adapter is completed.

9912-192, Session P6

Optimal non-circular fiber geometries for image scrambling in high-resolution spectrographs

Julian Stürmer, The Univ. of Chicago (United States); Christian Schwab, Macquarie Univ. (Australia) and Australian Astronomical Observatory (Australia); Stephan Grimm, André Kalide, Leibniz-Institut für Photonische

Technologien e.V. (Germany); Andreas Seifahrt, The Univ. of Chicago (United States); Kay Schuster, Leibniz-Institut für Photonische Technologien e.V. (Germany); Jacob L. Bean, The Univ. of Chicago (United States); Andreas Quirrenbach, Landessternwarte Heidelberg (Germany)

Optical fibers are a key component for high-resolution spectrographs to attain high precision in radial velocity measurements. We present a custom fiber with a novel core geometry - a 'D'-shape.

From a theoretical standpoint, such a fiber should provide superior scrambling and modal noise mitigation since, unlike the commonly used circular and polygonal fiber cross sections, it shows chaotic scrambling. This difference is demonstrated by simulations. We report on the fabrication process of the test fiber, and compare the optical properties, scrambling performance and focal ratio degradation of the D-fiber with those of common polygonal fibers.

9912-193, Session P6

High numerical aperture multimode fibers for prime focus use

KaiYuan Zhang, Nanjing Institute of Astronomical Optics & Technology (China); Jessica R. Zheng, Will Saunders, Australian Astronomical Observatory (Australia)

Modern 8-10m class telescopes have prime focus speeds too fast for direct use with normal silica-cored fibers, which are limited to ~f/2.5. Specifically, the current design for the proposed Mauna Kea Spectroscopic Explorer telescope is f/1.97 . Micro-fore optics can be used to slow the beam, as for PFS on Subaru, but this adds cost, complexity and losses. A simpler alternative is offered by high Numerical Aperture (but still purely silica-cored) fibers, which are now available from multiple vendors. The results of throughput and focal ratio degradation (FRD) tests on two samples of these high NA fiber are presented, and also on normal NA fiber with identical other properties, for comparison. It is found that high NA fibers exhibit acceptable performance, but that all fibers suffer a progressive loss of throughput as the NA is approached.

FRD is caused by the light scattering in the fiber, micro-bend of fiber from the stress and the imperfection quality of the fiber end face. The glue between the cladding and ferrule, the ferrule diameter and the length of fiber all can influence the FRD performance of the fiber. In this paper, we investigated the FRD performance with different glues, ferrule sizes and fiber length conditions. It is also investigated the near field centroid movement at the output of fiber when the input beam is varied and moved across the input fiber core.

The experiment results are reported about the FRD performance of high NA fiber for MSE. The high NA fibers are obtained from both Polymicro Inc. and CeramOptec Inc. To test the FRD at different spatial frequency, the collimated beam is injected to the fiber at different angle. The far field distribution obtained by the CCD camera is a ring of different thickness at different input angle. There are two peaks for the beam profile across the ring center, and the half distance between the peaks is the incidence angle of the input collimated beam. The FWHM of the ring is the measured FRD, which is the angle increment of the output beam. By changing the glues, ferrule size and the length, we investigated how those variables influence the FRD performance for different input beam angle.

During the operation of the telescope, the input at the fiber is a converging beam. Hence, to simulate and test the real situation for the telescope working conditions of these fibers, we also use the converging beam to test the FRD performance for the high NA fiber. The point source microscope is used to generate the optical beam of different NA. For each NA, we take a series of images of the far field disk of the output beam at different positions. By calculating the diameter of 90% encircled energy of a series beam, we can precisely measure the output NA. By using different objective lens with the point source microscope, the FRD performance is also investigated.

The near field performance of high NA fibers is also investigated. It is found that there is no significant movement of the output near-field centroid when the fiber input angle is varied and the input beam moves across the input fiber core.

9912-267, Session P6

A 24mm diameter fibre positioner for spectroscopic surveys

Philipp Hörler, Luzius Kronig, Mohamed Bouri, Jean-Paul Kneib, Hannes Bleuler, Ecole Polytechnique Fédérale de Lausanne (Switzerland)

Since the beginning of the last century, Einstein's theory of general relativity has shaped our understanding of the evo-lution of the universe. Using the equations of Friedman-Lemaître and the data of many astronomical surveys, the model predicts that the expansion of the universe is slowing down asymptotically to zero due to the gravitational force between the matter. In 1998, the observation of 42 type Ia Supernovae has revolutionized our understanding of the history of the universe. The generally accepted view of a flat universe was proven wrong. The measurements show that the expansion of the universe is not slowing down but accelerating. In order to unify the theory of general relativity and the measured acceleration of the expansion of the universe, an additional term was added to the equation: Dark Ener-gy.

This revolution has motivated a lot of researchers of fundamental physics and astrophysics to confirm the accelerating expansion and to measure it precisely throughout the history of the universe using different techniques.

Ten years ago, observation of the spatial distribution of galaxies, allowed to develop a new technique for measuring the expansion of the universe: the measurement of baryonic acoustic oscillations.

The key is to measure the 3D position of a multitude of galaxies: about 30 million. As of today, we know the exact 3D position of only ~3 million galaxies. The last million was measured during the last 3 years. At this rate the goal of 30 million will be obtained at the end of this century.

In order to measure a high number of galaxies in a practical amount of time, we need to observe multiple objects in parallel. Instead of a mounting a spectrograph directly, thousands of optical fibres are placed in the focal plane of a telescope. Each fibre is positioned in the focal plane such that it gathers the light of a certain object and transmits it to a spectrograph. In this way each fibre represents a moving pixel and almost all the fibres can transmit science infor-mation and the spectrograph is used more efficiently.

Each fibre has to be positioned to several μm precision in the focal plane of a telescope for each exposure. Each fibre is positioned by a 2-axis fibre positioner. In this paper we present such a fibre positioner with 24-mm diameter and driven by two brushless DC motors in combination with a backlash free gearbox. 1000 positioners can be fitted in a ~800-mm diameter focal plane. The positioner has an optimal central fibre path and improved angular alignment. In fact, the fi-bre runs through the centre of the positioner and is only bent at the top in order to reach its target position. In this way, the flexion and torsion of the fibre is minimal. In addition to the very high positioning accuracy, the design is optimized to allow a minimal tilt error of the fibre. This is demonstrated using a novel optical tilt measurement system.

9912-194, Session P7

MEGARA: high-precision alignment system for gluing fibers and microlenses

Ana Pérez-Calpena, Ernesto Sánchez-Blanco Mancera, Ismael Martínez Delgado, María Luisa García Vargas, FRACTAL S.L.N.E (Spain); Xabier Arrillaga Echaniz, AVS Added Value Industrial Engineering Solution S.L.U. (Spain); Hervé Aubé, SEDI-ATI Fibres Optiques (France); Armando Gil de Paz, Univ. Complutense de Madrid (Spain); Manuel Maldonado Medina, FRACTAL S.L.N.E (Spain); Jesús Gallego Maestro, Univ. Complutense de Madrid (Spain); Jorge Iglesias-Páramo, Instituto de Astrofísica de Andalucía (Spain); Esperanza E. Carrasco Licea, Instituto Nacional de Astrofísica, Óptica y Electrónica (Mexico); Francisco Manuel Sánchez-Moreno, Univ. Politécnica de Madrid (Spain); José M. Vílchez Medina, Instituto de Astrofísica de Andalucía (Spain); Raquel Cedazo, Univ. Politécnica de Madrid (Spain)

MEGARA (Multi Espectrógrafo en GTC de Alta Resolución para Astronomía) is the future optical Integral-Field Unit (IFU) and Multi-Object Spectrograph (MOS) for the 10.4-m Gran Telescopio CANARIAS (GTC). MEGARA will offer two different observing modes, the Large Compact Bundle (LCB) mode, an Integral Field Unit (IFU) composed by 567 fibers covering 12.5" x 11.3" on the sky and a Multi-Object Spectroscopy (MOS) mode that will allow observing 92 objects in a region of 3.5' x 3.5' around the LCB IFU. The MOS mode is composed of the robotic positioners carrying a minibundle of 7 fibers that covers a circular area of 1.6" diameter on the sky. Eight mini-bundles will observe sky during the observations with the LCB for calibration purpose.

The MEGARA focal plane subsystems will be located at the GTC Folded Cassegrain F (FC-F) focal station. The MEGARA optical components at the focal station are a field lens to provide telecentricity correction, the micro-lenses arrays to couple the telescope beam to the collimator focal ratio at the entrance of the fibers and the fiber bundles, to conduct the light from the FC-F to the pseudo-slit plates at the MEGARA spectrograph, placed at Nasmyth–A platform.

The microlens arrays shall define the FOV to be introduced in the fibers, adapting F# from f/17 (GTC telescope) to f/3 (Fibers) to minimize FRD and to provide a telescope pupil image on the 100?m fiber core. The spaxel size is 0.62 arcsec oversizing the pupil image and finding a compromise to optimize the following parameters: a) the flux recovered from point sources with each MEGARA MOS mini-bundle, b) the fraction of lost light when reimaging the pupil on the fiber core, c) the need of fully imaging the fiber core in order to preserve the quality of the fiber-to-fiber relative-flux calibration and d) the differential atmospheric refraction effects that has to be minimized.

The fraction of pupil imaged shall have a variation less than 10% from fiber to fiber. This requirement yields a 10 ?m tolerance for positioning the pupil image on the fiber core.

A detailed error budget was prepared for deriving the manufacturing tolerances of the frames supporting the fibers, the microlens diameters and positions at the array, the external fiber diameters, the positioning accuracy of the robotic positioner and, the performance of the gluing system between fiber and microlens, which must achieve a centering precision better than 5μm.

This article gives an overview of the MEGARA Fiber Bundles and presents the gluing system between fibers and microlens arrays developed for the MEGARA project to provide the alignment precision and the resulted performance measured during the real integration and verification phase.

9912-195, Session P7

Shock and vibration testing of digital micromirror devices (DMDs) for space-based applications

Dmitry Vorobiev, Anton Travinsky, Alan D. Raisanen, Zoran Ninkov, Rochester Institute of Technology (United States); Timothy A. Schwartz, NASA Goddard Space Flight Ctr. (United States); Massimo Robberto, Space Telescope Science Institute (United States); Sara R. Heap, NASA Goddard Space Flight Ctr. (United States)

One of the key goals of NASA's astrophysics program is to answer the question: How did galaxies evolve into the spirals and elliptical galaxies that we see today? A space mission concept called Galaxy Evolution Spectroscopic Explorer (GESE) was developed to address this question by making a large spectroscopic survey of galaxies at redshift z~1-2 (8-10 billion years lookback). A multi-object spectrometer based on a digital micromirror device (DMD) was designed for this mission. A DMD is an array of micromirrors which can be addressed individually and tilted into one of two states (+/- 12° w.r.t. the device plane), which makes it a very versatile binary light modulator. A Texas Instruments Cinema DMD (with approximately 2,000 rows of pixels in the cross-dispersion direction) can be used to obtain spectra from hundreds of point sources, simultaneously. GESE is designed to obtain spectra of approximately 100 galaxies per exposure (which is the number of galaxies in the field of view, bright enough to achieve S/N = 6, or better). Recently, the use of DMDs for ground-based multi-object spectrometers (MOS) has been demonstrated. The compact size and small weight of DMDs makes them especially attractive for a space-based MOS, where the only current alternative is an array of microshutters. DMDs were originally designed for visible range applications; therefore the protective glass window they are supplied with does not have sufficient throughput in the UV and has to be replaced. As part of a larger effort to investigate the use of DMDs in space telescopes (sponsored by a NASA Strategic Astrophysics Technologies grant), we developed a procedure to replace the DMD window and performed vibration and shock testing on Texas Instruments DMDs. In this work, we describe the procedure by which we replaced the standard window with UV-grade fused silica, sapphire and magnesium fluoride. We performed initial shock and vibrational tests to evaluate the mechanical robustness of the re-windowed devices to investigate the ability of these devices to survive the expected vibrational and shock loads endured in the launch phase (using typical parameters for a Falcon 9 launch). Furthermore, we performed residual gas analysis to study the outgassing properties of the new DMDs and evaluate the ability of the new seals to protect the device.

9912-196, Session P7

Development of an optical device "Field Stacker" for achieving accurate photometry in ground-based mid-infrared observations

Masahito S. Uchiyama, Takashi Miyata, Takafumi Kamizuka, Shigeyuki Sako, Ryou Ohsawa, Kazushi Okada, Kiyoshi Mori, Jumpei Yamaguchi, The Univ. of Tokyo (Japan); Kentaro Asano, Japan Aerospace Exploration Agency (Japan); Mizuho Uchiyama, National Astronomical Observatory of Japan (Japan)

Time-variation in atmospheric transmittance is a serious problem in ground-based mid-infrared observations. It degrades photometric accuracy and makes monitoring observations difficult. To improve the photometric accuracy, science and calibration objects should be observed simultaneously to compensate the time-variation in atmospheric transmittance. However such kind of observations cannot be practically conducted since a field of view is small and a number-density of bright objects is low in mid-infrared wavelength range.

To overcome this problem, we have developed a new optical device, "Field Stacker". It is an optical system mounted just before the entrance window of the MIMIZUKU (Kamizuka et al. 2014), which is a mid-infrared instrument for the TAO 6.5-m telescope (Yoshii et al. 2014). The Field Stacker is composed of two pick-up mirrors, one combining mirror, and three types

of moving stages (tilt stages, linear stages, and rotating stages). All components are placed at room temperature. The pick-up mirrors are moved by the moving stages and fetch two arbitrary fields from the TAO 6.5-m telescope's wide FoV (25 arc-minutes in diameter). The two fields are merged by the combining mirror and focused onto a single detector. By observing science and calibration objects simultaneously, the MIMIZUKU equipped with the Field Stacker will enable mid-infrared observations with a high photometric accuracy based on real-time calibration.

A requirement of photometric accuracy for achieving our science goals is 1%. There are two important points to be concerned. The first one is the position accuracy of the pick-up mirrors. The error in the angle of the pick-up mirror affects the system throughput. Since the photometric accuracy depends on the throughput ratio between the two fields, the tilt error degrades the photometric accuracy. Tilt errors are caused by the tilt stages and the linear stages. We measured tilt errors of each stage and confirmed that the tilt errors are small sufficiently to achieve the requirement. The second one is spatial variation in atmospheric transmittance. Since the spatial distribution of atmospheric transmittance in arc-minute scale is not well understood, we estimated the fine arc-minute scale spatial variation in atmospheric transmittance by analyzing a mid-infrared background flux variation, which traces the variation in the atmospheric transmittance. The flux data were taken by the MAX38, which is a mid-infrared instrument for the miniTAO 1-m telescope located in the same site as the TAO 6.5-m telescope.

In addition, we prepare a list of the calibration sources available for the Field Stacker and estimate the sky coverage where the Field Stacker functions successfully. Red super giants are good candidates for the calibration sources because normal stars are too faint in the mid-infrared. Red super giants are enough bright for ground-based mid-infrared instruments, and flux variability in red super giants is sufficiently small. We are investigating the distribution of the calibration sources using infrared all sky catalogs (AKARI, WISE, etc.).

The Field Stacker will be put to practical use by the MIMIZUKU which is commissioned in 2016. In this paper, the current development status of the Field Stacker will be presented.

9912-197, Session P7

Multi-resolution waveguide image slicer for the PEPSI instrument

Erik Beckert, Fraunhofer-Institut für Angewandte Optik und Feinmechanik (Germany); Klaus G. Strassmeier, Manfred Woche, Leibniz-Institut für Astrophysik Potsdam (Germany); Gerd Harnisch, Marcel Hornaff, Fraunhofer-Institut für Angewandte Optik und Feinmechanik (Germany); Michael Weber, Leibniz-Institut für Astrophysik Potsdam (Germany)

A waveguide image slicer for the LBT's PEPSI instrument was successfully developed and tested. It comprises of three different slicers that serve for the theoretical 43k, 120k and 270k resolutions of the spectrograph, incorporating in between 7x 70μm, 5x 175μm and 3x 500μm single waveguides that couple light from the telescope fibers (100 μm, 200 μm and 300 μm core), slice the images and re-project them into the slit of the spectrograph. Each type of slicer is manufactured from thin glass sheets of the respective thickness that are bonded together by an index matching adhesive (n=1.42) that serves for total internal reflection within the thin glass of D263T (n=1.5233) when coupling into it using the NA of the telescope fibers. The adhesive bonding layer is kept at a minimum of ca. 3..4μm between every thin glass slice to allow for a highest filling ration of waveguiding structures within the cross section of the slicer. The quadratic and best fiber diameter matching cross sections of the bonded waveguide stacks are realized by precision micromachining using grinding and polishing, total internal reflection then is also realized at the sides of the thin glass waveguides by bonding cover plates there using the same index matching adhesive. Anti-reflection coatings on windows at the entrance and the output of the image-slicers are used for minimal losses, the throughput of each image-slicer is ca. 92%. All image-slicers are integrated on one common substrate, allowing for an easy handling of this highly complex and miniaturized optical unit during alignment within the spectrograph.

Each individual waveguide slice is of different length, the distal end is polished under an angle of 45° and coated with protected silver. Thus, light exits the slicer at an angle of 90° with respect to the fiber entrance and with a spatial offset pitch of the sliced light. Because all three resolution modes are filling the slit CCD to a full extent, the slicer stack separation for all fiber cores in the focal plane of the collimator are the same. The ultra high resolution mode is using the smallest of the three fiber cores, the 100 μm fiber with a 0.74?? entrance aperture on the sky. It is sliced 7 times, reaching the practical limit due to the available space on the CCD detector.

9912-198, Session P7

Opto-mechanical design of an image slicer for the GRIS spectrograph at GREGOR

Nauzet Vega Reyes, Miguel Estéves, Instituto de Astrofísica de Canarias (Spain); Yves Salaun, Winlight Optics (France); Ariadna Z. Calcines, Durham Univ. (United Kingdom) and Instituto de Astrofísica de Canarias (Spain); Jorge Sánchez Capuchino, Roberto L. López, Christine Grivel, Manuel Collados Vera, Instituto de Astrofísica de Canarias (Spain)

GRIS is the spectrograph installed at the 1.5m Ø GREGOR telescope. It was initially designed to operate in a standard long-slit configuration together with the TIP polarimeter for high-spatial high-sensitivity spectropolarimetric observations. As a part of the SOLARNET project, an image slicer has been recently designed to make possible the simultaneous measurement of all points in a 2D field of view, as a prototype of the MuSICa integral field unit for the European Solar Telescope.

The general approach to upgrade GRIS consists in making removable the upper part of the instrument (which includes the long slit, the polarimeter and a folding mirror that sends the light to the floor below in the building, where the collimator and camera mirrors of the spectrograph are located) by mounting it on a removable bench called "SLIT bench" and inserting in its place the "IFU (Integral Field Unit) bench" for the 2D mode. Special tight requirements were derived from the small free room available at the spectrograph entrance to locate all the necessary optical and mechanical elements.

The IFU is composed of a slicer block, an array of collimator mirrors and an array of camera mirrors. With this optical setup, an input 2D field of view of 6.75" x 3" of the solar image will be cut and aligned to produce a single slit of 54" x 0.375" at the entrance of the spectrograph GRIS. This subsystem is currently being manufactured by Winlight optics, within the framework of the SOLARNET project. A specific mount for the IFU has been designed to ensure thermal stability and keep its nominal. Rotation adjustments around three axis are adjusted separately with a resolution better than 50". The rotation point is placed at the center of the IFU output slit, with a displacement error less than 20 microns.

A field-of-view scanning system has been designed to make possible the illumination of the IFU by different parts of the solar image produced by the telescope. This field-of-view scanning system is coupled to the IFU by means of an appropriate reimaging subsystem, composed of two identical spherical mirrors, RS1 and RS2. While scanning, the light beam goes towards RS1 with an error under 5 microns in position and 50" in angle. The distance between the entrance window and RS1 is constant to keep the system in focus, independently of the entrance window position.

To optimize mounting/dismounting and alignment operations, the long-slit and IFU configurations are based on two different interchangeable

plates positioned through kinematic contacts fixed on the main GREGOR instrument bench. Both plates will be integrated and aligned separately, firstly in laboratory and finally at GREGOR in real conditions.

This paper describes the opto-mechanical IFU bench and all the optical and mechanical components that lie on it, which will permit to validate the image slicer concept for 2D solar spectropolarimetry of EST.

9912-199, Session P7

Performance estimates for spectrographs using photonic reformatters

Robert J. Harris, Ruprecht-Karls-Univ. Heidelberg (Germany); Lucas Labadie, Univ. zu Köln (Germany); Ulrike Lemke, Georg-August-Univ. Göttingen (Germany); David G. MacLachlan, Robert R. Thomson, Heriot-Watt Univ. (United Kingdom); Sabine Reffert, Landessternwarte Heidelberg (Germany); Andreas Quirrenbach, Ruprecht-Karls-Univ. Heidelberg (Germany)

As the demands for stability and precision placed upon high resolution spectrographs increase, instrument designers are forced to make improvements and address errors in new areas. One such area is modal noise, which occurs due to the changing spatial distribution of light at the output end of the fibre. This results in uncertainties in the positions of the resulting wavelength on the detector, and uncertainties in radial velocity measurements.

Modal noise becomes more of a problem as instruments move from the visible to the Near Infra-Red (NIR). This wavelength range is of particular interest to the astronomers, both to characterize stellar activity and search for planets around smaller cooler stars.

As the wavelength increases the number of modes within the science fibre decreases, increasing statistical uncertainties. In addition, laser frequency combs, the current state of the art stabilization method, are fed from a single mode fibre. When these are coupled into multimode fibres the modal pattern can vary, resulting in further errors.

The effects of modal noise can be mitigated using fibre scramblers, fibre agitators and different core geometries such as square and octagonal fibres. However, if these are not properly implemented they can still lead to incomplete scrambling, leaving residual uncertainties due to modal noise in radial velocity measurements.

A device that could remove conventional modal noise is a photonic reformatter. This device first uses a photonic lantern to sample the mulitmode PSF from a telescope. This light is then split into many individual modes, which are then reformatted using an Ultrafast laser inscribed chip.

Very similar in concept to a conventional image slicer, the resultant slit is single moded in one axis and multimoded in the other. By dispersing across the single moded axis and then summing the resultant spectra in the multimode axis, the uncertainties due to modal noise are removed, whilst retaining throughput.

This comes at a price however. Though the modal noise is removed, the reformatting of the modes can result in extra pixels being required to sample the spectra at the detector. In turn this will increase detector and read noise. Thus it is important to minimize the number of modes and know which regimes where using photonic instruments will result in higher signal to noise and hence stability than a conventional instrument.

To evaluate this, we will theoretically derive achievable radial velocity measurements to compare photonic instruments and conventional ones. Along with these results we will include ways of making photonic devices more competitive, by changing how the output spectra are sampled. We will discuss the theoretical and experimental investigations that will need to be undertaken to optimize and prove the photonic reformatting concept. We will also discuss the potential problems and solutions that may arise with the use of a photonic reformatter.

9912-201, Session P7

Collimating slicer for optical integral field units

Florence Laurent, Observatoire de Lyon (France); François B. Hénault, Institut de Planétologie et d'Astrophysique de Grenoble (France) and Univ. Joseph Fourier (France) and CNRS (France)

The development of a Collimating Slicer is to propose a new type of optical integral field unit which should be more compact. The main idea is to combine the image slicer with the collimator of the spectrograph. The traditional combination of slicer, pupil and slit elements and spectrograph collimator is replaced by a new one composed of a slicer and spectrograph collimator only. After testing few configurations, this new system looks very promising for low resolution spectrographs.

In this paper, the state of art of integral field units using image slicers will be described. The new system based onto the development of a Collimating Slicer for optical integral field units will be depicted. First system analysis results and future improvements will be discussed.

9912-202, Session P7

Spectral slicing for METIS: an efficient alternative to cross-dispersion

Martyn Wells, Stephen Todd, Alistair C. H. Glasse, Jonathan Strachan, UK Astronomy Technology Ctr. (United Kingdom)

Image slicing integral field units were developed to provide spatially resolved spectroscopy over a two dimensional field of view. Spectral slicing applies similar design principles to provide an alternative to cross-dispersion. A slicing mirror placed at the output from a low resolution spectrometer, or pre-disperser system, can be used to select specific spectral ranges within the overall spectrum. As in an image slicing IFU, these slices can then be reformatted to form an input slit for a high resolution spectrometer.

The key benefit over cross dispersion is the greatly increased flexibility in selecting wavelength ranges within the overall spectrum, and control over how these sub-bands are positioned on the detector, allowing a more efficient use of detector space.

We will describe the design of a deployable spectral slicing mode as part of the METIS LM-band high resolution spectrometer. In this system the spectral slicing mode can optionally be deployed to allow increased wavelength coverage at the expense of observing a smaller area on the sky.

9912-203, Session P7

A trial production of a large format image slicer unit for a possible future mid-infrared instrument on the TMT

Itsuki Sakon, The Univ. of Tokyo (Japan); Yuji Ikeda, Photocoding (Japan); Hiroyuki Nakagawa, Crystal Optics Inc. (Japan); Mitsuhiko Honda, Kurume Univ. (Japan); Yoshiko K. Okamoto, Ibaraki Univ. (Japan); Hirokazu Kataza, Institute of Space and Astronautical Science (Japan) and Japan Aerospace Exploration Agency (Japan); Mark R. Chun, Univ. of Hawai'i (United States); Matthew J. Richter, Univ. of California, Davis (United

States); Christopher Packham, The Univ. of Texas at San Antonio (United States)

While the future space-based mid-infrared instruments will achieve the highest sensitivity and can target the faintest dusty structures extended more than several tens arcsec, a possible future mid-infrared instrument on the TMT with MIRAO opens up, for the first time, a new window to investigate the spectral variations among sub-arcsecond scale' structures of dust and gas in the mid-infrared. For example, Galactic nearby (< a few kpc) stellar sources of various stellar evolutionary stages and of various main sequence masses offer unique laboratories to investigate the life cycle of dust and gas in circumstellar environments. Those targets will be much more efficiently observed with the Integral Field Unit (IFU) spectroscopy having the FOV size of a few arcseconds by a few seconds rather than with the long slit spectroscopy having a few tens arcsecond's slit length. Facing on a growing demand of IFU spectroscopic capability in the mid-infrared for the TMT, we have carried out the trial production of large-format image slicer unit for the MICHI, a possible future TMT instrument, aiming to verify its technical feasibility. The key elements in our trial production are the monolithic large-format slice mirrors and the monolithic large-format pupil mirrors. The trial production piece of the monolithic large-format slice mirrors is designed to have 11 narrow mirrors (a thickness of 186μm), each of which has an angle offset between the neighboring mirrors by 2.4 degree against the incoming light. It has been produced from a single RSA6061 T6 aluminum block using ultra high-precision cutting machine with a single crystal diamond bite. The trial production piece of the monolithic large-format pupil mirrors is designed to have 11 spherical pupil mirrors and is produced from a single aluminum block. The results of our trial production of those key elements based on the ultra high-precision cutting techniques, the assembly of the large-format image slicer unit, the quality of pseudo slit image obtained by our trial production image slicer unit are described in this paper.

9912-268, Session P7

Measurements of the reflectance, contrast ratio, and scattering properties of digital micromirror devices (DMDs)

Dmitry Vorobiev, Anton Travinsky, Rochester Institute of Technology (United States); Manuel A. Quijada, NASA Goddard Space Flight Ctr. (United States); Zoran Ninkov, Alan D. Raisanen, Rochester Institute of Technology (United States); Massimo Robberto, Space Telescope Science Institute (United States); Sara R. Heap, NASA Goddard Space Flight Ctr. (United States)

Digital micromirror devices (DMDs) are micro-electro-mechanical systems, originally developed to display images in projector systems. A DMD in the focal plane of an imaging system can be used as a reprogrammable slit mask of a multi-object spectrometer (MOS) by tilting some of the mirrors towards the spectrometer and tilting the rest of the mirrors away, thereby rejecting the unwanted light (due to the background and foreground objects). A DMD-based MOS can generate new, arbitrary slit patterns in seconds, which significantly reduces the overhead time during astronomical observations. Critically, DMD-based slit masks are extremely lightweight, compact and mechanically robust, which makes them attractive for use in space-based telescopes. As part of a larger effort to investigate the use of DMDs in space telescopes (sponsored by a NASA Strategic Astrophysics Technologies grant), we characterized the optical performance of Texas Instruments DMDs to determine their suitability for use in multi-object spectrometers. The performance of a DMD-based MOS is significantly affected by its optical throughput (reflectance), contrast ratio (the ability of the DMD to reject unwanted light) and scattering properties (which could lead to crosstalk and reduced signal-to-noise ratio in the spectrometer). We measured and quantified the throughput and contrast ratio of a Texas Instruments DMD in several configurations (which emulate the operation of a typical DMD-based MOS) and investigated the scattering properties of the individual DMD mirrors. In this work we present the results of our analysis, describe the performance of a typical DMD-based MOS and discuss the practical limitations of these instruments (such as maximum density of sources and expected signal-to-noise ratio). This study is part of a new space mission concept, the Galaxy Evolution Spectroscopic Explorer (GESE), a multi-object spectroscopic survey in the ultraviolet (200 nm – 400 nm) regime.

9912-269, Session P7

Optical evaluation of digital micromirror devices (DMDs) with UV-grade fused silica, sapphire, magnesium fluoride windows and long-term reflectance of bare devices

Manuel A. Quijada, NASA Goddard Space Flight Ctr. (United States); Anton Travinsky, Dmitry Vorobiev, Zoran Ninkov, Alan D. Raisanen, Rochester Institute of Technology (United States); Massimo Robberto, Space Telescope Science Institute (United States); Sara R. Heap, NASA Goddard Space Flight Ctr. (United States)

Digital micromirror devices (DMDs) are commercial micro-electro-mechanical systems, consisting of millions of mirrors which can be individually addressed and tilted into one of two states (+/- 12°). These devices were developed to create binary patterns in video projectors, in the visible range. Commercially available DMDs are hermetically sealed and extremely reliable. Recently, DMDs have been identified as an alternative to microshutter arrays for space-based multi-object spectrometers (MOS). Specifically, the MOS at the heart of the proposed Galactic Evolution Spectroscopic Explorer (GESE) uses the DMD as a reprogrammable slit mask. Unfortunately, the protective borosilicate windows limit the use of DMDs in the UV and IR regimes, where the glass has insufficient throughput. In this work, we present our efforts to replace standard DMD windows with custom windows made from UV-grade fused silica, UV-grade sapphire and magnesium fluoride. We present transmission measurements of the antireflection coated windows and the reflectance of the re-windowed DMDs. Furthermore, we investigated the long-term stability of the DMD reflectance, once the protective window has been removed.

9912-270, Session P7

Heavy-ion radiation testing of digital micromirror devices (DMDs)

Anton Travinsky, Dmitry Vorobiev, Rochester Institute of Technology (United States); Jonathan Pellish, NASA Goddard Space Flight Ctr. (United States); Zoran Ninkov, Alan D. Raisanen, Rochester Institute of Technology (United States); Massimo Robberto, Space Telescope Science Institute (United States); Sara R. Heap, NASA Goddard Space Flight Ctr. (United States)

We present the results of heavy ion radiation testing of a digital micromirror device (DMD). A DMD is an array of micromirrors which can be addressed individually and positioned into one of two states, which makes the device a very versatile binary light modulator. DMDs are utilized in a variety of optical systems, especially projection systems. Recently, the use of DMDs for ground-based multi-object spectrometers (MOS) has been demonstrated. The compact size and small weight of DMDs makes them especially attractive for a space-based MOS, where the only current alternative is an array of micro shutters. As part of a larger effort

to investigate the use of DMDs in space telescopes (sponsored by a NASA Strategic Astrophysics Technologies grant), we performed radiation testing of Texas Instruments DMDs. Specifically, we investigated the suitability of DMDs for a new space mission concept, the Galaxy Evolution Spectroscopic Explorer (GESE). The orbit of the mission lies in deep space; therefore the DMDs used in the GESE MOS must be tolerant of cosmic rays. Earlier we presented the DMD's performance under accelerated proton radiation and in this work we present the results of accelerated heavy ion irradiation testing of the DMDs (with the control electronics shielded from radiation). Specifically, the testing focused on the detection of single-event effects (SEEs) including latch-up events. We present the results of testing with a range of different ions and calculated predictions for interplanetary space performance. In general, we found that DMDs are sensitive to non-destructive ion-induced state changes; however all SEEs were cleared with a soft reset (that is, sending a new pattern to the DMD). Our results suggest that an instrument exposed to background galactic cosmic rays in interplanetary space would experience a manageable single-event effect rate burden. During the testing the DMD did not experience single-event induced permanent damage or functional changes that required a hard reset (power cycle), even at high ion fluences.

9912-204, Session P8

How to achieve ultra-clean detectors and cryostats at astronomical instruments: measures to avoid contamination and dust at CCD detectors

Sebastian Deiries, Jean-Louis Lizon, Olaf Iwert, European Southern Observatory (Germany)

ESO (European Organisation for Astronomical Research in the Southern Hemisphere) developed in its detector laboratory a complete and comprehensive routine to achieve ultra-clean detectors with lasting effect which is given in detail in this paper: This is also a summary of ESOs achievements in this field over the last decades.

Only special suited materials are used for detector cryostats. After manufacturing they undergo some new surface treatments and processes and then are washed in ultrasonic baths with anti-corrosive soap or alcohol. After this all parts are baked to its maximum temperatures in very clean vacuum ovens. A final step would be the plasma cleaning of individual and also completely integrated and even closed detector vessel systems.

All handling and the complete integration is done in clean room environments of class 5

Before its integration the detectors are thoroughly inspected for particles and contaminations and If needed some new non-destructive methods e.g.: vapour cleaning are used for its removal.

Only after this the detectors are cooled down and operated. Then special routines of dust monitoring (pseudo FF dust counting, UV QE telescope on-side characterizations) can be taken as a contamination control over years. This is also added to the routine detector characterization beforehand in the head quarters laboratories..

The new approach is, that this final contamination control routine can be repeated after years of operation at the telescope site.

With all these in detail explained steps ultra-clean detectors are achieved which also do not degrade even after years of operation at the telescope sites.

After long years of experience ESO therefore guarantees to provide the astronomical community with very (long lasting) clean detectors at all its astronomical instruments.

9912-205, Session P8

The development of a cryogenic FTIR system for measuring very small attenuation coefficients of infrared material

Sayumi Kaji, Kenshi Nakanishi, Kyoto Sangyo Univ. (Japan); Yuki Sarugaku, The Univ. of Tokyo (Japan); Yuji Ikeda, Kyoto Sangyo Univ. (Japan) and Photocoding (Japan); Naoto Kobayashi, The Univ. of Tokyo (Japan); Sohei Kondo, Hideyo Kawakita, Kyoto Sangyo Univ. (Japan)

The high-resolution spectroscopy (?/?? > 20,000) in 2 – 20 ?m region is an important window for astrochemistry and astrobiology because we can access numerous ro-vibrational transitions of all kinds of molecules including those with zero permanent electronic dipole moment, which can never been observed in the radio region. However, it is technically difficult to realize high-resolution spectrographs for 30 m ground-based telescopes or space crafts because the spectrograph size becomes larger in proportion to the diameter of telescope for slit-limited spectroscopy or in proportion to the wavelength for diffraction-limited spectroscopy. Immersion grating can solve this issue by downsizing the spectrograph without any degradation of the spectral resolution. To realize a high-efficiency immersion grating for astronomy, the transmittance of material is essential because the typical optical path length in the immersion grating becomes greater than 100 mm, resulting in a significant degradation of the total efficiency even with a very small attenuation (the total energy loss of ~10% is expected for a Ge immersion grating with the attenuation coefficient of ?_att = 0.01 cm^-1 for the spectral resolution R = 100,000 at ? = 8 ?m). Therefore, we have started a project to quantitatively determine attenuation coefficients of various infrared materials applicable to immersion gratings with high-accuracy down to < 0.001 cm^-1. We have already reported the attenuation coefficients at the room temperature for the single-crystal Si, the single-crystal Ge, the CVD-ZnS, the CVD-ZnSe, and the high-resistivity single crystal CdZnTe (Ikeda et al. 2009 and Kaji et al. 2014). However, since the band gap and the edge of the lattice vibration band could slightly shift at the cryogenic temperatures, it is also inevitable to determine the attenuation coefficients at the cryogenic temperature for astronomical applications.

For these measurements, we developed a cryogenic FTIR system by adding a compact cryostat to the existing FTIR used for measuring transmittances at the room temperature. The volume of the cryostat is 315 mm (L) x 240 mm (W) x 270 mm (H), and the weight is about 28 kg including the cold-head of GM-cycle mechanical cooler. It is installed into the collimated beam of the FTIR system, and has two KBr entrance/exit windows with the clear aperture of 28 mm and the thickness of 8 mm. The samples can be cooled down to 20 K in this cryostat. Since we determine the accurate attenuation coefficient by comparing the transmittances between two samples made of same material with different thickness, they are required to be switched with good repeatability without any vacuum leak or temperature change. To meet with this requirement, we employ a linear-motion-feedthrough and a linear-motion-guide as a switcher of two samples. The linear-motion-guide can be stopped at fixed positions with a good repeatability by the grooved guide-wall that catches a roller plunger mounted on the side of the sample base plate. In this paper, we present the details of this cryogenic FTIR system, and report preliminary measurement results of some infrared materials under the cryogenic condition.

9912-206, Session P8

EUCLID near infrared spectro-photometer optical assembly (NI-OA) gluing interface ?qualification and gluing process development

Amir Mottaghibonab, Hans D. Thiele, Elena Gubbini, Maximilian Dubowy, Csaba Gal, Ahmad Mecsaci, Karina Gawlik, OHB-System AG (Germany); Frank U. Grupp, Univ.-Sternwarte München (Germany); Carolin Wimmer, Daniela Penka, Max-Planck-Institut für extraterrestrische Physik (Germany); Ralf Bender, Univ.-Sternwarte München (Germany) and Ludwig-Maximilians-Univ. München (Germany)

The Near Infrared Spectro-Photometer Optical Assembly (NI-OA) of EUCLID satellite project requires high-precision large lens holders with different lens materials. The aspherical-lenses are glued into their separate lens holder. The gluing of the lenses in their mounts with 2K-epoxy is selected as bonding process to minimize the stress in the lenses to achieve the required surface form error (SFE) performance (32nm) and lens position stability (±10μm) due to glue-shrinkage. Adhesive shrinkage stress occurs during the glue curing at room temperature and operation in cryogenic temperatures, which might overstress the lens, cause lens breakage or failure of the gluing interface.

The selection of the suitable glue and required bonding parameters, design and qualification of the gluing interface, development and verification of the gluing process was a great challenge because of the low TRL and heritage of the bonding technology. The different material combinations (CaF2 to SS316L and CuCr1Zr, LF5G15 and S-FTM16 to Titanium, SUPRASI3001 to Invar M93 and Nickel-Phosphor (NiP) coated Invar 36), large diameter (168mm) and thin edge of the lenses, cryogenic non-operational temperature (100K) and high-performance accuracy of the lenses were the main design driver of the development. The different coefficients of thermal expansion (CTE) between lens and lens mount produce large local mechanical stress. As hygroscopic crystal is calcium fluoride (CaF2) very sensitive to moisture, why an additional surface treatment of the gluing area is necessary.

Extensive tests e.g glue handling and single lap shear tests are performed to select the suitable adhesive. Interface connection tests are performed to verify the feasibility of selected design (double pad design), injection channel, the roughness and treatment of the metal and lens interfaces, glue thickness, glue pad diameter and the gluing process. CTE and dynamic measurements of the glue, thermal cycling, damp-heat, connection shear and tension tests with all material combinations at RT and 100K are carried out to qualify the gluing interface. The gluing interface of the glued lenses in their mounts is also qualified with thermal cycling, 3D coordinate measurements, Polarimetry and vibration test of the lens assemblies.

A multi-function double pad gluing tool and lens mounting tool is designed, manufactured and verified to meet the lens positioning and alignment performance of the lens in the holder which provides the possibility to glue lenses, filters, mirrors with different diameters, shapes and thickness with ±10μm accuracy in plane, out of plane and ±10 arcsec in tip/tilt with respect to the lens holder interface.

The paper presents the glue interface qualification results, the qualification/verification methods, the developed ground support equipment and the gluing process of the EUCLID high precision ?large cryogenic lens mounts. Test results achieved in the test campaign demonstrate the suitability of the selected adhesive, glue pad design, interface parameters and the processes for the precise gluing of the lenses in lens holders for all lenses. The developed process can also be used for other glass materials e.g. MaF2 and optical black coated metallic surfaces.

9912-207, Session P8

Final design of the Grism cryogenic mount for the Euclid-NISP mission

Christelle Rossin, Lab. d'Astrophysique de Marseille (France) and Observatoire de Physique du Globe de Clermont-Ferrand (France); Anne Costille, Amandine Caillat, Sandrine Pascal, Patrice Sanchez, Benjamin Foulon, Sébastien Vives, Lab. d'Astrophysique de Marseille (France); Lorenzo Zavattini, Andrea Moroni, Paolo Radaelli, CGS S.p.A. Compagnia Generale per lo Spazio (Italy)

The Euclid mission selected by ESA in the Cosmic Vision program is dedicated to understand dark energy and dark matter. One of the probes based on detection of Baryonic Acoustic Oscillations required the redshift measurement of millions of galaxies. This massive spectroscopic survey relies on the Near Infrared Spectro-Photometer (NISP) using grisms (for "grating prisms") allowing slitless spectroscopic mode. In this context, we designed a cryogenic mount for the four grisms which will be mounted together on a rotated wheel. This mount has to maintain optical performances and alignment at cryogenic temperature (130K) and to survive launch vibrations. Due to a very small mass and volume budget allowed to the Grism Wheel Assembly, our design relies on a weight relief Invar ring glued to the grism by tangential blades. Tangential blades have the advantage of small height but the drawback of less decoupling capabilities than bipods. First of all, we will present the final design of the grisms, and secondly the thermal and vibration tests (done in spring 2015) to successfully qualify the Grism Engineering Model in the Euclid space environment. In addition, the detailed Finite Element Analyses for the Flight Models will be presented, correlated to test results when possible, including random coupled analyses of the grisms on the complete wheel assembly and analysis of the impact of the interface preloads on the grism behavior.

CARMENES: NIR channel spectrograph cooling system AIV, thermo-mechanical performance of the instrument

Santiago Becerril, Instituto de Astrofísica de Andalucía - CSIC (Spain)

CARMENES is the new high-resolution high-stability spectrograph built for the 3.5m telescope at the Calar Alto Observatory (CAHA, Almería, Spain) by a consortium formed by German and Spanish institutions. This instrument is composed by two separated spectrographs, VIS channel (550-1050 nm) and NIR channel (900-1700 nm). The NIR-channel spectrograph's responsible is the Instituto de Astrofísica de Andalucía, IAA-CSIC. The channel has been manufactured, assembled, integrated and verified in the last two years. It was delivered to the observatory in fall 2015, and commissioned in December 2015. The expected performances comply with the scientific requirements and its science verification started.

One of the most challenging systems in the instrument involves the Cooling System of the NIR channel. Due to the highly demanding requirements applicable in terms of stability, the NIR Cooling System arises as one of the core systems to provide outstanding stability in cryogenic conditions (working temperature: 138K) to the NIR channel. Really at the edge of the state-of-the-art of the instrumentation so far applied to astrophysics, the CARMENES-NIR channel Cooling System is able to provide to the cold mass (1 Ton approx.) better thermal stability than few hundredths of degree within 24 hours, even achieving an astonishing goal of 0.01K per day.

The present paper describes the Assembly, Integration and Verification

phase (AIV) of the CARMENES-NIR channel Cooling System implemented at IAA-CSIC and later installation at CAHA 3.5m Telescope, where the CARMENES instrument is nowadays already running and producing valuable science. Relevant highlights are obviously shown in terms of real performance involving the key requirements requested to that system.

The CARMENES NIR-channel Cooling System has been implemented by the IAA-CSIC through very fruitful collaboration and involvement of the ESO (European Southern Observatory) cryo-vacuum department with Jean-Louis Lizon as its head and main collaborator. The present work sets an important trend in terms of cryogenic systems for future E-ELT (European Extremely Large Telescope) large-dimensioned instrumentation in astrophysics.

9912-209, Session P8

New cryogenic temperature monitor: PLT-HPT-32

Teodora Aleida Viera-Curbelo, Instituto de Astrofísica de Canarias (Spain)

The PLT-HPT-32, a new cryogenic temperature monitor, has been developed by the Institute of Astrophysics of the Canary Islands (IAC) and an external engineering company (Sergio González Martín-Fernández).

The PLT-HPT-32 temperature monitor offers precision measurement in a wide range of cryogenic and higher-temperature applications with the ability to easily monitor up to 32 sensor channels. It provides better measurement performance in applications where researchers need to ensure accuracy and precision in their low cryogenic temperature monitoring.

9912-210, Session P8

GMTIFS: cryogenic rotary mechanisms for the GMT integral-field spectrograph

Brady Espeland, Gabriel J. Bloxham, Robert Boz, David Bundy, John Davies, John Hart, Robert Sharp, Annino Vaccarella, Colin Vest, The Australian National Univ. (Australia)

The GMT Integral-Field Spectrograph (GMTIFS) is an infrared cryogenic instrument that combines both an Imager and an IFS. Both instruments are designed to operate with the Adaptive Optics System of the Giant Magellan Telescope. The instrument has eight mechanisms that have a rotational motion. The most stringent of these is the Science Selector which is a rotary mechanism with 5 positions that allow wavelength band selection between the Imager and the IFS. The IFS operates in reflection from the selected dichroic. As GMTIFS operates at the diffraction limit of the GMT, very small errors in the position of the reflected surface will lead to un-sensed errors in the IFS. The geometry of the optical design results in angular setting accuracy requirement of 0.34 arcseconds or 2.7x10-5 revolutions. This then requires a high dynamic range on the drive and position sensing systems. For the drive system this is achieved via a stepper motor and harmonic drive. For the position sensing we use a non-contact encoding technique. This technique uses eddy current sensors to sense the positional displacement of an eccentric target ring. As it is non-contact thermal issues are reduced and it is expected to be very reliable. The technique is also scalable to increase dynamic range with the addition of further sensors and target rings. This scalability is essential for the Science Selector. We present alternate versions of the technique adjusted for less stringent requirements. We provide a brief overview of the instruments different rotary mechanisms. We also present a variation of the position sensing technique applied to a linear mechanism. We report on the results of prototype testing of the eddy current sensors including cryogenic test results. This testing also includes cryogenic life testing of a harmonic drive and a bearing design.

9912-211, Session P8

Developing a long duration 3He fridge for the LSPE-SWIPE instrument

Gabriele Coppi, The Univ. of Manchester (United Kingdom); Paolo de Bernardis, Sapienza Univ. di Roma (Italy); Andrew J. May, Univ. of Manchester (United Kingdom); Silvia Masi, Sapienza Univ. di Roma (Italy); Simon J. Melhuish, Mark A. McCulloch, Lucio Piccirillo, The Univ. of Manchester (United Kingdom)

The Large-Scale Polarization Explorer (LSPE) is a ballon-borne experiment aiming to detect the B-mode component of the polarisation of the cosmic microwave background. To achieve this, it will host two different instruments: STRIP (STRatospheric Italian Polarimeter) and SWIPE (Short Wavelength Instruments for Polarization Explorer). STRIP is based on coherent polarimeters and will observe the sky at frequencies below 100 GHz. SWIPE is based on TES (Transition Edge Sensor) detectors and will observe the sky at higher frequencies (140 GHz, 220 GHz and 240 GHz). The flight is foreseen for the the winter of 2016/2017 and will be launched from Svalbard Island. The experiment will last for at least 15 days, achieving sky coverage of almost 25%.

In order to maximize the observation time for the SWIPE instrument, we are developing a Helium-3 fridge that will be cycled only once during the flight, resulting in a cycle duration of more than 7 days. The LSPE-SWIPE fridge will be capable of keeping the focal plane arrays at temperature below 300 mK, considering a total heat load on the evaporator of 20 uW. This result is achieved by keeping the condenser of the fridge at a temperature of 1.5K, maintained by a bath of liquid Helium-4. The heat load on the evaporator is minimised thanks to an optimization of the length of the wires from the detectors at sub-K temperatures to the SQUID at 1.5 K, as well as the use of carbon fibre rods for structural support of the focal planes. The value of the heat load due to the thermal conduction from the 1.5 K condenser to the evaporator is only a small amount of the the total (4 uW is expected considering a tube of stainless steel 316NL).

The heat load through the tube is in principle not the lowest achievable; however, it is taken to be a reasonable compromise to keep the fridge compact. Indeed, in this way we have been able to design the tube from the condenser to the evaporator with a height of less than 50 mm. The total height of the fridge will be almost 300 mm, including the charcoal cryopump and the evaporator (designed to have a cylindrical shape of radius 6 cm). This geometry is chosen to minimize the Kapitza resistance, rendering it negligible in respect of the total heat load on the evaporator. To operate for >7 days with an expected heat load of 20 uW, the fridge will be charged with 0.61 moles of Helium-3, (corresponding to less than 14 L STP).

9912-212, Session P8

Sorption-cooled continuous miniature dilution refrigeration for astrophysical applications

Andrew J. May, Paolo G. Calisse, Gabriele Coppi, Charles V. Haynes, Lorenzo Martinis, Mark A. McCulloch, Simon J. Melhuish, Lucio Piccirillo, The Univ. of Manchester (United Kingdom)

The search for B-mode polarisation anisotropies in the Cosmic Microwave Background is one of the primary preoccupations of modern cosmology. Detection would allow further constraining of cosmological parameters, as well as supporting the search for primordial gravitational waves and the testing of theoretical predictions of inflation. The next generation of telescopes to study the CMB will be based around bolometer arrays requiring sub-Kelvin operating temperatures. Furthermore, these ground-

based experiments will require longer hold times, greater temperature stability and accuracy, and extended operation in remote locations such as the Atacama Desert and Antarctica.

We report the latest progress on the development of a tiltable continuous miniature dilution refrigerator and associated 7-He sorption coolers being developed to meet the cryogenic requirements for several CMB experiments including POLARBEAR2, QUBIC and LSPE.

The twin-pumped recirculating diluter will provide cooling to 100 mK, with the condenser cooled continuously to 300 mK by two 7-He sorption coolers. The novel miniaturised system therefore benefits from a lack of external circulation pumps and a mechanically simple design (in particular the absence of cold moving parts).

The sorption pumps are operated by convective heat switches which also benefit from a lack of moving parts. The dilution unit features a thermally separated still, coil and step heat exchangers. The sorption coolers to provide 300 mK are combination 3He/4He fridges, where the 4He stage provides a 1 K pot to improve the condensation efficiency of the 3He stage. In order to optimise the sorption pump, extensive measurements have been made of the helium accumulation and pumping speed of a range of charcoal samples from a variety of sources and manufacturing processes.

9912-213, Session P8

CARMENES: NIR channel spectrograph, final design of an ultra-stable cooling system in the cryogenic range

Eduard Mirabet Puig, Santiago Becerril Jarque, Instituto de Astrofísica de Andalucía - CSIC (Spain); Jean-Louis Lizon, European Southern Observatory (Germany)

CARMENES is the new high-resolution high-stability spectrograph built for the 3.5m telescope at the Calar Alto Observatory (CAHA, Almería, Spain) by a consortium formed by German and Spanish institutions. This instrument is composed of two separated spectrographs: VIS channel (550-1050nm) and NIR channel (900-1700nm). The NIR-channel spectrograph is lead by the Instituto de Astrofísica de Andalucía, IAA-CSIC, and has been manufactured, assembled, integrated and verified in the last two years. It was delivered to the observatory in autumn 2015, and commissioned in December 2015. It has performed as expected, complying with the scientific requirements, and its science verification has begun.

Due to the highly demanding and difficult to attain long-term stability requirements of the high-accuracy radial-velocity measurements (?1 m s-1), an extremely robust cooling system using strategically positioned heat exchangers and fed with liquid nitrogen has been designed and integrated. The NIR channel of CARMENES has a working temperature of 138K and its cooling system is able to provide the cold mass housing the optics, of approximately 1 ton, with a thermal stability within 24 hours of a few hundredths of a degree, even achieving a goal of 0.01K per day.

The present paper describes the final design of the ultra-highly stable cooling system showing the mechanical assembly of the main parts and the components of the Cooling System hardware used to isolate in such an efficient way the instrument, which nowadays is running at the 3.5m telescope of CAHA.

The CARMENES NIR-channel Cooling System has been implemented by the IAA-CSIC through very fruitful collaboration and involvement of the ESO (European Southern Observatory) cryo-vacuum department with Jean-Louis Lizon as its head and main collaborator. The present work sets an important trend in terms of cryogenic systems for future E-ELT (European Extremely Large Telescope) large-dimensioned instrumentation in astrophysics.

9912-214, Session P9

Smart warping harnesses for active mirrors and stress polishing

Emmanuel Hugot, Sabri Lemared, Marc Ferrari, Johan Floriot, Anais Bernard, Lab. d'Astrophysique de Marseille (France)

Active Optics is the art of controlling the deformations of optical surfaces. It is not only related to the stability of large primary mirrors, but has many applications as well as a control of the wavefront is required.

By working on the shape of mechanical structures constituting the warping harnesses of active systems, smart solutions appear, requiring the use of a single actuator to generate a combination of aberrations with a very high accuracy.

We successfully applied these optimization methods to provide an active mirror for the VLT-SPHERE planet finder, allowing to recover the dynamic of the extreme AO system. The active toric mirrors harness is designed to generate a pure cylinder or a pure astigmatism, compensating the deformable mirror residual shape due to its ageing.

We also reduced the number of actuators required for the stress polishing of ELTs segments. Smart structures allow a fine control of aberrations present in off axis parabolas surfaces, paving the way to a fast and simple mass production process.

We present both developments as well as the methods we successfully used for astronomical telescopes and instrumentation.

9912-215, Session P9

Control system for an alternative actuator for the primary surface of the large millimeter telescope (LMT/GTM)

José Luis Hernández Rebollar, César E. Cuevas-Arteaga, Josefina Lázaro Hernández, Instituto Nacional de Astrofísica, Óptica y Electrónica (Mexico)

The Large Millimeter Telescope/Gran Telescopio Milimetrico (LMT/GTM), a 50m diameter millimeter-wave radio telescope situated on the summit of Sierra Negra, Puebla, at 4600 meters above sea level, is a bi-national project between Instituto Nacional de Astrofísica, Optica y Electronica in Mexico and University of Massachusetts Amherst in the USA. It is the world's largest, single dish, fully steerable, open air radio telescope designed for astronomical observations in millimeter wavelengths within 0.85 to 4mm. Its primary reflector is so massive that its shape deviates from the theoretical parabola due to gravitational effect as it moves in elevation. This deformation affects the gain, which is one of the most important features of a telescope, and one of the reasons why to build a radio telescope this big. To correct this elevation-dependent deformation, the primary reflector has been divided into 180 segments arranged in 5 concentric rings, with each segment being supported by 4 linear actuators with a range of motion of + 2mms. The segments in the three inner rings are currently being driven by an interim system that was reported in a previous SPIE paper. Unfortunately the lifetime expectancy is below the requirement and the cost of substituting the control electronics and mechanisms with the new actuators being developed for rings 4 and 5, may not be affordable. In this paper an alternative actuator control system is presented that uses most of the current electronics but uses a new motor and a completely redesigned mechanism. A companion paper is also presented regarding the mechanical changes. The results of the tests under positive and negative load are also presented, as well as the results on the performance; such as repeatability and accuracy, as well as the lessons learned when trying to compensate the large hysteresis found in the position sensor, a linear variable differential transformer (LVDT), that had not been reported in previous works. Preliminary data indicate that

this system is capable of achieving precision within plus minus 1 micron regardless of the size of the commanded step.

9912-216, Session P9

Thermal expansion as a precision actuator

Chris Miller, David M. Montgomery, Martin Black, Hermine Schnetler, UK Astronomy Technology Ctr. (United Kingdom); Gabby Aitink-Kroes, Felix C. M. Bettonvil, ASTRON (Netherlands); Emmanuel Hugot, Lab. d'Astrophysique de Marseille (France); Tibor Agócs, ASTRON (Netherlands); Szigfrid Farkas, György Mez?, Konkoly Observatory (Hungary)

The UK ATC has developed a novel thermal actuator design as part of the OPTICON FP-7 funded project focusing on the production of freeform mirrors (FAME). The actuator uses the well understood concept of thermal expansion to generate the required force and displacement. As power is applied to the actuator it expands linearly with increasing temperature.

A resistance temperature detector (RTD) device is embedded into the centre of the actuator and is used both as a heater and a sensor. Electronics are used to control the temperature of the RTD by injecting a varying amount of current into the device whilst measuring the voltage across it. Temperature control of the RTD has been achieved to within 0.01°C.

This thermal actuator design, by means of a partly 3D printed actuator, is currently being used at the ATC to deform a mirror. This concept shows several advantages that makes it suitable to other applications. The actuator is cheap to produce whilst obtaining a high accuracy and repeatability. This actuator design would be suitable for applications requiring large numbers of actuators and high precision.

9912-217, Session P9

Realization and testing of an active mirror mechanism for in-field pointing in eLISA

Gert Witvoet, Jet Human, Matthew Maniscalco, TNO (Netherlands)

The Evolved Laser Interferometer Space Antenna (eLISA), foreseen to be launched in 2034, is meant to detect gravitational waves. It will consist of three spacecraft containing proof masses, mutually 5 million kilometers apart, which essentially forms a giant interferometer. The distance between the masses will be measured with extreme precision, so that any disturbance caused by a passing gravitational wave can be detected.

Since eLISA will be stationed in L1, the first Langrangian point of the Earth's orbit around the Sun, the spacecraft will orbit the Sun with the same (rotational) speed. As such, the spacecraft will be subject to seasonal constellation breathing, causing the angles between the interferometer arms to slowly change over a year. Consequently, the beams have to be corrected to stay aligned. One possible solution for this is to steer the line of sight of each telescope via rotation (over ±2.5°) of a single small mirror in an intermediate pupil plane of the telescope. To do so, an extremely accurate mirror mechanism needs to be developed, the so-called In Field Pointing Mechanism (IFPM).

TNO has made a conceptual design of such an IFPM, which has now been manufactured, assembled and subjected to a first set of tests. It consists of a mirror guided by a Haberland hinge, and actuated by walking piezosteppers. The steppers provide minuscule motion which, due to the stiff connection between the actuator and the mirror, allow precise rotation of the mirror. The exact motion profile of the steppers is determined by the voltage waveforms sent to their individual phases.

The performance of the IFPM has been assessed in a lab environment. Its response has been measured by both a nanometer resolution internal encoder, which is part of the IFPM itself, and an interferometer aimed at the mirror, providing nrad resolution direct measurements on the mirror rotation. This way the open loop motion of the mechanism has been optimized, by tuning the voltage profiles sent to the piezosteppers. The resulting frequency response functions, which vary slightly along the actuator stroke, have been measured, assessed and related to the observed open-loop motion in time domain. Based on these frequency responses a robust linear controller has been designed and implemented. This indeed yields a highly accurate closed-loop rotation of the mirror. The spectral density of the resulting closed-loop motion shows that the IFPM meets the extreme science mode requirements of 5 nrad/√Hz over the full ±2.5° while moving with 12.5 nrad/s. This is even true when the (coarser) internal encoder is used as feedback sensor, thanks to which the IFPM can be successfully operated in a stand-alone configuration (i.e. without external metrology).

9912-218, Session P9

Focal plane actuation by hexapod for the development of a high-resolution suborbital telescope

Alexander D. Miller, Paul A. Scowen, Arizona State Univ. (United States); Todd J. Veach, NASA Goddard Space Flight Ctr. (United States)

We present a prototype hexapod image stabilization system as the enabling technology for a proposed suborbital balloon mission. The unique design thermally isolates an off-the-shelf non-cryogenic hexapod from the cryogenic focal plane enabling its use in a cryogenic environment. Balloon gondolas currently achieve 1-2 arcsecond pointing error, but cannot correct for unavoidable jitter movements (~50 microns at 20hz at the worst) caused by wind rushing over balloon surfaces, thermal variations, cryocoolers, and reaction wheels. The jitter causes image blur during exposures and limits the resolution of the system. Removal of this final jitter term decreases pointing error by an order of magnitude and allows for true diffraction-limited observation. Tip-tilt pointing systems have been used for these purposes in the past, but require additional optics and introduce multiple reflections. The hexapod system, rather, is compact and can be plugged into the focal point of nearly any configuration. For a 0.8m telescope the provided boost in resolution by this system would provide 0.1" angular resolution at 300nm, which is comparable to Hubble for a fraction of the cost. On an actual balloon, the hexapod system will actuate the focal plane to counteract the jitter using position information supplied by star-trackers. However, in the lab, we instead simulate such a mission, using a 1024 ? 1024 e2v science-grade CCD to take long exposures of a target attached to an X-Y stage driven with an actual suborbital balloon jitter signal (from the STO mission). Further confirmation of the positional accuracy and agility of the hexapod is achieved using a laser and fast-sampling position-sensitive diode. Endurance experiments were also carried out to determine the operational thermal and mechanical limitations of the system when operated for long periods. High-resolution time domain multispectral imaging of the gas giant outer planets, especially in the UV range, is of particular interest to the planetary community, and a suborbital telescope with the hexapod stabilization in place would provide a wealth of new data. On an Antarctic ~100-day Long-Duration-Balloon mission the continued high-resolution imaging of gas giant storm systems would provide cloud formation and evolution data second to only a Flagship orbiter.

9912-219, Session P9

Mechanical development of an alternative set of actuators for the outer rings of the LMT/GTM primary surface

Cesar E. Arteaga Magaña, Instituto Nacional de Astrofísica, Óptica y Electrónica (Mexico)

The Large Millimeter Telescope/Gran Telescopio Milimétrico (LMT/GTM) is a bi-national project between Mexico and the USA. It is the world's largest, single dish, fully steerable, open air radio telescope designed for astronomical observations in millimeter wavelengths within 0.85 to 4 mm. The primary reflector needs an active surface system in order to meet the specified surface accuracy. Each of the 180 primary surface segments forming the reflecting surface will be supported by four linear actuators, one for each corner. In the current state of the telescope, the interim active surface system provides control for the 84 segments long enough to allow completion of the rest of the reflecting surface and installation of the final actuators. The active surface is a parabola formed by 180 panels arranged in 5 rings. During the 2014 SPIE we presented the interim active surface system of 336 actuators, to operate the 3 inner rings. In order to complete the whole surface with the complete 5 rings, the project engineering team needs to install another 336 actuators for the 2 outer rings of segments. However the antenna back structure is such that the room for those actuators is reduced underneath the outer rings and in consequence the current actuators will not fit.

In this document, we present the development of a new set of alternative actuators for the LMT antenna´s outer rings, their new mechanical design which are developed to obtain a more compact geometry capable of fitting in the reduced space underneath the antenna's outer rings, we also present the advantages obtained, the design issues. Details are provided about how these actuators have been improved from the perspective of repeatability, accuracy, cost, producing time and expectancy of having final actuators for the complete surface, .Additional comments and recommendations are made for applying the lessons learned to the final actuator system.

The current actuators, improved mechanically two years ago, have been used during the early science program of the LMT/GTM, these actuators populate the 3 inner rings only, and consequently the rest of the collecting surface cannot be used, the project still has old actuators to be improved, but they cannot fit on the outer rings; a new modification had to be made in order to reduce the actuators size, as well as to further improve their performance.

9912-220, Session P9

The WEAVE focus translation system: from design to construction

Oscar Maroto, Albert Tomàs, NTE-SENER S.A. (Spain); Manuel Canchado, SENER Ingeniería y Sistemas S.A. (Spain); Carlos Martín-Nuño, NTE-SENER S.A. (Spain); Joan Manel Casalta, SENER Ingeniería y Sistemas S.A. (Spain); Joaquín Prida, Antonio Romero, NTE-SENER S.A. (Spain); Jose Alfonso López Aguerri, José Miguel Herreros Linares, Jose Miguel Delgado Hernandez, José Alonso Burgal, Instituto de Astrofísica de Canarias (Spain); Don Carlos Abrams, Isaac Newton Group of Telescopes (Spain); Gavin B. Dalton, Univ. of Oxford (United Kingdom); Piercarlo Bonifacio, Observatoire de Paris à Meudon (France); Scott C. Trager, Kapteyn Astronomical Institute (Netherlands); Antonella Vallenari, INAF - Osservatorio Astronomico di Padova (Italy)

WEAVE is a new wide-field spectroscopy facility proposed for the prime focus of the 4.2m William Herschel Telescope (WHT), placed in La Palma, Canary Islands, Spain.

To allow for the compensation of the effects of temperature-induced and gravity-induced image degradation, the WEAVE prime focus assembly will be translated along the telescope optical axis. The assembly comprises the prime focus corrector with integrated ADC, a central mount for the corrector, an instrument rotator and a twin-focal-plane fibre positioner. Translation is accomplished through the use of a set of purpose-built actuators; collectively referred to as the Focus Translation System (FTS), formed by four independently-controlled Focus Translation Units (FTUs), eight vanes connecting the FTUs to a central can, and a central can hosting WEAVE. Each FTU is capable of providing a maximum stroke of ±4mm with sufficient, combined force to move the five-tonne assembly with a positional uncertainty of ±20µm at a resolution of 5µm. The coordinated movement of the four FTUs allows ±3mm WEAVE focus adjustment in the optical axis and ±0.015º tilt correction in one axis. The control of the FTS is accomplished through a PLC-based subsystem that receives positional demands from the higher-level Instrument Control System.

SENER is responsible for designing, manufacturing and testing the FTS and the equipment required to manipulate and store the FTS together with the instrument.

This manuscript describes the final design of the FTS along with the analyses and simulations that were performed, discusses the manufacturing procedures and the results of early verification prior to integration with the telescope. The plans for mounting the whole system on the telescope are also discussed.

9912-222, Session P9

Space active optics for wide-field high-angular resolution observatories

Marc Ferrari, Clement Escolle, Lab. d'Astrophysique de Marseille (France); Sylvain Egron, Space Telecope Science Institute (United States); Vincent Michau, ONERA (France); Thierry Fusco, Lab. d'Astrophysique de Marseille (France) and ONERA (France); Rémi Soummer, Space Telescope Science Institute (United States); Aurélie Montmerle Bonnefois, ONERA (France); Céline Engel, Emmanuel Hugot, Lab. d'Astrophysique de Marseille (France)

To meet the challenges of Earth observation and astronomy, future space observatories will require telescopes of several meters in diameter. The various space environment constraints will induce deformations and misalignments of the telescope mirrors, thus degrading the optical quality of observations. The integration of active optics, used since the late 80s for alignment and preservation of the optical quality of the ground telescopes, becomes mandatory. Such a system consists of three elements: a measuring device, a correction set-up and a control loop which links both previous elements.

We present the development of a perturbations estimator minimizing the residual wave front in the telescope field of view. The analysis of this estimator and more generally of the ultimate performance of a space active optics system enabled us to highlight the impact of high spatial frequencies on optical quality. On the other hand, the presence of such high frequencies due to the primary mirror supports print through, urged us to evaluate the possibilities of their reduction in the case of large mirrors. Using a finite element model of such a mirror, we made local modifications of the mirror structure to adapt its deformation to the correcting capabilities of active optics.

We also present future trends for wide field active telescopes and the opportunity to optimize the optical combinations over subfields for dedicated instruments.

9912-223, Session P9

Active optics system for the 4m telescope of the Eastern Anatolia Observatory (DAG)

Grégory P. Lousberg, Emeric Mudry, Christian Bastin, Jean-Marc Schumacher, Eric Gabriel, Olivier Pirnay, Carlo Flebus, AMOS Ltd. (Belgium)

AMOS has recently been awarded for the design, manufacturing and installation of a new 4m-class telescope for the Turkish Eastern Anatolia Observatory (DAG). The telescope is based on a Ritchey-Chretien configuration with two folded Nasmyth focal planes. The optical train is composed of three mirrors: the primary mirror (M1) with an optical aperture of 4m, a convex secondary mirror (M2), and a flat folding mirror (M3). Because the telescope will be ultimately used with an adaptive optics system in order to reach diffraction-limited performances, specific design provisions need to be implemented at telescope level for enhancement of its intrinsic quality. In particular, an active optics system needs to be developed so as to meet the challenging top-level requirements. The active optics system consists in (a) an adjustable support for M1 with a low temporal bandwidth, and (b) two hexapods supporting M2 and M3. Both M1 support and the hexapods are actively controlled during regular telescope operations.

The design of the support of the primary mirror is driven by the need of (1) minimizing the support-induced mirror distortions under telescope operating conditions, (2) shaping the mirror surface to the desired profile, and (3) providing a high stiffness against the wind loads. In order to fulfill these requirements, AMOS proposes an innovative design that consists of 66 pneumatic actuators associated to 9 hydraulic actuators that are arranged in three independent circuits. The pneumatic actuators actively compensate for low-order telescope pupil aberrations (mainly astigmatism, coma, 3rd-order spherical, trefoil and quatrefoil) that are generated by the mirror support itself or by polishing residuals on the three mirrors of the telescope. The hydraulic system is used to rigidly fix the mirror position while offering a high stiffness against wind loads. Associated with an optical feedback from a wavefront sensor, the active support of the primary mirror can be adjusted on regular basis during telescope operations so as to minimize the induced errors on the telescope pupil. Under this condition, the active support of M1 allows limiting the induced telescope wavefront aberrations to less than 20 nm RMS WFE.

In parallel, the M2 and M3 mirrors are mounted on hexapods whose position can be adjusted during telescope operations. This adjustment compensates telescope mis-alignments that regularly occur due to variations of the conditions of observations (change of temperature or tube elevation angle). The active control of the position of M2 and M3 is performed either with look-up tables (open-loop control) or using optical feedback from a wavefront sensor (closed-loop control). Hexapods with high accuracies allows positioning the M2 and M3 with a precision better than 1µm and 2 arcsec.

9912-224, Session P10

A three-layer eight-octant phase mask towards broadband high-contrast observations

Naoshi Murakami, Hokkaido Univ. (Japan); Jun Nishikawa, National Astronomical Observatory of Japan (Japan) and The Graduate Univ. for Advanced Studies (Japan); Natsumi Akaiwa, Yusuke Komuro, Hokkaido Univ. (Japan); Naoshi Baba, Hokkaido Univ. (Japan) and Muroran Institute of Technology (Japan); Motohide Tamura, National Astronomical Observatory of Japan (Japan) and The Univ. of Tokyo (Japan)

For direct detection of exoplanets, we have been developing focal-plane coronagraphic phase masks based on photonic crystals, artificial periodic nanostructures of high and low refractive indices. The photonic-crystal technology is advantageous for coronagraphic phase masks owing to its extremely small manufacturing defects. The photonic-crystal phase masks are composed of space-variant half-wave plates (HWPs), that is, HWPs with space-variant fast axes. Phase modulation required for the coronagraphic mask can be realized by utilizing the Pancharatnam-Berry's phase, which depends on orientation angles of the fast axes of the space-variant HWPs. For example, the orientation angles have to be set to +/- 45 degrees in each eight-octant sector of the mask for realizing the 0/pi phase modulation required for the 8OPM. However, the photonic-crystal HWPs exhibit chromatic characteristics because their phase retardations depend on a wavelength. In other words, extremely high-contrast observations can be realized only at an optimized wavelength. For realizing broadband high-contrast observations, polarization-filtered photonic-crystal coronagraphic masks have been proposed and developed (e.g., Murakami et al. (2010), ApJ, 714, 772; Murakami et al. (2013), Opt. Express, 21, 7400; Murakami et al. (2014), Proc. SPIE, 9143, 914334). However, the polarizing filters would cause additional wavefront aberrations, resulting in degradation of an achievable contrast. Furthermore, optical throughput of the coronagraphic system for planetary light would degrade due to the polarization filters. For resolving these problems of the photonic-crystal coronagraphic masks, we designed a three-layer 8OPM (Murakami et al. (2014), Proc. SPIE, 9143, 914334). It is expected that an extremely high contrast of 1e-10 can theoretically be realized by the three-layer 8OPM without the polarization filters over a broad wavelength range.
As an important next step, we recently manufactured a first-trial three-layer 8OPM, based on the photonic-crystal technology, optimized over a wavelength range between 500 and 800 nm. The manufactured 8OPM is composed of three-layered eight-octant HWPs with fast axes of 75.0 and 15.15 degrees (first layer), -15.0 and -74.85 degrees (second layer), and 75.0 and 15.15 degrees (third layer) in each eight-octant sector, instead of +/- 45 degrees for the previous single-layer 8OPM mentioned below. We have been carrying out laboratory experiments of the manufactured three-layer 8OPM using visible light sources to evaluate the coronagraphic performance and manufacturing errors. Here we report our recent progress on the three-layer photonic-crystal 8OPM, as well as related observational techniques, towards broadband high-contrast imaging of exoplanets.

9912-225, Session P10

Advances in starshade technology readiness for an exoplanet characterizing science mission in the 2020's

David R. Webb, Samuel C. Bradford, Stuart B. Shaklan, Brian Hirsch, Douglas Lisman, John Steeves, Mark Thomson, Jet Propulsion Lab. (United States)

With the discovery of so many exoplanets, it is of keen and urgent interest to characterize these planets. Starshade, an external occulter, could fly in formation with a telescope, allowing us to peer into the atmospheres of these planets and characterize them. Recent technology development, in coordination with system design, has added much needed detail to define the technology development needs for a science mission in the 2020's. This paper addresses the current state of technology for the starshade mechanical system, the successful efforts to date, and upcoming efforts. The starshade is a complicated deployable instrument that requires hundreds of joints and members to rotate, unfurl and release with exacting precision in order to provide the requisite on-orbit shape profile needed to create the 1e-10 contrast for imaging of exoplanets. The starshade is an elegant design that incorporates flight heritage and precedence to advance the footing of the starshade technology, however much work has to be performed to demonstrate that systems function together as required to meet the optical needs. The starshade mechanical instrument comprises an inner and opaque disk as well as 28 opaque petals along its periphery that limit diffraction of the starlight into the telescope.

Successful efforts have shown the ability to manufacture petals to flight tolerances, as well the ability to deploy that petals to the correct position, a key milestones for a starshade mission. Current efforts are larger in scope and require the combination of multiple systems and their system interaction. Work is being performed to define and build a half scale functioning optical shield prototype for the inner disk, a critically important member in occulting the light of the star, and a complicated subsystem in itself. Separately, having shown the ability to produce the shape of the petal to the specified tolerances, it is critically important to demonstrate the design, manufacture and test of a flight like petal with all the necessary interfaces to the rest of the system, including launch restraints and the petal optical shield. Critically important in all of the individual subsystem efforts, is definition of the full system architecture to inform and direct the subsystem design. Recent NASA funded efforts have allowed for full system mechanical definition that dovetails with potential science missions for the 2020's with telescopes such as WFIRST.

9912-226, Session P10

Development of speckle nulling technique for the Savart-plate lateral-shearing interferometric nuller for exoplanets (SPLINE)

Kenta Yoneta, Naoshi Murakami, Hokkaido Univ. (Japan); Takayuki Kotani, National Astronomical Observatory of Japan (Japan); Hajime Kawahara, The Univ. of Tokyo (Japan); Taro Matsuo, Osaka Univ. (Japan); Naoshi Baba, Hokkaido Univ. (Japan) and Muroran Institute of Technology (Japan); Motohide Tamura, National Astronomical Observatory of Japan (Japan) and The Univ. of Tokyo (Japan)

The Savart-plate lateral-shearing interferometric nuller for exoplanets (SPLINE) is a kind of a visible nulling coronagraph for directly imaging exoplanets (Murakami & Baba (2010), Opt. Lett., 35, 3003). One of advantages of the SPLINE is its simple configuration because it consists of only a Savart plate placed between two crossed polarizers. The Savart plate splits incoming unpolarized light beam into two orthogonally polarized ones with lateral shear. For on-axis starlight, an optical-path difference (OPD) is not introduced between the two light beams split by the Savart plate. The on-axis starlight is canceled out by the SPLINE, since a fully achromatic ϖ phase difference between the two light beams is caused by the Savart-plate placed between two crossed polarizers. For off-axis exoplanetary light, on the other hand, the Savart plate introduces an additional OPD between the two light beams which depends on an off-axis angle of the planet. Thus, the planetary light is not canceled out and can directly be detected. Theoretically the SPLINE can null the stellar light even when an entrance pupil function is complex such as segmented-mirror extremely large telescopes. However, achievable contrast of the SPLINE is limited by phase and amplitude aberrations due to imperfect optical surfaces of the optical elements. The stellar speckles caused by the aberrations disturb direct detection of exoplanets. Thus, reduction of the stellar speckles is required to improve the achievable contrast. We propose to introduce a speckle nulling technique to the SPLINE. The speckle nulling with the SPLINE is conducted in two steps; speckle field measurement on a focal plane and wavefront correction using a liquid-crystal spatial light modulator (LCSLM) on a pupil plane. For measuring the speckle field on the focal plane of the SPLINE, we propose to apply the self-coherent camera (SCC) (e.g., Galicher et al. (2008), A&A, 488, L9). A polarizing beam splitter (PBS) is replaced with the second polarizer to apply the SCC for the SPLINE. The PBS allows us to obtain bright and nulled outputs simultaneously. The nulled output (science channel) consists of both stellar light and planetary light. On the other hand, the stellar light is dominant in the bright output. By producing a reference plane wavefront from the bright output (reference channel), interference fringes between the reference and science channels are acquired on the focal plane. The speckle field can be derived by post processing based on the SCC technique. For correcting the wavefront aberrations, the LCSLM is placed behind the Savart plate of the SPLINE to introduce space-variant phase difference between two orthogonally-polarized wavefronts generated by the Savart plate. By applying appropriate phase modulation, the stellar speckles can be canceled out to create a dark hole in a certain region on the focal plane. Thus we expect that the achievable contrast of the SPLINE can be greatly improved. We report recent progress on computer simulation and laboratory experiments of the speckle nulling technique applied to the SPLINE.

9912-227, Session P10

Development and characterization of Four-Quadrant Phase Masks coronograph (FQPM)

Marion Bonafous, Pierre Baudoz, Raphaël Galicher, Faouzi M. Boussaha, Marie Josiane Firminy, Observatoire de Paris à Meudon (France)

The goal of a coronograph is to reduce the flux of a bright object (e.g. a star) in order to distinguish its faint near environment (e.g. an exoplanet). In this context, we developed and studied the four-quadrant phase mask coronograph (called FQPM). Like all phase mask coronagraph, the FQPM uses a Lyot stop in a pupil plane to stop the stellar light that is diffracted by the focal phase mask. The planet image however is not affected by the coronagraph and is detected in the final image.

In collaboration with the GEPI laboratory, we built several monochromatic FQPM since 2000. Over the year, we have established systematic procedures for fabrication and characterization of the coronagraph. A visual inspection with a microscope is performed for every component and a dedicated test bench was set up in a clean room.

This process gives us a quick feedback on the quality and performance of the component. It enabled us to understand the influence of various parameters, such as transition, alignment of the transitions or step depth. The mask design and the fabrication process were modified and we are now able to build a FQPM for any given optimal wavelength in visible or near-infrared with a success rate close to 100%. Moreover, we improved the performance of the components, reaching attenuations of more than 10,000 on the central peak.

The best of these components are now used on the THD bench, an optical bench developed for the study of high contrast imaging techniques.

On my poster, I will present the procedure we developed to build and test the phase mask, as well as details on the performance of the FQPM coronograph.

9912-228, Session P10

Analysis of nulling phase functions suitable to image plane coronagraphy

François B. Hénault, Alexis Carlotti, Christophe Vérinaud, Institut de Planétologie et d'Astrophysique de Grenoble (France)

Coronagraphy is a very efficient technique for identifying and characterizing extra-solar planets orbiting in the habitable zone of their parent star, especially in a space environment. An important family of coronagraphs is actually based on phase plates located at an intermediate image plane of the optical system, and spreading the starlight outside the "Lyot" exit pupil plane of the instrument. In this commutation we present a set of candidate phase functions generating a central null at the Lyot plane, and study how it propagates to the image plane of the coronagraph. These functions include linear azimuthal phase ramps (the well-known optical

vortex), azimuthally cosine-modulated phase profiles, and circular phase gratings. Nnumerical simulations of the expected null depth, inner working angle, sensitivity to pointing errors, effect of central obscuration located at the pupil or image planes, and effective throughput including image mask and Lyot stop transmissions are presented and discussed. The preliminary conclusion is that azimuthal cosine functions appear as an interesting alternative to the classical optical vortex of integer topological charge.

9912-230, Session P10

Development of PIAACMC for large aperture ground-based telescopes

Kevin E. Newman, The Univ. of Arizona (United States); Ruslan Belikov, NASA Ames Research Ctr. (United States); Olivier Guyon, The Univ. of Arizona (United States)

The Phase Induced Amplitude Apodization Complex Mask Coronagraph (PIAACMC) is an architecture for directly observing extrasolar planets, and can achieve performance near the theoretical limits for any direct-detection instrument. The PIAACMC architecture includes aspheric PIAA optics, and a complex phase-shifting focal plane mask that provides a pi phase shift to a portion of the on-axis starlight. The phase-shifted starlight is forced to interfere destructively with the un-shifted starlight, causing the starlight to be eliminated, and allowing a region for high-contrast imaging near the star.

The PIAACMC architecture can be designed for segmented and obscured apertures, so it is particularly well suited for ground-based observing with the next generation of large telescopes. There will be unique scientific opportunities for directly observing Earth-size planets around nearby low-mass stars. We will discuss design strategies for adapting PIAACMC for the next generation of large ground-based telescopes, and present progress on the development of the focal plane mask technology. We also present simulations of wavefront control with PIAACMC, and suggest directions to apply the coronagraph architecture to future telescopes.

9912-262, Session P10

WFIRST/AFTA coronagraph contrast performance sensitivity studies: simulation versus experiment

Erkin Sidick, Byoung-Joon Seo, David S. Marx, Ilya Y. Poberezhskiy, Bijan Nemati, Jet Propulsion Lab. (United States)

The WFIRST/AFTA 2.4 m space telescope currently under study includes a stellar coronagraph for the imaging and the spectral characterization of extrasolar planets. The coronagraph employs sequential deformable mirrors to compensate for phase and amplitude errors. Using the Modelable Coronagraph Testbed (MCB) at the Jet Propulsion Laboratory, we have investigated through simulations the sensitivity of dark hole contrast in a Hybrid Lyot Coronagraph (HLC) for several error cases, including lateral and longitudinal translation of an occulting mask, lateral translation of a Lyot stop, tip/tilt of the occulting mask and the Lyot stop, DM1 and DM2 misalignment, and the occulter/Lyot masks fabrication errors. In some cases we confirmed the theoretical predictions with the testbed measured results.

9912-272, Session P10

Design and construction of a 76m long-travel laser enclosure for a space occulter testbed

Michael Galvin, Yunjong Kim, N. Jeremy Kasdin, Princeton Univ. (United States); Dan Sirbu, NASA Ames Research Ctr. (United States); Robert J. Vanderbei, Dan Echeverri, Princeton Univ. (United States); Kunjithapatham Balasubramanian, Stuart B. Shaklan, Douglas Lisman, Jet Propulsion Lab. (United States)

Princeton's High-Contrast Imaging Lab (HCIL) is expanding our space occulter testbed from 11m to 76m in order to achieve a Fresnel number that is flightlike for candidate space occulter reference missions. This expansion requires the construction of a 76m long-travel laser enclosure. Requirements for the enclosure include:

1) Light-tight

2) Large (~1m) diameter clear aperture along the whole beam path

3) Baffles at regular spacing

4) Characterization of low-reflectivity paint for inner walls

5) Characterization and mitigation of jitter and diurnal beam drift environments

6) Three accessible, enclosed optical table stations (at the midpoint and both endpoints) with manual fine alignment of each optical table

7) Modular (for further length expansion in the future).

Here we present the mechanical design and construction status of the enclosure, with a focus on the efforts made to achieve expandable modularity and use nearly all commercial off-the-shelf (COTS) or semi-COTS parts.

9912-232, Session P11

Extending ground-based astronomy into the infrared

Kyler Kuehn, Simon Ellis, Australian Astronomical Observatory (Australia)

Highly variable emission in the upper atmosphere from hydroxyl molecules significantly impedes accurate photometric and spectroscopic measurements of objects beyond the atmosphere -- where all of the targets of astronomical observations reside. Orbiting observatories are one possible solution to this problem, but they are exorbitantly expensive and upgrading (or even simply maintaining) their capabilities is extremely challenging (and dangerous). And even the highest-resolution ground-based instruments are thwarted by scattered light contaminating the interline region. But if ground-based instruments can suppress this OH emission, observations beyond wavelengths of 1 micron become far more effective.

There are several different technological solutions being developed to solve this problem, including Fiber Bragg Gratings (FBGs), demonstrated on the GNOSIS instrument and being developed further for the AAO's PRAXIS instrument. An alternative technology for suppressing specific wavelengths of light corresponding to the OH emission, and one that potentially rivals FBGs in terms of efficiency, cost-effectiveness, ease of manufacture and adaptability is micro-ring resonators. In particular, micro-ring resonators are lithographically printed in silicon, and so are very modular and possibly to integrate with other on-chip photonic components, such as array waveguide gratings.

There are several steps required to realize a functional instrument incorporating this novel technology:

1) Fabricating silicon wafers with a suite of waveguides and associated ring resonators

2) Coupling light from fibers into and out of the waveguides

3) Simulating various configurations to optimize both the desired throughput and the position and depth of OH suppression features, in parallel with engineering efforts to construct these modeled systems

4) Measurement of both throughput and suppression in a packaged system, ultimately to be incorporated into an astronomical instrument used at an observational facility.

We describe our recent progress on all four of these steps in the process of ring-resonator based OH suppression for ground-based infrared spectroscopy.

9912-233, Session P11

Laser induced satellite relay switching for data transmission in between Mars and Earth for space craft GPS navigation and telescopic data transfer for surveying and imaging using radio frequency modulation with laser beam converting transducer

Mohammad M. Anwar, Asiatic Society of Bangladesh (Bangladesh)

Laser beam transmitter: Laser transmitter:

To produce Laser signal for a great distance such as moon or orbiting satellite chemical laser is used where laser beam is produce by chemical reaction of halogen and hydrogen.

Laser beam produce by this mechanism is very energetic and intense. By taking laser beam from chemical laser source then passing through a fiber optic cable made up of metal – synthetic glass then by wave front division automatically making multiple beam concave, convex or plane wave.

This signal will transmit via telescopic laser transmitter as it is. In bed weather situation by combining other wavelengths of laser producing by different reaction making a mixture of wave length will be transmitted taking into account of absorption scattering reflection.

Laser beam receiver: Laser receiver (on boarded to air plane):

The receiver will be a light electric signal transducer that that will convert radio signal and other signal to laser beam

9912-234, Session P11

CHOUGH: petite ADC for a high-order adaptive optics system

Daniel Hölck, Nazim A. Bharmal, Durham Univ. (United Kingdom); Martin Black, David M. Henry, UK Astronomy Technology Ctr. (United Kingdom); Richard M. Myers, Durham Univ. (United Kingdom)

We discuss the design, construction and lab test results of a 50mm diameter Atmospheric Dispersion Corrector (ADC) for The CANARY-Hosted Upgrade for High-Order Adaptive Optics (CHOUGH). Usually to avoid pupil actuator-lenslet array mismatch, the ADC is Customarily placed very close to the pupil plane. This design aims to achieve a non-pupil conjugated ADC suitable to be located in any place inside the collimated beam path, this is due to the restrictions given by CHOUGH optical relay. The ADC also needs to satisfy the very small pupil shift requirement, for pupil stability. The ADC is of the Amici prism type, made up of two plates of cemented double prisms. The two plates counter rotate correcting for the different Zenith angles, from the Zenith up to 60°. We report on the testing methodology and the obtained labs results in order to confirm the expected correction and requirements.

9912-235, Session P11

CMB polarization modulation for the Atacama Cosmology Telescope using continuously rotating half-wave plates

Jonathan T. Ward, Univ. of Pennsylvania (United States)

The Atacama Cosmology Telescope is a six-meter diameter telescope located at 17,000 feet (5,200 meters) on Cerro Toco in the Andes Mountains of northern Chile. The ACTPol instrument is a polarization sensitive receiver featuring TES bolometer detector arrays that operate at 90 and 150 GHz. ACTPol is currently making high resolution measurements of the polarized Cosmic Microwave Background (CMB). Development of instrumentation for the next generation Advanced ACTPol (AdvACT) experiment began in late 2014 and will include the deployment of four multichroic detector arrays over the next several years. AdvACT will cover five frequency bands (28, 41, 90, 150, and 230 GHz), which will allow for cleaning of both synchrotron and dust foregrounds. At scales of $l < 100$, the primary goal of AdvACT is to measure the B-mode polarization from primordial gravitational waves generated during inflation. A key instrumental upgrade to achieve this goal is a set of three warm, continuously rotating half-wave plates (HWPs). The wave plates modulate the incoming polarization signal to drastically reduce 1/f noise and reduce polarization systematics. A fully operational rotation system based on air bearings was deployed on the ACT telescope in January 2015, followed by several iterations of prototype HWP optics. The positions of the rotating HWPs are obtained using a custom-built encoder system and software algorithm. The full design of the rotation, control, and readout system along with analysis of the mechanical performance are discussed in detail. We also present preliminary results from data taken with the rotation system operating at 2Hz, including HWP structure subtraction and demodulation technique. The final, demodulated data exhibits a significant reduction in atmospheric fluctuations allowing for the successful recovery of cosmological information at large angular scales.

9912-236, Session P11

Progress in developing a prototype simple vph-based high-resolution imaging spectro-polarimeter

Samuel C. Barden, Leibniz-Institut für Astrophysik Potsdam (Germany); Alessio Zanutta, Andrea Bianco, INAF - Osservatorio Astronomico di Brera (Italy)

We present progress on the development of a simple, imaging spectro-polarimeter that exploits the polarization dependence of volume-phase holographic gratings. When the incidence plus diffraction angles equal 90 degrees, the linear polarization state that is parallel to the fringes is diffracted and dispersed at effectively 100 percent efficiency while the orthogonal polarization state is transmitted into zeroth order without dispersion with similar efficiency. This allows the production of a high dispersion, relatively narrow band spectro-polarimeter as previously described by Barden (2012SPIE.8446E..39B). Recently, two 35 mm diameter gratings were produced at the INAF - Osservatorio Astronomico di Brera with optimal diffraction at the Hydrogen alpha line. Such volume phase holographic gratings are based on high performance Bayfol® photopolymers that made possible to perform the writing step directly on the prisms without any other glass subtrate. With this approach, it has been possible to minimize the number of optical interfaces with a potential important reduction of reflection losses and ghosts. The grating performance has been measured and a prototype instrument is

in development. Our paper will discuss the performance of the gratings and initial performance of the prototype instrument along with suggested applications for such an instrument.

9912-237, Session P11

Daytime sky polarization calibration campaign with the HiVIS spectro-polarimeter and system polarization modeling

David M. Harrington, National Solar Observatory (United States)

Calibrating the Mueller matrices of large aperture telescopes and associated coude instrumentation requires astronomical sources and several modeling assumptions to predict the behavior of the system polarization with field of view, altitude, azimuth and wavelength. Recent daytime sky based polarization calibrations of the AEOS telescope and HiVIS spectropolarimeter have provided system Mueller matrices over full telescope articulation for a 15-reflection coude system. Polarization modeling predictions using Zemax have successfully matched the altitude-azimuth-wavelength dependence on HiVIS with the few percent amplitude limitations of several instrument artifacts. Polarization predictions for coude beam paths depend greatly on modeling the angle-of-incidence dependences in powered optics and the mirror coating formulations. A 6 month HiVIS daytime sky calibration plan has been analyzed for accuracy under a wide range of sky conditions and data analysis algorithms. Comparisons between the calibration measurements, laboratory data and the Zemax model predictions with a range of coating formulations show agreement accurate enough to predict system level performance. The variation of daytime-sky derived telescope Mueller matrices with data processing algorithms and observing condition limitations along with new systems modeling tools have impact for future polarimeter design and calibration efforts on both night time and day time large aperture telescopes.

9912-238, Session P11

Progress in modeling polarization optical components for the Daniel K. Inouye Solar Telescope

Stacey R. Sueoka, David M. Harrington, National Solar Observatory (United States)

The Daniel K Inouye Solar Telescope (DKIST) will have a suite of first-light polarimetric instrumentation requiring calibration of a complex off-axis optical path. The DKIST polarization calibration process requires modeling and fitting for several optical, thermal and mechanical effects. Three dimensional polarization ray trace codes (PolarisM) allow modeling of polarization errors inherent in assuming a linear retardation as a function of angle of incidence for our calibration retarders at Gregorian and Coudé foci. Stress induced retardation effects from substrate and coating absorption, mechanical mounting stresses, and inherent polishing uniformity tolerances introduce polarization effects at significant levels. These effects require careful characterization and modeling for mitigation during design, construction, calibration and science observations. Modeling efforts, amplitude estimates and mitigation efforts will be presented for the suite of DKIST calibration optics planned for first-light operations.

9912-239, Session P11

System polarization modeling and calibration strategies for the Daniel K Inouye Solar Telescope (DKIST)

David M. Harrington, National Solar Observatory (United States)

The Daniel K Inouye Solar Telescope (DKIST) polarimetric instrumentation requires very high accuracy calibration of a complex coude path with an off-axis f/2 primary mirror, time dependent optical configurations and substantial field of view to accomplish the critical science observations. Accurate polarization predictions across a diversity of optical configurations, tracking scenarios, slit geometries and vendor coating formulations are critical to the telescope and instrument development efforts for both the design and fabrication process as well as during calibrations and post-processing mitigation efforts. Recent successes in daytime sky polarization calibrations and Zemax system polarization modeling of the 4m AEOS telescope and HiVIS spectropolarimeter show feasibility of making reasonably accurate system performance predictions. AEOS and HiVIS are a DKIST analog with a many-fold coude optical feed creating 100% polarization cross-talk with altitude, azimuth and wavelength. Predictions of polarimetric performance for the DKIST first-light instrumentation suite have been created under a range of configurations. These new modeling tools and predictions have substantial impact for the design and calibration process in the presence of manufacturing issues, science use-case based performance predictions and ultimate system limitations in the complex DKIST optical train.

9912-263, Session P11

An efficient stable optical polariser module for calibration of the S4UVN earth observation satellite

Stephen Rolt, Ariadna Z. Calcines, Bart A. Lomanowski, David G. Bramall, Durham Univ. (United Kingdom)

We describe here an optical polariser module intended to deliver well characterised polarised light to an imaging spectrometer instrument. The instrument in question is the Sentinel-4/UVN Earth observation spectrometer due to be deployed in 2019 in a geostationary orbit. The polariser module described here will be used in the ground based calibration campaign for this instrument. One critical task of the calibration campaign will be the highly accurate characterisation of the polarisation sensitivity of instrument. The polariser module provides a constant, uniform source of linearly polarised light whose direction can be adjusted without changing the output level or uniformity of the illumination.

Essentially, the polariser is a collimator that provides a collimated beam of about 80 mm diameter from a small, localised and central field. The size of this field is a few arcminutes. The collimated light is to be provided within the two instrument passbands in the UV-VIS (305 – 500 nm) and the NIR (750 – 775 nm). The design presented here is a transmissive design with collimation provided by an achromatic doublet consisting of a calcium fluoride and silica lens pair. Of course, choice of lens materials is dictated by the requirement for transmission into the UV; selection of optical glasses is no longer an option. Close to the focal plane, where the small object target is located, a small crystal module linearly polarises the light. Illumination of the object target is either via a continuum light source or a tunable laser source depending on the specific calibration activity.

The polarising crystal arrangement is loosely based upon a Glan-Taylor polarising prism. The Glan-Taylor polariser transmits the extra-ordinary polarised ray whilst rejecting the ordinary ray by total internal reflection. However, the transmitted extra-ordinary ray is close to the critical angle and it experiences some loss which is significantly dependent upon the ray angle. A critical requirement, however, of the polariser module is that

the illumination is uniform across the exit pupil. In addition, the classical Glan-Taylor arrangement also introduces image ghosts from reflection of the front and rear facets. Therefore, a novel, modified arrangement is proposed. To avoid ghost reflections from front and rear facets of the prism, the prism is specially cut such that both facets are presented at the Brewster angle to the extra-ordinary ray. Ghost reflections are reduced to insignificant levels. Pupil uniformity is enhanced by combining two sets of prisms in opposing orientations.

A detailed tolerancing analysis of the design is presented, paying particular attention to the orientation of the polarising prisms and their manufacturing tolerances. Further analysis of polarisation sensitivity effects, such as stress induced birefringence will be presented together with accompanying thermo-mechanical analysis. Since the straylight performance of the instrument itself is to be characterised in great detail, it is necessary to model the straylight performance of the polarisation module and results of this analysis are presented here.

9912-240, Session P12

IMU based attitude sensor: analysis and modeling of noises and performance improvement by sensor fusion and filtering

Nirmal K., Sreejith Aickara Gopinathan, Joice Mathew, Mayuresh N. Sarpotdar, Ajin Prakash, Margarita Safonova, Jayant Murthy, Indian Institute of Astrophysics (India)

We describe the modeling and measurement of the noise in an IMU based attitude sensor. This attitude sensor is used in a balloon borne pointing system which is intended to carry out observations in ultraviolet regime. Different analysis, such as Allan Variance and Power Spectral Density (PSD) analysis are done on the IMU to identify and estimate the measurement noises.

We modeled the IMU measurement noise as a Gaussian probability density function and formulated a Kalman filter to combine accelerometer and gyroscope reading to obtain more accurate attitude estimation rather than attitude estimated from accelerometer or gyroscope.

The design and development of different digital smoothing filter such as moving average, Savitzky Golay implemented to filter the noises in IMU, their performance and drawbacks are also explained.

9912-241, Session P12

Photoconductive deformable mirrors as potential technology for astronomical instrumentation

Martino Quintavalla, INAF - Osservatorio Astronomico di Brera (Italy); Stefano Bonora, Istituto di Fotonica e Nanotecnologie (Italy); Dario Natali, Politecnico di Milano (Italy); Andrea Bianco, INAF - Osservatorio Astronomico di Brera (Italy)

Photo controlled deformable mirrors (PCDMs) are based on an electrostatic membrane mirror where a photoconductive material replaces the conventional electrode pads, so that the mirror surface deforms according to a light pattern projected on the photoconductor. As a consequence, the number, shape and size of the actuators can be optimized according to the corrections to the wavefront to be performed.

In order to open the route towards applications of PCDMs in astronomical field, the increase of the mirror aperture and the improvement of the performances (response speed, maximum displacement) are required. This can be achieved by a suitable design and selection of the photoconductive material.

Here, we report the modelling of PCDMs, defining the key parameters both geometrical and physical that affect the mirror performances.

We applied this approach to both inorganic and organic photoconductors, highlighting the advantages and drawbacks of both technologies. In this way general guidelines to the best choice of the photoconductive layer are provided, focusing mainly to the potential application in astronomical instrumentation.

9912-242, Session P12

Low cost single-mode fiber Etalon for sub-m/s wavelength calibration

Christopher H. Betters, The Univ. of Sydney (Australia); Maxime Hermouet, Thomas Blanc, The Univ. of Sydney (Australia) and Institut National des Sciences Appliquées de Toulouse (France); James I. Colless, Joss Bland-Hawthorn, Sergio G. Leon-Saval, The Univ. of Sydney (Australia)

A fundamental limitation of precision radial velocity measurements is the accuracy and stability of the calibration source. Here we present a low cost alternative to classical systems that utilises a single-mode fibre Fabry-Perot etalon. There are three key elements: i) a fibre etalon with a TEC; ii) a Rb saturation absorption spectroscopy setup; iii) a tunable laser and data acquisition system. We simultaneously measure the Rb transitions near 780.2nm and the closest etalon line. A PID loop controls the etalon temperate to maintain the position of its combs with an RMS error <10cm/s in a 10 minute integration.

The fibre etalon is manufactured by Micron Optics, Inc. to have a finesse of ~40 and a ~400um cavity (giving a FSR of 0.3nm @ 780nm). The etalon used is designed to maintains this finesse for the entire visible band, but other options for use in the NIR and IR regime are also available. The etalon is enclosed with a small thermoelectric cooler. This allows the transmission spectrum to be turned using small changes in temperature. The small size of the cavity allows for relatively quick changes (multiple degree changes can settle in less than a second). A saturation absorption spectroscopy setup allows for precise measurements of the Rb D2 hyperfine transition lines. These lines are known to be very stable (frequency stable to better then 1 in 10^12) and thus provide an excellent reference for calibrating the fibre etalon.

A combined optical path allows the same tunable laser source to simultaneously measure both the Rb hyperfine absorption lines and the etalon combs spectrum. Each spectrum is measure by using a photodiode and a synchronised high-speed analogue-to-digital converter. The Rb spectrum is used as an absolute reference to fix, and ultimately lock, the wavelength of the etalon peaks by varying (or maintaining) the temperature of its cavity. This information feeds a PID control loop that changes the set point of a small TEC controller at a rate of 2-3Hz. The TEC controller itself is a custom board based on the Analog Technologies, Inc. TECA1 chip. Combined with the Rb locking signal it achieves temperature stability of a few mK, which translates to 10s of cm/s error shift in the etalon combs wavelengths.

The etalon spectrum is transmitted to a spectrograph using a series of single-mode fibre switches to swap the input and output of the etalon to between a white light source and the tunable laser to feed either the spectrograph or Rb locking setup respectively. This option will provide a time-domain multiplexing of the etalon between feeding the spectrograph and feeding the locking setup. This also allows for a degree of exposure control by limiting the amount of calibrating light reaching the spectrograph.

9912-243, Session P12

An astro-comb calibrated solar telescope to search for the radial velocity signature of Venus

David F. Phillips, Harvard-Smithsonian Ctr. for Astrophysics (United States); Alexander G. Glenday, Komodo Health (United States); Xavier Dumusque, Nicolas Buchschacher, Observatoire de Genève (Switzerland); Andrew C. Cameron, Univ. of St. Andrews (United Kingdom); Massimo Cecconi, Fundación Galileo Galilei - INAF (Spain); David B. Charbonneau, Harvard-Smithsonian Ctr. for Astrophysics (United States); Rosario Cosentino, Adriano Ghedina, Fundación Galileo Galilei - INAF (Spain); David W. Walsworth, Harvard-Smithsonian Ctr. for Astrophysics (United States)

Detecting terrestrial exoplanets in the habitable zones of Sun-like stars using the radial velocity (RV) method is currently challenged by perturbations induced by stellar surface inhomogeneities including spots, plages and granules leading to jitter in the measured stellar RV. Such stellar jitter is not well understood and is difficult to study in stars other than the Sun because their surfaces are unresolved. We are therefore observing the RV of the Sun by using a small, low-cost solar telescope and the HARPS-N spectrograph, calibrated with a green astro-comb, a laser frequency comb optimized for calibrating high-resolution astrophysical spectrographs. This simple solar telescope, consisting of a lens feeding an integrating sphere and coupled to the HARPS-N spectrograph via an optical fiber, now operates automatically, every clear day. We characterized this telescope both in the lab and on-sky to insure: (i) sufficient scrambling by the integrating sphere; (ii) insensitivity to guiding; and (iii) consistent throughput, independent of acceptance angle such that light from the Sun fed to HARPS-N mimics the light of an unresolved star. We recently demonstrated sub-m/s sensitivity in measuring the Earth-Sun RV with this instrument. Daily observations of the Sun will allow us to characterize the sources of stellar RV jitter; and with the help of solar satellites such as the Solar Dynamics Observatory (SDO), we will characterize the correlation between observed RV and detailed imaging of the solar photosphere. We plan to use these tools to mitigate the effects of stellar jitter with the goal of the detection of Venus from its solar RV signature, thus showing the potential of the RV technique to detect true Earth-twin exoplanets.

NASA's physics of the cosmos and cosmic origins programs manage Strategic Astrophysics Technology (SAT) development

Thai Pham, Bernard D. Seery, NASA Goddard Space Flight Ctr. (United States); Opher Ganel, Knowledge Web, LLC (United States)

The strategic astrophysics missions of the coming decades will help answer the questions "How did our universe begin and evolve?" and "How did galaxies, stars, and planets come to be?" Enabling these missions requires advances in key technologies far beyond the current state of the art. NASA's Physics of the Cosmos (PCOS) and Cosmic Origins (COR) Program Offices manage technology maturation projects funded through the Strategic Astrophysics Technology (SAT) program to accomplish such advances. The PCOS and COR Program Offices, residing at the NASA Goddard Space Flight Center (GSFC), were established in 2011, and serve as the implementation arm for the Astrophysics Division at NASA Headquarters. We present an overview of the Programs' technology development activities and the current technology investment portfolio of 23 technology advancements. We discuss the process for addressing community-provided technology gaps and Technology Management Board (TMB)-vetted prioritization and investment recommendations that inform the SAT program. The process improves the transparency and relevance of our technology investments, provides the community a voice in the process, and promotes targeted external technology investments by defining needs and identifying customers. The Programs' priorities are driven by strategic direction from the Astrophysics Division, which is informed by the National Research Council's (NRC) "New Worlds, New Horizons in Astronomy and Astrophysics" (NWNH) 2010 Decadal Survey report, the Astrophysics Implementation Plan (AIP), and the Astrophysics Roadmap "Enduring Quests, Daring Visions." These priorities include technology development for missions to study dark energy, gravitational waves, X-ray and inflation probe science, and large far-IR and UV/optical/IR telescopes to conduct imaging and spectroscopy studies. The SAT program is the Astrophysics Division's main investment method to mature technologies that will be identified by study teams set up to inform the 2020 Decadal Survey process on several large astrophysics mission concepts.

9912-245, Session P12

Development of high-resolution arrayed waveguide grating spectrometer for astronomical applications: first results

Pradip Gatkine, Yiwen Hu, Tiecheng Zhu, Yang Meng, Sylvain Veilleux, Univ. of Maryland, College Park (United States); Joss Bland-Hawthorn, The Univ. of Sydney (Australia); Mario Dagenais, Univ. of Maryland, College Park (United States)

Astrophotonics is a promising new approach that provides the means to miniaturize next-generation spectrometers for large telescopes and make them more robust and inexpensive. Our research group is developing an on-chip photonic spectrograph to be used for astronomical applications in the near infrared bands (J Band: 1.1-1.4 microns; H band: 1.4-1.7 microns). The target requirements for our spectrograph are: moderate resolving power (~3000), wide spectral range (J and H bands), free spectral range of about 20nm, low on-chip loss of about 20% (1 dB loss), low crosstalk between adjacent on-chip wavelength channels of about 0.1% (-30 dB) and uniform spectral response. A promising photonic technology to achieve these requirements is Arrayed Waveguide Gratings (AWGs).

We have developed our preliminary AWG device using a silica-on-silicon substrate with a very thin layer of Si_3N_4 in the core of our waveguides. We use electron beam lithography to write the AWG pattern to ensure precision and that no gaps are introduced at the interfaces of different geometries on the chip. The waveguide bending losses are minimized by optimizing the geometry of the waveguides. We use 2.8-micron wide and 0.1-micron high silicon nitride core buried inside 15-micron thick SiO_2 cladding. Our first device designed for H band has a resolving power of ~1350 and free spectral range of ~9.5 nm around a central wavelength of 1600 nm. The device footprint is only 12 mm ? 6 mm. The device is broadband (1500-1650 nm), has minimum on-chip loss of about 35% (1.8 dB loss) and crosstalk of about 1% (-20 dB). These results confirm the

functionality of our design, fabrication and simulation methods. Currently, the device is designed for TE polarization and all the results are for TE mode. We are developing separate J- and H-band AWGs with higher resolving power and throughput and lower crosstalk over a wider free spectral range to make them better suited for astronomical applications.

9912-246, Session P12

A monolithic Michelson interferometer-based very high precision Doppler calibration source

Jian Ge, Univ. of Florida (United States)

Searching for habitable Earth-like planets around other stars is one of NASA's major objectives for its space missions. This requires ground-based Doppler spectrographs to reach ~0.1 m/s radial velocity (RV) calibration precision or better to detect (Doppler surveys) or characterize (space transit survey follow-ups) of low-mass planets. However, current RV calibration precision with traditional Thorium-Argon (ThAr) emission lamps can only reach about 0.3 m/s. The technical issues, such as the sparse line density, flux variation, and lamp aging, have limited ThAr emission lamps to this calibration precision. Alternative calibration sources need to be developed to meet the next generation Doppler measurement requirements.

At UF, substantial progress has been made in developing a new calibration source based on a UF patented Monolithic Michelson Interferometer for the TOU optical very high resolution spectrograph (R=100K, 0.38-0.9 microns, 0.7 m/s long-term RV stability) and FIRST near infrared high resolution spectrograph (R=50K, 0.9-1.8 microns). It consists of a temperature-controlled monolithic Michelson interferometer fed with a continuum light source through a multiple mode fiber. It creates sinusoidal spectral lines over a very broad band (0.38-1.8 microns). The light beam interference between the two interferometer arms produces dense sinusoidal combs. This new Sine calibration source has demonstrated ~0.3 m/s RMS scatters over ~12 days with TOU measurements while the median photon limited RV uncertainty is 0.08 m/s. A major effort is being carried out to reduce the non-photon measurement errors while the planned replacement of the tungsten lamp with a broad-band super-continuum would double the photon-limited precision. The latest improvement results will be presented.

9912-248, Session P12

Auxiliary free space optical communication project to ensure continuous transfer of data for DAG the 4m telescope

Onur Keskin, Isik Üniv. (Turkey); Cahity Yesilyaprak, Atatürk Üniv. (Turkey); Sinan K. Yerli, Middle East Technical Univ. (Turkey)

The continuity of the amount of data that the 4m DAG (Eastern Anatolia Observatory in Turkish) telescope will produce and transfer to Ataturk University is critical not to jeopardize the science programs. Though the fiber optics and radio link infrastructures are in place, these systems are still volatile against earthquakes, and possible excavation damages. Thus the 4m DAG telescope will be equipped with a free space optical communication system to ensure the continuity of the data transfer as a backup system. In order to cope with the disturbances introduced by the atmospheric turbulence, the transceiver FSO system will be equipped with a wavefront corrector. In this paper, the cassegrain optical design, and working principle of this system as well as expected performance analyses will be presented.

9912-249, Session P12

Adaptive optics fed single-mode spectrograph for high-precision Doppler measurements in the near-infrared

Christian Schwab, Macquarie Univ. (Australia) and Australian Astronomical Observatory (Australia); Tobias Feger, Macquarie Univ. (Australia); Nemanja Jovanovic, Subaru Telescope, National Astronomical Observatory of Japan (United States); Julian Stürmer, The Univ. of Chicago (United States); Yulia V. Gurevich, Landessternwarte Heidelberg (Germany); David W. Coutts, Macquarie Univ. (Australia); Maria R. Moreno, Australian Astronomical Observatory (Australia) and Univ. Nacional Autónoma de México (Mexico); Gudmundur K. Stefánsson, The Pennsylvania State Univ. (United States); Surangkhana Rukdee, Pontificia Univ. Católica de Chile (Chile); Mark Bakovic, Macquarie Univ. (Australia); Nick Cvetojevic, Australian Astronomical Observatory (Australia) and The Univ. of Sydney (Australia); Samuel P. Halverson, The Pennsylvania State Univ. (United States); Jonathan S. Lawrence, Australian Astronomical Observatory (Australia) and Macquarie Univ. (Australia); Suvrath Mahadevan, The Pennsylvania State Univ. (United States); Leonardo Vanzi, Pontificia Univ. Católica de Chile (Chile)

We present the design and preliminary results for a high resolution near infrared spectrograph. It is fed by a single mode fibre coupled to a high performance adaptive optics system, leading to an extremely stable instrument with high total efficiency. The optical design is a cross dispersed Echelle spectrograph based on a white pupil layout. The instrument uses an R6 Echelle grating with 13.3 grooves per mm, enabling very high resolution with a small beam diameter. The optical design is diffraction limited to allow for optimal performance; this leads to subtle differences compared to spectrographs with large input slits.

9912-250, Session P12

Optical system for Galaxy Evolution Spectroscopic Explorer (GESE)

Qian Gong, Sara R. Heap, NASA Goddard Space Flight Ctr. (United States); Tony B. Hull, The Univ. of New Mexico (United States)

The scientific goal of GESE mission is to answer the question: How did galaxies evolve into the spiral, elliptical, and irregular galaxies that we see today? This paper concerns the optical tools needed to achieve this goal. A UV multi-object slit spectrometer is designed to conduct a large ultraviolet spectroscopic survey of galaxies at a redshift, z~1-2. A camera is designed to acquire the target galaxies in the slits of the spectrometer. A Digital Micromirror Device (DMD) serves as a slit mask, sending light from the target galaxies to the spectrometer, and light from the remainder of the field of view, to the camera. This paper focuses on the designs of the 1.2m Three-Mirror Anastigmat (TMA) telescope and the "offner like" spectrometer and camera. In the latter design, the spherical mirrors in the offners, for both spectrometer and camera, are replaced with free-form aspheric mirrors in order to achieve the required spectral and special resolutions over the large field of view. The optical alignment and metrology will also be addressed. Finally, the connection between the science goal and optical system specification is also presented.

9912-251, Session P12

Optimizing small space telescopes

Tony B. Hull, The Univ. of New Mexico (United States); Sara R. Heap, NASA Goddard Space Flight Ctr. (United States)

Science-driven metrics are convolved with current technology to seek an optimum approach to small space telescopes. Our optimization is for cost, since cost includes management of risk, robustness of optical design, resilience to thermal environments, and overall opto-mechanical stability. These factors will be discussed in the context of the 1.2m Galaxy Evolution Spectroscopic Explorer (GESE) mission concept.

9912-264, Session P12

Back-propagating the light of field stars to probe Euclid mirrors aberrations

Ferréol Soulez, Frederic Courbin, Michael Unser, Ecole Polytechnique Fédérale de Lausanne (Switzerland)

To meet Euclid's stringent requirements on the PSF knowledge, we propose a wavefront based method to estimate the PSF over the whole field of view. Indeed, the PSFs at every position of the field of view are fully characterized by aberrations of each optical surface of the telescope and can be computed using Fourier beam propagation (Roey et al. 1981, J. Opt. Soc. Am., 71, 803). Although these aberrations can be calibrated on ground, it is probable that they will not remain stable enough after launch. One possible way to measure the wavefront on orbit would be to strongly defocus and refocus the telescope, an operation that is highly risky and that will not be implemented by ESA.

We therefore propose a method to use scientific observations to estimate wavefront aberrations on the few optical surfaces of Euclid telescope. It uses each observed bright star as a source of a coherent plane wave to probe these aberrations in the same manner it was already done for diffraction tomography (Kamilov et al. 2015, Optica, 2, 517). This method will monitor the surface of every Euclid's mirrors bringing a new access to all its optical component status without any need to move optical elements. In addition, as it will use stars present in the scientific channel, it will not require any additional calibration time. Finally, the knowledge of these optical surfaces will give the mean to estimate the PSF at all wavelength and in each point of the field of view solving the problem of PSF interpolation on positions of lensed galaxies.

This problem of determining mirrors aberrations using many images of stars is solved in an inverse problem framework. For each star, the forward model is free space propagation of a plane wave (whose angle is given by the star position) across the telescope optics ended by intensity recording in the detector plane. This model is non linear, however, as propagation between each mirror is a linear operation, modeling errors can be back propagated and used to update the estimated aberrations of each mirrors. These back propagated errors for many stars across the field of view are used by a continuous optimization algorithm (VMLMB, Thiébaut 2002, SPIE Proc. 4847, 174-183) to probe precisely these aberrations. In this algorithm, the phase retrieval problem given the measured intensity is solved by the mean of an adapted proximity operator (Schutz 2014, J. Opt. Soc. Am. A 31, 2334-2345). In this communication, we will present results on simulated data for a simplified Euclid telescope model for both narrow and broad band.

9912-265, Session P12

Optimization of high sensitivity parametric transducers for the Gravitational Wave Detector "Mario Schenberg".

Vincenzo Liccardo, Instituto Tecnológico de Aeronáutica (Brazil); Elvis Ferreira, Rogeiro Oliveira, Odylio Aguiar, Instituto Nacional de Pesquisas Espaciais (Brazil)

The Mario Schenberg Gravitational Wave Detector, which has a spherical resonant antenna, started commissioning operation on September 2006 and involves collaboration between many Brazilian institutions such as INPE, USP, ITA, IFSP and also some foreign universities. The Schenberg antenna is the only spherical antenna equipped with a set of parametric transducers for gravitational wave detection. When coupled to the detector, transducers are able to monitor its mechanical quadrupolar modes. On the basis of the recent good results obtained in terms of sensitivity, a new set of transducer, which makes use of superconducting reentrant cavities, are being developed at the National Institute for Space Research (INPE). In this work we will establish a systematic procedure to manufacture high sensitivity transducers with the aim of obtaining Q-factors of the order of 10^5 in cryogenic conditions.

9912-266, Session P12

The Reconnaissance & Early-warning Optical System Design for Dual Field of Space-Based "Solar Blind Ultraviolet"

Wang Wencong, Shandong Aerospace Electro-technology Institute (China)

With the development of modern technology, especially the development of information technology at high speed?the ultraviolet (UV) early warning system plays an increasingly important role. In the modern warfare, how to detect the threats earlier, prevent and reduce the attack of precision-guided missile has become a new challenge of missile warning technology [2]. Because the ultraviolet warning technology has high environmental adaptability, the low false alarm rate, small volume and other advantages, in the military field applications it has been developed rapidly .

The ultraviolet optical system is in the forefront of the ultraviolet early warning system, so it is equivalent to the eye of the entire system. Its main task is to collect the infrared radiation from the target and background to the detector. For the UV early warning system, the optimal working waveband is 250 nm ~280 nm (Solar Blind UV) due to the strong absorption of ozone layer .

According to current application demands for solar blind UV detection and early warning, this paper proposes a reconnaissance & early-warning optical system, which covers solar blind UV (250nm-280nm) and dual field. This structure takes advantage of a narrow field of view and long focal length optical system to achieve the target object detection, uses wide-field and short focal length optical system to achieve early warning of the target object. It makes use of an UV beam-splitter to achieve the separation of two optical systems. According to the detector and the corresponding application needs of two visual field of the optical system, the calculation and optical system design were finished. A single pixel energy concentration is greater than 80%.

The paper is organized as follows. Section one systematically expounds the principle of ultraviolet-detection technology and detector devices of the structure and performance. The development of ultraviolet early warning system at home and abroad is introduced Designs the missile simulation systems and the ultraviolet-objective of alarm systems were summarized. Section two tries to state the working principle of the reconnaissance & early-warning optical system. Section three completes the work of the

study and the optical system design of the reconnaissance & early-warning optical system. This work includes the calculation of the parameter of the optical system, the selection of original configuration and the optimization of the solar blind ultraviolet optical system. Section four gives the design results and evaluation of image quality.

9912-84, Session 16

Advances in far-ultraviolet reflective and transmissive coatings for space applications

Luis Rodríguez-de Marcos, José Antonio Méndez, José Antonio Aznárez, Juan I. Larruquert, Manuela Vidal-Dasilva, Consejo Superior de Investigaciones Científicas (Spain); A. Marco Malvezzi, Univ. degli Studi di Pavia (Italy); Angelo Giglia, Istituto Officina dei Materiali (Italy) and Consiglio Nazionale delle Ricerche (Italy); Gerardo Capobianco, Giuseppe Massone, Silvano Fineschi, INAF - Osservatorio Astrofisico di Torino (Italy); Stefano Nannarone, Istituto Officina dei Materiali (Italy) and Consiglio Nazionale delle Ricerche (Italy)

Exploitation of far ultraviolet (FUV, 100-200 nm) observations extends to most areas of modern astronomy, from detailed observations of Solar System objects, the interstellar medium, exoplanets, stars and galaxies, to studies of crucial cosmological relevance. Despite several developments in recent decades, yet many observations are not possible due to technical limitations, of which one of the most important is the lack of optical coatings with high throughput. Development and optimization of such efficient FUV coatings have been identified in several roadmap reports as a key goal for future missions. The success of this development will ultimately either improve the performance of nowadays feasible optical instruments or enable new scientific imaging capabilities.

In this communication, FUV coatings for space observations developed at GOLD will be reviewed. These coatings include transmittance filters, narrowband mirrors, along with efficient polarizers.

Hence we will present the performance of narrowband and broadband transmittance filters based on Al and MgF_2. These filters are tuned on several spectral lines or bands in the FUV, presenting a high peak-to-visible rejection ratio with a good FUV performance.

New advances in reflective coatings will be also shown. Reflectors based on either combinations of MgF_2 and LaF_3 or combinations of LiF, Al, and SiC have been developed. Target ranges include lines of high interest for space observations, such as H Lyman ? (121.6 nm) and ? (102.6 nm), OI (130.4 nm), and OVI (103.2-103.8 nm).

Finally, we will also show our recent developments on coating polarizers based on Al and MgF_2, which are tuned at H Lyman ? line and operate either by reflectance or transmittance. Reflective polarizers present a high throughput; moreover, a new concept of transmissive polarizers including spectral filtering properties (such as narrowband profile and visible rejection) has been designed and preliminarily tested.

9912-85, Session 16

Use of plasma enhanced ALD to construct efficient interference filters for astronomy in the FUV

Paul A. Scowen, Robert Nemanich, Brianna Eller, Arizona State Univ. (United States); Matthew Beasley, Planetary Resources, Inc. (United States); Hongbin Yu, Arizona State Univ. (United States); Thomas Mooney, Materion Corp. (United States); Franz Koeck, Arizona State Univ. (United States)

Our program uses a range of materials to implement stable optical layers suitable for protective overcoats with high UV reflectivity and unprecedented uniformity, and use that capability to leverage innovative ultraviolet/optical filter construction to enable a range of observational astronomical science in the far ultraviolet (FUV). The materials we will use include aluminum oxide and hafnium oxide (as an intermediary step for development only) and progressing to a range of fluoride-based compounds (for production). These materials are deposited in a multilayer format over a metal base to produce a stable construct. Specifically, we will employ the use of PEALD (plasma-enhanced atomic layer deposition) methods for the deposition and construction of reflective layers that can be used to construct unprecedented filter designs for use in the ultraviolet. Our designs indicate that by using PEALD, we can further reduce adsorption and scattering in the optical films as a result of the lower concentration of impurities and increased control over the stoichiometry to produce vastly superior quality and performance over comparable traditional thermal ALD techniques currently being developed by other NASA-funded groups.

Our program seeks to demonstrate several things:

• That films of material can be deposited as a demonstration of the approach using PEALD techniques to produce low-loss oxide films of materials such as Si, Hf and Al. The resulting coatings will be of a thickness and a purity far higher than can be delivered by current techniques that involve sputtering deposition.

• That using the same deposition techniques, PEALD can be used to deposit thin (10s of nm) low-loss films of fluoride materials such as MgF_2, LiF, AlF_3, LaF_3, CaF_2, BaF_2 that will be used as protective overcoats for materials that can easily be oxidized by exposure to air.

• That Al deposition, protective layer deposition and characterization can be completed in-situ. Such a controlled environment will minimize the oxidation forming undesirable compounds, to improve the reflectivity of the resulting films and their interfaces by reducing scattering and adsorption.

• That deposition of such protective overcoats over aluminum metal can be achieved with PEALD to provide a sufficiently crystalline, uniform and stable structure that extend the range of diagnostic emission and absorption lines available for science.

• To apply multiple alternating layers of metals and dielectrics using our PEALD approach to produce multi-cavity structures exhibiting very high performance. This goal is currently limited by the inability to deposit very thin layers with great accuracy, while demonstrating film toughness and 'bulk' thin film material losses.

• To apply the PEALD approach to the construction of multi-layer dielectric layers to act as reflection filters or high reflectors in narrow band systems.

• To similarly construct multi-layer broadband reflective surfaces which are thought to exhibit higher performance than metal-based mirrors (using a short wave extension to prototype dichroics our group is already developing for space).

9912-86, Session 16

Update on UCO's advanced coating lab development of silver-based mirror coatings

Andrew C. Phillips, Univ. of California Observatories (United States); David M. Fryauf, Nobuhiko P. Kobayashi, Univ. of California, Santa Cruz (United States); Brian DuPraw, Univ. of California Observatories (United States); Spencer M. Cheleden, Pacific Collegiate School (United

States); Christopher T. Ratliff, Michael Bolte, David J. Cowley, Univ. of California Observatories (United States)

We present progress in efforts underway at the University of California Observatories to develop high performance durable silver-based mirror coatings for telescope and instruments. Silver-based coatings are extremely prone to tarnish and/or corrosion, and successful coatings depend not only on the materials used but also the deposition processes employed. Our PVD deposition chamber allows both sputtering and ion-assisted e-beam depositions for head-to-head comparison of deposition processes, and we present results of these comparisons. We present a systematic study to determine which oxides, nitrides and fluorides provide the best protection in environmental tests. We are exploring a number of new materials that show some promise for increased durability. We also report on our further studies using Atomic Layer Deposition (ALD) over-coating of Ag, which a pilot study demonstrated significant benefit to durability. We also describe our large ALD research chamber currently under construction that will demonstrate ALD processes on larger substrates (70 cm diameter). This chamber should be operational around the time of the conference.

9912-87, Session 16

Advanced astronomical filter design: challenges, strategy, and results to meet current and future requirements

Steffen Reichel, SCHOTT AG (Germany) and Hochschule Darmstadt (Germany); Ralf Biertümpfel, SCHOTT AG (Germany); Ulf Brauneck, Sébastien Bourquin, SCHOTT Suisse SA (Switzerland); Antonio Marín-Franch, Ctr. de Estudios de Física del Cosmos de Aragón (Spain)

The Observatorio Astrofísico de Javalambre in Teruel, Spain (OAJ) is a astronomical facility whose primary role will be to conduct all-sky astronomical surveys. The OAJ facility has a wide-field telescope, the JST/T250; a 2.55 m telescope with a 3º diameter field of view (FoV) designed to perform the Javalambre Physics of the Accelerating Universe Astrophysical Survey (JPAS). In addition the Javalambre Auxiliary Survey Telescope (JAST/T80) is an 80 cm Ritchey Chrétien telescope with a 2º diameter FoV, particularly defined for carrying out large sky photometric surveys. For both telescopes challenging steep edge narrow bandpass filters are needed requiring the development of new filter designs. The filters had typically a FWHM bandwidth of 14.5 nm and center wavelengths (cwl) from about 380 nm to 900 nm.

The filters work under fast convergence and observe with a mosaic of multiple filters simultaneously. Therefore the filters must have outstanding performance to ensure high quality scientific image. Due to the requirement of broad blocking and low reflectivity a combination of color glass (absorption filter) and coated clear glass (interference filter) was used. In order to assure the image quality the effective refractive index of the filter assembly had to be determined and the filter thickness was adopted by optical design simulations for each filter. Measuring the wavelength dependent refractive index of color glass is difficult since color glass absorbs light and a measurement method based on transmission is not sufficient. Here a prism coupling method was necessary for the wavelength dependent refractive index determination of the used color glass. Based on these measurements the filter assembly was designed and used for optical design of the whole system to determine the effective filter thickness used for the final filter. In addition the transmitted wavefront error (TWE) over the clear aperture of about 100 mm x 100 mm had to be strictly below lambda/2 at 633 nm. Due to the broad blocking of the narrow bandpass filter, a standard TWE measurement was not possible. Therefore a new white-light Shack Hartmann wavefront measurement system was needed that measures the TWE at the passband. Moreover the spectral edges have to be steep for a small transition width from 5% to 80% and so typically a 6 cavity interference filter design had to be chosen. The steep edges together with a center wavelength uniformity (< ±0.2 %), high transmission (Tmax > 85 %), and broad blocking (out of band blocking with average transmission less than 10-5 from 250 nm and up to 1050 nm) lead to an interference filter design of well above 100 layers and a total coating layer thickness of a few micrometers. The final filter assembly consisting of color glass and coated clear glass were fully characterized and fulfilled the spectral, the transmitted wavefront, and final scientific image quality requirements due to the chosen design, characterization of all sub-components, and manufacturing strategy.
All these requirements have to be fulfilled for an operation temperature between -20°C and + 20°C.

9912-88, Session 16

Advanced optical coatings for astronomical instrumentation

Fabien Pradal, REOSC (France)

Recently REOSC worked and progresse on various thin film technology for : Large mirrors with low stress and stabel coatings

Large lens elements with strong curvature and precise layer specifications

Large filters with high spectral response uniformity specifications

IR coatings with low stress and excellent resistance to cryogenic environment for NIR to LWIR domains.

Results will presented and discussed on the basis of several examples.

9912-89, Session 17

The broad-band vector Apodizing Phase Plate (vAPP) coronagraph: NIR liquid crystal performance and future developments

Gilles P. P. L. Otten, Frans Snik, Matthew A. Kenworthy, Christoph U. Keller, Leiden Observatory (Netherlands); Jared R. Males, Katie M. Morzinski, Laird M. Close, Philip M. Hinz, Johanan L. Codona, The Univ. of Arizona (United States); Michael J. Escuti, North Carolina State Univ. (United States)

The Apodizing Phase Plate (APP) is a phase-only pupil-plane coronagraph that suppresses starlight in a predefined region (typically D-shaped and 2 to 7 lambda/D) by several orders of magnitude. Being located in the pupil plane its performance is insensitive to residual tip-tilt variations.

Using liquid crystal technology we developed a novel and improved version of the APP: the broadband vector Apodizing Phase Plate (vAPP). The vAPP consists of an achromatic half-wave retarder pattern with a varying fast axis on <10 micron spatial scales. The fast axis encodes the required phase pattern through the vector phase, while multiple twisting liquid crystal layers produce a nearly constant half-wave retardance over a broad wavelength range. The liquid crystal manufacturing method allows a high control of the phase of the plate with high spatial resolution and a broad-band near half-wave retardance. Because the pupil phase pattern is antisymmetric, this device produces two complementary PSFs with dark holes on opposite sides, after splitting opposite circular polarizations. To enable easy installation in existing instruments a phase ramp is added to the vAPP phase pattern that splits the two PSFs without adding optics, effectively creating a coronagraphic polarization grating (aka grating-vAPP / gvAPP).

After shortly explaining the principle behind the vAPP we present a progress update of its on-sky performance in terms of the broad-band NIR (2 to 5 micron) achromaticity (zeroth order leakage / retardance) and throughput. These values are derived from on-sky measurements with the

vAPP coronagraph installed on MagAO/Clio2.

As the gvAPP is one of the baseline coronagraphs for E-ELT/METIS we furthermore present phase designs that can be implemented on the E-ELT. This includes both conventional D-shaped designs and 360 degree suppressing solutions which use the leverage provided by the high spatial resolution of liquid crystal manufacturing.

9912-90, Session 17

Mathematical modeling and experimental evaluation of a ferrofluid deformable mirror for high-contrast imaging

Aaron J. Lemmer, Princeton Univ. (United States); Ian M. Griffiths, Univ. of Oxford (United Kingdom); Tyler D. Groff, Princeton Univ. (United States); Andreas W. Rousing, Technical Univ. of Denmark (Denmark); N. Jeremy Kasdin, Princeton Univ. (United States)

Deformable mirrors (DMs) are an enabling and mission-critical technology in any coronagraphic instrument designed to directly image earth-like exoplanets in the habitable zone of their parent stars. In order to maximize the number of characterizable planets, a space-borne observatory with this mission must achieve a high degree of contrast between a target star and the region of space surrounding it, and this high-contrast search region must be as large as possible. Stellar coronagraphs designed to achieve this capability suffer from optical aberrations, which create speckles that compromise the contrast over this field of view. Closed-loop wavefront control techniques, implemented with deformable mirrors, must suppress---to the order of 10^{-10} over the search window--any speckles which might obscure or be indistinguishable from a planet. A new ferrofluid deformable mirror technology for high-contrast imaging is currently under development at Princeton, featuring a flexible optical surface manipulated by the local electromagnetic and global hydraulic actuation of a reservoir of ferrofluid. The ferrofluid DM is designed to prioritize high optical surface quality, high-precision/low-stroke actuation, and excellent low-spatial-frequency performance---capabilities which meet the unique demands of high-contrast coronagraphy in a space-based platform. To this end, the ferrofluid medium continuously supports the DM facesheet, a configuration which eliminates actuator print-through (or, quilting) by decoupling the nominal surface figure from the geometry of the actuator array. The global pressure control decouples focus control from the local actuation, bestowing the device with a mode of high-fidelity low-order control impossible with contemporary technologies. Mediated by the pressure and magnetic body force within the ferrofluid, the hydraulic actuator and electromagnetic transducer array shape the flexible facesheet by controlling the distribution of the transverse load across its surface. Here we describe this interaction with an analytical model for the two-dimensional quasi-static deformation response of the DM facesheet to both magnetic and pressure actuation. These modeling efforts serve to (a) identify the key design parameters (e.g., facesheet thickness, actuator size/strength, fluid reservoir depth, or mechanical boundary conditions) and quantify their contributions to the DM response, (b) model the relationship between actuation commands and DM surface-profile response, and (c) predict performance metrics such as achievable spatial resolution and stroke precision for specific actuator configurations. Our theoretical approach addresses the complexity of the boundary conditions associated with mechanical mounting of the facesheet, and makes use of asymptotic approximations by leveraging the three distinct length scales in the problem---namely, the low-stroke ($\sim$nm) actuation, facesheet thickness ($\sim$mm), and mirror diameter ($\sim$cm). In addition to describing the theoretical treatment, we report the results of laboratory experiments with our most recent prototype and compare our models with the experimental observations.

9912-91, Session 17

Advanced coronagraph designs for segmented aperture telescopes

Garreth J. Ruane, California Institute of Technology (United States); Dimitri Mawet, California Institute of Technology (United States) and Jet Propulsion Lab. (United States); Laurent Pueyo, Space Telescope Science Institute (United States) and Johns Hopkins Univ. (United States); Jeff Jewell, Stuart B. Shaklan, Jet Propulsion Lab. (United States) and California Institute of Technology (United States)

Current state-of-the-art high contrast imaging instruments take advantage of a number of elegant coronagraph designs to precisely suppress starlight and image nearby faint objects, such as exoplanets and protoplanetary disks. However, the ideal performance of coronagraphs depends strongly on the shape of the telescope aperture. Large primary mirrors tend to have segmented pupils with various obstructions, which often result in severe limitations on the ideal contrast performance of conventional coronagraph designs. We present optical systems that take advantage of numerically optimized amplitude and phase masks to provide improved performance with realistic telescope apertures. The planet to star contrast is enhanced over a relevant field of view and broad wavelength range without significant loss in throughput. We use synergistic design methods that may be applied to arbitrary apertures, including large ground-based telescopes, such as Keck and the Thirty Meter Telescope (TMT), as well as potential next-generation space telescopes.

9912-92, Session 17

Digital adaptive coronagraphy using SLMs: promising prospects of a novel approach, including high-contrast imaging of multiple stars systems

Jonas G. Kuhn, Polychronis Patapis, ETH Zürich (Switzerland)

We introduce a new technological framework for high-contrast coronagraphy, namely digital adaptive coronagraphy (DAC). The approach makes use of pixelated spatial light modulators (SLMs) in place of manufactured phase-mask focal-plane coronagraphs, taking advantage of the recent advances in this technology. Indeed, commercially-available SLM devices nowadays offer pixel sizes well below 10 um with fill-factor in excess of 90%, and some models now provide full phase-only modulation up to H-band at a framerate of 60Hz. In principle, this can make SLMs credible alternatives to fixed pre-manufactured phase masks for a range of chronographic configurations in the visible and near-infrared, opening an uncharted discovery space for adaptive coronagraphy.

Here we present a set of proof-of-principle experimental results obtained in the visible on our high-contrast imaging bench at ETH Zurich. First, we show that SLMs can be successfully implemented as focal-plane phase-mask coronagraphs for realistic instrumental F/#, delivering competitive peak-to-peak starlight rejection ratio beyond 1:100, hence meeting requirements set by typical on-sky Strehl ratios delivered by the current 2nd-generation AO systems. In practice, a variety of classical coronagraphic phase maps can be readily programmed into the SLM, like four-quadrants phase mask (FQPM), eight-octants phase mask (EOPM), and scalar vortex phase ramps with various topographic charges.

Second, we highlight a specific application where SLM-based adaptive coronagraphic might be particularly well suited, which is high-contrast imaging of multiple stars systems (binaries, triples, etc...). Indeed, we show that SLM phase maps can be readily re-programmed to simultaneously

null multiple point sources in the focal plane by carefully weighted superposition of coronagraphic phase patterns for a given target system, thus enabling to reach deep contrast inside a 360-degree field-of-view, whereas the regular static phase mask approaches would be adversely affected by the leakage of the stellar companion(s). To this purpose, we present comprehensive laboratory results exploring the parameter space covering the case of imaging binaries, in terms of separation, brightness ratio, pixel sampling at the SLM level, and geometry of the phase maps.

Finally, we attempt to broadly cover other applications where we think SLM-based adaptive coronagraphy may show great potential in the future, including wavefront sensing, optimized phase profiles for realistic telescope pupils, seeing- and aberration-matched real-time close-loop adaptive operations, synchronous detection, etc... We show corresponding preliminary proof-of-principle results, whenever already available.

9912-93, Session 17

Subwavelength grating vortex of charge 4 (SGV4): manufacturing assessment and performance analysis

Christian Delacroix, Cornell Univ. (United States); Dmitry Vorobiev, Rochester Institute of Technology (United States); Garreth J. Ruane, Dimitri Mawet, California Institute of Technology (United States); Ernesto Vargas Catalan, Mikael Karlsson, Uppsala Univ. (Sweden); Olivier Absil, Univ. de Liège (Belgium)

Vortex coronagraphs are instrumental solutions allowing high contrast direct imaging of exoplanets at small inner working angles, down to the diffraction limit of the telescope. These coronagraphs are composed of a focal-plane spiral-like phase mask, that can be made achromatic over large bandwidths by etching subwavelength gratings onto a synthetic diamond substrate. Over the past 3 years, several subwavelength grating vortex (SGV) phase masks, referred to as annular groove phase masks (AGPM), have been manufactured by our team (i.e. the VORTEX Project), validated on dedicated optical benches, and installed on 10m class ground-based telescopes (VLT/NACO, VLT/VISIR, LBT/LMIRCam, and Keck/NIRC2). More recently, we have proposed several original designs of next generation SGVs with higher topological charges (i.e. number of vortex phase revolutions). In this talk, we report on our latest development of an SGV4 (i.e. charge-4 vortex phase mask). We present our final design with minimized discontinuities and optimized phase ramp, and we show the results of our 3D rigorous numerical simulations using a finite-difference time-domain (FDTD) algorithm. We then show the results of our first manufacturing tests, using diamond-optimized microfabrication techniques such as reactive ion etching and nano-replication technique. Finally, we conclude with the performance analysis of our first prototypes based on surface profile metrology, as a prelude to laboratory tests on a dedicated coronagraphic testbed.

9912-94, Session 17

Precision optical edges for a starshade external occulter

John Steeves, Stefan R. Martin, Douglas Lisman, David R. Webb, Stuart B. Shaklan, Jet Propulsion Lab. (United States)

Starshades offer a method of performing high contrast imaging using space-based telescopes. The primary function of a starshade is to suppress light from a target star in order to image its orbiting planets. In order to provide the proper apodization function the edges of the starshade must follow a precise in-plane profile (accurate to < 50 μm RMS). However of equal importance is the issue of light from our own sun scattering off of the edges and entering the telescope. A method to alleviate this problem is to make the edges extremely sharp (< 1 μm radius) such that the area available for light-scattering is minimized. The combination of these two requirements, along with the need to integrate the edges into a 30-40 m dia. deployable structure, present a number of significant engineering challenges.

Substrate etching techniques are used to obtain the intended profile as well as the edge sharpness. Current efforts have implemented an isotropic etching process on thin metal substrates. With this technique a 1.0 m long substrate is patterned with the in-plane profile via photolithography techniques. The substrate is then immersed in an acidic solution and the material away from the photomask is removed in a near-isotropic fashion. This produces a “sickled” cross-section with a sharp terminal edge. Currently, amorphous metal substrates have been implemented due to their high elasticity, availability in thin sheet form, and absence of grain boundaries. However, high levels of internal stress inherent to the material have created a number of problems that ultimately reduce the quality of the edges across its entire length. Therefore, studies have been performed related to material selection, substrate thickness, and etching conditions in an effort to optimize the results of the etching process. Highly-directional etching techniques as well as post-manufacturing processes have also been explored and the advantages/challenges of each will be presented.

In addition to the initial manufacturing process, proper handling of the delicate edges during spacecraft assembly as well as survivability during launch are also of great concern. Prevention of damage during assembly is challenging as the edges are essentially unprotected optical elements. In addition, the variation in environmental conditions from the time of manufacture to the final launch date can result in a degradation of quality as a whole. Studies pertaining to edge durability and its effect on scattered light performance will be outlined. Techniques to mitigate damage before launch and upon orbit will also be presented.

Conference 9913: Software and Cyberinfrastructure for Astronomy IV

Sunday - Thursday 26–30 June 2016

Part of Proceedings of SPIE Vol. 9913 Software and Cyberinfrastructure for Astronomy III

9913-1, Session 1

SKA Telescope Manager (TM): status and architecture overview *(Invited Paper)*

Swaminathan Natarajan, Tata Consultancy Services, Ltd. (India); Yashwant Gupta, National Ctr. for Radio Astrophysics (India); Paul Swart, Gerhard Le Roux, SKA South Africa (South Africa); Alan Bridger, UK Astronomy Technology Ctr. (United Kingdom); Subhrojyoti R. Choudhury, Tata Consultancy Services, Ltd. (India); Mauro Dolci, Istituto Nazionale di Astrofisica (Italy); Domingos Barbosa, Instituto de Telecomunicações (Portugal); Lize Van den Heever, SKA South Africa (South Africa); Juan C. Guzman, Commonwealth Scientific and Industrial Research Organisation (Australia); Sonja Vrcic, NRC - Herzberg Astronomy & Astrophysics (Canada)

The Square Kilometer Array Radio Telescope project is building two telescopes, one each in Australia and South Africa. The Australian telescope, SKA-Low, will include hundreds of dipole array stations, while the South African telescope, SKA-Mid, includes over a hundred dishes with wideband single pixel feeds, and will incorporate the MeerKAT telescope currently under construction. Both telescopes will include pulsar search and pulsar timing capabilities. This is phase 1 of SKA: subsequent phases will expand the scale and baselines by a factor of 30-50, and possibly include additional telescopes and more receiver types.

A central feature of the project is the decision to maximize commonality among the telescopes. Accordingly, a key approach to development of the telescope management systems of the two telescopes is a common design, with limited variabilities, by a consortium from several countries, including India, South Africa, UK, Italy, Portugal, Canada and Australia. The project is currently in the design phase. A Preliminary Design Review of the architecture has been successfully completed, along with a rebaselining effort that re-scaled the SKA project to fit within available budget. The rebaselining included deferring a third proposed telescope (SKA Survey), resizing the two existing telescopes, and some significant feature changes. That such changes did not necessitate significant architectural changes to the Telescope Manager speaks to the success of the team's endeavour to create a generic specifications-driven radio telescope control and observations management architecture.

This paper will provide a status update on the control systems design effort, including the selection of the TANGO control systems framework and other technology choices. It will also discuss key challenges in the TM architecture, and our approaches to addressing them. The scale of the SKA, especially phase 2 which would expand it to thousands of receptors and baselines of thousands of kilometers, poses several challenges. This includes the need for high-levels of automated operation, creation of effective operator displays avoiding alarm floods and operator overload, dealing with faults and failed elements as a given during normal operations in a large system and allowing commissioning, integration and upgrades to co-exist with normal operations without disrupting it. The requirement to integrate precursors that are themselves currently under construction, accommodate heterogeneous receptor types and frequency bands, and support evolution during the 50-year observatory lifetime all necessitate a design that allows for monitoring and control of a heterogeneous and continuously evolving system.

We present our approach to addressing these challenges, including the adoption of a data-driven control systems architecture, standardized interfaces to system elements and the concept of Capabilities that facilitates resource management and scheduling. While this paper provides an architectural overview, other papers also submitted to this conference cover specific aspects, including the observation control system, challenges in observation management, the monitoring and control system design, self-management system and TM maintenance.

9913-2, Session 1

The software architecture to control the Cherenkov Telescope Array

Igor Oya, Matthias Fuessling, Deutsches Elektronen-Synchrotron (Germany); Pablo Oliveira Antonino, Fraunhofer-Institut für Experimentelles Software Engineering (Germany); Vito Conforti, INAF - IASF Bologna (Italy); Lars Hagge, Deutsches Elektronen-Synchrotron (Germany); Andreas Morgenstern, Fraunhofer-Institut für Experimentelles Software Engineering (Germany); Gino Tosti, Univ. degli Studi di Perugia (Italy); Ullrich Schwanke, Humboldt-Univ. zu Berlin (Germany); Joseph Schwarz, INAF - Osservatorio Astronomico di Brera (Italy); Peter Wegner, Deutsches Elektronen-Synchrotron (Germany); Josep Colomé, Institut de Ciències de l'Espai (Spain); Etienne Lyard, Univ. de Genève (Switzerland)

The Cherenkov Telescope Array (CTA) is an initiative to build two large arrays of Cherenkov gamma-ray telescopes. CTA will be deployed as two installations, one in the northern, and the other in the southern hemisphere, containing tens of telescopes of different sizes. CTA is a big step forward in the field of ground based gamma-ray astronomy, not only because of the expected scientific return, but also due to the order of magnitude larger scale of the instrument to be controlled. The performance requirements associated to such a large and distributed astronomical installation require a thoughtful analysis to determine the best software solutions.

The array control and data acquisition (ACTL) project within CTA will deliver the software to control and acquire the data from the CTA instrumentation. In this contribution we present the current status of the formal ACTL system decomposition in software building blocks, and the relationship between them. The system is modelled via the Systems Modeling Language (SysML) formalism. To cope with the complexity of the system, this architecture model is sub-divided into different perspectives. The relationships with the stakeholders and external systems are used to create the first perspective, the context of the ACTL software system. Use cases are used to describe the interaction of those external elements with the ACTL system, and are traced to a hierarchy of functionalities (abstract system functions) describing the internal structure of the ACTL system.

These functions are then traced to fully specified logical elements (software components), the deployment of which, as technical elements, is also described. This modelling approach allows us to decompose the ACTL software in elements to be created and the flow of information within the system, allowing a clear way to identify sub-system interdependencies. This architectural approach allows us to build the ACTL project model, linking requirements with deliverables as well as permitting the implementation of a flexible use-case driven software development approach thanks to the traceability from use cases to the logical software elements. The Alma Common Software (ACS) container/component framework, used for the control of Atacama Large Millimeter/submillimeter Array (ALMA) is the basis for the ACTL software, and as such it is considered as an integral part of the software architecture.

9913-3, Session 1

The transition from construction to operations on the ALMA control software

Ralph G. Marson, Rafael Hiriart, National Radio Astronomy Observatory (United States)

The Atacama Large Millimeter/Submillimeter Array (ALMA) is a set of 66 millimeter wave radio dishes high in the Andes in Northern Chile. All antennas are connected and operate as an interferometer making ALMA the most powerful millimeter telescope in the world. In 2013 ALMA was inaugurated and this formally marked the end of construction and the beginning of operations. This paper will focus on the impact, on the ALMA control software, of this transition from construction to operations.

The ALMA control software controls the hardware that does the observations. It reads an XML document, called a scheduling block, which contains a specification of an observation. This is interpreted by a hierarchy of software that converts this specification to a set of scans, adds any missing calibrations & determines what calibrators are most suitable. The scans are scheduled to It then sends detailed commands, at just the right time, to all the relevant pieces of hardware, including the correlator, front-end & antennas. There are around 100 separate computers, most of them running a real-time operating system, that work as one system to ensure that suitable astronomical data, and all necessary meta-data, is sent to the archive for use by the data reduction software.

During the construction period, of over ten years, the ALMA control software was a crucial piece of all ALMA activity. Any tests that needed control of more than one piece of hardware and could not be done in a lab required the coordination of the ALMA control software. Numerous "throwaway" bits of software were produced for various specialized purposes. The emphasis was not on writing the software to support science observations but on supporting the commissioning tests and software to check that the hardware was meeting specifications. Because the software to support science observations could not be ignored there frequently were conflicting demands on the control software team. Important priorities often took second place to the urgent ones.

The transition to operations over the last few years has seen a significant change in the activities of the ALMA control software team. While the software is no less crucial there is an increased emphasis on efficiency and robustness and a corresponding de-emphasis on new features. Many of the bits of commissioning software are being discarded as there is insufficient staff and inadequate justification to support all the software that was produced during construction. The core software is being consolidated into a more maintainable product that can efficiently be supported and flexibly evolved over the next few decades.

9913-4, Session 1

The growth of complexity in the evolution of control systems for ESO telescopes and instruments

Mario J. Kiekebusch, Gianluca Chiozzi, Christian Lucuix, Krister Wirenstrand, European Southern Observatory (Germany)

ESO continuously extends and improves the observation capabilities of its observatories by developing further its telescopes and its instrumentation programme. Every new generation of instruments, starting from the early instruments on the La Silla telescopes and going to the instruments being designed for the E-ELT is more sophisticated than the previous one. Several generations of instruments are overlapping now on the VLT/VLTI telescopes with new ones under development. In comparison with first generations, new instruments need to control larger and faster detectors, implement more complex acquisition sequences and a larger number of observation templates, control a bigger number of motorized opto-mechanical functions, have superior cryogenic control capabilities, as well as handle increased requirements on reliability. However, the growing complexity is reflected not only on the scale of the involved control systems but also in the nature of modern control techniques such as fringe tracking or adaptive optics systems, which are required to run at high frequencies with many interdependencies, in order to achieve diffraction limited observations.

This growth in structural and functional complexity of the control systems has been managed at ESO with the introduction of state of the art solutions in different engineering disciplines such as electronics, control and software. At the same time, ESO has been able to reduce the impact of implementing more complex systems and to keep uniformity across the observatories by integrating the new solutions into existing frameworks, and by improving and extending them.

In this paper we will use our privileged possibility of accessing specifications, design and implementation of the control system for more than 30 instruments and several generations of telescope control systems in a time span of 50 years, developed following a coherent and consistent plan. This paper will analyse several aspects in the evolution of the control systems throughout the different generations and it will try to compare their complexity and the solutions adopted to facilitate the task of implementing more complex control systems. We will try to give an historical perspective and to look forward at the challenges for the coming control systems of E-ELT generations.

9913-6, Session 2

The active surface control system for the Tian Ma Telescope

Jian Dong, Shanghai Astronomical Observatory (China) and Chinese Academy of Sciences (China); Huiliang Jin, Qian Ye, Shanghai Jiao Tong Univ. (China); Qinghui Liu, Zhiqiang Shen, Li Fu, Wei Gou, Shanghai Astronomical Observatory (China) and Chinese Academy of Sciences (China)

The Tian Ma Telescope (TM) is the largest fully steerable radio telescope in Asia. It has a primary reflector of 65-m in diameter with a shaped Cassegrain configuration. The first-developed large active surface system made a breakthrough in China. Some key technologies have been successfully solved during the development process in the following: 1) Development of high-precision, high-reliability and long-life actuators; 2?Thousands of points real-time, distributed, high reliability monitoring and collaborative control can achieve the real-time distributed monitoring of 1104 actuators. In this paper we will describe the the active surface control system at the TM Telescope including control of the metrology systems, the actuator systems. We will also describe the design and implementation of the software and hardware for the active surface control system.

9913-7, Session 2

Computer-aided star pattern recognition with astrometry.net: in-flight support of telescope operations on SOFIA

Karsten Schindler, NASA Ames Research Ctr. (United States) and Deutsches SOFIA Institut (Germany); Dustin Lang, Univ. of Toronto (Canada); Elizabeth M. Moore, NASA Ames Research Ctr. (United States); Martin Hümmer, NASA Ames Research Ctr. (United States) and Deutsches SOFIA Institut (Germany); Jürgen Wolf, Deutsches SOFIA Institut (United States) and NASA

Ames Research Ctr. (Germany); Alfred Krabbe, Deutsches SOFIA Institut (Germany)

SOFIA is an airborne observatory, operating a 2.7 m telescope on-board a modified Boeing 747SP. When SOFIA opens its door to the night sky, the initial telescope pointing is estimated from the aircraft's position and heading as well as the orientation of the telescope relative to the airplane. To be accurate, this estimate has to be calibrated with images from the sky.

SOFIA has three guidance cameras (WFI, FFI, FPI) with complementing field of views (6°, 1°, 0.13°) that provide image data to solve this task. The telescope operator (TO) has to recognize a number of catalog stars in these pictures by eye, mark them in the pictures by drawing boxes on an image overlay, and select the corresponding catalog identifier from a drop down menu. This allows a correlation of image data with catalog data to determine field rotation, right ascension and declination of the telescope, and to calibrate the telescope pointing accordingly.

Even with lots of training and experience, manual pattern recognition is time consuming. Every time the heading of the aircraft changes for another observation in a different part of the sky, the telescope operator has to check and calibrate the telescope pointing again. Although an inertial measurement is provided by laser-based gyroscopes, continuous centroid measurements of guide stars are required to compensate their drift. During periods without optical guiding, this drift deteriorates the telescope pointing estimate.

Manual pattern recognition can be especially difficult in sparse or dense star fields. As computer-aided star pattern recognition is standard practice in astrometric data reduction, we were looking for a tool that supports the TO with this task. This could potentially save some valuable minutes on every SOFIA flight in favor of collecting more science data, further increasing the efficiency of the observatory.

The astrometry.net package appears to be the ideal solution as it provides a very robust, reliable and fast algorithm for blind astrometric calibration of images. It does not require any a-priori information or an initial coordinate guess which simplifies integration. It was developed on Linux and is free open source software. We extensively tested the package with image data from various ground-based and airborne observations as well as data from all three SOFIA guiding cameras. The algorithm showed an exceptional robustness against all kinds of image artefacts and calculated not a single false positive.

We report about the integration of the astrometry.net package on the TO workstations on SOFIA that are running Solaris 10. SOFIA's wide field imager (WFI) is typically running at integration times of 2.5-3.0 s. Our tests show that WFI images can be solved faster than that, which allows us to display an almost instant, continuous feedback of right ascension, declination and rotation angle values on the TO GUI that are calculated from the stream of WFI images. This information can be used to correct telescope pointing errors instantly. We conclude with an outlook on other possible use cases.

9913-8, Session 2

Control and monitoring software for the Greenland Telescope

Nimesh A. Patel, Harvard-Smithsonian Ctr. for Astrophysics (United States)

The Greenland telescope (GLT) is 12 meter diameter ALMA prototype antenna that was awarded to the Smithsonian Astrophysical Observatory (SAO) by the National Science Foundation (NSF) in 2011. SAO and Academia Sinica Institute of Astronomy and Astrophysics, Taiwan, are working together to retrofit and relocate this antenna near the NSF Summit station in Greenland, to establish an observatory for submillimeter wavelength VLBI and single-dish astronomy approaching THz frequencies. We present the current status of the antenna control and monitoring software for the GLT. The primary goal of this software is to provide an efficient and reliable interface to the lower level software provided by the vendors of the primary antenna and secondary hexapod drive systems. This higher level software also performs the astronomical calculations for single-dish and VLBI observations, and supports special modes for antenna testing such as pointing calibration and holography mapping.

The initial version of this software was tested on the prototype antenna at the NRAO JVLA site near Socorro, New Mexico, in 2011-2012.

This version conforms with the ALMA system, including a heartbeat pulse for timing synchronization of every command, and CAN-bus communication with the Antenna Control Unit (ACU). The antenna's drive system required significant refurbishing and retrofitting for operation in the cold temperature (mean: -30 C) at Greenland. Several new components are installed: drive system motors, gearboxes, encoders, tiltmeters, limit switches and ACU, by Vertex Antennentechnik in Germany. The subreflector hexapod is a new system built by ADS International, in Italy. The revised higher-level software uses Ethernet instead of CAN-bus for communication with the low-level control systems, but we have retained the timing synchronization and CAN-bus as an option, for compatibility in future, to support the use of an ALMA receiver on the GLT. Although there will be on-site telescope operators at the GLT, remote operation and monitoring, over a low-bandwidth network connection, is one of the significant requirements for the software.

Parts of the control the new control software were tested at Vertex and ADS, during factory acceptance tests of the new servo system and the new subreflector hexapod unit, in 2014-2015. The antenna will be deployed at the Thule US Air Force Base in Greenland, in the summer of 2016. The higher-level control and monitoring software is coded in C and Python, and is adopted from the software developed for the Submillimeter Array. The scope of the software described here, is to provide control and monitoring support for initial testing and commissioning of the antenna in Thule, and also carry out VLBI observations. We will also outline the future development of the software, as the project evolves with the installation of various receivers and backend instrumentation, for the next phase of operation at the Summit station in Greenland, anticipated in 2019.

9913-9, Session 2

LSST control software component design

Paul J. Lotz, Association of Universities for Research in Astronomy, Inc. (United States) and LSST (United States); Gregory P. Dubois-Felsmann, Infrared Processing and Analysis Ctr. (United States); Kian-Tat Lim, SLAC National Accelerator Lab. (United States); Dave Mills, Association of Universities for Research in Astronomy, Inc. (United States) and LSST (United States); Tony Johnson, SLAC National Accelerator Lab. (United States); Srinivasan Chandrasekharan, LSST (United States) and Association of Universities for Research in Astronomy, Inc. (United States); German Schumacher, Association of Universities for Research in Astronomy, Inc. (Chile) and LSST (United States); Francisco Delgado, Philip N. Daly, Association of Universities for Research in Astronomy, Inc. (United States) and LSST (United States); Stephen Pietrowicz, National Ctr. for Supercomputing Applications (United States); Brian M. Selvy, LSST (United States) and Association of Universities for Research in Astronomy, Inc. (United States); Jacques Sebag, Association of Universities for Research in Astronomy, Inc. (United States) and LSST (United States); Stuart Marshall, SLAC National Accelerator Lab. (United States); Timothy Jenness, LSST (United States) and Association of Universities for Research in Astronomy, Inc. (United States)

Construction of the Large Synoptic Survey Telescope system involves several different organizations, a situation that poses many challenges at the time of the software integration of the components. To ensure commonality for the purposes of usability, maintainability, and robustness, the LSST software teams have agreed to the following for system software components: a summary state machine, a manner of managing settings, a flexible solution to specify controller-controllee relationships reliably as needed, and a paradigm for responding to and communicating alarms. This paper describes these agreed solutions and the factors that motivated these.

9913-106, Session 2

Improving the pointing and tracking performance of the Keck telescopes

Shui Hung Kwok, James E. Lyke, Kevin Tsubota, Kevin L. McCann, Tomas Krasuski, Jeffrey A. Mader, W. M. Keck Observatory (United States)

Pointing and tracking performance is one of the key metrics that characterize a telescope's overall efficiency. The pointing performance of the Keck telescopes has been surpassed by newer large telescopes due to the use of rotary friction encoders to provide position feedback to the control system. While poor tracking can be compensated by guiding, poor blind pointing performance can lead to loss of observing time.

In this paper we present a history of the efforts to reduce the impact of poor pointing, as well as the improvements achieved after the installation of new tape encoders. We will discuss the calibration and testing methods and the tools for monitoring and maintaining the desired pointing performance. A comparative analysis of the pointing performance before and after the telescope control system upgrade will also be presented.

9913-10, Session 3

An automated qualification framework for the MeerKAT CAM (Control-And-Monitoring) system

Lize Van den Heever, SKA South Africa (South Africa)

The MeerKAT 64-dish radio telescope is currently in full production in South Africa's Karoo region. This paper introduces an Automated Qualification Framework that was developed for the formal Qualification Testing of the Control-And-Monitoring (CAM) subsystem of MeerKAT. It discusses the approach and implementation and lastly reports on the lessons learnt and benefits.

The goal of the Automated Qualification Framework (AQF) was to perform as much as possible of the formal CAM Qualification Testing through automating the integrated CAM tests, automating the evaluation, capturing the results, and automatically producing the test procedures and test results documents. The integrated CAM tests are run daily through a Jenkins continuous integration server on a fully simulated MeerKAT CAM system, producing the qualification test result as a test artifact.

The AQF allows each Integrated CAM Test to reference the MeerKAT CAM requirement it covers and automatically produces the Qualification Test Procedure and Qualification Test Report from the test steps and evaluation steps coded in the test. The AQF uses an export of the CORE requirements model of MeerKAT to produce a cross-verification matrix of the test results against the CAM requirements. Peer reviews are performed on each Integrated CAM Test as as a quality assurance step to ensure the test actually performs the steps and checks as claimed in the AQF steps.

The AQF is implemented as a nosetest plugin that allows a developer of each Integrated CAM Test to specify the CAM requirement that is covered by the test, to define the test steps to be performed and the verification steps to evaluate the test results.

To test that a critical alarm is raised when a fire is detected, the test will reference with the appropriate requirement number, will trigger the fire sensor, will check that the alarm is detected, will check that the alarm level is critical and is logged, will then reset the fire sensor.

A second DEMO test for Qualification Demonstration then only verifies the display of the alarm to the operators.

The CAM Acceptance Testing on site against the actual MeerKAT deployed subsystems also makes use of the AQF by developing automated tests specifically for site Acceptance Testing and also by tagging applicable qualification tests as acceptance tests (those that can be run on the real system like antenna pointing tests vs those that can't like veritying the shutdown procedure after simulating a cooling failure in the processing building).

A first version of the AQF was used for Timescale A Qualification of MeerKAT CAM as demonstration to the System Engineers for MeerKAT and the AQF was fully implemented and used for the second development iteration for Timescale B Qualification of MeerKAT CAM. The MeerKAT System Engineers are extremely happy with the AQF results, but mostly by the approach and process it enforces. Although it took time to develop and mature the AQF (and it is an ongoing effort as it can always be improved further) and it is a "real mission" sometimes to keep developing and updating the Integrated CAM Tests as implementation details changes and new functionality is added, the benefits of having this Automated Qualificaiton Framework far out-weighs the resource commitment. And in the long run may not take much more resources than it would to "manually" test and find the problems.

9913-11, Session 3

Rules of thumb to increase the software quality through testing

Marco Buttu, INAF - Osservatorio Astronomico di Cagliari (Italy); Marco Bartolini, Carlo Migoni, Andrea Orlati, Sergio Poppi, Simona Righini, INAF - Istituto di Radioastronomia (Italy)

The software maintenance typically requires 40-80% of all project costs, and this considerable variability mostly depends on the software internal quality: the more the software is designed and implemented to constantly welcome new changes, the lower will be the maintenance costs. The internal quality is typically enforced through testing, which in turn also affects the development and maintenance costs. This is the reason why testing methodologies have become a major concern for any company that builds or is involved in building software.

Although there is no testing approach that suits all contexts, we infer some general guidelines learned during the Development of the Italian Single-dish COntrol System (DISCOS), which is a project aimed to produce the control software for the three INAF radio telescopes (the Medicina and Noto dishes, and the newly-built SRT). These guidelines concern both the development and the maintenance phases, and their ultimate goal is to maximize the DISCOS software quality through a Behavior-Driven Development (BDD) workflow beside a continuous deployment pipeline.

We consider different topics and patterns; they involve the proper apportion of the tests (from end-to-end to low-level tests), the choice between hardware simulators and mockers, why and how to apply TDD and dependency injection to increase the test coverage, the emerging technologies available for test isolation, bug fixing, how to protect the system from the external resources changes (firmware updating, hardware substitution, etc.) and, eventually, how to accomplish BDD starting from functional tests and going through integration and unit tests.

We discuss pros and cons of each solution and point out the motivations of our choices either as a general rule or narrowed in the context of the DISCOS project.

9913-12, Session 3

Behavior driven testing in ALMA telescope calibration software

Juan Pablo Gil, Mario Garces, Tzu-Chiang Shen, ALMA (Chile); Dominique Broguière, Institut de Radio Astronomie Millimétrique (France)

ALMA observatory has reached its operational stage in 2013, but its software is still under active development, which implements new capabilities to be offered to the scientific community. The current software release process involves the delivery of short releases that includes a set of new features for one or more subsystems of ALMA Software. Also, the testing stage of the same process involves not only developers and testers, but also stakeholders (i.e: scientists and engineers). Currently, there are still some drawbacks in the used testing methodology. One of the most relevant problem is that most software subsystems relies on functional tests that are executed either by exploratory analysis or by custom scripts. As a consequence, the current methodology produce a knowledge gap between developers, testers and scientist in the sense of comprehension and/or repeatability of testing results. In that way, Behavior Driven Development (BDD) was proposed in order to increase test formalisation and automation of testing activities. BDD is an agile technique derived from Test Driven Development that encourages communication between roles by defining and automating test cases using natural language. In BDD, each requirement is translated into several test cases (scenarios) that covers the correctness of the requirement functionality. In addition, the use of natural language within test cases definition allows participants to develop a common domain language and to perform, in advance, peer reviews to assure correctness of the defined testing strategy for a specific release. The selected subsystem for this first experience was Telescope Calibration (TELCAL), which objective is to produce a set of calibration data in near real-time by the observations. Regarding TELCAL OFFLINE version (instead of its ONLINE version), results can be reproducible by using an input dataset. These characteristics make this subsystem a perfect candidate for BDD approach. This paper describes how we have implemented and maintained test cases to verify TELCAL based on BDD, the infrastructure needed to support them and explore mechanism to expand this technique to other subsystems, in particular to online parts of the TELCAL subsystem that interact with real time observing processes.

9913-13, Session 3

The evolution of the simulation environment in the ALMA Observatory

Tzu-Chiang Shen, Rubén Soto, Norman Sáez, Tomás Staig, ALMA (Chile); Gastón Vélez, Soledad Fuica, Nicolás Ovando, Joint ALMA Observatory (Chile); Jorge Ibsen, European Southern Observatory (Chile)

The Atacama Large Millimeter /submillimeter Array (ALMA) will be a unique research instrument composed of 66 reconfigurable high-precision antennas, located at the Chajnantor plain in the Chilean Andes at an elevation of 5000 m.The observatory has entered into operation phase since 2014. This transition changed the priorities within the observatory, in which, most of the available time will be dedicated to science observations at the expense of technical time that software testing used to have available in abundance (since software/hardware integration was the former priority during construction phase)

The scarcity of the technical time surfaces one of the weakest points in the existent infrastructure available for software testing: the simulation environment of the ALMA software. In ALMA, simulation capabilities were initially developed to satisfy Control and Correlator subsystem needs, supplying them with virtual hardware devices to interface with the software components being developed. Additional simulation layers and capabilities were added during the years by different teams, but they were focused on the functionality aspect but not on the real operation scenarios with all the antennas. Therefore, scalability and performance problems introduced by new features or hidden in the current accepted software cannot be verified until the actual problem explodes during operation. The lack of a representative testing environment will seriously impact the efficiency of the ALMA incremental software release process.

Therefore, it was planned to design and implement a new simulation environment, which must be comparable - or at least- be representative of the production environment. Duplicating the production environment was not an option, since it would be prohibitive from the point of view of the associated cost. Adjustments in the existent production architecture had to be introduced, but with special care on keeping the simulation environment comparable in term of CPU load, network bandwidth throughput, memory usage and software configurations. The selected platform to provide computing power is based on blade technology of Cisco Unify Computing System (UCS). Concepts of model in the loop (MIL) and hardware in the loop (HIL) were explored to allow that the application code deployed in the simulation environment is the same as the one deployed in the production environment.

The new simulation platform will provide the required amount of time for testing purposes, which includes verification of new features, fixes of detected bugs and long term stability and scalability of the system, at same time it allows us to maximize the efficiency of the reduced technical time available in the production environment, which will be dedicated only for the final validation of a release and small set of features that interact directly with hardware.

In this paper we will review experiences gained and lessons learnt during the design and implementation of a full simulated environment.

9913-14, Session 3

Modernized build and test infrastructure for control software at ESO: highly flexible building, testing, and automatic quality practices for telescope control software

Federico Pellegrin, Bogdan Jeram, Jochen Haucke, Sylvie Feyrin, European Southern Observatory (Germany)

An automatic and reliable build and test system is a basic prerequisite for the success of every modern software project. Modifications made by developers need to be included into the system, integrated and verified as soon as possible. This is even more the case when the software has to be deployed on systems for which downtime is a critical factor like ESO's telescopes and instruments.

In this context from a long time, the control software engineers at ESO have been very eager to adopt automatic procedures for building, testing and integrating with an in-house software solution named NRI (Nightly Report Infrastructure). The in-house solution was created at a time when there were not many common off-the-shelf products of this type and it has accomplished its duties successfully for many years. Its operations and interface were highly customized to the project's needs, but on the negative side the solution was not very scalable and required often important code changes to be maintained and to accommodate new upcoming requests. Therefore, after an internal investigation for a more versatile solution, in the last year the control software infrastructure at ESO migrated to an open-source solution, Jenkins CI, which provides an improved distributed and cross-platform infrastructure for highly parallelized builds and tests for most of the projects managed.

The paper will present common building and testing infrastructure concepts, the previous solution used at ESO and the migration to the new infrastructure, showing the big improvements made in terms of reduced overall execution time, parallel testing on different versions and architectures and higher reproducibility of testing conditions. Keeping

impact on the developer at a minimum by reproducing to a very high degree the features of the user interface of the previous solution was also of primary importance. Additionally the new infrastructure improves also automatic execution of quality assurance tools, such as static code checking tools, code coverage analysis and memory and system resources leakages and leverages on practices such as using automatic virtual machines management and Linux containers for test environment reproducibility. Builds and tests are carried out with various patterns: on-commit continuous-integration style, on user demand and nightly or weekly scheduling, all this in an environment with many internal developers but also external developers from Consortia or contractors. Results are available and archived via Web, but problem notifications are sent immediately to developers and managers. The results include a variety of system logs and debugging information that should immediately point the developer into the right direction in the debugging session. Intermediate build results are also stored and new versions of software can be packed and deployed automatically to different machines. Automatically generated documentation is also immediately prepared and published alongside the binaries.

Many good practices had to be enforced in the development cycle to achieve the full potential of the infrastructure: patterns of usage of the code repository, SVN in our case, build system, such as modularized and parallelizable GNU make recipes, and test scripts, written so they incorporate as little information on the context they will be executed in. External shared resources access has to be carefully managed with locking mechanisms and with interfaces to an extensible booking system. Hardware resources are managed at power level via network driven power switches to maximize their uptime even in case of low level failure blocking their functionalities. The transition to the new system proved to be quite cheaper time-wise than previously expected, original effort estimation being one of the motivations that the transition was postponed, and there was practically no need for additional training for users given the similarity to the previous system and ease of use of the new interface .

The usage of the new infrastructure for the VLT and SPARTA based adaptive optic systems will be described in detail. The infrastructure is also prepared to host the new EELT project that poses very important new challenges such as a wider variety of architectures, programming languages and operating systems to be supported. Currently for EELT internal prototypes have been added and the first code modules should be integrated in 2016.

9913-16, Session 4

Investigating interoperability of the LSST data management software stack with Astropy

Timothy Jenness, LSST (United States); Jim Bosch, Princeton Univ. (United States); Russell Owen, John K. Parejko, Univ. of Washington (United States); Jonathan Sick, LSST Corp. (United States); John D. Swinbank, Miguel de Val-Borro, Princeton Univ. (United States)

The Large Synoptic Survey Telescope will be an 8.4m optical survey telescope sited in Chile and capable of imaging the entire sky twice a week. The data rate of approximately 15 TB per night and the requirements to both issue alerts on transient sources within 60 seconds of observing and also to create annual data releases means that automated data management systems and data processing pipelines are a key deliverable of the LSST construction project. The LSST data management software has been in development since 2004 and, like other software developed in that era such as CASA, is based on a C++ core with a Python control layer. The software consists of nearly quarter of a million lines of code covering the system from fundamental WCS and table libraries to pipeline environments and distributed process execution.

The Astropy project began in 2011 as an attempt to bring together disparate open source Python projects and build a core standard infrastructure that can be used by and built upon by the astronomy community. This project has been phenomenally successful in the years since it has begun and has grown to be the de facto standard for Python software in astronomy. Astropy brings with it considerable expectations from the community on how astronomy Python software should be developed and it is clear that by the time LSST is fully operational in the 2020s many of the prospective users of the LSST software stack will assume that Astropy software will be integrated.

In this paper we will describe the overlap between the LSST science pipeline software and Astropy software and investigate areas where the LSST software provides new functionality. We will also discuss the possibilities of re-engineering the LSST science pipeline software to build upon Astropy, including the option of contributing affiliated packages.

9913-17, Session 4

VIALACTEA knowledge base: homogenizing access to Milky Way data

Marco Molinaro, Robert Butora, INAF - Osservatorio Astronomico di Trieste (Italy); Marilena Bandieramonte, Ugo Becciani, INAF - Osservatorio Astrofisico di Catania (Italy); Massimo Brescia, Stefano Cavuoti, INAF - Osservatorio Astronomico di Capodimonte (Italy); Alessandro Costa, INAF - Osservatorio Astrofisico di Catania (Italy); Anna M. Di Giorgio, Davide Elia, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Akos Hajnal, Hermann Gabor, Peter Kacsuk, MTA-SZTAKI (Hungary); Scige J. Liu, Sergio Molinari, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Giuseppe Riccio, INAF - Osservatorio Astronomico di Capodimonte (Italy); Eugenio Schisano, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Eva Sciacca, INAF - Osservatorio Astrofisico di Catania (Italy); Riccardo Smareglia, INAF - Osservatorio Astronomico di Trieste (Italy); Fabio Vitello, INAF - Osservatorio Astrofisico di Catania (Italy)

The EU-FP7 funded project VIALACTEA has a work package dedicated to “Tools and Infrastructure” (WP5) among whose tasks task 1 is named “Database and Virtual Observatory Infrastructure”.

This task aims at providing an infrastructure to store all the resources needed by the, more purposely, scientific work packages of the project itself.

This infrastructure includes a combination of: storage facilities, relational databases and web services on top of them, and has taken, as a whole, the name of VIALACTEA Knowledge Base (VLKB).

The storage part of the VLKB simply holds all of the observational data files (FITS format data multi dimensional cubes and 2D images, grouped by survey means) required by the VIALACTEA community as the input information for scientific production. It consists of about 20 surveys (if considering the single species and transitions investigated) of galactic plane radio observations in form of FITS cubes with a 3rd axis dedicated to velocity spectra, and about 15 2D image surveys in the radio continuum. All of them form a collection of about 14000 datasets.

The VLKB database is the content holder for both the metadata of the stored files and data resources themselves in terms of catalogues of compact or diffuse objects.

The database part consisting of FITS collection metadata part is used by the discovery and access services.

The data part, consisting of catalogues, completes the input base for scientific exploitation.

Part of these catalogues consists of some FITS files processing (of selected surveys).

These catalogues are also output of the scientific work of the project; they consist of: compact sources identified in single radio bands (of the above surveys) and then combined into a band merged catalogue with all the multi band SED information connected together, filamentary and bubble like diffused structures, computational SED models, velocity peak information to compute distance estimation of sources.

The VLKB database, metadata and data, is also the information resource on top of which an IVOA TAP service has been attached to let the VIALACTEA community users integrate their data with the VO available resources outside the project (i.e. without the need to download and reload data files each time they need to cross correletae information).

Alongside the TAP service a set of services to allow discovery, retrieval and cutout of the available data cubes and images has been provided, to answer the explicit request for positional and velocity range searches and cut on the provided radio surveys of the galactic plane.

These latter services make use of the WCS information of the FITS to perform discovery and cutout on such a dishomogeneous collection of datasets and its design is inspired by the IVOA discovery, cutout and access protocols.

This contribution illustrates the current status of the infrastructure. It details the set of resources put together to serve as the actual data resources; describes the database that allows data discovery through VO inspired metadata mainteinance; illustrates the discovery, cutout and access services built on top of the former two for the users to exploit the data content.

9913-18, Session 4

A case study in adaptable and reusable infrastructure at the Keck Observatory Archive: VO interfaces, moving targets, and more

Graham B. Berriman, Christopher R. Gelino, Shin-Ywan Wang, John C. Good, California Institute of Technology (United States); Hien D. Tran, Jeffrey A. Mader, W. M. Keck Observatory (United States)

The Keck Observatory Archive (KOA) (https://koa.ipac.caltech.edu) curates all observations acquired at the W. M. Keck Observatory (WMKO) since it began operations in 1994, including data from eight active instruments and two decommissioned instruments. The archive is a collaboration between WMKO and the NASA Exoplanet Science Institute (NExScI). Since its inception in 2004, the science information system used at KOA has adopted an architectural approach that emphasizes software re-use and adaptability. This paper describes how KOA is currently leveraging and extending open source software components to develop new services and to support delivery of a complete set of instrument metadata, which will enable more sophisticated and extensive queries than currently possible. We plan to post all the code described below on GitHub by Summer 2016.

In August 2015, KOA deployed a program interface to discover public data from all instruments equipped with an imaging mode. The interface complies with version 2 of the Simple Imaging Access Protocol (SIAP), under development by the International Virtual Observatory Alliance (IVOA), which defines a standard mechanism for discovering images through spatial queries. The heart of the KOA service is an R-tree based database-indexing mechanism prototyped by the Virtual Astronomical Observatory (VAO) and further developed by the Montage Image Mosaic project to provide fast access to large imaging datasets, as a first step in creating wide-area image mosaics (such as mosaics of subsets of the 4.7 million images of the SDSS DR9 release). The KOA service uses wrappers around existing modules to query an SQLite database that references the indices and returns results to the user. The service uses a JSON configuration file to describe the association between instrument parameters and the service query parameters and so make it applicable beyond the Keck instruments.

The images generated at the Keck telescope usually do not encode the image footprints as WCS fields in the FITS file headers. Because SIAP searches are spatial, much of the effort in developing the program interface involved processing the instrument and telescope parameters to understand how accurately we can derive the WCS information for each instrument. This knowledge is now being fed back into the KOA databases as part of a program to include complete metadata information for all imaging observations.

The R-tree program was itself extended to support temporal and spatial indexing, in response to requests from the planetary science community for a search engine to discover observations of Solar System objects. With this 4D-indexing scheme, the service performs very fast time and spatial matches between the target ephemerides, obtained from the JPL SPICE service. Our experiments indicate that these matches can be more than x100 faster than when separating temporal and spatial searches. Images of the tracks of the moving targets, overlaid with the image footprints, are computed with a new command-line visualization tool, mViewer, released with the Montage distribution. The service is currently in test and will be released in Spring 2016.

9913-134, Session 4

High-contrast imaging in the cloud

Asher Baltzell, Eric H. Lyons, Nirav Merchant, Jared R. Males, Katie M. Morzinski, Laird M. Close, The Univ. of Arizona (United States)

Astronomical data sets are growing ever larger, and the area of high contrast imaging of exoplanets is no exception. With the advent of fast, low-noise detectors operating on the orders of 10 to 1000 Hz, huge numbers of images can be taken during a single hours-long observation. High frame rates offer several advantages, such as improved registration and jitter rejection, frame selection, and potentially significant gains in speckle calibration using temporal information. However, applying advanced image processing algorithms to such large data sets is computationally challenging. Here we describe a cloud-based data reduction system developed for the Magellan AO VisAO camera, which is capable of processing tens of thousands of images at a time. We demonstrate these capabilities with several large visible-wavelength high contrast data sets of the exoplanet host star beta Pictoris. Finally, we describe our prototype system for storing, transporting, and distributing such large data sets from a remote site in Chile.

9913-19, Session 5

The astronomer, the software engineer, and the cloud *(Invited Paper)*

Frossie Economou, Josh Hoblitt, J. Matt Peterson, Jonathan Sick, LSST (United States); Gregory E. Daues, Univ. of Illinois at Urbana-Champaign (United States)

We are in the midst of a transition in the way that computing resources are obtained in the sciences. Cloud-based architectures play an increasing role in scientific processing as well as scientific communication, leveraging the considerable technical investment in these platforms. Typically astronomers have believed that the economics drive them away from this model, however these calculations often fall short of the total cost of delivering computing infrastructure. Moreover there is a often a false dichotomy between commercial cloud services (like Amazon Web Services) and traditional bare-metal "special snowflake" hardware; privately deployed clouds (such as university OpenStack clusters) represent a path forward with many of the technological advantages of

working in an open standardized infrastructure while avoiding some of the direct costs of the commercial clouds. Here we describe how we have navigated some of these issues in the context of engineering the LSST Data Management's developer infrastructure, which includes a cross-platform cloud-based continuous integration architecture.

9913-20, Session 5

A cyber infrastructure for the SKA Telescope manager

Domingos Barbosa, Instituto de Telecomunicações (Portugal); João Paulo Barraca, Instituto de Telecomunicações (Portugal) and Univ. de Aveiro (Portugal); Dalmiro Maia, Univ. do Porto (Portugal); Antonio Cruz, Portugal Telecom (Portugal); Gerhard Le Roux, SKA South Africa (South Africa); Swaminathan Natarajan, Tata Research Development and Design Ctr. (India); Paul Swart, SKA South Africa (South Africa); Yashwant Gupta, National Ctr. for Radio Astrophysics (India)

The Square Kilometre Array Telescope Manager (SKA TM) will be responsible for the SKA Operations and Observation Management, carrying out System diagnosis and collecting Monitoring & Control data from the SKA sub-systems and components. To provide adequate compute resources, scalability, operation continuity and high availability, as well as strict Quality of Service, the TM cyber-infrastructure (embodied in the Local Infrastructure - LINFRA) consists of COTS hardware and infrastructural software (for example: server monitoring software, host operating system, virtualization software, device firmware), providing a specially tailored Infrastructure as a Service (IaaS) and Platform as a Service (PaaS) solution. The TM infrastructure provides services in the form of computational power, software defined networking, power, storage abstractions, and high level, state of the art IaaS and PaaS management interfaces.

This cyber platform will be tailored to each of the two SKA Phase 1 telescopes (SKA-MID in South Africa and SKA_LOW in Australia) instances, each presenting different computational and storage infrastructures and conditioned by location. This cyber platform will provide a compute model enabling TM to manage the deployment and execution of its multiple sub-components (observation scheduler, proposal submission tools, etc). In this sense, LINFRA is primarily focused towards the provision of isolated instances, mostly resorting to virtualization technologies, while defaulting to bare hardware if specifically required due to performance, security, availability, or other requirement. Under this assumption, TM executes sub-elements components in instances that can be deployed, migrated, replicated and upgraded, while providing key performance indicators regarding the execution conditions of each execution instance created. The deployment functionality enables the easy deployment of instances from development into production environments. The Migration functionality enables the instances to be moved between physical hardware resources in order to increase availability and redundancy. The Replication functionality enables redundancy and automatic scaling to cope with bursts of requests. The Upgradability functionality enables components to be replaced by updated versions with fixes or new features. For each instance, key operational parameters will be reported, allowing the SKA TM to track the correct execution condition of its components and maintaining high operational availability.

In this paper, we describe the basic tools and building blocks of the compute and virtualization technologies constituting the tailored IaaS and PaaS service to the SKA Telescope Manager.

9913-22, Session 5

The AST3 controlling and operating software suite for automatic sky survey

Yi Hu, National Astronomical Observatories (China); Zhaohui Shang, Tianjin Normal Univ. (China) and National Astronomical Observatories (China); Bin Ma, National Astronomical Observatories (China)

Because of both the extreme environment in Antarctica and a whole year unattended operation, the controlling and operating hardware system of AST3 must be highly customized compared with ground-based telescopes in other observatories. As a consequence, the controlling and operating software system must also be highly specialized and ast3suite was thus designed to run AST3 remotely and robotically. In order to make the software system be modular and suitable for both remote command-line based test and automatic observation, ast3suite is designed to be composed of three parts: daemon servers, basic commands, and survey script. The daemons are those programs running constantly in background when the host operating system starts. They directly communicate with various devices of AST3's hardware system and provide services to their clients. The basic commands are actually the client programs of these daemons. They send requests to the daemons and ask them to operate on certain devices. After the daemons finish requests, the client programs fetch results back and usually print them to standard output and/or log files. If logic flow allows, the daemons should be moderately concurrent. The same client processes can simultaneously send requests to a daemon. Since the clients indirectly operate on devices, there are no resource race conditions. Such a server/client architecture adopted in ast3suite makes our software system very consistent and reliable. The communication between daemons and clients is via TCP/IP, so that ast3suite also has capability to do synchronous observations of a telescope array in the future. The survey script executes the basic commands sequentially in a loop to achieve automatic sky survey. Ast3suite was deployed on the real hardware system of AST3 and had been carefully tested in Mohe for five months before it was actually used at Dome A in 2015. The test and running results, including running logs and saved images, show that ast3suite accommodates to robotic telescope in Antarctica and has the potential to be gerneralized for broad use.

9913-23, Session 5

Thirty Meter Telescope common software update

Kim Gillies, Thirty Meter Telescope (United States); Allan Brighton, Thirty Meter Telescope (United States); Hanne Buur, Thirty Meter Telescope (United States)

The TMT Software System consists of software components that interact with one another through a software infrastructure called TMT Common Software (CSW). CSW consists of software services and library code that is used by developers to create the subsystems and components that participate in the software system. CSW also defines the types of components that can be constructed and their functional roles in the software system.

TMT CSW has recently passed its preliminary design review. The unique features of CSW include its use of multiple, open-source products as the basis for services, and an approach that works to reduce the amount of CSW-provided infrastructure code. Considerable prototyping was completed during this phase to mitigate risk with results that demonstrate the validity of this design approach and the selected service implementation products. This paper describes the latest design of TMT CSW, key features, and results from the prototyping effort.

The core of CSW is implemented on the JVM in the Scala programming language with both Java and Scala programming interfaces. The CSW

programming environment is based on the Akka distributed application library. The source code CSW is open source and available on Github.

9913-24, Session 5

DDS as middleware of the Southern African Large Telescope control system

Deneys S. Maartens, Janus D. Brink, South African Astronomical Observatory (South Africa) and Southern African Large Telescope (South Africa)

The Southern African Large Telescope (SALT) software control system is realised as a distributed control system, implemented predominantly in National Instruments' LabVIEW. Communication between the telescope control subsystems employs a cyclic publish-subscribe, state-based message-passing architecture. Transmitting a message is accomplished by performing an HTTP PUT request to a WebDAV directory on a centralised Apache web server; receiving involves polling the web server for new messages. While the method is simple and lightweight, it contains a number of weaknesses; a scalable distributed communication solution with minimal overhead is a better fit for control systems.

This paper describes our exploration of the Data Distribution Service (DDS) as middleware for SALT. DDS is a formal standard specification, defined by the Object Management Group (OMG) that presents a data-centric publish-subscribe model for distributed application communication and integration. It provides an infrastructure for platform-independent many-to-many communication.

A number of vendors provide implementations of the DDS standard; RTI, in particular, provides a DDS toolkit for LabVIEW. We have evaluated this toolkit against the needs of SALT, and have identified a few deficiencies, particularly when bearing in mind backward compatibility with the existing architecture. The most important aspect is that data elements of the toolkit messages are not dynamically resizable: the data elements have to be pre-declared to be of a particular maximum size, that cannot be increased at run-time. To overcome this restriction we have developed our own implementation that interfaces LabVIEW to DDS.

Our LabVIEW DDS interface implementation is built against the RTI DDS core component, provided by RTI under their Open Community Source licence. The wide variety of platforms we use at SALT dictate that the interface implementation be platform independent. Since RTI provides access to the RTI DDS core source code, we are able to build the required software libraries for all of the platforms on which we require support.

The communications functionality of our implementation is based on UDP multicasting. Multicasting is an efficient communications mechanism with low overheads, which avoids the duplication of point-to-point data transmission on a network where there are multiple recipients of a particular item of data.

We present a performance evaluation of DDS against the current HTTP based implementation with a discussion on specific optimisations developed for the Prime Focus Guidance System Upgrade project. We also discuss the lessons learnt and describe planned future work.

9913-128, Session 5

The NOAO data lab: science-driven development

Michael J. Fitzpatrick, National Optical Astronomy Observatory (United States); Matthew J. Graham, California Institute of Technology (United States) and National Optical Astronomy Observatory (United States); Knut Olsen, Kenneth J. Mighell, Patrick Norris, Stephen T. Ridgway, Elizabeth B. Stobie, Adam Bolton, National Optical Astronomy Observatory (United States)

We are developing the [it]NOAO Data Lab[it] to provide the infrastructure needed to maximize community use of the high-value survey datasets now being collected with NOAO telescopes and instruments, in particular the Dark Energy Camera. The Data Lab will allow users to access and search databases containing large catalogs, visualize, analyze, and store the results of these searches, combine search results with data from other archives or facilities, and share these results with collaborators through a central workspace or publication service. In the process of implementing the needed services, we are using specific science cases to guide development of the system framework and tools. The result is a Year-1 capability demonstration that implements nearly all of the major software components in the context of a functioning science use case.

The science case used for developing this demonstration is a search for faint Milky Way satellite galaxies, using the Data Lab infrastructure to show how one can search for dwarfs across increasingly larger sets of data. We begin this demonstration using an interactive approach to reproduce the discovery of the Hydra II dwarf [Martin et al, 2015] in the SMASH [Nidever et al, 2013] survey catalog. Next, we expand the search using a scripted approach incorporating the same techniques to examine other SMASH target fields and large-area surveys. Finally, we demonstrate a search for dwarfs starting with image data publicly available from the NOAO Science Archive, processing the images through a quick-look photometric pipeline, and filtering the resulting catalogs.

9913-25, Session 6

The readout and instrument control system of the Dark Energy Spectroscopic Instrument (DESI)

Klaus Honscheid, Ann Elliott, The Ohio State Univ. (United States); Elizabeth Buckley-Geer, Stephen Kent, Fermi National Accelerator Lab. (United States); David R. Kirkby, Univ. of California, Irvine (United States); Anze Slosar, Brookhaven National Lab. (United States); Kevin A. Reil, SLAC National Accelerator Lab. (United States); Santiago Serrano, Francisco Castander, Univ. de Barcelona (Spain)

DESI, the dark energy spectroscopic instrument, is a fiber-fed multi-object spectrograph currently under constructions. DESI will be installed on the Mayall 4-m telescope at Kitt Peak National Observatory in 2018. A new wide-field corrector will provide an 8 square degree field-of-view at prime focus. 5,000 optical fibers will feed 10 triple-arm high-throughput spectrographs, simultaneously covering 360–980 nm and reaching spectral resolution R = 4000 in the infrared. Individual actuators rapidly position the fibers with the help of an integrated feedback mechanism that compares fiber position to the requested target locations allowing a rapid cadence of observations. We present the design of the DESI readout and instrument control system. We will focus on nouvelle design aspects of the system architecture and discuss the fiber positioning software including how we map on sky targets to focal plane coordinates with real time measurements of optical distortions, telescope pointing and environmental parameters.

9913-26, Session 6

Efficient receiver tuning using differential evolution strategies

Caleb H. Wheeler, Arizona State Univ. (United States); Trevor G. Toland, General Dynamics Mission Systems (United States); Christopher E. Groppi, Arizona State Univ. (United States)

Differential evolution (DE) is a powerful and computationally inexpensive optimization strategy that can be used to search an entire parameter space or to converge quickly on a solution. The Kilopixel Array Pathfinder Project (KAPPa) is a heterodyne receiver system delivering 5 GHz of instantaneous bandwidth of the tuning range 645-695 GHz. The fully automated KAPPa receiver test system uses performance feedback and DE to find optimal receiver tuning without any human intervention. We present an adaptation of DE for use in rapid receiver characterization. The KAPPa DE code is written in Python 2.7 and is fully integrated with the KAPPa instrument control code, data processing, and visualization code.

The goal of KAPPa is to develop the technologies needed to realize heterodyne focal plane arrays containing ~1000 pixels. The receiver characterization phase of KAPPa provides many challenges, one of which is investigating large parameter spaces to find optimal receiver tuning, a task that was considerably difficult using via by-hand techniques. For example, a typical parameter space includes Superconducting-Insolating-Superconducting (SIS) junction bias voltage, magnetic field strength across the SIS junction, local oscillator (LO) power, LO frequency, and output frequency (IF) bandwidth. For future, large-scale arrays, it is desirable to do characterization or tuning in an automated fashion without the need for human intervention. Many optimization strategies exist, but DE can be set to converge to a solution rapidly with minimal computational overhead, making it ideal for time and budget constraints.

One of the more subtle aspects of DE is setting the “cost function” which is used to rank sets of input parameters. The cost function can be any linear combination of receiver performance, receiver stability, or any other measureable property. We present our DE strategies and show some simple cost functions that may be useful for other similar applications. Some additions to the DE strategy were required to address receiver instability that may give an anomalously high cost function result.

We discuss how DE is used in the KAPPa system and how well it preforms. Our system is fundamentally limited by the settling time of the electronics in response to input parameter changes and the speed of our optical chopper, thus some parameter spaces are still too large to consider the parameter space robustly searched. Currently, measuring the receiver sensitivity for a single set of parameters takes 4 seconds. We look toward the future of ~1000 pixel array receivers and consider how the KAPPa DE system might be applied. Additionally, we will present future ideas for adapting the current code to rapidly tune telescope receivers and choose the best possible mix of stability and sensitivity for a given run or installation.

9913-27, Session 6

The SAAO instrumentation software architecture and the SHOC instruments

Carel H. D. R. van Gend, Briehan Lombaard, Hamish Whittal, Amanda A. Sickafoose, South African Astronomical Observatory (South Africa)

In addition to the premium Southern African Large Telescope (SALT), the South African Astronomical Observatory (SAAO) operates a number of smaller telescopes. These productive and well-established telescopes are kept scientifically relevant by being updated with a modern suite of instruments. We describe a software architecture suitable for modern instrumentation projects at the SAAO, and present as a case study the Sutherland High-Speed Optical Cameras (SHOC).

Traditionally, instrumentation software at the SAAO was developed by astronomers using the instruments. As such, a range of programming styles and languages was used, user interfaces were not always intuitive, and modern practices such as version control were rare (and often the source code was no longer available). It was frequently hard to meld the output of third-party software with the locally- developed software in such a way that the all parameters relevant to observations were included in the output data. We wanted to develop a standardized way of doing software, incorporating modern design principles, with the aim of easing maintenance, promoting code re-use, and allowing coherent user interfaces and data outputs.

To this end, we have developed a distributed architecture, with individual instrument components represented by free-standing drivers. These may be programmed in whichever language is most suitable; we have largely standardized on C++ and Python. The driver processes are held together and communicate over a network with a central controlling process. The interfaces are defined using Apache Thrift, which provides both data serialization and a way to make remote procedure calls. The controller process is written in Python, and allows a variety of user interfaces to to be developed. These include command line interfaces (used for development, testing and diagnostics), traditional Qt-based graphical user interfaces, and web-based interfaces.

The modularity of the system means that components can be worked on individually, and added to the system as needed. Furthermore a fault in a single component need not bring down the whole system. Components are are inherently network-aware, and as such the new software architecture facilitates our goal of creating instruments which are remotely accessible and which should eventually be robotically operable.

The SHOC systems were designed for high-speed, accurately timed imaging work, primarily on the 74-inch and 40-inch telescopes at the SAAO’s Sutherland observing station. The base SHOC systems comprise a filter wheel, a GPS receiver for timing triggers, an Andor iXon camera, and a control PC. Plug-in modules allow access to telescope pointing coordinates and information about current atmospheric conditions. The controller layer is responsible for coordinating each of these, and arranges for information from each of the subsystems to be stored in the output data.

The SHOC user interface is web-based, and allows remote control and viewing of the instrument components from a PC, tablet or phone. The interface uses JS9 to provide a configurable view of the data as it is captured. JS9 is a JavaScript port of the well-known DS9 software, and so is familiar to many observers.

9913-28, Session 6

World coordinate information for the Daniel K. Inouye Solar Telescope

Chris Mayer, Steve Wampler, Bret D. Goodrich, National Solar Observatory (United States)

It is a top level science requirement that data from the Daniel K Inouye Solar Telescope (DKIST) is archived and made available to the world wide astronomical community. Data from DKIST must contain sufficient meta data to allow proper post processing. In this paper we describe how the Telescope Control System (TCS) and Instrument Control Systems (ICS) work together with the camera systems to provide the information to achieve this goal. In particular we will show how the world coordinate information (WCI) produced by the various subsystems can be used to generate FITS headers for post-processing off summit, how it is used to meet the Observatory Control System (OCS) requirements to map between solar coordinate systems and pixels in an image, how positions on one detector can be mapped onto positions on another and how if multiple instruments are in use then the appropriate WCI is attached.

We will show how the Wavefront Correction Control System (WCCS) context viewer plays a key role in establishing the transformation chain from pixels in an image to sky coordinates as it provides the link between the instrument coordinate frames that are fixed relative to each other in the coude room and the TCS defined x, y coordinate frame.

9913-29, Session 6

The Infrared Imaging Spectrograph (IRIS) for TMT: motion planning with collision avoidance for the on-instrument wavefront sensors

Edward L. Chapin, Jennifer S. Dunn, NRC - Herzberg Astronomy & Astrophysics (Canada); Jason L. Weiss, Univ. of California, Los Angeles (United States); Kim Gillies, Thirty Meter Telescope (United States); Yutaka Hayano, Advanced Technology Ctr., NAOJ (Japan); Christopher A. Johnson, James E. Larkin, Univ. of California, Los Angeles (United States); Anna M. Moore, Reed L. Riddle, California Institute of Technology (United States); Ji Man Sohn, Univ. of California, Los Angeles (United States); Roger M. Smith, California Institute of Technology (United States); Ryuji Suzuki, National Astronomical Observatory of Japan (Japan); Gregory Walth, Shelley A. Wright, Univ. of California, San Diego (United States)

The InfraRed Imaging Spectrograph (IRIS) will be a first-light client instrument for the Narrow Field Infrared Adaptive Optics System (NFIRAOS) on the Thirty Meter Telescope. IRIS includes three configurable tip/tilt (T/T) or T/T/focus On-Instrument Wavefront Sensors (OIWFS). These sensors are positioned over natural guide star (NGS) asterisms using movable polar-coordinate pick-off arms (POAs) that patrol an approximately 2-arcminute circular field-of-view (FOV). The POAs are capable of colliding with one another, so an algorithm for coordinated motion that avoids contact is required. We have adopted an approach in which arm motion is evaluated as the downhill gradient of a scalar potential field that includes an "attractive" component towards the goal configuration (locations of target stars), and repulsive components to avoid obstacles (proximity to adjacent arms). This technique is computationally inexpensive, and produces smooth and efficient trajectories. Results of full motion simulations, including mitigation of problematic system configurations, with acquisition time statistics, are presented.

9913-30, Session 6

AAO Starbugs: software control and path-finding algorithms

Nuria P. F. Lorente, Minh V. Vuong, Australian Astronomical Observatory (Australia); Sungwook E. Hong, Korea Institute for Advanced Study (Korea, Republic of); Michael Goodwin, Kyler Kuehn, Australian Astronomical Observatory (Australia); Christophe Satorre, Ecole Polytechnique Fédérale de Lausanne (Switzerland)

The AAO's TAIPAN instrument deploys 150 9mm diameter Starbug robots to position optical fibres to accuracies of 0.5 arcsec, on a 30cm glass field plate on the focal plane of the 1.2 m UK-Schmidt telescope. This paper describes the software system developed to control and monitor the Starbugs, with particular emphasis on the automated path-finding algorithms, and the metrology software which keeps track of the position and motion of individual Starbugs as they independently move in a crowded field.

The software employs a tiered approach to find a collision-free path for every Starbug, from its current position to its target location. This consists of three path-finding stages of increasing complexity and computational cost. For each Starbug a path is attempted using a simple method. If unsuccessful, subsequently more complex (and expensive) methods are tried until a valid path is found or the target is flagged as unreachable.

The challenge is to ensure that a given path takes a minimum amount of time to execute, but that doing this does not prevent a neighbouring Starbug from reaching its target. Additionally, the algorithm must ensure that the umbilical which tethers each Starbug to the instrument (and carries the science fibre) is not entangled with that of other Starbugs in their simultaneous movement across the field plate, as this would increase the risk of reconfiguration failure in subsequent exposures.

Simulations show that this multi-stage approach allows the field to be reconfigured within the required 5 minutes for the majority of expected target configurations. We will show the results of initial tests with the instrument using the final production Starbugs.

9913-31, Session 6

Collision-free coordination of fiber positioners in multi-object spectrographs

Laleh Makarem, Jean-Paul Kneib, Mohamed Bouri, Denis Gillet, Ecole Polytechnique Fédérale de Lausanne (Switzerland)

Many fiber-feb spectroscopic survey projects, such as DESI, PFS and MOONS, will use thousands of fiber positioners packed at a focal plane. To maximize observation time, the positioners need to move simultaneously and reach their targets swiftly. We have previously presented a motion planning method based on a decentralized navigation function for the collision-free coordination of the fiber positioners in DESI. In MOONS, the end effector of each positioner handling the fiber can reach the centre of its neighbours. There is therefore a risk of collision with up to 18 surrounding positioners in the chosen dense hexagonal configuration. Moreover, the length of the second arm of the positioner is almost twice the length of the first one. As a result, the geometry of the potential collision zone between two positioners is not limited to the extremity of their end effector, but surrounds the second arm.

In this paper, we modify the navigation function to take into account the larger collision zone resulting from the geometrical shape of the positioners. The proposed navigation function takes into account the configuration of the positioners as well as the constraints on the actuators, such as their maximal velocity and their mechanical clearance. Considering the fact that all the positioners' bases are fixed to the focal plane, collisions can occur locally and the risk of collision is limited to the 18 surrounding positioners. The decentralizing motion planning and trajectory generation takes advantage of this limited number of positioners and the locality of collisions, hence significantly reduces the complexity of the algorithm to a linear order. The linear complexity ensures short computation time. In addition, the time needed to move all the positioners to their targets is independent of the number of positioners. These two key advantages of the chosen decentralization approach turn this method to a promising solution for the collision-free motion-planning problem in the next-generation spectroscopic survey projects. A motion planning simulator, exploited as a software prototype, has been developed in Python.
The pre-computed collision-free trajectories of the actuators of all the positioners are fed directly from the simulator to the electronics controlling the motors. A successful demonstration of the effectiveness of these trajectories on the real positioners as well as their simulated counterparts are put side by side in the following online video sequence (https://goo.gl/YuwwsE).

9913-32, Session 7

Exploratory visualization of astronomical data on ultra-high-resolution wall displays *(Invited Paper)*

Emmanuel Pietriga, INRIA Chile (France) and Univ. Paris-Saclay (France); Fernando del Campo, Amanda Ibsen, INRIA Chile (Chile); Romain Primet, INRIA Saclay - Île-de-France (France); Olivier Chapuis, Caroline Appert, Univ. Paris-Sud 11 (France) and Univ. Paris-Saclay (France); Roberto Muñoz, Maren Hempel, Susana Eyheramendy, Andres Jordan, Pontificia Univ. Católica de Chile (Chile); Hervé Dole, Institut d'Astrophysique Spatiale (France) and Univ. Paris-Saclay (France)

Ultra-high-resolution wall-sized displays feature a very high pixel density over a large physical surface. For instance, WILD, the first wall display we set up in our laboratory, has a total resolution of 20480?6400 = 131 megapixels for a surface area of 5.5m?1.8m. Such platforms have properties that make them well-suited to the visualization of very large datasets. They can represent the data with a high level of detail while at the same time retaining context: users can transition from an overview of the data to a detailed view simply by physically moving in front of the wall display. Wall displays also offer good support for collaborative work, enabling multiple users to simultaneously visualize and interact with the displayed data. To make them interactive, wall-sized displays are increasingly coupled with input devices such as touch frames, motion-tracking systems and wireless multitouch devices, in order to enable multi-device and multi-user interaction with the displayed data.

Application areas for such visualization platforms range from the monitoring of complex infrastructures and crisis management situations to tools for the exploratory visualization of scientific data. In this paper, we describe one such application, called FITS-OW, that enables astronomers to visualize and interact with very large FITS images and collections thereof. They can pan and zoom in images that are several hundred thousand pixels in both width and height, overlay the results of data analyses, fetch and display additional images of a specific object or region in the sky, showing observations in different ranges of the electromagnetic spectrum or at different times. Additionally, FITS-OW lets astronomers query databases such as Simbad servers, and visualize the results of such queries in-place, right next to the corresponding source in the image. The very high pixel density of wall displays means that detailed information can be shown for multiple sources simultaneously, including multiple measurements as well as research articles retrieved dynamically through links found in relevant databases.

We explain how we enable astronomers to perform these operations using interaction techniques that were designed specifically for wall displays, using direct manipulation and gestures performed on the wall's surface or on handheld tablets: adjusting the scale and color mapping used to render the raw, high-dynamic-range FITS data; overlaying and manually compositing multiple bands; measuring the brightness, colors and light curves of astronomical sources; making queries and adjusting object filters. We also explain how we addressed related technical challenges. Indeed, ultra-high-resolution wall displays are often driven by clusters of computers (the above-mentioned WILD platform uses 32+1 graphics processing units in 16+1 computers) and involve heterogeneous input devices, which causes problems of data sharing, graphics rendering, and handling multiple user input channels. We describe FITS-OW's architecture and our solution to the specific challenges that this application raised: the generation of FITS tile pyramids and their multi-scale rendering; the computation of sky coordinates; queries to sky catalogs; the dynamic adjustment of scale, color mapping and graphics compositing settings, and the underlying input management framework.

9913-33, Session 7

Prototyping the graphical user interface for the operator of the Cherenkov Telescope Array

Iftach Sadeh, Igor Oya, Deutsches Elektronen-Synchrotron (Germany); Joseph Schwarz, INAF - Osservatorio Astronomico di Brera (Italy); Emmanuel Pietriga, INRIA Saclay - Île-de-France (France)

The Cherenkov Telescope Array (CTA) is a planned gamma-ray observatory. CTA will utilize imaging atmospheric Cherenkov telescopes (IACTs), using three different telescope types. The telescopes will be deployed in two sites, Northern and Southern, which will respectively include about 100 and about 20 telescopes. Previous IACT experiments were restricted to up to five telescopes. Consequently, the design of a graphical user interface (GUI) for the operator of a CTA site involves new and interesting challenges. To name a few, the GUI will need to convey information for various levels of complexity; on the level of the entire array (100 telescopes); the level of sub arrays (between 1 and 32 groups); or the level of a single telescope and the associated sub-systems. In addition, multi-telescope views for a given sub-system will also be required, taking into account the differences between the telescope types. The GUI will also need to be highly responsive, and to integrate different interfaces to CTA software (databases, live feeds etc.).

CTA members have started collaboration with experts from INRIA in the field of human-computer interface. Such interaction has proven beneficial for other multi-instrument experiments, such as the Atacama Large Millimeter/submillimeter Array (ALMA). Following a two-day workshop in DESY in May 2015, we have defined an initial set of requirements for the operator GUI, and have begun prototyping activity.

Our current prototype is based on web technology. The back-end is a Python based server called Pyramid. A Python framework has the advantage of being very versatile, incorporating the ability to use many off-the-shelf libraries for computation, communication, multi-threading and multi-processing. The front-end is a web browser; it displays data generated with Javascript, using an open-source library called d3.js. The latter is a data-driven framework, with integrated mechanisms for displaying, updating and animating vector graphics. Communication between the back-end and the front-end of the GUI is performed using web-sockets. These allow asynchronous communication, facilitating quick and responsive GUI behaviour. As part of the prototyping process, we have implemented such features as panel synchronization, and semantic zooming. The latter provides a contextual level of complexity; based on the actions of the user, graphical elements change and reflect different types of information.

9913-34, Session 7

Firefly: embracing future web technologies

William W. Roby, Xiuqin Wu, Loi Ly, Tatiana Goldina, Lijun Zhang, California Institute of Technology (United States)

We are currently in the golden age of JavaScript web technology. We now can build web applications on a scale that would have never been considered a few years ago. With its unprecedented sophistication, web development is constantly changing and improving in speed, capabilities and ease of development.

At IPAC/Caltech, we have developed the Firefly web archive and visualization system used in production for the last eight years in many missions while giving the scientist significant capabilities to study data. Firefly provided the first completely web based FITS viewer as well has having significant data, tabular and plotting visualizers. Further, it will be

used for the science user interface of the LSST telescope which goes online in 2021. Firefly must meet the needs of archive access and visualization for the 2021 LSST telescope, and must serve astronomers beyond the year 2030.

Currently, our team has faced the fact that this software will become obsolete in the next couple of years. This is our challenge with the Firefly visualization library.

In the last year, we have ported the Firefly to cutting edge web technologies. Embarking on this massive overhaul is no small feat to say the least. Choosing the technologies that will maintain a forward trajectory in a future development project is always hard and often overwhelming. When a team must port 200,000 lines of code for a production-level product there is little room to make poor choices. In this approach, we believe our new code will utilize all the current breakthroughs in stability, testability, speed, and reliability while still allowing our teams to work on large applications.

This talk will give an overview of the most modern web technology and lessons learned in our conversion from GWT based system to React/Redux based system.

9913-35, Session 7

Observation management challenges of the Square Kilometre Array

Alan Bridger, Stewart J. Williams, Mark Nicol, UK Astronomy Technology Ctr. (United Kingdom); Pamela Klaassen, UK Astronomy Technology Ctr (United Kingdom); Roger S. Thompson, SciSys UK Ltd. (United Kingdom); Cristina Knapic, Giovanna Jerse, INAF - Osservatorio Astronomico di Trieste (Italy); Andrea Orlati, Marco Messina, INAF - Istituto di Radioastronomia (Italy); Snehal Valame, Persistent Systems Ltd. (India)

The Square Kilometre Array (SKA) will be the world's most advanced radio telescope, designed to explore some of the biggest questions in astronomy today, such as the epoch of re-ionization, the nature of gravity and the origins of cosmic magnetism. SKA1, the first phase of SKA construction, is currently being designed by a large team of experts world-wide. SKA1 comprises two telescopes: a 200-element dish interferometer in South Africa and a 130000-element dipole antenna aperture array in Australia.

To enable the ground-breaking science of the SKA an advanced Observation Management system is required to support both the needs of the astronomical community users and the SKA Observatory staff. This system will ensure that the SKA realises its scientific aims and achieves optimal scientific throughput. This paper provides an overview of the design of the system that will accept proposals from SKA users, and result in the execution of the scripts that will obtain science data, taking in the stages of detailed preparation, planning and scheduling of the observations and onwards tracking. It describes the unique challenges of the differing requirements of two telescopes, one of which is very much a "software telescope", including the need to schedule the data processing as well as the acquisition, and to react to both internally and externally discovered transient events. The scheduling of multiple parallel sub-array use is covered, along with the need to handle commensal observing - using the same data stream to satisfy the science goals of more than one project simultaneously. An international team from academia and industry, drawing on expertise and experience from previous telescope projects, the virtual observatory and comparable problems in industry, has been assembled to design the solution to this challenging but exciting problem.

9913-36, Session 8

Status report of the SRT radiotelescope control software: the DISCOS project

Andrea Orlati, Marco Bartolini, INAF - Istituto di Radioastronomia (Italy); Marco Buttu, Carlo Migoni, Sergio Poppi, INAF - Osservatorio Astronomico di Cagliari (Italy); Simona Righini, INAF - Istituto di Radioastronomia (Italy); Antonietta Fara, INAF - Osservatorio Astronomico di Cagliari (Italy)

The Sardinia Radio Telescope (SRT) is a 64-meter fully steerable radio telescope. It is provided with active surface to correct for gravitational deformations, allowing observations from 300 MHz to 100 GHz. At present, three receivers are available: a coaxial LP-band receiver (305-410 MHz and 1.5-1.8 GHz), a C-band receiver (5.7-7.7 GHz) and a 7-feed K-band receiver (18-26.5 GHz). Several back-ends are also available in order to perform the different data acquisition and analysis procedures requested by the various scientific projects.

The design and development of the SRT control software started in 2004, and now belongs to a wider project called DISCOS (Development of the Italian Single-dish Control System), which provides a common infrastructure to the three Italian radio telescopes (Medicina, Noto and SRT dishes). DISCOS is based on the Alma Common Software (ACS) framework, and currently consists of more than 500K lines of code. It is organized in a common core and three specific product lines, one for each telescope. Recent developments, carried out after the conclusion of the technical commissioning of the instrument (December 2013), consisted in the addition of several new features in many parts of the observing pipeline, spanning from the motion control to the digital backends for data acquisition and data formatting; we will briefly describe such improvements.

More importantly, in the last two years we have assisted the astronomical validation of the SRT radiotelescope, leading to the opening of the first public call for proposal in late 2015. During this period, while assisting both the engineering and the scientific staff, we massively employed the control software testing all of its features: in this process we received our first feedback from the users and we could see how the system performed in a real-life scenario, drawing the first conclusions about the overall system stability and performance. We will take into exam how the system behaves in terms of network load and system load, how it reacts to failures and errors, and what components and services seem to be the most critical parts of our architecture, showing how the ACS framework has an impact on those aspects.

Moreover, the exposure to public utilization has highlighted the major flaws in our development and software management process, which had to be tuned and improved in order to achieve faster release cycles in response to user feedback and safer deploy operations. In this regard we will show how the introduction of testing practices, along with continuous integration, helped us to meet higher quality standards.

Having identified the most critical aspects of our software, we will conclude showing our intentions for the future development of DISCOS, both in terms of software features and software infrastructures.

9913-37, Session 8

Status report of the end-to-end ASKAP software system: towards early science operations

Juan C. Guzman, Commonwealth Scientific and Industrial Research Organisation (Australia); Jessica Chapman, Malte Marquarding, Matthew Whiting, CSIRO Astronomy and Space Science (Australia)

The Australian SKA Pathfinder (ASKAP) is a novel centimetre radio synthesis telescope currently in the commissioning phases and located in the midwest region of Western Australia. It comprises of 36 x 12 m diameter reflector antennas each equipped with state-of-the-art and award winning Phase Array Feeds (PAF) technology. The PAFs provide a wide, 30 square degree field-of-view by forming up to 36 separate dual-polarisation beams at once. This results in a high data rate: 70 TB of correlated visibilities in an 8 hour observation, requiring custom-written, high-performance software running in dedicated High Performance Computing (HPC) facilities. The first 6 antennas equipped with first-generation PAF technology (Mark I), named the Boolardy Engineering Test Array (BETA) has been in used since 2014 as a platform to test PAF calibration and imaging techniques, and along the way it has been producing some great science results. Commissioning of the ASKAP Array Release 1, that is the first 6 antennas with second-generation PAFs (Mark II) is currently under way.

An integral part of the instrument is the Central Processor platform hosted at the Pawsey Supercomputing Centre in Perth, which executes the custom-written software pipelines, designed specifically to meet the ASKAP imaging requirements of wide field of view and high dynamic range. There are three key hardware components of the Central Processor: The ingest nodes (16 x node cluster), the fast temporary storage (1 PB Lustre filesystem) and the processing supercomputer (200 TFlop system). This High-Performance Computing (HPC) platform is managed and supported by the Pawsey support team. Due to the limited amount of data generated by BETA and the first ASKAP Array Release, the Central Processor platform has been running in a more “traditional” or user-interactive mode. But this is about to change: integration and verification of the online ingest pipeline starts in early 2016, which is required to support the full 300 MHz bandwidth for Array Release 1; followed by the deployment of the real-time data processing components. In addition to the Central Processor, the first production release of the CSIRO ASKAP Science Data Archive (CASDA) has also been deployed in one of the Pawsey Supercomputing centre facilities and it is integrated to the end-to-end ASKAP data flow system.

This paper describes the current status of the “end-to-end” data flow software system from preparing observations to data acquisition, processing and archiving; and the challenges of integrating an HPC facility as a key part of the instrument. This paper also shares some lessons learned since the start of integration activities and the challenges ahead in preparation for the start of the Early Science program.

9913-38, Session 8

MAISIE: a multi-purpose astronomical instrument simulator environment

Alan O’Brien, Steven M. Beard, Vincent Geers, Pamela Klaassen, UK ATC (United Kingdom)

Astronomical instruments often need simulators to preview their data products and test their data reduction pipelines. Instrument simulators tend to be purpose-built with a single instrument in mind, and attempting to reuse one of these simulators for a different purpose is often a slow and difficult task. MAISIE is a simulator framework designed for reuse on different instruments. An object-oriented design encourages reuse of functionality and structure, while offering the flexibility to create new classes with new functionality. MAISIE can just as easily build simulators for single or multi-channel instruments and ground or space based instruments. To remain easy to use and to facility the sharing of simulators across teams, MAISIE is written in Python, a freely available and open-source language. New functionality can be created for MAISIE, on a general or specific basis, by creating new classes that represent optical mediums. This approach allows new and novel instrument to add functionality and take advantage of the existing MAISIE classes. MAISIE has recently been used successfully to develop the simulator for the JWST/MIRI- Medium Resolution Spectrometer.

9913-39, Session 8

ALMA common software from development to operations

Alessandro Caproni, European Southern Observatory (Germany); Pau Colomer Criach, GTD Ingeniería de Sistemas y de Software S.A. (Spain); Bogdan Jeram, European Southern Observatory (Germany); Miguel M. Mañas, GTD Ingeniería de Sistemas y de Software S.A. (Spain); Heiko Sommer, Gianluca Chiozzi, European Southern Observatory (Germany)

ALMA, an international partnership of Europe, North America and East Asia in cooperation with the Republic of Chile, is one of the largest astronomical observatories in existence. It operates a single telescope composed of 66 antennas located on the Chajnantor plateau in Chile. All antennas are now at the ALMA site and the observatory is transitioning towards full-scale science operations.

The ALMA Common Software (ACS), developed by ESO in collaboration with its partners, provides the infrastructure of the distributed software system of ALMA and other projects, being available under the open source LGPL licence.

ACS, built on top of CORBA and DDS middleware, is based on a Component-Container paradigm and provides an API that hides the complexity of the middleware allowing the developer to focus on domain specific issues.

ACS adopts a different interoperable implementation for each of the three supported languages, C++, Java and Python and provides services for distributed programming like transparent remote object invocation and activation, component lifecycle management, publisher/subscriber, distributed error logging, alarm management, configuration database, simulation, deployment, testing and debugging tools.

The transition of the ALMA observatory from construction to operations brings with it that ACS efforts focuses primarily on scalability, stability and robustness to address operational issues rather than on the delivery of new features (although few are still introduced to satisfy operational requirements). The transition came together with a new, shorter, release cycle and a more extensive on-site testing.

For scalability, the most problematic area has been the CORBA notification service, used to implement the publisher subscriber pattern. Problems in that area are intrinsically difficult to debug, because of the asynchronous nature of the paradigm. Therefore, a lot of effort has been spent to improve notification service stability and recovery from run time errors, without having to restart the whole software system.

An investigation of the replacement of CORBA notification channels with DDS has been conducted times ago and looked promising, but further development has been put on hold until the ALMA software will be considered stable enough. A comparison of DDS with a messaging library like ZeroMQ is also foreseen.

The original bulk data mechanism, implemented using the CORBA Audio/Video Streaming Service, showed its limitations and has been replaced with a more performant and scalable DDS implementation.

Operational needs showed soon the difference between releases cycles for Online software (i.e. used during observations) and Offline software, which requires much more frequent releases. As a consequence, offline subsystems started to reduce their dependency on ACS that could not ship libraries and tools common to all the subsystems without substantially impacting their release cycles. The updating of some of the strategic tools like Java must now be done more frequently, e.g. to promptly respond to security issues of web applications.

This paper aims to describe the impact the transition from construction to operations had on ACS, the solution adopted so far and a look into future evolution.

9913-40, Session 8

The ESO astronomical site monitor upgrade

Gianluca Chiozzi, Heiko Sommer, Marc S. Sarazin, Thomas Bierwirth, Dario Dorigo, Ignacio Vera Sequeiros, European Southern Observatory (Germany); Julio Navarrete, Diego del Valle, European Southern Observatory (Chile)

Monitoring and prediction of astronomical observing conditions are essential for planning and optimizing observations at all modern observatories. For this purpose, ESO, in the 90's, developed the concept of an Astronomical Site Monitor (ASM), as a facility fully integrated in the operations of the VLT observatory.

Two essentially identical systems were installed both at Paranal and La Silla, providing comprehensive local weather information (wind, humidity, temperature and dust at different locations) and a Differential Image Motion Monitor (DIMM) for seeing measurement.

By now we had three very good reasons for a major upgrade of these systems:

• The need of introducing new sensors and features to satisfy the requirements of observations using Adaptive Optics.

• Managing hardware and software obsolescence.

• Making the system more maintainable and expandable by integrating off-the-shelf hardware solutions and up to date software technologies.

The new ASM integrates:

• a new DIMM paired with a Multi Aperture Scintillation Sensor (MASS) to measure the vertical distribution of turbulence in the high atmosphere by analysing the scintillation of bright stars.

• a new SLOpe Detection And Ranging (SLODAR) telescope, for measuring the altitude and velocity of turbulent layers in the low atmosphere by means of a triangulation method, in which the turbulence profile is recovered from observations of bright binary stars using a Shack-Hartmann wavefront sensor.

• a water vapour radiometer to monitor with high precision and time resolution water vapour content of the atmosphere, allowing to execute observations in the infrared in periods of low precipitable water vapour.

• the old weather tower, that is being refurbished with new sensors.

The telescopes used and the devices integrated are commercial products and we have used as much as possible the control system provided by the vendors, limiting our work to the high level coordination and integration and reducing considerably the amount of software developed with respect to the older system.

Still, the existing external interfaces and the overall system architecture, based on the VLT standards, have been maintained for full backward compatibility.

All data produced by the system are now directly fed in real time into a relational database in Paranal which is replicated to Garching. This allows accessing the data easily both for operations and data analysis, in the same way, using traditional RDBMS tools.

A completely new web-based display replaces the obsolete plots with a flexible and highly configurable application that is also made available to external users.

While access to the live data of old system had to be limited to few consoles in the control room because of computing resources and even though the new system makes available much more information, we can now provide a very scalable access both within and outside the observatory.

In this paper we will analyse the architectural and technological choices for the upgrade and discusses the motivations and trade-offs.

9913-41, Session 9

ASTRI SST-2M prototype and mini-array data reconstruction and scientific analysis software in the framework of the Cherenkov Telescope Array

Saverio Lombardi, INAF - Osservatorio Astronomico di Roma (Italy) and ASDC (Italy); Lucio A. Antonelli, INAF - Osservatorio Astronomico di Roma (Italy) and ASI Science Data Ctr. (Italy); Denis Bastieri, Univ. degli Studi di Padova (Italy); Immacolata Donnarumma, INAF - IASF Roma (Italy); Fabrizio Lucarelli, ASI Science Data Ctr. (Italy); Alberto Madonna, Michele Mastropietro, INAF - Osservatorio Astronomico di Roma (Italy)

In the framework of the international Cherenkov Telescope Array (CTA) gamma-ray observatory, the Italian National Institute for Astrophysics (INAF) is developing a dual-mirror, small-sized, end-to-end prototype (ASTRI SST-2M), inaugurated on September 2014 at Mt. Etna (Italy), and a mini-array composed of nine ASTRI SST-2M telescopes, proposed to be installed at the southern CTA site. The ASTRI mini-array is a collaborative effort led by INAF in synergy with the University of Sao Paulo and FAPESP (Brazil) and the North-West University (South-Africa). The project is also including the full data handling chain from raw data up to final scientific products. To this end, a dedicated software for the on-line/on-site/off-site data reduction and scientific analysis is under development for both the ASTRI SST-2M prototype and mini-array. The software is conceived following a modular approach in which each single component and the entire pipeline are developed in compliance with the CTA requirements. Data reduction components are coded in C++/Python/CUDA and wrapped by efficient pipelines written in Python in order to better exploit the parallel computing architectures (multi-core CPUs) and new hardware architectures based on low-power consumption processors (e.g. ARM) and graphic accelerators (e.g. GPUs). The final scientific products are then achieved by either using standard tools (ctools) adopted by the CTA Consortium or using specifically developed Science Tools if needed. In this contribution, we present the framework and the main software components of the ASTRI SST-2M prototype and mini-array data reduction and scientific analysis package, and report the status of its development.

9913-42, Session 9

Implementing a real-time data stream for time-series stellar photometry

Milan Bogosavljevic, New York Univ. Abu Dhabi (United Arab Emirates); Zach Ioannou, Sultan Qaboos Univ. (Oman)

At present, a number of small and medium-sized robotic telescope facilities are equipped to automatically acquire data of transient sources based on alerts received over the Internet. In most cases the data reduction is automated as well and thus results should be available very quickly. However, the publishing of the latest measurements to the wider astronomical community commonly still involves a step requiring human intervention (for example, writing a descriptive Astronomical telegram). As a consequence, even when there is a desire to publish simple magnitude measurements as fast as possible (in case of a currently unfolding transient event of wider interest) there is typically a time lag of a day or more before the community learns if anyone was observing the event at a given time and what measurements were they able (or interested) to perform. This creates a particular problem for the efficient use of a small observatory: should an alert received today about a transient event be included in the observation schedule, or is this event already being (or been) observed by

a larger telescope and the results of the follow-up are just not sent by a telegram yet?

As a first step to remedy this situation, we present a new automated photometric pipeline optimized for time-series photometry that includes a real-time data streaming service. An observer using this resource can automatically reduce images frame by frame as they are being obtained and stream photometric data of selected sources over the Internet. Other observers can then monitor the data stream in real time and make an informed decision whether to perform complementary observations of a transient event in progress. Our current implementation relies on ZeroMQ, a high-performance asynchronous messaging library. The photometric pipeline itself is controlled through the widely used SAOImage DS9 package, so that the interface is user friendly and already familiar to the astronomical community. Incoming images from a telescope are processed in sequence immediately after readout and download, including standard data reduction (bias, dark, flat-fielding, pixel-masking), frame to frame registration in pixel-space and time stamping. Accurate photometric measurements are carried out using both standard aperture as well as optimal photometry algorithms for maximum S/N extraction. For every observed frame, the photometric measurements for a pre-set list of objects are automatically streamed through a TCP/IP port in real-time and the end client can view them either as simple text or an auto-updating plot. Our pipeline is currently being tested with observations made by the 60cm telescope at Astronomical Station Vidojevica in Serbia. The pipeline uses a modular design so that it can be easily implemented or customized as a real-time robotic telescope pipeline on any observatory.

9913-43, Session 9

Automated spectral reduction pipelines

Robert J. Smith, Robert M. Barnsley, Andrzej S. Piascik, Iain A. Steele, Liverpool John Moores Univ. (United Kingdom)

We present results from the development and operation of the automated data reduction pipeline being used for a diverse range of spectrographs on the Liverpool Telescope. The pipelines perform both the removal of instrumental signatures (bias, dark, flat, distortion etc) and provide science-ready, wavelength calibrated data products to the astronomers promptly after observation. Efficient execution of the observatory's highly automated operations model requires substantial commonality between the software for all the instruments and the spectrographs use a common code base. The unique science drivers of each instrument led to novel hardware solutions which required detailed reassessment of some of the conventional CCD reduction recipes rather than using the widely available software packages. For example, we describe the derivation and application of bias and dark corrections on detectors with neither overscan or shutter. In the context of spectroscopy we compare the quality of flat fielding resulting from different algorithmic combinations of dispersed and non-dispersed sky and lamp flats in the case of spectra suffering from 2d spatial distortions. The LT, a robotic, fully-automated, common-user observatory owned and operated on La Palma by Liverpool John Moores University has a broad optical instrument suite including three spectrographs; the original, facility spectrograph, FRODOSpec and two more specialised instruments developed to address particular science needs. SPRAT offers very high throughput at low dispersion for use in rapidly typing transient sources and LOTUS is heavily optimised for the near ultra-violet (3300-4000A).

9913-44, Session 9

StarDock: shipping customized computing environments to the data

Michael D. Young, Soichi Hayashi, Arvind Gopu, Indiana Univ. (United States); Ralf Kotulla, Univ. of Wisconsin-Madison (United States)

The ever-increasing size of astronomical data volumes is making the transfer, storage, and processing of data a significant burden for the traditional astronomer. Institutional repositories and pipelines, such as the One Degree Imager - Portal, Pipeline, and Archive (ODI-PPA) have attempted to address some of these concerns by allowing users to remotely configure and run a limited set of software, i.e. for ODI-PPA users, the QuickReduce (QR) pipeline and SWarp stacking application have been made available. While this arrangement is satisfactory for most users, there exists a significant fraction whose work could greatly benefit by being able to run their own customized reduction and analysis software directly on the bulk raw or unstacked images. Satisfying the disparate desires of all potential users into a single pipeline is unfeasible, as is integrating their customized software onto our systems and crafting a usable interface. For a solution, we turn towards Docker, a virtual container system that abstracts the application layer and allows software to run in diverse environments. Our system, under the working title StarDock, begins with a suite of micro-service containers of commonly-used astronomical software tools, including astropy, IRAF, QR, SWarp, Montage, and others. Through our Portal interface, a user creates a template image, defining which of the pre-configured micro-services they'll depend on, downloads the template to their local system along with a sample dataset, and adds their own routines and software. When they are satisfied with their customized container, they upload it back to our system, and request processing time, which can be automated or interactive depending on how they have configured their container. The user also specifies a dataset upon which to operate. Leveraging the existing infrastructure of ODI-PPA and Indiana University, the desired dataset is staged, the container is loaded, and the user can exert exact control of the processing and analysis of their data, and retrieve the results when completed. In this presentation we will discuss the mechanics of StarDock, delve into the construction of the templates, address security concerns, and go through a typical workflow. Although StarDock represents a great shift in how astronomical data analysis has traditionally been done, it is a necessary one to keep astronomers from drowning in the data volumes of tomorrow.

9913-21, Session PS1

Is the workflow model a suitable candidate for an observatory supervisory control infrastructure?

Philip N. Daly, German Schumacher, LSST (United States)

The LSST requires a hierarchical control of principal sub-systems to co-ordinate the scientific survey and support (early) commissioning. Such software must be implemented in either Java, C++ or Python under Linux. We also require a web-based interface to this system and the ability to run scripts at different sites (main telescope and auxiliary telescope) either independently or in a co-ordinated fashion. We have identified two open source candidates that provide workflow development systems and run-time engines. One (Bonita BPM) is based upon an OMG standard called BPMN 2.0 and the other (Taverna) was supported by European Union funds but has since move to Apache Incubator Project status. In this paper, we report on the current state of these evaluations for observatory supervisory control.

9913-71, Session PS1

WAS: the archive for the WEAVE spectrograph

Emilio Molinari, Marcello Lodi, Jose Guerra Sr., Telescopio Nazionale Galileo (Spain); Gavin B. Dalton, Univ. of Oxford (United Kingdom); Scott C. Trager, Univ. of Groningen (Netherlands); Don Carlos Abrams, Isaac Newton Group of Telescopes (Spain); Piercarlo Bonifacio, Observatoire de Paris à Meudon (France); Jose Alfonso López Aguerri, Instituto de Astrofísica de Canarias (Spain); Antonella Vallenari, INAF - Osservatorio Astronomico di Padova (Italy); Esperanza E. Carrasco Licea, Instituto Nacional de Astrofísica, Óptica y Electrónica (Mexico); Kevin F. Middleton, STFC Rutherford Appleton Lab. (United Kingdom)

The WEAVE spectrograph will be mounted at the WHT 4m telescope and will provide millions of spectra in a 5 years program, starting after its foreseen first light, late 2017. The targets will be stars and galaxies, providing follow up for the GAIA catalogue and a valuable database for the extragalactic community for nearby clusters of galaxies.

The access and retrieval of the information will be through its dedicated archive, the WEAVE Archive System (WAS). This will be developed and maintained at the TNG premised in the same island of the WHT. Its structure foresees the main axis of scalability, virtualization, and high availability.

The NoSQL Cassandra by Apache has been identified as capable to deal with big data and its Solr indexing package as being able to quickly answer to selection criteria needed to exploit the large set of data. The possibility to further expand the variety of tools via its analytics Spark package may reveal the way to proceed for future pipelines on big dataset.

The scalability of this architecture will allow us to expand the hardware as the observations increase the volume needed on disks as well as load on the servers, in a way which would not be possible using more traditional databases. The same, distributed network of resources will allow a very high availability of the system even in case of a point failure. Virtualization could cut overall costs but possibly at expenses of performance.

We present here the first performances on a simulated data set of 20M spectra, using different architectures and hardware choices. The results will be a benchmark for the final, real solution for the WAS archive, which will be built in the next two years.

9913-76, Session PS1

The very high energy source catalogue at the ASI science data center

Alessandro Carosi, INAF - Osservatorio Astronomico di Roma (Italy) and ASI Science Data Ctr. (Italy); Fabrizio Lucarelli, Lucio A. Antonelli, INAF - Osservatorio Astronomico di Roma (Italy) and ASI Science Data Ctr. (Italy); Paolo Giommi, ASI Science Data Ctr. (Italy)

The increasing number of Very High Energy (VHE) sources discovered by the current generation of Cherenkov telescopes made particularly relevant the creation of a dedicated source catalogs as well as the cross-correlation of VHE and lower energy bands data in a multi-wavelength framework. The “TeGeV Catalogue” hosted at the ASI Science Data Center (ASDC) is a catalogue of VHE sources observed by ground-based Cherenkov telescopes. The TeGeVcat collects all the relevant information publicly available about the observed GeV/TeV sources. The catalogue contains also information about public light curves while the available spectral data are included in the ASDC SED Builder tool directly accessible from the TeGeV catalogue web page. In this contribution we will report comprehensive description of the catalogue and the related tools.

9913-79, Session PS1

Telemetry correlation and visualization at the Large Binocular Telescope Observatory

Kellee R. Summers, Douglas M. Summers, Stephen Hooper, Large Binocular Telescope Observatory (United States)

Highly efficient observatory operations rely upon quality metrics evaluation. High quality metrics requires robust and complete observatory telemetry. At the LBTO, a wide variety of telemetry-capturing mechanisms exist. In an effort to make this telemetry data available to a wide audience, we are developing a suite of tools based on in-house and COTS applications. This paper will explore our strategies for consolidating, parameterizing, and correlating this data to achieve easily available, web-based 2D and 3D time series data visualization. This paper discuses the initial set of tools, details for correlation implementation and future considerations for more advanced correlation techniques.

9913-83, Session PS1

The ALMA high-speed optical communication link is here: an essential component for reliable present and future operations

Giorgio Filippi, European Southern Observatory (Chile); Jorge Ibsen, European Southern Observatory (Chile) and ALMA (Chile); Sandra Jaque, Red Univ. Nacional (Chile); Fernando Liello, Consortium GARR (Italy); Nicolás Ovando, Joint ALMA Observatory (Chile); Albert Astudillo, Red Univ. Nacional (Chile); Jose A. Parra, Christian Saldias, ALMA (Chile)

Announced in 2012, started in 2013 and completed in 2015, the ALMA high-bandwidth communication system has become a key factor to achieve the operational and scientific goals of ALMA. This paper summarizes the technical, organizational, and operational goals of the ALMA Optical Link Project, focused in the creation and operation of an effective and sustainable communication infrastructure to connect the ALMA Operations Support Facility and Array Operations Site, both located in the Atacama Desert in the Northern region of Chile, with the point of presence of REUNA in Antofagasta, about 400km away, and from there to the Santiago Central Office in the Chilean capital through the optical infrastructure created by the EC-funded EVALSO project and now an integral part of the REUNA backbone. This new infrastructure. This new infrastructure completed in 2014 and now operated on behalf of ALMA by REUNA, the Chilean National Research and Education Network, uses state of the art technologies, like dark fiber from newly built cables and DWDM tra nsmission, allowing extending the reach of high capacity communication to the remote region where the Observatory is located. The paper also reports on the results obtained during the first year and a half testing and operation period, where different operational set ups have been experienced for data transfer, remote collaboration, etc. Finally, the authors will present a forward look of the impact of it to both the future scientific development of the Chajnantor Plateau, where many installations area are (and will be) located, as well as the potential Chilean scientific backbone long term development.

This paper could also be in AS-103 - Observatory infrastructure.

9913-87, Session PS1

The online analysis tool of the AGILE gamma-ray mission based on the Level 3 data archive hosted at the AGILE data center

Fabrizio Lucarelli, Carlotta Pittori, Francesco Verrecchia, ASI Science Data Ctr. (Italy) and INAF - Osservatorio Astronomico di Roma (Italy); Marco Tavani, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy) and Univ. degli Studi di Roma "Tor Vergata" (Italy)

The AGILE gamma-ray space mission is dedicated to the observation of astrophysical sources of photons with energy E > 100 MeV. The satellite has been launched in April 2007 and it has just completed its ninth year of operations.

The scientific analysis of the AGILE Gamma Ray Imaging Detector (GRID) data, using the official software tools, is based on the creation of scientific maps (sky, exposure and diffuse model maps) and then on the application of Maximum Likelihood algorithms for the detection of sources and extraction of scientific products (source fluxes, spectra, light curves, ...). A scientific analysis that covers all or part of the public AGILE data archive (till 30 June 2015) might need a very long time. In order to speed up this process, a high-level archive of exposure and counts maps in FITS format on 1-day integrations was created. These 1-day integration maps are summed together to cover pre-selected time intervals (2-, 7- and 28-days), and archived together with the corresponding diffuse gamma-ray background maps.

This archive, called the AGILE Level 3 (LV3) archive, can be used as seed for the GRID scientific data analyses of point sources. An interactive AGILE analysis web tool (AGILE-LV3 tool) has been developed at the AGILE Data Center (within the ASDC) to perform these scientific analyses on time scales that may vary from days to months or even longer total time intervals.

In what follows, we will present the web tool interface and the scientific capabilities achieved using the LV3 GRID Archive. The tool allows extracting almost in real time flux and light curve of a source of interest on a specific time interval without the need to locally install any dedicated software. Preliminary results on the study of transient gamma-ray sources over 7- and 28-days timescale using this tool and the AGILE LV3 archive will be also presented.

9913-91, Session PS1

Construction is over! Where do we go from here to further develop the ALMA software?

Jorge Ibsen, ALMA (Chile) and European Southern Observatory (Chile); A. Maurizio Chavan, European Southern Observatory (Germany); Jeffrey S. Kern, National Radio Astronomy Observatory (United States); George Kosugi, Subaru Telescope, National Astronomical Observatory of Japan (Japan); Morgan Griffith, National Radio Astronomy Observatory (United States); Erich Schmid, European Southern Observatory (Germany); Rubén Soto, ALMA (Chile); Manabu Watanabe, National Astronomical Observatory of Japan (Japan)

The ALMA software was developed over the course of more than 15 years by a worldwide computing team led by ESO, NAOJ and NRAO. At the end of the construction phase in 2012 this team moved seamlessly into the Integrated Computing Team (ICT), with the inclusion of software integration, support and operations groups at the Joint ALMA Observatory (JAO) in Chile. Three years after starting the early ALMA operational phases the ICT is still busy developing improvements to the delivered system and gradually changing focus from new features to stability, robustness, and operational efficiency aspects. As the observatory continues to steadily move forward to reach full operations a plan for the following five years of operations, namely the period 2017-2021, started to be developed jointly by the science, engineering and computing teams in ALMA. The purpose of this paper is to report the key initiatives currently been brought forward by the ICT for the five years look ahead plan and to explain how they will contribute to ALMA strategic goals in the years to come.

9913-95, Session PS1

Operational logs analysis at ALMA observatory based on ELK stack

Juan Pablo Gil, Tzu-Chiang Shen, Johnny W. Reveco, ALMA (Chile)

During the operation in the ALMA observatory, a huge amount of logs files are generated in daily basis. As the ALMA software is still under continuous evolution, logs are not only useful to diagnose failures detected during operation, but are also needed to depict long term performance analysis and provides a quick. Historically, log files are kept in XML format and saved into a file repository. Developers and front line support engineers are the most common users of this files in daily basis. Depending on the problem to diagnose, specific groups of files are downloaded and inspected with editors at users preference, which doesn't allow to filter or search efficiently. We decided to improve the usability, and in addition, to exploit the valuable information available in logs files.

The size of our current log database is measured in Terabytes, so an infrastructure to handle big data is required in order to answer the different questions. In this work we describe the implemented solution to face this problem, its applications and the intermediate steps that led to the final architecture. After initial evaluation with different alternatives, we chose ElasticSearch (ES) as the backend database, coupled with Logstash as pipeline and Kibana as a graphical front end. This set of tools is known in the literature as ELK stack and is the de facto open source standard for storing logs and further data analysis. ES features horizontal growth capability and high speed responses upon queries. In the other hand, Kibana provides a very good framework which allow us to quickly create graphs and group them into dashboards focused on specific topics.

To interface with ALMA software, once logs files are generated and moved into an external storage, a process reads XML logs and insert them into the this platform. This approach provides a fully decoupled mechanism and has zero impact in the operation. During normal operation, the software generates an average of 10.000 logs per second, and 3 Terabytes of disks space are required in order to keep 6 months of logs online. During the last year, Software Operation Support group (SOFTOPS) has created several dashboards that display fresh information regarding to the observation behavior of previous night. For example, to track new occurrences of well known issues which avoids repeat the investigation, another example is an estimation of system usage, system restarts, antenna hardware failures, etc. All these dashboards are displayed in a set of screens located in the front of SOFTOPS offices and during each morning, they provide an early overview of the amount of works that need to be addresses by the rest of the day. Finally, we propose further actions that can be done with this infrastructure, i.e: performance trending analysis, software release characterizations, errors prediction, among others.

9913-99, Session PS1

The open microscopy environment: open image informatics for the biological sciences

Colin Blackburn, Univ. of Dundee (United Kingdom) and Ctr. for Gene Regulation & Expression (United Kingdom); Chris Allan, Glencoe Software, Inc. (United States); Sébastien Besson, Jean-Marie Burel, Mark Carroll, Richard K. Ferguson, Helen Flynn, David Gault, Kenneth Gillen, Univ. of Dundee (United Kingdom) and Ctr. for Gene Regulation & Expression (United Kingdom); Roger Leigh, Univ. of Dundee (United Kingdom); Simone Leo, Univ. of Dundee (United Kingdom) and Ctr. for Gene Regulation & Expression (United Kingdom); Simon P. Li, Dominik Lindner, Univ. of Dundee (United Kingdom) and Ctr. for Gene Regulation & Expression (United Kingdom); Melissa Linkert, Glencoe Software, Inc. (United States); Josh Moore, Univ. of Dundee (United Kingdom) and Ctr. for Gene Regulation & Expression (United States) and Glencoe Software Inc. (United Kingdom); William J. Moore, Univ. of Dundee (United Kingdom) and Ctr. for Gene Regulation & Expression (United Kingdom); Balaji Ramalingam, Univ. of Dundee (United Kingdom) and Ctr. for Gene Regulation and Expression (United Kingdom); Emil Rozbicki, Glencoe Software, Inc. (United States); Gabriella Rustici, Aleksandra Tarkowska, Petr Walczysko, Univ. of Dundee (United Kingdom) and Ctr. for Gene Regulation & Expression (United Kingdom); Eleanor Williams, Univ. of Dundee (United Kingdom); Jason R. Swedlow, Univ. of Dundee (United Kingdom) and Ctr. for Gene Regulation & Expression (United States) and Glencoe Software, Inc. (United Kingdom)

Despite significant advances in biological imaging and analysis, major informatics challenges remain unsolved: file formats are proprietary, storage and analysis facilities are lacking, as are standards for sharing image data and results. While the open FITS file format is ubiquitous in astronomy, astronomical imaging shares many challenges with biological imaging, including the need to share large image sets using secure, cross-platform APIs, and the need for scalable applications for processing and visualisation.

The Open Microscopy Environment (OME) is an open-source software framework developed to address these challenges. OME tools include - an open data model for multi-dimensional imaging (OME Data Model); an open file format (OME-TIFF) and library (Bio-Formats) enabling free access to images (5D+) written in more than 145 formats from many imaging domains including FITS; and a data management server (OMERO).

The Java-based OMERO client-server platform comprises an image metadata store, an image repository, visualization and analysis by remote access, allowing sharing and publishing of image data. OMERO provides a means to manage the data through a multi-platform API. OMERO's model-based architecture has enabled its extension into a range of imaging domains, including light and electron microscopy, high content screening, digital pathology and recently into applications using non-image data from clinical and genomic studies. This is made possible using the Bio-Formats library.

The current stable release, OMERO 5.2, includes a single mechanism for accessing image data of all types -- regardless of original file format -- via Java, C/C++ and Python and a variety of applications and environments (e.g. ImageJ, Matlab and R). OMERO includes SSL-based secure access, distributed compute facility, filesystem access for OMERO clients, and a scripting facility for image processing. An open script repository allows users to share scripts with one another. A permissions system controls access to data within OMERO and enables sharing of data with users in a specific group or even publishing of image data to the worldwide community through a web client. This web client provides a framework the creation of custom applications.

Importing these large datasets is fast, and data are stored and used in their original file format, without duplication, and can be accessed by 3rd party software. Several applications using OMERO have now been released by the OME Consortium, including Matlab-based fluorescence lifetime exponential fitting and object tracking modules, two image-based search applications, and an automatic image tagging application.

OMERO and Bio-Formats run the JCB DataViewer, the world's first on-line scientific image publishing system and several other institutional image data repositories.

9913-103, Session PS1

An overview of space weather data system

Ji-Hye Baek, Seonghwan Choi, Jongyeob Park, Korea Astronomy and Space Science Institute (Korea, Republic of)

Space Weather Data System (SWDS) has become a main factor for space weather research and data service in Korea Astronomy and Space Science Institute (KASI). This paper describes the hardware system, pipeline, data archive, process and visualization software, and web service of SWDS. The goal of SWDS is fast, stable and effective data publish. The hardware system consists of several servers and storage which are separated by function or data type. Between servers and storage communicate through the 10Gbps network switch. SWDS doesn't have database management system but instead, we use file system of directory structure. We have implemented specific application software for various data source, data format and communication protocol, and developed web services to distribute space weather data.

9913-107, Session PS1

Advanced GLS map-making for the Herschel's photometers

Lorenzo Piazzo, Maria C. Raguso, Marco Mastrogiuseppe, Sapienza Univ. di Roma (Italy); Luca Calzoletti, Bruno G. M. Altieri, European Space Astronomy Ctr. (Spain)

INTRODUCTION: The Herschel space telescope hosted two infrared photometers, namely the Photodetector Array Camera and Spectrometer (PACS) and the Spectral and Photometric Imaging Receiver (SPIRE). The production of sky images from the photometers' output, a process called data reduction or map-making, is critical for the full exploitation of the instruments and is a difficult task, due to the many disturbances affecting the data. Generalised Least Squares (GLS) estimation is an important map-making technique, exploited by several reduction software. However, implementation of GLS for Herschel data is far from trivial and requires specific pre- and post-processing, as better illustrated in [1]. In this paper, we present three improvements of the GLS processing pipeline, aimed at increasing the estimation quality.

INITIAL GUESS: The GLS image estimate has a closed form expression which, however, involves the inversion of large matrices and cannot be evaluated directly. As a result, the image is obtained by means of an approximate, iterative algorithm, which requires an initial guess to start with. In theory, the iterative procedure will converge irrespectively of the initial guess. However, in practice, the convergence may be difficult or impossible to achieve if the guess is not properly selected. In the paper, we

discuss three ways of selecting the initial guess and their relative merits.

DATA SYNCHRONISATION: The sensors of PACS and SPIRE are bolometers placed on the focal plane. During an observation, the telescope pointing is moved along a given scan trajectory, covering the sky area under observation, and the output of each bolometer is sampled at regular times, producing a sequence of readouts that is termed a timeline. Among other problems, the timelines may be affected by a time-shift, due to delays in the processing or to a systematic error in the timing system. This time-shift translates into a systematic pointing error, which shifts all the readouts along the scan trajectory. The shift has a detrimental impact on the image quality, which may be severe for some observation modes. In the paper, we tackle this problem and, in particular, we first extend the data model of [1] in order to account for the shift and next develop an Iterative Synchronisation Algorithm (ISA) for estimating and compensating the shift.

PIXEL NOISE: The estimated image is constituted by a regular array of pixels. However, the readouts' sampling points are not disposed on a regular grid. In other words, the sampling point is not in the pixel center but is randomly placed inside the pixel. This fact is usually neglected by GLS map-makers, which typically employ a nearest neighbour rule, assigning all the readouts to the pixel center. As we show in the paper, this effect can be modelled as an additional noise affecting the readouts, called the pixel noise. This noise may severely reduce the image quality and may introduce a strong distortion in the estimate. In the paper, we tackle this problem and, in particular, we first extend the data model of [1] in order to account for the pixel noise and next discuss how the GLS estimation has to be modified accordingly.

RESULTS: We discuss the image quality improvement that can be achieved using the techniques introduced in the paper by presenting a rich set of examples and experiments, using both real and simulated data.

[1] L. Piazzo et al.: "Unimap: a Generalised Least Squares Map Maker for Herschel Data", {em MNRAS.}, Vol. 447, pp. 1471-1483, 2015.

9913-110, Session PS1

Data reduction software for the Mid-Infrared E-ELT Imager and Spectrograph (METIS) for the European Extremely Large Telescope (E-ELT)

Michael Mach, Univ. Wien (Austria); Rainer Köhler, Univ. of Innsbruck (Austria) and Univ. Wien (Austria); Oliver Czoske, Univ. Wien (Austria); Wolfgang Kausch, Univ. of Innsbruck (Austria); Thorsten Ratzka, Karl-Franzens-Univ. Graz (Austria); Werner Zeilinger, Manuel Güdel, Univ. Wien (Austria); Bernhard R. Brandl, Leiden Univ. (Netherlands)

In this paper we present the current status of the design of the science data reduction pipeline and the corresponding data flow system for METIS.

It will be one of the first three instruments for the E-ELT and feature diffraction limited imaging, low/mid resolution spectroscopy and high resolution integral field spectroscopy (IFS) at mid-infrared wavelengths between 3 - 19 μm (L/M/N/Q1 bands). METIS will employ a variety of observing modes that consist of L/M band imaging and spectroscopy, N/Q1 band imaging and spectroscopy and L/M/N band integral field spectroscopy. METIS will be able to work in parallel mode, which means that it can observe simultaneously with the L/M detector and N/Q1 detector.

Due to the thermal radiation from the telescope, detector and the Earth's atmosphere, the detection noise is orders of magnitude higher than the flux received from the science target. Instrument elements (mirrors, detectors, mechanics, support structures, etc.) will thus be encapsulated and cooled below 40 Kelvin in order to eliminate as many sources of unwanted thermal radiation as possible. The warm elements of the telescope and the sky itself still contribute massive amounts of flux compared to the radiation of the science target. Therefore, the detectors will have to be read out on sub-second time scales. The maximum amount of data produced is roughly 6 terabyte per 10 hours of observation in burst mode of the L/M detector with a read out rate of 20 frames per second.

A reliable and robust data flow system is necessary in order to properly handle the acquired data. We will deliver software that conforms to ESO's (European Southern Observatory) standards and processes data in a cascade of three levels. First, the observatory pipeline provides event driven and on the fly data processing. Second, the quality control (QC) pipeline processes data of a complete observing night and delivers QC parameters, generates master calibration frames and quantifies data to check for instrument health. Third, the science grade pipeline & desktop environment enables processing of the data with the best calibration frames achievable and provides modular software recipes. Finally, a set of workflows for ESO REFLEX will provide clear and neatly arranged science grade data reduction cascades for METIS.

This software will make heavy use of the common pipeline library (CPL) and the upcoming high level data reduction library (HDRL) provided by ESO.

9913-116, Session PS1

A distributed infrastructure for publishing VO services: an implementation

Francesco Cepparo, INAF - Osservatorio Astronomico di Trieste (Italy); Ivan Scagnetto, Univ. degli Studi di Udine (Italy); Marco Molinaro, Riccardo Smareglia, INAF-OATs (Italy)

A complete astrophysical publishing environment, working as a helper system for an astrophysical data center, requires various components, from custom data back ends up to standardized front end solutions. VO technologies, standards and implementations, promoted by the International Virtual Observatory Alliance (IVOA), are a suitable solution for front end interfaces devoted to data discovery and access. A publishing system to generate VO services out of configuration steps can be a useful help to data providers and, for this reason, the Italian center for Astronomical Archives data center developed a first prototype to perform this task. However, being the software monolithic and difficult to maintain due to standard's changes and scalability requirements, a new solution was needed. This contribution describes both the design and the implementation details of the latter, enlightening its maintainable, distributed, modular and scalable architecture. Indeed, the new publisher is multithreaded and multiprocess to be scalable both vertically and horizontally. Multiple instances of the modules can run on different machines to ensure high performance and high availability, and this will be true both for the interface modules of the services and the back end data access ones. The system uses message passing to let its components communicate through an AMQP message broker that can itself be distributed to provide better scalability and availability. An initial implementation of the system has been realized by a couple of IVOA Simple Cone Search protocol based services. The first one uses a servlet as the interface module and a JDBC based MySQL database as the back end one, thus relying completely and coherently on Java technology. The second one, even if it is using a similar servlet interface, passes its incoming requests through the broker to a Python coded back end module, accessing a JSON formatted catalogue. Both the services were made to work together in two different scenarios: a simple cloud environment and a single machine. In particular, the second deployment was carried out with the aim of comparing performances with the previous publishing solution, which will be discontinued. It is worth to notice that, even if this environment is not optimal (since it does not fully exploit the scalability features of our new proposal), the performance comparison with respect to the previous publisher resulted very encouraging to further pursue the development of this new publishing framework.

9913-122, Session PS1

DockQR: a dockerized quick reduce astronomical pipeline

Soichi Hayashi, Indiana Univ. (United States); Ralf Kotulla, Univ. of Wisconsin-Milwaukee (United States); Arvind Gopu, Michael D. Young, Indiana Univ. (United States)

The QuickReduce pipeline has been an invaluable part of the One Degree Imager - Portal, Pipeline, and Archive (ODI-PPA) system, with its role in producing both operator produced standard calibrated data products and user customized calibrated images, and in enabling the execution of the SWarp stacking application within PPA. QuickReduce is also available for ODI users and others to download and deploy on their own compute resources but this requires a certain level of expertise with the Linux Operating System, including deployment of specific packages like Python and Python modules (numpy/scipy, etc.), the installation of additional software libraries (e.g. the GNU Scientific Library) as well as observatory-supplied calibration data; some of these steps also require administrative privileges. Some astronomers have successfully executed QuickReduce on their own resources but we wanted to to expand the breadth of users who are able to do this. We considered potential solutions, for example: bundling software into RPMs or the like but executing the pipeline in a virtual container environment quickly bubbled up to the top as the simplest and most practical solution. We picked the widely used Docker as our container application, and built a readily available Docker container, DockQR, that includes not only the QuickReduce pipeline source code but also all of its dependences with various possible execution schemes as outlined below. The key advantage to this approach over the bundled software approach is that it is platform independent, and does not require different sets of bundles (for example: RPMs for Red Hat Linux distros, DMG on Mac); Users of any modern Docker-enabled Operating System (Linux distributions like RHEL7, CentOS7, Debian, Ubuntu, SLES; Mac OS) can get a ready-to-execute pipeline without being expert Linux system administrators and without superuser privileges. Users can also execute DockQR on popular cloud platforms like Amazon S3. Currently, DockQR allows for the following execution schemes: (1) Simple execution of the pipeline on one input FITS image with the output written to a designated output directory (2) Complex execution of a workflow sequence defined via a parameter file within the input directory (3) A completely independent pipeline that listens to an Advanced Messaging Queue Protocol (AMQP) server and executes the pipeline as instructed while also passing back status updates to the same AMQP server. While we focus on the Dockerized QuickReduce pipeline container in this paper, the underlying methodology extends to any complex pipeline setup, as illustrated in our StarDock paper, even setups that require legacy codes like IRAF with specific pre-requisites (for example: a specific and an older version of Python that conflicts with an Operating System requirement).

9913-125, Session PS1

The HARPS-N archive through a Cassandra, noSQL database suite

Emilio Molinari, Jose Guerra Sr., Marcello Lodi, Avet Harutyunyan, Telescopio Nazionale Galileo (Spain)

The TNG-INAF is developing the science archive for the WEAVE instrument. The underlying architecture of the archive is based on a non relational database, more precisely, on Apache Cassandra cluster, which uses a noSQL technology. In order to test and validate the use of this architecture, we created a local archive which we populated with all the HARPS-N spectra collected at the TNG since the instrument's start of operations in mid-2012, as well as developed tools for the analysis of this data set. In our design, Cassandra works side by side Apache Solr (Search engine) and Apache Spark (Real-Time Analytics) for an efficient data indexing, extraction and analysis.

The HARPS-N data set is two orders of magnitude smaller than WEAVE, but we want to demonstrate the ability to walk through a complete data set and produce scientific output, as valuable as that produced by an ordinary pipeline, though without accessing directly the FITS files. The analytics is done by Apache Solr and Spark and the work-load is split up on a cluster. As an example, we produce observables like metallicity indexes for the complete set of the targets in the archive and compare the results with the ones coming from the HARPS-N regular data reduction software.

The aim of this experiment is to explore the viability of a high availability cluster and distributed noSQL database as a platform for complex scientific analytics on a large data set. We additionally want to demonstrate the horizontal scalability of such a system to cope growing processing and storage demands by adding more resources.

9913-131, Session PS1

Virtualizing observation computing infrastructure at Subaru Telescope

Eric Jeschke, Takeshi Inagaki, Russell D. Kackley, Subaru Telescope, National Astronomical Observatory of Japan (United States)

Subaru Telescope, an 8-meter class optical telescope located in Hawaii, has been using a high-availability commodity cluster as a platform for our Observation Control System (OCS). Until recently, we have followed a tried-and-tested practice of running the system under a native (Linux) OS installation with dedicated attached RAID systems and following a strict cluster deployment model to facilitate failover handling of hardware problems (we have a paper on this high-availability cluster design in SPIE Astronomical Telescopes and Instrumentation 2010).

Following the lead and apparent benefits of virtualizing (i.e. running in virtual machines) many of our non-observation critical systems at the base facility, we recently began to explore the idea of migrating other parts of the observatory's computing infrastructure to virtualized systems, including the summit OCS, data analysis systems and even the front ends of various Instrument Control Systems.

In this paper we describe our experience with the initial migration of the Observation Control System to virtual machines running on the cluster and using a new generation tool--ansible--to automate installation and deployment. This change has significant repercussions for ease of cluster maintenance, upgrades, snapshots/backups, risk-management, availability, performance, cost-savings and energy use. In this paper we discuss some of the trade-offs involved in this virtualization and some of the impacts for the above-mentioned areas, as well as the specific techniques we are using to accomplish the changeover and simplify installation and management complexity.

9913-137, Session PS1

Information and Communications Technology (ICT) Infrastructure for the ASTRI SST-2M telescope prototype for the Cherenkov Telescope Array

Fulvio Gianotti, Alessandro Tacchini, INAF - IASF Bologna (Italy); Giuseppe Leto, Eugenio Martinetti, Pietro Bruno, Giancarlo Bellassai, INAF - Osservatorio Astrofisico di Catania (Italy); Vito Conforti, INAF - IASF Bologna (Italy); Stefano Gallozzi, INAF - Osservatorio Astronomico di Roma (Italy); Giuseppe Malaguti, Massimo Trifoglio, INAF - IASF Bologna (Italy)

In the framework of the International Cherenkov Telescope Array (CTA) project, the Italian National Institute for Astrophysics (INAF) is developing the ASTRI SST-2M end-to-end prototype telescope, which is being installed at the INAF observing station located in Serra La Nave on Mt. Etna, Italy. The ASTRI mini-array, composed of nine of these telescopes, is proposed to be installed at the Southern CTA site.

Among the various infrastructures, the correct Information and Communication Technology (ICT) equipment is necessary to achieve high efficiency in all operations of computing and data storage, as well as control of the entire telescope

Thus a complete and stand-alone computer centre has been designed and implemented. The design goal is to obtain basic ICT equipment, with an adequate level of redundancy, that might be scaled up for the ASTRI mini-array, taking into account the necessary control, monitor and alarm system requirements. This contribution presents the ICT equipment currently installed at the Serra La Nave observing station where the ASTRI SST-2M prototype will operate. The computer centre and the control room are described with particular emphasis on the Local Area Network scheme, the computing and data storage system, and the telescope control and monitoring.

9913-182, Session PS1

Radio data archiving system

Cristina Knapic, INAF - OATs (Italy); Alessandra Zanichelli, INAF - IRA (Italy); Erik Dovgan, INAF - OATs (Italy); Mauro Nanni, Matteo Stagni, Simona Righini, INAF - IRA (Italy); Massimo Sponza, INAF - OATs (Italy); Francesco Bedosti, INAF - IRA (Italy); Andrea Orlati, INAF - Istituto di Radioastronomia (Italy); Riccardo Smareglia, INAF - OATs (Italy)

Radio Astronomical Data models are becoming very complex since the huge possible range of instrumental configurations available with the modern Radio Telescopes.

What in the past was the last frontiers of data formats in terms of efficiency and flexibility is now evolving with new strategies and methodologies enabling the persistence of a very complex, hierarchical and multi purpose information.

Such an evolution of data models and data formats require new data archiving techniques in order to guarantee data preservation following the directives of Open Archival Information System and the International Virtual Observatory Alliance directives for the data sharing and publication.

Currently, various formats (FITS, MBFITS, VLBI's XML description files and ancillary files) of data acquired with the Medicina and Noto Radio Telescopes are under storing and handling by a common Radio Archive. It aims at providing the (inter)national community with a state-of-the-art archive for radio astronomical data and delegate as much as possible to the software setting on how and where the descriptors (metadata) are saved, while the users perform user friendly queries translated by the web interface into complex interrogations on the database to retrieve data. In such a way, the Archive is ready to be Virtual Observatory compliant and as much as possible user friendly.

9913-70, Session PS2

Pre-selecting muon events in the camera server of the ASTRI telescopes for the Cherenkov Telescope Array

Maria C. Maccarone, Teresa Mineo, Milvia Capalbi, INAF - Istituto di Astrofisica Spaziale e Fisica Cosmica di Palermo (Italy); Vito Conforti, INAF - IASF Bologna (Italy); Martina Coffaro, Univ. degli Studi di Palermo (Italy)

As already demonstrated by all existing Imaging Atmospheric Cherenkov Telescopes, the analysis of muon rings is a powerful and precise method to calibrate the optical throughput of each telescope. Due to the variety of telescope types and sizes foreseen in the Cherenkov Telescope Array (CTA) and degradation of the optical elements, differences in efficiency can however be present. While Large and Medium Size telescopes will be able to detect muon images under a stereo trigger, for the Small Size telescopes the stereo muon rate will tend to zero, given their small mirror area and large inter-telescope distance. Nevertheless, fully contained muon rings can be used as calibrators of each individual telescope since they can be efficiently recognized from un-calibrated images in their camera server and flagged as such, even if no stereo coincidence is available. This is the case for the ASTRI SST-2M telescopes, which are able to detect muon events during regular data taking without requiring a dedicated trigger.

In this contribution we present an efficient and fast algorithm to recognize useful single-muon ring images within the ASTRI camera server. The algorithm, applied to uncalibrated but cleaned images, is essentially based on the application of the Taubin method which enables the rapid determination of the geometrical parameters of the circle enclosing the ring (center, radius, ring width). The study has been performed on simulated data starting from the basic telescope configuration of the ASTRI SST-2M end-to-end prototype installed in Italy at the Serra La Nave observing station, and applying the geographical coordinates and atmospheric conditions foreseen for the CTA southern site where nine ASTRI telescopes have been proposed to be installed to form the so-called ASTRI mini-array. The simulation results and the cuts applied on the reconstructed Taubin parameters show that the algorithm achieves more than 90% efficiency for muons while keeping the number of proton-induced triggers as low as possible to minimize useless readout in the CTA array data acquisition system. The events flagged as possible single-muon ring images will then be analyzed in detail during the phase of the off-line scientific and calibration analysis.

9913-74, Session PS2

Automatization of the guiding process in the GTC

Jordi Molgo, GRANTECAN S.A. (Spain); Carlos Alvarez, W. M. Keck Observatory (United States) and GRANTECAN S.A. (Spain); Rosa M. Macías, Jose Antonio A. Rodríguez Losada, Manuel Huertas, Dailos Guerra Ramos, Francisco Ramos Landaeta, Héctor De Paz, Henry Brito, Tim D. Gaggstatter, GRANTECAN S.A. (Spain)

The "Gran Telescopio de Canarias" (GTC) is an optical-infrared 10-meter segmented mirror telescope at the ORM observatory in Canary Islands (Spain). The GTC Control System (GCS) is continuously evolving to enhance the operational efficiency.

In this work we present the new GCS subsystem to automatize the guiding setup process, both for Fast Guiding and for Slow Guiding. Previously, the telescope operator had the responsibility to choose the guide star and to setup the A&G subsystems. Some of these processes are time consuming when performed by a human being. This had an unwanted impact on the operational efficiency.

The new system automatizes all the guide process. A set of restrictions (including photometric computations and vignetting with the main science instrument) are used to select the stars appropriate for guiding. Then a merit function with tunable parameters is used to choose the best one. Finally, the system computes the optical configuration that fits better the selected star, automatically performs the guide star acquisition process and closes the guide loop.

This is the first step of a more extended project that will analyze the operational processes at GTC from a global point of view, and improve them towards a more automatic and efficient system.

9913-78, Session PS2

Wendelstein Observatory control software

Jan M. Snigula, Max-Planck-Institut für extraterrestrische Physik (Germany); Claus A. Gössl, Mihael Kodric, Arno Riffeser, Michael Wegner, Jörg Schlichter, Univ.-Sternwarte München (Germany)

LMU Muenchen operates an astrophysical observatory on the summit of Mt. Wendelstein in the Bavarian Alps. The 2m Fraunhofer telescope (Proc. SPIE 7733, 8444, 9145) is equipped with a 64 Mpixel, 0.5 x 0.5 square degree FoV wide field camera (WWFI, Proc. SPIE 7735, 8446) and a 3 channel optical/NIR camera (3kk, Proc. SPIE 7735 and this conference). Two fiber coupled spectrographs (upgraded Echelle spectrograph FOCES with wavecomb, Proc SPIE 7735, 8446; and IFU spectrograph VIRUS-W, Proc. SPIE 7014, 8446, currently operated at the 2.7 m telescope at the McDonald Observatory in Texas) and a wavefront sensor will be added in the near future. In addition we plan to upgrade the observatory's 40cm telescope and its camera and spectrograph for the students lab. The observatory also hosts a multitude of supporting hardware, i.e. allsky cameras, webcams, meteostation, air conditioning etc. All scientific instruments and related hardware are monitored by and can be controlled through a single, central "Master Control Program" (MCP). Here we explain concept and implementation of the MCP as a multi-threaded Python daemon in the area of conflict between debugability and DRY (don't repeat yourself). The MCP has been built to enable complex automated observations schemes. It supplies meta data for scientific data containers (i.e. FITS keys) and can be used to trigger simple quicklook, calibration, or even full-fledged data reduction processes.

9913-82, Session PS2

Integration of the instrument control electronics for the ESPRESSO spectrograph at ESO-VLT

Veronica Baldini, Igor Coretti, Giorgio Calderone, Roberto Cirami, Stefano Cristiani, Paolo Di Marcantonio, Paolo Santin, INAF - Osservatorio Astronomico di Trieste (Italy); Denis Mégevand, Observatoire de Genève (Switzerland); Marco Riva, INAF - Osservatorio Astronomico di Brera (Italy)

ESPRESSO, the Echelle SPectrograph for Rocky Exoplanet and Stable Spectroscopic Observations of the ESO - Very Large Telescope site, is now in its integration phase.

The large number of functions of this complex instrument are fully controlled by a Beckhoff PLC based control electronics architecture.

Four small and one large cabinets host the main electronic parts to control all the sensors, motorized stages and other analogue and digital functions of ESPRESSO. The Instrument Control Electronics (ICE) is built following the latest ESO standards and requirements. Two main PLC CPUs are used and are programmed through the TwinCAT Beckhoff dedicated software.

The assembly, integration and verification phase of ESPRESSO, due to its distributed nature and different geographical locations of the consortium partners, is quite challenging.

After the preliminary assembling and test of the electronic components at the Astronomical Observatory of Trieste and the test of some electronics and software parts at ESO (Garching), the complete system for the control of the four Front End Unit (FEU) arms of ESPRESSO has been fully assembled and tested in Merate (Italy) at the beginning of 2016.

After these first tests, the system will be sent to the Genéva Observatory (Switzerland) for the Preliminary Acceptance Europe (PAE) and finally shipped to Chile for the commissioning.

This paper will describe the integration strategy of the ICE workpackage of ESPRESSO, the hardware and software tests that have been performed, with an overall view of the experience gained during these project's phases.

9913-86, Session PS2

The ICT monitoring system of the ASTRI SST-2M prototype proposed for the Cherenkov Telescope Array

Fulvio Gianotti, INAF - IASF Bologna (Italy); Pietro Bruno, INAF - Osservatorio Astrofisico di Catania (Italy); Alessandro Tacchini, Vito Conforti, INAF - IASF Bologna (Italy); Alessandro Grillo, INAF - Osservatorio Astrofisico di Catania (Italy); Claudio Tanci, INAF - Osservatorio Astronomico di Brera (Italy); Giuseppe Leto, INAF - Osservatorio Astrofisico di Catania (Italy); Giuseppe Malaguti, Massimo Trifoglio, INAF - IASF Bologna (Italy)

In the framework of the international Cherenkov Telescope Array (CTA) observatory, the ASTRI Consortium, lead by the Italian National Institute for Astrophysics (INAF) has developed the ASTRI SST-2M end-to-end prototype. It is installed at the INAF observing station located at Serra La Nave on Mt. Etna, Italy. The ASTRI mini-array, composed of nine of these telescopes, is proposed to be installed at the Southern CTA site. This contribution presents the solutions implemented to realize the monitoring system for the Information and Communication Technology (ICT) infrastructure of the ASTRI-SST-2M prototype.

The ASTRI ICT monitoring system has been implemented by integrating traditional tools, used in the computer centre, with specific custom tools which interface via Open Platform Communication Unified Architecture (OPC UA) to the Alma Common Software (ACS) that is used to operate the ASTRI-SST-2M prototype. The traditional monitoring tools are based on Simple Network Management Protocol (SNMP) and commercial solutions and features embedded in the devices themselves. They generate alerts by E-mail and SMS. The specific custom tools convert the SNMP protocol into the OPC UA protocol and implement an OPC UA server. The server interacts with an OPC UA client implemented in an ACS component that, through the ACS Notification Channel, sends monitor data and alerts to the central console of the ASTRI-SST-2M prototype. The same approach has been proposed also for the monitoring of the CTA on-site ICT infrastructures.

9913-90, Session PS2

Challenges and strategies for the maintenance of the SKA telescope manager

Mauro Dolci, Matteo Di Carlo, INAF - Osservatorio Astronomico di Teramo (Italy); Riccardo Smareglia, INAF - Osservatorio Astronomico di Trieste (Italy)

The Square Kilometre Array (SKA) is an ambitious project to build a radio telescope that will enable breakthrough science and discoveries, not possible with the existing facilities, over the next 50 years.

This huge facility, composed by a set of specific elements (e.g. Dishes, Low-Frequency Aperture Arrays, Signal and Data Transport, Infrastructure), will be orchestrated by a core element, Telescope Manager (TM), aimed to coordinate observation scheduling and management, collect health and performance data from the Elements and interface with external operators. TM will be mostly a software-based system, running on a dedicated hardware, that will interact with a large set of external units, represented

by the Local Monitoring and Control systems (LMCs) of the SKA Elements, composed in turn by hardware and software systems.

Given the large lifespan for the project, the evolution in hardware and software, both for TM itself and for the LMCs, is expected to generate a continuously-, and perhaps dramatically-changing environment which will need a deep analysis in terms of maintenance.

Considering TM software, in particular, new requirements are expected to emerge, old requirements could change during application lifetime, errors will be discovered or performance will need to be improved: software maintenance is therefore critical to maintain the value of the software developed.

In this paper the strategy of maintenance for both TM hardware and software is presented. The four main areas of such a plan, Maintenance Process, Organization, Resources and Performance tracking are described in detail.

9913-94, Session PS2

The technical CCDs in ESPRESSO: usage and performance

Giorgio Calderone, Veronica Baldini, Roberto Cirami, Igor Coretti, Paolo Di Marcantonio, INAF - Osservatorio Astronomico di Trieste (Italy); Marco Landoni, Marco Riva, INAF - Osservatorio Astronomico di Brera (Italy); Jens Knudstrup, European Southern Observatory (Germany); Stefano Cristiani, INAF - Osservatorio Astronomico di Trieste (Italy); Denis Mégevand, Observatoire de Genève (Switzerland)

The Echelle SPectrograph for Rocky Exoplanets and Stable Spectral Observations (ESPRESSO), built for the ESO Very Large Telescope at Paranal (Chile), requires active–loop stabilization on both the pupil and field images. This is accomplished by using components off-the-shelf (COTS) cameras to acquire the images, a custom algorithm to find the center of the fiber feeding the spectrograph, and piezoelectric actuators to correct the light beam. A further camera is required to monitor the amount of light collected by the scientific detectors (exposure meter). Therefore, in the most demanding configuration (4 telescopes), ESPRESSO will use up to 9 cameras and 8 piezo actuators simultaneously.

The ESPRESSO control software and the VLT-Technical Detector Control Software (TDCS, developed at ESO) works in conjunction to pursue such a challenging task, and the experience gained during ESPRESSO integration will be used also on future ESO instruments.

In this work we discuss the optimal technical CCD configuration and usage, the overall system performance and the network bandwidth requirements for the ESPRESSO operations.

9913-98, Session PS2

The SKA observation control system

Stewart J. Williams, Science & Technology Facilities Council (United Kingdom); Roger S. Thompson, SciSys UK Ltd. (United Kingdom); Alan Bridger, Science & Technology Facilities Council (United Kingdom); Subhrojyoti R. Choudhury, Tata Consultancy Services Ltd (India); Alan O'Brien, Science & Technology Facilities Council (United Kingdom); Richa Malhotra, Mangesh Patil, Tata Consultancy Services, Ltd. (India)

The Square Kilometre Array (SKA) will be the world's most advanced radio astronomy observatory, designed to be many times more sensitive and hundreds of times faster at mapping the sky than current facilities. The first phase of the SKA will be delivered in the form of two telescopes: a 200-element dish interferometer in South Africa and a 130000-element dipole antenna aperture array in Australia.

The scale and requirements of the SKA present new challenges in the area of observation control. Firstly, the SKA is designed from the outset to maximise observing efficiency by allowing multiple concurrent observations. The observation control system must facilitate, co-ordinate and control each observation while remaining responsive and retaining overall control.

Secondly, with so many hardware elements present in each SKA telescope, a more intelligent approach to failures must be used; observations should not be terminated on every hardware failure, but only those that mean the science goals cannot be achieved. This requires a continuous assessment of the science capabilities that the active hardware configuration offers, and how the failure of an element impacts those capabilities.

Observing sequences can also be controlled and altered in real time, for example, to accommodate the calibration needs of the telescope or to urgently switch to a Target of Opportunity. Achieving this while still presenting a predictable and accessible interface to astronomers is another challenge that the SKA observation control system must face.

This poster will give an overview of the SKA Observation Execution function and how its design will address these challenges.

9913-102, Session PS2

Rejecting harmonic vibrations at Gemini with real-time vibration tracking

Mathew J. Rippa, Gemini Observatory (United States); Thomas L. Hayward, Gemini Observatory (Chile)

Fighting vibrations on large telescopes is an arduous task. At Gemini, vibrations originating from cryogenic coolers have been shown to degrade the optical wave front, in certain cases by as much as 40%. This paper discusses a general solution to vibration compensation by tracking the real time vibration state of the telescope and using M2 to apply corrections. Two approaches are then presented: an open loop compensation at M2 based on the signal of accelerometers at the M1 glass, and a closed loop compensation at M2 based on optical measurements from the wave front sensor. The paper elaborates on the pros and cons of each approach and the challenges faced during commissioning. A conclusion is presented with the final results of vibration tracking integrated with operations.

9913-109, Session PS2

Research on measurement and control technology of active reflector for FAST

Dongjun Yu, National Astronomical Observatories (China)

The active reflector is a sphere with a diameter of 500 meters and a radius of 300 meters, which is composed of a main body supporting structure, an actuator, a back frame and a reflective panel. The active variable is the biggest characteristic of the FAST reflector, and the 300m aperture is formed in the observation direction by controlling the 2225 actuators along the radial motion. The observing paraboloid is moving along with observation area at a range of 500m diameter spherical, so as to achieve the following observation.

The overall technical indicators of active reflector as follows, reflecting surface profile accuracy requirements outgo RMS 5mm; The source changing time less than 10 minutes; The actuator adjusting speed is faster than 1.6mm/s; Paraboloid pointing angle range from - 40 deg to 40 deg.

In order to ensure the safe and accurate operation of the reflective surface system, The main reflective surface control system, the reflective surface

measurement system and the reflective surface health monitoring system need to work together.

Active reflector control system mainly form precise position and accurate parabolic surface by adjusting the actuating elongation of reflector node position according to astronomical target trajectory planning and measurement data. In order to realize the control target, the software of control algorithm?the reliability and the real-time performance of the communication and the effective storage and management of the data need to be developed.

In the operation of the telescope, the measurement of the different total station instrument is carried out by the computer. The time of measurement within the effective aperture is less than 10 minutes, and then the measurement results are transmitted to the control system in real time.

The main reflective surface health monitoring system is used to ensure the safety, integrity, applicability and durability of the structure by monitoring the internal force, structural deformation and other parameters of the structure and evaluating the safety level of structure on the basis of regular monitoring data and structural environment load monitoring data.

9913-112, Session PS2

LSST OCS status and plans

Philip N. Daly, German Schumacher, LSST (United States)

The Large Synoptic Survey Telescope (LSST) received construction funding in 2014, on an 8.3 years construction and commissioning schedule. The LSST is a complex system of systems with demanding performance and operations requirements. A critical component of the LSST Telescope and Site software is the Observatory Control System (OCS), that comprehends the master control system that schedules, coordinates, commands and monitors the observatory. This poster reports progress on the OCS and outlines future development plans.

9913-115, Session PS2

Motion planning techniques for MIRADAS robotic probe arms

Josep Sabater, Institute of Space Studies of Catalonia (Spain) and Univ. de La Laguna (Spain); Jorge Riera-Ledesma, Santiago Torres, Univ. de La Laguna (Spain); Francisco Garzón López, Instituto de Astrofísica de Canarias (Spain); Jordi Torra, José María Gómez, Institute of Space Studies of Catalonia (Spain)

Many of the leading scientific challenges in modern Astrophysics can only be addressed in an efficient manner with the use of moderate to high spectral resolution instruments mounted in large collecting area telescopes. Therefore, the demand for instruments with multiple-object spectrography (MOS) capabilities has significantly increased in the last years as they are indispensable for answering many of the unresolved questions in several research fields. The Mid-resolution InfRAreD Astronomical Spectrograph (MIRADAS) is a near-infrared MOS for Gran Telescopio Canarias, which is able to concurrently observe up to 20 targets at a variety of user-defined locations. This task is performed by 20 independent and deployable Integral Field Units (IFU) based on robotic probe arms with pick-off mirrors. As these arms move in a very cluttered environment, one of the key points of the instrument control system is to plan collision-free trajectories for all the arms.

Traditionally, scientists have followed two different approaches to coordinate the motions of multiple robots: coupled and decoupled. Coupled strategies might be guaranteed to find optimal collision-free motions as they consider the full search space. However, their complexity exponentially increases with the number of robots. On the other hand, decoupled approaches try to reduce the computational costs by seeking solutions in search spaces of lower dimensionality. These algorithms are frequently faster, but, unfortunately, they are not complete and might not find a safe motion plan even though it exists. In this document, we present the particular decoupled approach adopted in the final design review (FDR) of MIRADAS, which took place in the first semester of 2015. The problem of finding collision-free motions basically consist of three distinct steps: paths generations, determining of the coordination groups and, finally, velocity tunning of the paths of each coordination group. In the first stage, suitable paths are independently generated for each arm, then interaction between arms are considered and after, in the last stage, the velocities of the arms are properly adjusted to avoid collisions. This solution takes into account and is heavily influenced by the severe motion constraints imposed by the industrial off-the-shelf cryogenic electronic controllers that drive the stepper motors present in the arm joints. Finally, we also present a coupled approach that has been currently explored in order to determine its computational feasibility and performance.

9913-118, Session PS2

GHOST and GIAPI: experience using Gemini's new instrument control system framework

Peter J. Young, Jon Nielsen, The Australian National Univ. (Australia)

The new Gemini High Resolution Optical Spectrograph (GHOST) will be controlled with software developed against the new Gemini software framework - the Gemini Instrument Application Programmer Interface (GIAPI). The developers describe their experience using this framework and compare it to control systems developed for earlier Gemini instruments using the original Gemini Core Instrument Control System (CICS) framework.

9913-121, Session PS2

Using muon rings for the optical calibration of the ASTRI telescopes for the Cherenkov Telescope Array

Teresa Mineo, Maria C. Maccarone, Giancarlo Cusumano, Valentina La Parola, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Patrizia Romano, INAF - Osservatorio Astronomico di Brera (Italy)

Ring images generated from high-energy muons constitute a very useful tool to calibrate the total optical throughput of any telescope forming the Cherenkov Telescope Array (CTA). Differences in precision and efficiency can however be present due to the variety of telescope types and sizes. The preliminary results of the detailed study described in this contribution show that a set of high-quality muon ring images can be collected by the ASTRI small-size dual-mirror (SST-2M) telescope.

The study was performed starting from the basic configuration of the ASTRI SST-2M prototype installed in Italy at the Serra La Nave observing station. The prototype is able to reconstruct muons with energy greater than 20 GeV with a precision on the direction reconstruction of the order of the pixel size in the ASTRI SST-2M camera (0.17 degrees). The results will be validated from the analysis of real data acquired after the Commissioning Phase of the prototype.

Better quality images will be provided by the new silicon photomultipliers used for the nine ASTRI SST-2M telescopes that will form the ASTRI mini-array proposed to be installed at the final CTA southern site thanks to their higher detection efficiency and a strong reduction of optical cross talk and after pulsing.

9913-124, Session PS2

Weather stations of the ALMA Observatory

Tzu-Chiang Shen, Rubén Soto, ALMA (Chile); Jorge Sepúlveda, Joint ALMA Observatory (Chile); Johnny W. Reveco, Patricio Merino, ALMA (Chile); Gastón Vélez, Joint ALMA Observatory (Chile)

The physical area covered by the ALMA Observatory requires a series of weather stations which provide valid measurements for the online calibrations and corrections used during scientific observations. These weather stations are deployed strategically to deliver valid corrections for antennas located nearby. The first meteo station was installed at the beginning of the construction phase (2007) and recently the last sets were deployed in preparation to the Long Baseline Campaign. A total of 11 sets of weather stations were deployed according to the original design. Each weather station contains 7 sensors which are sampled at 1 Hz, totaling 6.6M of measurements being persisted in daily basis.

In this paper we present the software architecture of the weather station subsystem, which was built on top of the Internet Communication Engine (ICE), an open source distribute programming framework provided by Zeroc Inc. This framework provides binding to C/C++, Java, Python and PHP among others, which allow us to choose the most appropriate programming language for data acquisition, hardware devices life cycle control, data persistent layer and web interface. Publish & subscribe service named IceStorm are used in this design to distribute sampled data among several processes. Additionally services such as IceBox, IceGrid facilitate the deployment aspects. Finally, a mechanism to communicate between ICE and ALMA Common Software (ACS) was implemented to provide weather data to the control observation software.

Measurements of each weather stations are not only used for the scientific observations but also useful for planning of other entities in the observatory, which generate queries in the platform that is not easy to predict. To avoid unexpected delay and provide deterministic responses, a cache mechanism based on Redis was introduced. In addition, due to the amount of samples generated in daily basis, the original design using a relational database was causing difficulties in the maintenance aspect. Given the special nature of this kind of data, in which samples are already sorted at the moment of insertion and typical queries are based on a range of data instead of a single sample associated to a timestamp, we explored non-SQL alternatives to persist the data.

9913-127, Session PS2

INO340 telescope control system: mount control system

Asghar Jafarzadeh, Reza Ravanmehr, Iranian National Observatory (Iran, Islamic Republic of)

The INO340 stands for Iranian National Observatory, which is an Alt-Az reflecting optical telescope with 3.4m main mirror diameter. The telescope's field of view is 0.3° and the designed F?ratio is f/11. At the moment conceptual design of Telescope is finished and the detail design of the Telescope is developing. The Telescope will be placed in Peak of Gargash Mountain near Kashan City. The result of Microthermal and seeing measurements shows the site can deliver high image quality thus the good image quality is defined as a priority in the telescope design.

The INO340 Control System (INOCS) is responsible for delivering the light from an object to the science instruments. It performs so by controlling all available mechanisms and optical elements according to specified requirements in the presence of specified disturbances. INOCS provides suitable user interface means for obtaining the observe information from scientists and also user interface means for telescope operation in defined modes.

The INOCS comprises the following systems: Observation Monitoring System (OMS), Telescope Control System (TCS), Interlock System (ILS) and Observation System Supervisor (OSS). All systems include necessary electronic, hardware and software components as well as computers and network components. INOCS includes the network infrastructure necessary for communication between its systems.

OSS and OMS subsystems have been explained in other related papers of INO340 and they are out of the scope of this paper. However, Telescope Control System (TCS) of INO340 has not been discussed in details in any relevant papers till now. TCS is responsible for the control of the telescope structure with its mirrors and the dome including 4 major subsystems: Telescope Control System Supervisor (TCSS), Mount Control System (MCS), Active Optics System (AOS). The purpose of this paper, is to present the details architecture of TCS and to discuss one of the major subsystem of TCS called MCS. AOS and TCSS as other major subsystems of TCS will be discussed in future.

The MCS is responsible for pointing and tracking of the main axes and rotator of the telescope and controlling the auxiliary system for mirror cover and cable wrapping. An anti-backlash gear based mechanism using two servomotors applying force against each other is being selected to drive the main Alt and Az axes. The simulations will show the performance of the designed system and will help us to define the specifications of the required elements.

This paper first presents the TCS architecture of INOCS, and then it focuses on the requirements and the major functionalities of MCS. In next section of paper, we provide different analysis of MCS using related parameters such as wind effect, encoder resolution and etc. Then, based on the simulation results the optimum sets of parameters and functions of different modules are concluded. In last section of paper, we present final design of MCS and evaluate the results based on the pre-defined requirements. In addition, the final tracking accuracy over time with the presence of different disturbances is provided.

9913-130, Session PS2

Status, upgrades, and advances of RTS2: the open source astronomical observatory manager

Petr Kubánek, Institute of Physics of the ASCR, v.v.i. (Czech Republic)

RTS2 is an open source observatory control system. Being developed from early 2000, it continue to receive new features in last two years. RTS2 is a modulat, network-based distributed control system, featuring telescope drivers with advanced tracking and pointing capabilities, fast camera drivers and high level modules for "bussinees logic" of the observatory, connected to a SQL database. Running on all continents of the planet, it accumulated a lot to control parts or full observatory setups.

9913-133, Session PS2

Using Robotic Operating System (ROS) to control autonomous observatories

Francesc Vilardell, Gabriel Artigues, Josep Sanz, Álvaro García-Piquer, Josep Colomé, Ignasi Ribas, Institut d'Estudis Espacials de Catalunya (Spain)

Observatories are complex systems requiring the integration of numerous devices (dome, telescope, instruments, environment sensors, etc.) into a common control system. This is specially challenging in autonomous observatories, where intelligent and coordinated responses are required to solve unexpected situations, either due to the environment (e.g., weather) or to instrumental requirements.

The field of robotics has similar challenges. In a robot, all the sensors have to work together in order to allow the robot to react to any unforeseens or being able to adapt to a new environment. In addition, the field of robotics has experienced a huge growth during the last years, partly due to cheaper hardware and partly due to the appearance of open-source platforms. In this sense, the Robot Operating System (ROS), supported by the Open Source Robotics Foundation, has become one of the most widely used open-source platforms for robot control. The ROS environment allows the integration of any kind of robots, from amateur home-made robots to those requiring the most strict industrial standards, and even for robots in space.

Nowadays, several autonomous observatories are successfully operating worldwide. However, the process of building a new autonomous observatory usually requires a long software development process where all the different devices have to be integrated into a common platform. The large flexibility of ROS, together with the large community behind it, encouraged us to develop a new ROS package to control observatories. We pursue three main goals with this new package. Firstly, to prove that autonomous observatories can be successfully controlled using ROS. Secondly, to provide the observatory with a decision making procedure based on automated planning and scheduling. Finally, to introduce a simple, well tested and widely distributed platform into the world of autonomous observatories.

The current version of our new ROS package integrates several commercial devices to create a fully autonomous observatory. The observatory is composed by a Baader Planetarium dome, a Meade telescope, a SBIG camera and a Boltwood sensor for environment monitoring. All systems are integrated into ROS through custom-made drivers. The autonomous response of the observatory is provided by OpenROCS (Colomé et al., SPIE, 2012) which implements all the required know-how to make the observatory operation both safe and operationally optimal, communicating with all the different devices thanks to ROS.

The combination of OpenROCS and ROS is opening a new window for autonomous observatories. Creating a new observatory autonomous will no longer require a long software development process. It can be easily integrated into the regular construction of a new observatory without additional overheads.

9913-136, Session PS2

On-board target acquisition for CHEOPS

Philipp Loeschl, Roman Ferstl, Franz Kerschbaum, Roland Ottensamer, Univ. Wien (Austria)

The CHaracterising ExOPlanet Satellite (CHEOPS) is the first ESA S-class and exoplanetary follow-up mission headed for launch in 2017. It will perform high-precision photometry of stars hosting confirmed exoplanets, whereas V-magnitudes range from 6 to 12. Besides the identification of the presence of significant atmospheres down to Earth-sized planets, its mission goals include measurements of radii for hot Neptune planets and energy flux determinations for hot Jupiter planets, while also looking for unknown co-aligned smaller mass planets.

The CHEOPS payload instrument is a 32cm telescope with a passively cooled optical CCD. The star images are defocused (12 pixels radius) to mitigate the effect of individual pixels. Only a single target star is observed at a time, which needs to be centred and guided with high precision within a 200x200" window on the CCD. As a result of CHEOPS' structural design, there is an uncertainty between the alignment of its star trackers and the payload instrument telescope due to thermal deformations, resulting in an absolute pointing error of up to 120". Additionally, the rotation rate of CHEOPS' field of view is 4 degrees per minute, consequently the initial identification must be rotation invariant. In order to guarantee the autonomous identification of the target star and to infer the corrections of the pointing for the attitude and orientation control subsystem (AOCS), a special target acquisition algorithm is included in the instrument flight software (IFSW). This software is developed by the University of Vienna for the data processing unit (DPU). Its tasks are instrument control, health monitoring and on-board data processing. The processing tasks include data compression steps, live centroid calculation for fine-guiding and the initial target acquisition, which will be described in detail in this paper.

The target acquisition system will deal with star densities varying from empty fields containing only the target to crowded fields where stars may partly overlap. The star identification requires an initial source extraction, followed by an identification algorithm suitable for solving the current star configuration. Besides the trivial single star case, we investigated two main approaches for the identification problem. The nominal algorithm is a modified Liebe (Liebe et al. 1993), which operates through the extraction of inter-star angles and distances. The second algorithm (Padgett et al. 1997) is based on pattern recognition for certain star constellations.

Both algorithms compare the parameters derived from the image with a predefined dataset, specifically created for each observation on ground. As the uplink is highly limited, these datasets need to be smaller than 1 kiB. It is crucial for the star identification to be fully reliable and autonomous, as science operation outside of communication windows is required.

Only a limited share of the DPU resources is available for the star identification task. Hence the implemented algorithms are optimised for fast processing. In order to evaluate the algorithms' reliability, thousands of random star configurations were analysed in Monte-Carlo simulations.

We present the performance results as well as recommended parameters that guarantee a successful identification under all conditions.

9913-139, Session PS2

Towards integrated modeling: full image simulations for WEAVE

Gavin B. Dalton, Univ. of Oxford (United Kingdom) and STFC Rutherford Appleton Lab. (United Kingdom); Sun-Jeong Ham, Univ. of Oxford (United Kingdom); Scott C. Trager, Univ. of Groningen (Netherlands); Kevin Rogers, STFC Rutherford Appleton Lab. (United Kingdom)

We present an integrated end-end simulation of the spectral images that will be obtained by the WEAVE spectrograph, which aims to include full modelling of all effects from the top of the atmosphere to the detector. These data are based in input spectra from a combination of library spectra and synthetic models, and will be used to provide inputs for an end-end test of the full WEAVE data pipeline and archive systems, prior to 1st light of the instrument.

9913-140, Session PS2

Cherenkov Telescope Array science data analysis using the c-tools

Jürgen Knödlseder, Institut de Recherche en Astrophysique et Planétologie (France); Michael Mayer, Humboldt-Univ. zu Berlin (Germany); Christoph Deil, Max-Planck-Institut für Kernphysik (Germany); Nathan Kelley-Hoskins, Rolf Bühler, Deutsches Elektronen-Synchrotron (Germany); Thierry Louge, Institut de Recherche en Astrophysique et Planétologie (France); Hubert Siejkowski, Academic Computer Ctr. CYFRONET AGH (Poland); Karl Kosack, Commissariat à l'Énergie Atomique (France); Lucie Gerard, Anneli Schulz, Deutsches Elektronen-Synchrotron (Germany); Pierrick Martin, Institut de Recherche en Astrophysique et Planétologie (France); David Sanchez, Lab. d'Annecy-le-Vieux de Physique des Particules (France); Stefan Ohm, Deutsches

Elektronen-Synchrotron (Germany); Tarek Hassan, Institut de Física d'Altes Energies (Spain)

The ctools are an open source software package developed for the scientific analysis of Imaging Air Cherenkov Telescope data. This includes data from existing telescopes, such as H.E.S.S., VERITAS and MAGIC, and the upcoming data of the Cherenkov Telescope Array (CTA). ctools are comprised of a set of ftools-like binary executables with a command-line interface for interactive step-wise data analysis, and a Python module that exposes all executables as Python classes. Extensions of the ctools package by user-defined binary executables or Python scripts is supported. A first stable version of the ctools package has now been released. We will present the package to the community and illustrate its capabilities by means of typical analysis examples.

9913-141, Session PS2

SKA CSP monitor and controls: technological challenges

Carlo Baffa, Elisabetta Giani, INAF - Osservatorio Astrofisico di Arcetri (Italy); Sonja Vrcic, NRC - Dominion Radio Astrophysical Observatory (Canada)

The Square Kilometer Array (SKA) project is an international effort to build the world's largest radio telescope, with eventually over a square kilometer of collecting area. For SKA Phase 1, Australia will host the low-frequency instrument with more than 500 stations, each containing around 250 individual antennas, whilst South Africa will host an array of close to 200 dishes. The scale of the SKA represents a huge leap forward in both engineering and research and development towards building and delivering a unique instrument, with the detailed design and preparation now well under way. As one of the largest scientific endeavors in history, the SKA will brings together close to 100 organizations from 20 countries.

Every aspect of the design and development of such a large and complex instrument requires state-of-the-art technology and innovative approach.

This poster addresses some aspects of the SKA monitor and control system, and in particular describes the development and test results of the CSP Local Monitoring and Control prototype.

At the SKA workshop in April 2015, SKA monitor and control community has chosen TANGO Control System as a technology of choice for the implementation of the SKA monitor and control. This decision will have a large impact on Monitor an Control development of SKA. As work is on the way to incorporate TANGO Control System in SKA, we have started a prototype development for the SKA Central Signal Processor to mitigate the associated risks. In particular we now have developed a uniform class schema proposal for the sub-Element systems of the SKA-CSP.

9913-143, Session PS2

Remote observing environment using a KVM-over-IP for the OAO 188 cm telescope

Kenshi Yanagisawa, National Astronomical Observatory of Japan (Japan); Goki Inoue, Subaru Telescope, National Astronomical Observatory of Japan (Japan); Daisuke Kuroda, Hideyuki Izumiura, National Astronomical Observatory of Japan (Japan)

We have prepared remote observing environment for the 188 cm telescope at Okayama Astrophysical Observatory in which a KVM-over-IP is employed to redirect displays and keyboards to remote sites. The operation through the remote console is almost indistinguishable from that through the on-site telescope console. The environment was opened for common-use since 2015, more than 10 groups have experienced remote observation. No serious trouble due to the KVM-over-IP has reported so far. In this paper we will present specification, configuration of the hardware as well as performance evaluated through the actual observations.

Okayama Astrophysical Observatory is a branch of National Astronomical Observatory of Japan. The observatory has a 188 cm reflector manufactured in 1960 by Grubb & Parsons, England, and three observatory instruments which are capable of optical high resolution spectroscopy (HIDES), optical imaging and low resolution spectroscopy (KOOLS) and near infrared imaging and low to medium resolution spectroscopy (ISLE).

We have prepared the remote observing environment for the telescope aiming for better use of the facility and to increase the products.

KVM-over-IP is a network device to redirect target PC's displays, mice and keyboards to a remote site over internet. We selected Dominion-KX III 808 from Raritan for the KVM-over-IP, which can be a host of eight target PCs and offers simultaneous access from eight remote console for every targets. Host PCs, such as for telescope or instruments consoles, are connected to the KVM-over-IP via dedicated adopters and UTP cables.

The use of the remote observing environment is easy. An authorized observer can make a remote observation by three steps: the user first establish the VPN connection to the observatory sub-net, login the KVM-over-IP via an internet browser, and click the target PC to be used from the list of targets on the browser. Then the selected on-site console appears on the local console. The KVM-over-IP can transfer digital sound over internet by default. Remote observers listen the sound of dome rotation, telescope slewing or alert voice on status change via remote speaker attached to the local PC.

VNC technique has been widely used to build remote observing environment and the application of KVM-over-IP will be rare case. However, KVM-over-IP is advantageous in many aspects. The remote observer will not be forced to install a dedicated software. T the maintenance effort is quite low, just upgrade the firmware prepared by the vendor. KVM-over-IP can manage users so that an administrator can grant access right to observers of a certain night. The function is quite useful to maintain the information security of observers, and no VNC software does not support the function as long as we know.

9913-144, Session PS2

The Cherenkov Telescope Array Observatory top-level use cases

Andrea A. Bulgarelli, INAF - IASF Bologna (Italy); Karl Kosack, Commissariat à l'Énergie Atomique (France); James A. Hinton, Max-Planck-Institut für Kernphysik (Germany); Gino Tosti, Univ. degli Studi di Perugia (Italy); Ullrich Schwanke, Humboldt-Univ. zu Berlin (Germany); Joseph Schwarz, INAF - Osservatorio Astronomico di Brera (Italy); Vito Conforti, INAF - IASF Bologna (Italy); Bruno Khélifi, Institut National de Physique Nucléaire et de Physique des Particules (France) and AstroParticule et Cosmologie (France); Johannes Goullon, CTA Project Office (Germany); Rene A. Ong, Univ. of California, Los Angeles (United States); Sera B. Markoff, Univ. van Amsterdam (Netherlands); Lucio A. Antonelli, INAF - Osservatorio Astronomico di Roma (Italy); Ciro Bigongiari, INAF - Osservatorio Astronomico di Torino (Italy) and Istituto Nazionale di Fisica Nucleare (Italy); Catherine Boisson, Observatoire de Paris (France) and Univ. Paris Diderot (France); Zeljka Bosnjak, CEA-IRFU (France); Sylvie Brau-Nogué, IRAP (France); Alessandro Carosi, INAF - Osservatorio Astronomico di Roma (Italy); Andrew W. Chen, WITS University (South

Africa); Josep Colomé, Institut de Ciències de l'Espai (Spain); Garret Cotter, Univ. of Oxford (United Kingdom); Stefano Covino, INAF - Osservatorio Astronomico di Brera (Italy); Michael K. Daniel, Univ. of Liverpool (United Kingdom); Giovanni De Cesare, INAF - IASF Bologna (Italy); Domenico della Volpe, Univ. de Genève (Switzerland); Federico Di Pierro, Istituto Nazionale di Fisica Nucleare (Italy) and INAF - Osservatorio Astrofisico di Torino (Italy); Valentina Fioretti, INAF - IASF Bologna (Italy); Matthias Fuessling, Univ. Potsdam (Germany); Markus Garczarcyk, Deutsches Elektronen-Synchrotron (Germany); Markus Gaug, Univ. Autònoma de Barcelona (Spain); Paolo Goldoni, AstroParticule et Cosmologie (France) and Institut National de Physique Nucléaire et de Physique des Particules (France); Diego Götz, CEA-Ctr. de SACLAY (France); Paola Grandi, INAF - IASF Bologna (Italy); Matthieu Heller, Univ. de Genève (Switzerland); German Hermann, Max-Planck-Institut für Kernphysik (Germany); Jürgen Knödlseder, Institut de Recherche en Astrophysique et Planétologie (France); Jean-Philippe Lenain, UPMC Sorbonne Univ. (France); Elina Lindfors, Univ. of Turku (Finland); Saverio Lombardi, INAF - Osservatorio Astronomico di Roma (Italy); Pedro Luque, Univ. de Jaén (Spain); Gernot Maier, Deutsches Elektronen-Synchrotron (Germany); Martino Marisaldi, INAF - IASF Bologna (Italy); Josep Martí, Univ. de Jáen (Spain); Carole G. Mundell, Univ. of Bath (United Kingdom); Nadine Neyroud, Lab. d'Annecy-le-Vieux de Physique des Particules (France) and Univ. de Savoie (France); Koji Noda, Max-Planck-Institut für Physik (Germany); Paul O'Brien, Univ. of Leicester (United Kingdom); Pierre-Olivier Petrucci, Institut de Planétologie et d'Astrophysique de Grenoble (France); Marc Ribó, Univ. de Barcelona (Spain); Jerome Rodriguez, Commissariat à l'Énergie Atomique (France); Patrizia Romano, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy) and Istituto Nazionale di Astrofisica (Italy); Julia Schmid, CEA-Ctr. de SACLAY (France); Fabian Schussler, CEA-IRFU (France); Natalia Serre, CTA GmbH (Germany); Hélène Sol, UPMC Sorbonne Univ. (France) and Lab. de Physique Nucléaire et des Hautes Énergies (France); Antonio Stamerra, INAF - Osservatorio Astrofisico di Torino (Italy) and Istituto Nazionale di Fisica Nucleare Sezione di Torino (Italy); Thierry Stolarczyk, CEA-Ctr. de SACLAY (France); Justin Vandenbrouck, Univ. of Wisconsin-Madison (United States) and Wisconsin IceCube Particle Astrophysics Ctr. (United States); Stefano Vercellone, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Susanna D. Vergani, Observatoire de Paris à Meudon (France); Emma D. Oña Wilhelmi, Institut de Ciències de l'Espai (Spain); Andrea Zoli, INAF - IASF Bologna (Italy)

Today the scientific community is facing an increasing complexity of the scientific projects, from both a technological and a management point of view. The reason for this increase is in the advance of science itself, where new experiments with unprecedented levels of accuracy, precision and coverage (time and spatial) are realised. Astronomy is one of the fields of the physical sciences where a strong interaction between the scientists, the instrument and software developers is necessary to achieve the goals of any Big Science Project. The Cherenkov Telescope Array (CTA) will be the largest ground-based very high-energy gamma-ray observatory of the next decades. To achieve the full potential of the CTA Observatory, the system must be put into place to enable users to operate the telescopes productively. The software will cover all stages of the CTA system, from the preparation of the observing proposals to the final data reduction, and must also fit into the overall system. Scientists, engineers, operators and others will use the system to operate the Observatory, hence they should be involved in the design process from the beginning. We have organised a workgroup and a workflow for the definition of the CTA Top Level Use Cases in the context of the Requirement Management activities of the CTA Observatory. Scientists, instrument and software developers are collaborating and sharing information to provide a common and general understanding of the Observatory from a functional point of view. Scientists that will use the CTA Observatory will provide mainly scientifically driven Use Cases, whereas technical people will subsequently provide more detailed Use Cases, comments and feedbacks. The main purposes are to define observing modes and strategies, and to provide a framework for the flow down of the Use Cases and requirements (from general to detailed Use Cases and specifications) to check missing requirements and the already developed Use-Case models at CTA sub-system level. The Use Cases will also provide the basis for the definition of the Acceptance Test Plan for the validation of the overall CTA system. In this contribution we present the organization and the workflow of the workgroup.

9913-145, Session PS2

Remote operations at UKIRT, Cassegrain included, 2 years later

Maren Hauschildt-Purves, Craig A. Walther, Ryan M. Berthold, East Asian Observatory (United States)

UKIRT has been operated remotely with only WFCAM since 2010. Since UKIRT was acquired by new owners it was pursued to also operate the Cassegrain instruments again, but stay with remote operations.

The first remotely operated Cassegrain block at UKIRT took place in the summer of 2014 and we got to the end of its 3rd remotely operated Cassegrain block in November 2015. For the first one we only operated short infrared instruments UFTI and UIST, for the second and third also mid-infrared imager/spectrometer Michelle that we hadn't had available since 2004. Between the Cassegrain blocks we of course switched back to WFCAM operations. Building on the experience already gained with operating remotely with WFCAM, remote Cassegrain operations turned out not too big a deal.

9913-147, Session PS2

Agile development approach for the observatory control software of the DAG 4m telescope

Bulent Gucsav, Cahit Yesilyaprak, Atatürk Üniv. (Turkey); Sinan K. Yerli, Middle East Technical Univ. (Turkey); Onur Keskin, Isik Üniv. (Turkey); Lorenzo Zago, HEIG-VD (Switzerland)

Observatory Control Software for the upcoming 4m infrared telescope of DAG (Eastern Anatolian Observatory in Turkish) is in the beginning of its lifecycle. After the process of elicitation-validation of the initial requirements, we have been focused on preparation of a rapid conceptual design not only to see the big picture of the system but also to clarify the further development methodology. The existing preliminary designs for both software (including TCS and active optics control system) and hardware shall be presented here in brief to exploit the challenges the

DAG software team has been facing with. The potential benefits of an agile approach for the development will be discussed depending on the published experience of the community and on the resources available to us.

9913-149, Session PS2

The CARMENES instrument control software suite

Josep Colomé, Josep Guàrdia, Institut de Ciències de l'Espai (Spain); Hans-Juergen Hagen, Hamburger Sternwarte (Germany); Rafael Morales Muñoz, Instituto de Astrofísica de Andalucía (Spain); José A. Caballero, Ctr. de Astrobiología (Spain); Lluis Gesa, Ignasi Ribas, Álvaro García-Piquer, Francesc Vilardell, Institut de Ciències de l'Espai (Spain); Mathias Zechmeister, Georg-August-Univ. Göttingen (Germany); Jörg Schiller, Thüringer Landessternwarte Tautenburg (Germany); Enrique de Guindos, Enrique de Juan, Jose Ignacio Vico, Daniel Benítez, Ctr. Astronómico Hispano-Alemán (Spain); Andreas Quirrenbach, Landessternwarte Heidelberg (Germany); Pedro J. Amado González, Instituto de Astrofísica de Andalucía (Spain); Ansgar Reiners, Georg-August-Univ. Göttingen (Germany); Walter Seifert, Landessternwarte Heidelberg (Germany)

The main goal of the CARMENES instrument is to perform high-accuracy measurements of stellar radial velocities (1 m/s) with long-term stability. CARMENES is installed at the 3.5 m telescope in the Calar Alto Observatory (Spain) and it is equipped with two spectrographs covering from the visible to the near-infrared. The fundamental science objective of CARMENES is to carry out a survey of ?300 late-type main-sequence stars with the goal of detecting low-mass planets in their habitable zones. It uses its near-IR capabilities by observing late-type stars, whose peak of the spectral energy distribution falls in the relevant wavelength interval. We present the software packages that are included in the instrument control layer. The coordination and management of CARMENES is handled by the Instrument Control System (ICS), which is responsible for carrying out the operations of the different subsystems providing a tool to operate the instrument in an integrated manner from low to high user interaction level. The ICS interacts with the following subsystems: the near-infrared (NIR) and visible channels, composed by the detectors and exposure meters; the calibration units; the environment sensors; the front-end electronics; the acquisition and guiding module; the interfaces with telescope and dome; and, finally, the software subsystems for operational scheduling of tasks, data processing, and data archiving. All the software packages run in a coherent infrastructure that uses the CARMENES protocol and the Internet Communications Engine (ICE) and EPICS frameworks for secure and reliable communication among subsystems. The control suite that implements the CARMENES operational design is integrated in the instrument since the end of 2015. The CARMENES workflow covers from the translation of the survey strategy into a detailed schedule to the data processing routines that extract radial velocity data from the observed targets. The software control framework and all the software modules and layers for the different subsystems contribute to maximize the scientific return of the instrument. The control software enables the efficient and dynamic reaction to schedule the observations with both NIR and visible channels by combining the static constraints that are known a priori (i.e., target visibility, sky background, required periodogram coverage) and the dynamic change of the system conditions (i.e., weather). We also present the graphical user interface and the software validation process, together with the analysis of the first season performance taking into account the key indicators for the first months of operation. Finally, the software engineering procedures implemented that guaranteed the project success are discussed.

9913-151, Session PS2

Target-based fiber assignment for large survey spectrographs

Christoph Schaefer, Laleh Makarem, Jean-Paul Kneib, Ecole Polytechnique Fédérale de Lausanne (Switzerland)

Next generation fiber-fed massive spectroscopic survey projects have to process a massive amount of targets and assign these to their fiber positioners. To ensure that the preparation of subsequent observations are feasible in a reasonable amount of time, quick target assignment is essential. Existing fiber assignment algorithms, for example the drainage algorithm by Morales et al., concentrate primarily on optimizing fibre positioner usage but remain computationally heavy for efficient target assignment at high target densities. These algorithms also produce target solutions, which may present additional challenges for the path-finding problem. Therefore ensuring that the assigned targets could be reached without collisions and deadlock would result an important gain of efficiency.

Therefore we will present a fast algorithm for target assignment for the next generation of massive spectroscopic survey projects using fiber positioner robots. This algorithm is designed, given a vast number of targets, to be able to assign targets to positioners quickly and with the least loss in the assignment efficiency. The proposed algorithm uses a target-based approach which reduces the complexity of the algorithm to O(log(n)). This paper provides details about the characteristics of the algorithm and how and when to use it for optimal survey strategies. We also investigate optimization methods for the "ease of path-finding" with the goal to reduce the number of situations of impossible path finding problems therefore improving overall coverage efficiency.

Improving the usability and the efficiency of the pre-observation software should result in smooth and efficient operating of fiber-fed massive spectroscopic survey projects considerably.

9913-153, Session PS2

The 4MOST facility control software

Holger G. Mandel, Alexander Pramskiy, Florian M. Rothmaier, Ingo Stilz, Landessternwarte Heidelberg (Germany); Roland Winkler, Leibniz-Institut für Astrophysik Potsdam (Germany)

The 4MOST (4 m Multi-Object Spectrographic Telescope) Consortium will be running spectroscopic all-sky public surveys on the ESO VISTA telescope at Paranal Observatory expected to begin in 2019. Two low-resolution spectrographs at R ~ 5000 covering the wavelength range between about 390 and 950 nm and one high-resolution spectrograph at R ~ 18000 operating at 392.6-436.5 nm, 521-571 nm and 606-675 nm or 612-681 nm will be fed by approximately 2400 fibres. Both types of spectrographs will be fixed-configuration, three-channel spectrographs. The instrument utilises the tilting spine Echidna concept to simultaneously obtain spectra of about 2400 independent objects, distributed over an hexagonal field-of-view of four square degrees.

This paper aims at giving an overview of the control software design, which is based on the standard ESO VLT software architecture and customised to fit the needs of the 4MOST instrument. In particular, the facility control software is intended to arrange the precise positioning of the fibres, to schedule and observe many surveys in parallel, and to combine the output from the three spectrographs.

In order to avoid performance bottlenecks, the system is divided into three subinstruments: the main system QMOST which contains the Supervisory Observation Software (SOS) and interfaces with the telescope control software, QMOSTS controlling the spectrograph functions and QMOSTP responsible for the fibre positioner. The SOS process will control the observation software of the two other subsystems. The observation

sequences in 4MOST will be designed to use spectrographs in parallel with synchronous points for the data exchange between the individual subinstruments. To minimise instrument reconfiguration overhead, the fibres are repositioned while the telescope acquires a new field. This procedure requires a complex choreography of telescope and the entire instrument in order to align various actions in the most time-efficient way.

Under the continuous movement of the telescope during science exposures, changes in the gravity vector may result in a flexure of the fibres. To compensate, a secondary guiding system will be implemented that is driven by up to twelve 7-core fibre bundles mounted on spines as well.

Moreover, 4MOST's software will include user-friendly GUIs that enable the night observer to interact with the facility control system and to monitor all data-taking and calibration tasks of the instrument.

In order to control hardware devices, Programmable Logic Controller (PLC) components will be used, following the new fieldbus extension standard for future instruments at ESO.

9913-156, Session PS2

Modified deformable mirror stroke minimization control for direct imaging of exoplanets

He Sun, N. Jeremy Kasdin, Robert J. Vanderbei, A. J. E. Riggs, Tyler D. Groff, Princeton Univ. (United States)

For direct imaging of faint exoplanets, coronagraphs are widely used to suppress light and achieve a high contrast. Wavefront correction algorithms based on adaptive optics are introduced simultaneously to mitigate aberrations in the optical system. Stroke minimization is one of the common control algorithms used for high-contrast wavefront control. This technique calculates the minimum deformation across the DM's surface under the constraint that a targeted contrast level in the search area is achieved, namely the dark hole. In this paper we present a modified stroke minimization algorithm. Instead of using single constraint on intensity averaged over all pixels, we constrain the intensity of each pixel in the dark hole. By introducing auxiliary variables, we switch to an inequality constraints from the equality constraints. Using numerical simulation, we find that the revised algorithm leads to a more uniform dark hole and faster convergence. We also show experimental results of the new control algorithm from the Princeton High-Contrast Imaging testbed.

9913-158, Session PS2

The instrument control software package for the Habitable-zone Planet Finder spectrometer

Chad F. Bender, Paul M. Robertson, Gu?mundur Kári Stefánsson, The Pennsylvania State Univ. (United States); Steven L. Chen, Teledyne Scientific & Imaging, LLC (United States); Andrew J. Monson, Tyler B. Anderson, Samuel P. Halverson, Frederick R. Hearty, Eric I. Levi, Suvrath Mahadevan, The Pennsylvania State Univ. (United States); Matthew J. Nelson, Univ. of Virginia (United States); Lawrence W. Ramsey, Arpita Roy, The Pennsylvania State Univ. (United States); Christian Schwab, Macquarie Univ. (Australia); Ryan C. Terrien, National Institute of Standards and Technology (United States)

The Habitable-zone Planet Finder (HPF) spectrograph will enable precise radial velocity searches for low-mass planets orbiting M-dwarfs, and will be installed on the Hobby-Eberly Telescope (HET) in 2016. We have constructed a novel Instrument Control Software (ICS) package for HPF to control and monitor instrument subsystems, facilitate communication with the HET, and provide user interfaces for observers and telescope operators. The core of the ICS is the asynchronous messaging router, which uses the network software stack provided by the Python Twisted engine, and runs on a CentOS Linux platform. This infrastructure provides a modern, object-based, event driven backbone that is fault resistant and easily extensible to additional hardware or even other instruments. Instrument subsystems communicate through a suite a custom software protocols, primarily written in Python. Bi-directional communication with the HET is enabled directly through network protocols built into the backend. We have created two front-end interfaces to the ICS: a command-line system built in Python, which provide direct access to all ICS functionality; and a modern, graphical Qt interface to provide the regularized interaction desired by observers and telescope operators. We will describe the core frontend and backend systems.

In addition, we will describe several of the customized subsystem communication protocols that provide access to and help maintain the numerous hardware systems that comprise HPF. In particular, we will show how asynchronous communication benefits the numerous hardware components that make up the Environmental Control Subsystem and facilitate HPF's exquisite temperature and pressure control. We will also discuss our Detector Control Subsystem, built as a set of custom Python wrappers around the linux-based c-library that provides native access to the SIDECAR Asic and Hawaii-2RG detector system used by HPF. HPF will be one of the first astronomical instruments on-sky to utilize this native linux capability.

The flexible nature of the HPF ICS makes it easily adaptable to other astronomical instruments. Such code reuse has the potential to provide significant cost and schedule savings, while also reducing operational risk with a field tested backend. The Penn State instrument concept for NASA's Extreme Precision Doppler Spectrometer for the WIYN Telescope inherits a significant amount of ICS functionality from HPF, reusing the entire backend messaging system, and large portions of the subsystem protocols and frontends. We will describe this extension of the ICS, and the potential for use in other astronomical instruments.

9913-75, Session PS3

Development of a real-time data processing system for a prototype of the Tomo-e Gozen wide field CMOS camera

Ryou Ohsawa, Shigeyuki Sako, Hidenori Takahashi, Yuki Kikuchi, Mamoru Doi, Naoto Kobayashi, Kentaro Motohara, Takashi Miyata, Tomoki Morokuma, Tsutomu Aoki, Takao Soyano, Ken'ichi Tarusawa, Yuki Sarugaku, Hiroyuki Mito, Yoshikazu Nakada, Mitsuru Kokubo, Kazuma Mitsuda, Yuki Taniguchi, Makoto Ichiki, Jumpei Yamaguchi, Noriyuki Matsunaga, Fumihiko Usui, Ataru Tanikawa, The Univ. of Tokyo (Japan); Junichi Watanabe, Masaomi Tanaka, Hiroyuki Maehara, Ko Arimatsu, National Astronomical Observatory of Japan (Japan); Nozomu Tominaga, Konan Univ. (Japan); Yoshifusa Ita, Hiroki Onozato, Tohoku Univ. (Japan); Seitaro Urakawa, Japan Space Guard Association (Japan); Toshihiro Kasuga, Chiba Institute of Technology (Japan); Mikiya Sato, Kawasaki Municipal Science Museum (Japan)

The Universe is full of transient events, such as novae and supernovae. Such rare and energetic events drive the chemical evolution of galaxies. Time-domain astronomy aims to understand the transients in the Universe. It is difficult to predict the loci of the transients. A wide-field camera is

required to detect the transients events. The Tomo-e Gozen is an extremely wide-field optical camera, equipped with 84 CMOS sensors. The Tomo-e Gozen, installed in the Kiso 105-cm Schmidt telescope, will cover about a 20 sq-degree area, continuously recording universe at 2 Hz. The Tomo-e Gozen will be one of the most powerful instruments to investigate the sub-second Universe, such as an optical counter part of fast radio bursts, meteors, and near-earth objects. We have developed a prototype of the Tomo-e Gozen (Tomo-e PM), which has 8 CMOS sensors aligned in the RA direction, to evaluate the basic design of the Tomo-e Gozen.

The CMOS sensor equipped by the Tomo-e PM has about 2.2M pixels. A single exposure by the Tomo-e PM produces data as much as 35MB. The Tomo-e PM can obtain images continuously at 2 Hz. The data rate of the Tomo-e PM is about 70 MB/s and about 250 GB data are generated in an hour. We have developed an operating system to handle a large amount of data generated by the Tomo-e PM. The Tomo-e PM is operated by two PCs. Each of them retrieves data from four CMOS sensors. The data are converted into fits images and immediately sent to another PC for a storage. The operating system is successfully installed in the Kiso observatory and all the operations can be executed in a remote connection.

Fast transient events (fast radio burst counterparts) and fast moving objects (meteors) are main targets of the Tomo-e PM. Such objects appear only in a handful of images among the data generated by the Tomo-e. We have been developing softwares to detect such a rare event in a tons of data. Since the data are continuously generated, the data reduction should be as fast as the data production by the Tomo-e PM. Parallel computation, eliminating time-consuming tasks, and reducing IO overhead are key technologies. The Tomo-e Gozen camera with 84 sensors will generate about 10-times as much data as the Tomo-e PM does, corresponding to 30 TB/night. It is not realistic to store all the data generated by the Tomo-e Gozen. An on-site data reduction system and fast signal detection algorithms are crucial to make the best use of the Tomo-e Gozen.

9913-80, Session PS3

Introduction to measurement and control system of FAST active reflector

Xinyi Li, Lichun Zhu, Zhiwei Zhang, National Astronomical Observatories (China)

Five-hundred-meter Aperture Spherical radio Telescope (FAST) will be the largest single dish radio telescope in the world which is under construction in Guizhou province in China. Being different from traditional telescopes, FAST's active main reflector is deformable and composed of over 4400 triangular panels. While the telescope is observing, panels transform into corresponding paraboloids which apertures are 300 meters. In order to achieve the reflector's active deformation, we have reflector measurement system and reflector control system to track and control the whole reflector with high precision and high efficiency.

The active main reflector has a cable mesh composed of ~7000 strands of steel cables. Over 4400 triangular panels are mounted on it. Thus there are 2225 nodes in the cable net and 2225 down-tied cables connecting nodes to the ground. The actuators are installed at the end of down-tie cables so that they can adjust the positions of the nodes and shape the reflector through stress deformation of the cable mesh.

The reflector measurement system mainly consists of 10 total stations as survey stations, 2225 targets which are installed on all the nodes, 24 foundation piers as differential reference stations and two control servers. The measurement precision requirement in calibration mode is RMS 1.5mm, in observing mode is RMS 2mm. The measurement efficiency requirement in calibration mode is measuring the whole reflector in 1.5 hour, in observing mode is measuring the corresponding paraboloid in 10 minutes.

The aim of reflector control system is to shape the precise paraboloid by controlling the 2225 actuators according to observation trajectory planning and measurement data. All the 2225 nodes are divided into 12 control areas. Each area has a relay station to communicate with master control room through double-ring fiber Ethernet. The master control room receives data and alarm information from PLCs at 12 relay stations. Meanwhile, it sends data to PLCs, including control instructions, time synchronization information, nodes' measurement information, etc. At the local control layer, PLCs receive the data from sensors installed on the actuators and send target location information to the actuators.

This paper will introduce the measurement system and control system of FAST active reflector respectively. In the measurement system part, we will introduce the system's overall design, working process, software detailed design and implementation. In the control system part, we will focus on its overall design, working process, hardware detailed design and implementation.

9913-84, Session PS3

A reorganization cyber infrastructure of history observing data in China

Ganghua Lin, National Astronomical Observatories (China); Haisheng Ji, Purple Mountain Observatory (China); Jun Lin, Yunnan Observatories (China); Chengmin Tan, Suo Liu, Zhanle Du, Cui Zhao, Xiao Yang, Xiaofan Wang, Yuanyong Deng, National Astronomical Observatories (China)

Astronomical data analysis depends on the accumulation of data, including integrity of data in observing location, time, and diversity of data. We are now developing a reorganization project of solar physics history data of China. There are 90 years, 44 kinds of solar observing data in china. In the project, we will finish imagination, digitalization and standardization for these data. This article introduces the project framework, data, data processing, and how to share.

9913-88, Session PS3

The survey operation software system development for prime focus spectrograph on Subaru Telescope

Atsushi Shimono, Naoyuki Tamura, Kavli Institute for the Physics and Mathematics of the Universe (Japan); Naruhisa Takato, Subaru Telescope, National Astronomical Observatory of Japan (United States); Naoki Yasuda, Nao Suzuki, Kavli Institute for the Physics and Mathematics of the Universe (Japan); Craig P. Loomis, Robert H. Lupton, Princeton Univ. (United States); Yuki Moritani, Kiyoto Yabe, Kavli Institute for the Physics and Mathematics of the Universe (Japan)

The Prime Focus Spectrograph (PFS) is a wide field multi-fiber spectrograph using the prime focus of the Subaru telescope, with capable of observing up to 2400 astronomical objects containing ~200 calibration targets.

Entire software system is designed as loosely coupled system, and is categorized into four packages. The instrument control system will execute the observation procedure communicating with hardware control subsystems and also will run in collaboration with the sequencing system for entire the Subaru telescope. The exposure targeting software calculates assignments of target objects to fibers and their positions for each exposure with various deformations and displacements caused by optics and observational conditions in consideration such as atmospheric dispersion, residual of its correction by ADC, and deformations of the prime focus instrument. The data reduction pipeline will reduce acquired data to spectroscopic parameters, and also will be used for on-site exposure quality assurance mainly using calibration stars.

The survey planning and tracking software is for managing entire survey plans and tracking their progress, based on the field tiling definition supplied from science survey operators. This package will coordinate efficient assignment of target objects to multiple exposures for each tile, and also will track progress of the entire survey to update sequences and configurations of planned exposures.

Based on loosely coupled system, these packages are consisted with functional modules and sequences. Functional system sequences provided from each package, such as exposure by the instrument, calibration, or map list of targets to fibers, will be used by operators of observations and survey, or users to do their science with PFS, and are built with calling selected modules providing functionality in need from both within and external packages to complete each purpose. These external interfaces provided from modules will be modeled over standardized data model, and could be switchable depends on targets.

Subsystem modules of the instrument control software will be mostly connected each other and called from sequences through the messaging hub server, which we selected the tron system used for SDSS, and its sequencer is also built as a module connected to the server. Some modules from other PFS software packages will be called from this sequencer locally, but not adding wrappers to these modules to the server.

In the survey planning and tracking software and the data reduction pipeline, sequencers will call required subsystem modules or other packages locally or through framework for parallel computing.

To carry out survey operations efficiently, information necessary to proceed survey, such as properties of target objects from imaging surveys, or survey coordination including exposure configurations, will be stored in database system shared among software packages.

These database system will be located at multiple places depends on its purpose, especially for observation execution, its database need to be at the site of observation for secure operation to deal with sudden disconnection from external.

Flows of data between these databases will be studied following development of the software packages and their data models.

9913-92, Session PS3

Status of the array control and data acquisition system for the Cherenkov Telescope Array

Matthias Fuessling, Igor Oya, Deutsches Elektronen-Synchrotron (Germany); Ullrich Schwanke, Humboldt-Univ. zu Berlin (Germany); Joseph Schwarz, INAF - Osservatorio Astronomico di Brera (Italy); Gino Tosti, Univ. degli Studi di Perugia (Italy); Peter Wegner, Deutsches Elektronen-Synchrotron (Germany); Josep Colomé, Institut de Ciències de l'Espai (Spain); Arnim Balzer, David Berge, Univ. van Amsterdam (Netherlands); Jerzy Borkowski, Nicolaus Copernicus Astronomical Ctr. (Poland); Jordi Campreciós, Institut de Ciències de l'Espai (Spain); Vito Conforti, Fulvio Gianotti, INAF - IASF Bologna (Italy); Stéphane Colonges, Univ. Paris 7-Denis Diderot (France) and APC - AstroParticule et Cosmologie (France); Thierry Le Flour, Lab. d'Annecy-le-Vieux de Physique des Particules (France); Rico Lindemann, Deutsches Elektronen-Synchrotron (Germany); Etienne Lyard, ISDC Data Ctr. for Astrophysics (Switzerland); Michael Mayer, Humboldt-Univ. zu Berlin (Germany); Michael Punch, Univ. Paris 7-Denis Diderot (France); David Melkumyan, Torsten Schmidt, Deutsches Elektronen-Synchrotron (Germany); Claudio Tanci, Univ. degli Studi di Perugia (Italy); Kushbu Verma, Deutsches Elektronen-Synchrotron (Germany); Roland Walter, Univ. de Genève (Switzerland); Amanda Weinstein, Iowa State Univ. of Science and Technology (United States); Stephan Wiesand, Ralf Wischnewski, Deutsches Elektronen-Synchrotron (Germany)

The Cherenkov Telescope Array (CTA) will be the next-generation ground-based observatory using the atmospheric Cherenkov technique. The CTA instrument will allow researchers to explore the gamma-ray sky in the energy range from 20 GeV to 300 TeV. CTA will comprise two arrays of telescopes, one with about 100 telescopes in the Southern hemisphere and another smaller array of telescopes in the North. CTA poses novel challenges in the field of ground-based Cherenkov astronomy, due to the demands of operating an observatory composed of a large and distributed system with the needed robustness and reliability that characterize an observatory.

The array control and data acquisition system of CTA (ACTL) provides the means to control, readout and monitor the telescopes and equipment of the CTA arrays. The ACTL system must be flexible and reliable enough to permit the simultaneous and automatic control of multiple sub-arrays of telescopes with a minimum effort of the personnel on-site. In addition, the system must be able to react to external factors such as changing weather conditions and loss of telescopes and, on short timescales, to incoming scientific alerts from time-critical transient phenomena. The ACTL system provides the means to time-stamp, readout, filter and store the scientific data at aggregated rates of a few GB/s. Monitoring information from tens of thousands of hardware elements need to be channeled to high performance database systems and will be used to identify potential problems in the instrumentation. This contribution provides an overview of the ACTL system and a status report of the ACTL project within CTA. (For the CTA Consortium)

9913-96, Session PS3

ODI-PPA: 2016 project updates related to upgraded 5x6 ODI instrument

Arvind Gopu, Indiana Univ. (United States); Ralf Kotulla, Univ. of Wisconsin-Madison (United States); Michael D. Young, Soichi Hayashi, Indiana Univ. (United States); Wilson M. Liu, Daniel R. Harbeck, WIYN Observatory (United States); Robert Henschel, Indiana Univ. (United States); Jayadev K. Rajagopal, WIYN Observatory (United States)

The One Degree Imager – Portal, Pipeline, and Archive (ODI-PPA), a web science gateway providing astronomers a single point of access to ODI data as well as rich computational and visualization capabilities, has been in operation since early 2012. Related to the significant upgrade of the ODI instrument focal plane to a 5x6 array (from a 3x3 array) of Orthogonal Transfer Arrays (OTAs), we made several improvements to ODI-PPA to elegantly handle the larger data sizes and the associated changes in expectations from the WIYN Operational and the ODI user perspective. While 3x3 pODI's data volumes were significant enough to deter downloading and processing of raw data into calibrated science data and stacks, the 5x6 data volumes are roughly 3 times the size of pODI data so it became even more important for us to provide rock-solid calibration and stacking functionality within PPA. We improved the QuickReduce workflow within PPA to allow use of twilight flats or custom calibration images (instead of using operator produced monthly master calibrations), as well as more extensive customization of the corrections applied to each input raw image. We also integrated the SWarp stacking pipeline, and verified it works with the larger 5x6 ODI images. This cloud-based stacking can be used with any stacking pipeline, and adds significantly to the overall usefulness of the archive, as a) essentially all

ODI data is obtained using dithering, with the total exposure time being spread out over several shorter exposure spatially offset from each other; b) generating stacks of even a single, typically 9-point, dither sequence requires significant computational resources and large amounts of disk space for both input and intermediate data files (>20 GB for a single sequence, 250+ GB for deeper observations or wider fields). Co-locating data storage (archive) and processing (portal) therefore enables users from the general astro-community to get the most out of their data while minimizing data transfers and local computing demands. We maintain data provenance for stacks produced within PPA in a manner similar to QuickReduce images and their association with raw images (which are now more comprehensive). Apart from the above improvements we also made several other user interface enhancements including: a uniform job status monitoring view for all Tier 2 workflows including QuickReduce and SWarp leveraging the Trident SCA Progress microservice, an improved Image Explorer functionality via the Trident SCA Image X microservice, and improved heuristic searches providing 'best available data' for any selection criteria while separating operator produced and user-derived data products (especially useful for novice users). Other updates include improved scaling for QuickReduce image tiles used by the ImageX visualization feature, the ability to seamlessly acquire compute nodes as needed to match processing demands, and operational stability enhancements providing better monitoring of underlying backend services.

9913-100, Session PS3

The TESS science processing operations center

Jon M. Jenkins, Joseph D. Twicken, Sean D. McCauliff, Jennifer Campbell, Dwight T. Sanderfer, NASA Ames Research Ctr. (United States); David K. Lung, NASA Ames Research Ctr. (United States) and Millennium Engineering and Integration Co. (United States); Masoud Mansouri-Samani, Forrest R. Girouard, Peter Tenenbaum, Todd C. Klaus, Jeffrey C. Smith, Douglas A. Caldwell, Aaron D. Chacon, Christopher Henze, NASA Ames Research Ctr. (United States); Cory Heiges, NASA Goddard Space Flight Ctr. (United States); David W. Latham, Harvard-Smithsonian Ctr. for Astrophysics (United States); Edward H. Morgan, Massachusetts Institute of Technology (United States); Daryl A. Swade, Space Telescope Science Institute (United States); Stephen A. Rinehart, NASA Goddard Space Flight Ctr. (United States)

The Transiting Exoplanet Survey Satellite (TESS) was selected by NASA's Explorer Program to conduct a search for Earth's closest cousins starting in late 2017. Tess will conduct an all-sky transit survey of F, G and K dwarf stars between 4 and 12 magnitudes and M dwarf stars within 200 light years. TESS is expected to discover ~1,000 small planets less than 4X the size of Earth, and to measure the masses of at least 50 of these small worlds. Because these stars are typically 10X closer and 100X brighter than the Kepler's, they are much more amenable to follow-up observations and characterization. Indeed, the James Webb Space Telescope should be able to characterize the atmospheres of many of the TESS discoveries.

The TESS science pipeline is being developed by the Science Processing Operations Center (SPOC) at NASA Ames Research Center based on the highly successful Kepler pipeline. Like the Kepler pipeline, the TESS pipeline will provide calibrated pixels, simple and systematic error-corrected aperture photometry, and centroid locations for all 200,000+ target stars, observed over the 2-year mission, along with associated uncertainties. The science data will be processed on the NAS Pleiades Supercomputer for efficiency. The pixel and light curve products are modeled on the Kepler archive products and will be archived to the Mikulski Archive for Space Telescopes (MAST). In addition to the nominal science data, the 30-minute Full Frame Images (FFIs) simultaneously collected by TESS will also be calibrated by the SPOC and archived at MAST.

Each 27.4-day period, TESS will observe a 24° by 96° swath of sky extending from ~6° above ecliptic equator to the ecliptic pole in the anti-Sun direction. TESS rotates by 27.7° after each observing "sector" in order to cover one hemisphere during the first year of observations. The spacecraft then flips over to cover the other hemisphere during the second year. While most of the stars are only observed for 27.4 days, the "pole" camera is centered on the celestial pole, allowing a ~450 square degree area in each hemisphere to be observed continuously for a year.

The TESS pipeline will search through all light curves for evidence of transits that occur when a planet crosses the disk of its host star. The Data Validation pipeline will generate a suite of diagnostic metrics for each transit-like signature discovered, and extract planetary parameters by fitting a limb-darkened transit model to each potential planetary signature. The results of the transit search will be modeled on the Kepler transit search products (tabulated numerical results, time series products, and pdf reports) all of which will be archived to MAST.

This paper provides an overview of the TESS science pipeline and describes the development of the SPOC remaining before launch in August 2017. The data rate for TESS is 10X that of Kepler, presenting challenges for keeping up with the 27-day cadence of observations for a mission with 26 distinct fields of view. We describe innovations allowing us to scale the Kepler design to meet TESS's demanding requirements.

9913-104, Session PS3

The Infrared Imaging Spectrograph (IRIS) for TMT: software design

Jason L. Weiss, Christopher A. Johnson, Ji Man Sohn, Univ. of California, Los Angeles (United States); Jennifer S. Dunn, Edward L. Chapin, NRC - Herzberg Astronomy & Astrophysics (Canada); Shelley A. Wright, Gregory Walth, Univ. of California, San Diego (United States); Roger M. Smith, Reed L. Riddle, California Institue of Technology (United States); Kim Gillies, Thirty Meter Telescope (United States); Ryuji Suzuki, National Astronomical Observatory of Japan (Japan); Yutaka Hayano, Advanced Technology Ctr., NAOJ (Japan); James E. Larkin, Univ. of California, Los Angeles (United States); Anna M. Moore, California Institue of Technology (United States)

IRIS (InfraRed Imaging Spectrograph) is a first light near-infrared diffraction-limited imager and integral field spectrograph being designed for the future Thirty Meter Telescope (TMT). We present the preliminary software design for the instrument, which features on-instrument wavefront sensors, an imaging focal plane consisting of four infrared detectors, and an integral field spectrograph with both lenslet array and mirror slicing IFUs. Challenging aspects of the software design include a real-time and offline data reduction system, the use of on-detector guide windowing to provide tip/tilt information to the AO system, and the approach to detector exposure data gathering that consists of continuously clocking the detector and storing all non-destructive reads. The system is part of the TMT Observatory Software system and will make use of TMT Common Software for its services.

9913-69, Session PS4

Software design of the ASTRI camera server proposed for the Cherenkov Telescope Array

Vito Conforti, Massimo Trifoglio, Fulvio Gianotti, Giuseppe Malaguti, Andrea A. Bulgarelli, Valentina Fioretti, Andrea Zoli, INAF - IASF Bologna (Italy); Osvaldo Catalano, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Milvia Capalbi, Pierluca Sangiorgi, INAF - Istituto di Astrofisica Spaziale e Fisica Cosmica di Palermo (Italy)

The Italian National Institute for Astrophysics (INAF) is leading the ASTRI project within the ambitious Cherenkov Telescope Array, CTA. In the framework of the small size class of telescopes, a first goal of the ASTRI project is the realization of the end-to-end prototype in dual-mirror configuration (SST-2M) with the camera at the focal plane composed by a matrix of Silicon photo-multiplier sensors managed by innovative front-end and back-end electronics. The ASTRI SST-2M prototype is installed in Italy at the INAF "M.G. Fracastoro" observing station located at Serra La Nave, 1735 m a.s.l. on Mount Etna, Sicily. As a second step, the ASTRI project is focussed on the implementation of the ASTRI mini-array composed of nine SST-2M telescopes and proposed to be placed at the CTA southern site.

This paper outlines the design of the camera server software that will be installed on the ASTRI mini-array. The software is based on the version installed on the ASTRI SST-2M prototype operating in a single telescope configuration. The migration from the single telescope to the mini-array context has required additional interfaces in order to guarantee high interoperability with other software and hardware components. In the mini-array configuration each camera communicates with the relevant camera server via a dedicated high rate data link. The primary goal of the camera server is to acquire the bulk data, packet by packet, without any data loss and to timestamp with each packet very precisely.

During array operation, the camera server receives from the SoftWare Array Trigger (SWAT) the list of science events that participate in a stereo triggered events. These events, and all the other events that are flagged either by the Camera as interleaved calibration or by the camera server as possible single-muon events, are sent to the Array DAQ. All remaining events will be discarded.

A suitable buffer is provided to perform this processing on all the incoming event packets. The camera server provides interfaces to the array control software to allow for monitoring and control during array operations.

In this paper we present the design of the camera server software with particular emphasis on the external interfaces. In addition we report the results of the first integration activities and performance tests.

9913-73, Session PS4

From source control to continuous delivery through integration and testing: a story of software automation

Marco Bartolini, Andrea Orlati, INAF - Istituto di Radioastronomia (Italy); Sergio Poppi, Carlo Migoni, Marco Buttu, Antonietta Fara, INAF - Osservatorio Astronomico di Cagliari (Italy); Simona Righini, INAF - Istituto di Radioastronomia (Italy)

Software projects are often approached with enthusiasm and they are easily managed during their early life stages, when developers are fully committed to the new product, but as a software project grows in size and complexity its lifecycle needs to be managed with increasingly powerful and standardized tools and practices, in order to keep its releases stable, tested and deployable in predictable times. This was also the case for DISCOS, the "Development of the Italian Single-dish COntrol System": a software project born for the control of the newly-built SRT radiotelescope and now extended to be used at all the Italian dishes.

If a version control system was essentially enough for managing the first stages of the project, when our codebase grew over 500,000 lines of code - encompassing different tags and different configurations installed at different telescopes - the old naive approach began to face its limits. For this reason we are gradually evolving our software management infrastructure and our software development process, with the goal of a complete continuous delivery.

In this paper we examine the shortcomings of the less structured approach and its impact on the development activity. We show how we are addressing the continuous integration and software management automation, with a particular focus on the lessons learned in introducing these techniques during a late stage of a project life. We illustrate how this impacted on the project itself in terms of how the code was developed and structured, and in terms of how the deployment operations were performed by our DevOps staff, analyzing the difficulties we encountered and the necessary tradeoffs we had to accept.

We describe how we automated the machine provisioning with the usage of virtual machines and containers, based on Vagrant, VirtualBox and docker, and how we automated the build jobs, using Jenkins for integrating our build process with our version control system. We show how we modified our project in order to make space for unit testing and functional testing in Python and C++, using Google Tests and the python unittest module, then adding automated testing duties to our build server giving access to new practices such as acceptance testing and implementation of regression tests. All these improvements can now be exploited during the deployment operations, using automated provisioning and binary artifacts of production and development releases of DISCOS for obtaining a repeatable and predictable deployment process in a safer environment.

In conclusion we examine the status of this transition towards a more modern software management process, discussing the future steps towards continuous delivery, showing how developing such an infrastructure is worth the initial effort and why it is going to pay off in the long run in terms of productivity and stability of the released software products.

9913-77, Session PS4

ZeroC ICE distributed middleware in the Tian Ma Telescope observing control system

Jian Dong, Xiuting Zuo, Rongbing Zhao, Qinghui Liu, Shanghai Astronomical Observatory (China) and Chinese Academy of Sciences (China)

The Tian Ma Telescope (TM) is the largest fully steerable radio telescope in China. It has a primary reflector of 65-m in diameter with a shaped Cassegrain configuration. It operates in a wide frequency range from 1.4 GHz to 43 GHz.

There are many challenges controlling the TM and one of them is establishing reliable and robust communications between different parts of the telescope such as antenna, active surface, backend and so on. We selected Zeroc ICE middleware as a communication foundation to support control and status query. Now the observing control system based on the middleware works well. In this paper we discuss advantages of the ZeroC ICE middleware and implementation details of the observing control system.

9913-81, Session PS4

SINBAD flight software: the on-board software of NOMAD in Exomars 2016

Maria del Carmen Pastor-Morales, Julio F. Rodríguez Gómez, Rafael Morales Muñoz, Beatriz Aparicio del Moral, Instituto de Astrofísica de Andalucía (Spain); Gian Paolo Candini, Juan M. Gómez López, José M. Jerónimo Zafra, José Juan López-Moreno, Nicolás Robles Muñoz, Rosario Sanz Mesa, Instituto de Astrofísica de Andalucía - CSIC (Spain); Eddy Neefs II, Ann Carine Vandaele, Rachel Drummond, Ian R. Thomas, Sophie Berkenbosch, Roland Clairquin, Sofie Delanoye, Bojan Ristic, Jeroen Maes, Sabrina Bonnewijn, Belgian Institute for Space Aeronomy (Belgium); Manish R. Patel, Mark Leese, Jon P. Mason, The Open Univ. (United Kingdom); Giancarlo Bellucci, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy)

The Nadir and Occultation for MArs Discovery instrument (NOMAD), in mission ExoMars Trace Gas Orbiter (TGO), has as goal looking for trace gases that could be signatures of active biological or geological processes in Mars. This instrument is a spectrometer suite that consists of three separate channels, solar occultation (SO), limb nadir and occultation (LNO), and ultraviolet and visible spectrometer (UVIS).

The Spacecraft INterface and control Board for NomAD (SINBAD) is the electronic interface in charge of managing the power and communication inside NOMAD.

The SINBAD Flight Software (SFS) is the flight software embedded in SINBAD. It main tasks have been defined as follows.

Manage the communication interfaces with TGO spacecraft. These interfaces are implemented by a MIL-STD-1553B bus for telecommands (TCs) and housekeeping (HK) transmissions and a Spacewire bus for massive data transmission.

Control the observation sequence of NOMAD channels (SO, LNO and UVIS). When a telecommand with an observation is received, SFS sends the appropriate set of parameters to the channels and afterwards it reads the data produced. These data are transmitted later to the spacecraft.

Manage code and data patches. These patches can be implemented with file system operation or directly accessing to the system memory.

Implement the NOMAD contingency and recovery plan to detect and recover the instrument until the next communication with ground.

Control other devices of NOMAD such as: the LNO flip mirror, current and temperature sensors and operational heaters.

The ExoMars TGO mission has hard restrictions in number of TCs (750 every 5 days) and size (64 B per TC). All the communications with NOMAD (command observations, send patches, warn of powering off, etc...) should be done through TCs and some of them need a great number of TCs. In order to reduce the number of required TCs for nominal operations, such as observations, SINBAD stores the observation parameters in the on board memory in Channel Observation Parameters (COP) tables. With these structures, one single TC is needed to command a complete observation.

SINBAD uses a Non-Volatile magneto resistive random access memory (MRAM). It is the first time that this kind of memory is used as main memory in a flight mission.

This paper includes a summary of the most remarkable aspects about the SFS design and a description of the main problems and lessons learned during the software development.

9913-85, Session PS4

Porting the ALMA correlator data processor from hard real-time to plain Linux

Rodrigo Amestica, Richard Lacasse, Jesus Perez, National Radio Astronomy Observatory (United States); Alejandro Saez, ALMA (Chile)

The ALMA correlator back-end consists of a cluster of 16 computing nodes and a master collector/packager node. The mission of the cluster is to process time domain lags into auto-correlations and complex visibilities, integrate them for some configurable amount of time and package them into a workable data product. Computers in the cluster are organized such that individual workloads per node are kept within achievable levels for different observing modes and antennas in the array. During the course of an observation the master node transmits enough state information to each involved computing node to specify exactly how to process each set of lags received from the correlator. For that distributed mechanism to work, it is necessary to unequivocally identify each individual lag set arriving at each computing node. The original approach was based on a custom hardware interface to each node in the cluster plus a real-time version of the Linux Operating System. A modification recently introduced in the ALMA correlator consists of tagging each lag set with a time stamp before delivering them to the cluster. The time stamp identifies a precise 16-millisecond window during which that specific data set was streamed to the computing cluster. From the time stamp value a node is able to identify a centroid (in absolute time units), base-lines, and correlator mode during that hardware integration. That is, enough information to let the digital signal processing pipeline in each node to process time domain lags into frequency domain auto-correlations per antenna and visibilities per base-line. The scheme also means that a good degree of concurrency can be achieved in each node by having individual CPU cores process individual lag sets at the same time, thus rendering enough processing power to cope with a maximum 1 GB/sec output from the correlator. The present paper describes how we time stamp lag sets within the correlator hardware, the implications to their on-line processing in software and the benefits that this extension has brought in terms of software maintainability and overall system simplifications.

9913-89, Session PS4

Implementing the concurrent operation of sub-arrays in the ALMA correlator

Rodrigo Amestica, Richard Lacasse, Jesus Perez, National Radio Astronomy Observatory (United States); Alejandro Saez, ALMA (Chile)

The ALMA correlator processes the digitized signals from 64 individual antennas to produce a grand total of 2016 correlated base-lines, with runtime selectable lags resolution and integration time. The on-line software system can process a maximum of 125M visibilities per second and producing an archiving data rate close to one sixteenth of the former (7.8M visibilities per second with a network transfer limit of 60 MB/sec). Mechanisms in the correlator hardware design make it possible to split the total number of antennas in the array in smaller subsets, or sub-arrays, such that they can share correlator resources while executing independent observations. The software part of the sub-system is responsible for configuring and scheduling correlator resources in such a way that observations among independent sub-arrays occur simultaneously while internally sharing correlator resources under a cooperative arrangement. Configuration of correlator modes through its CAN-bus interface and periodic geometric delay updates are the most relevant activities to schedule concurrently while observations happen at the same time among a number of sub-arrays. For that to work correctly the software

interface to sub-arrays schedules shared correlator resources sequentially before observations actually start on each sub-array. Start times for specific observations are optimized and reported back to the higher level observing software. After that initial sequential phase has taken place then simultaneous executions and recording of correlated data across different sub-arrays move forward concurrently, sharing the local network to broadcast results to other software sub-systems. The present paper presents an overview of the different hardware and software actors within the correlator sub-system that implement some degree of concurrency and synchronization needed for seamless and simultaneous operation of multiple sub-arrays, limitations stemming from the resource-sharing nature of the correlator, limitations intrinsic to the digital technology available in the correlator hardware, and milestones so far reached by this new ALMA feature.

9913-93, Session PS4

The ASTRI mini-array software system (MASS) implementation: a proposal for the Cherenkov Telescope Array

Claudio Tanci, INAF - Osservatorio Astronomico di Brera (Italy); Gino Tosti, Univ. degli Studi di Perugia (Italy); Vito Conforti, INAF - IASF Bologna (Italy); Joseph Schwarz, INAF - Osservatorio Astronomico di Brera (Italy); Elisa Antolini, Univ. degli Studi di Perugia (Italy); Lucio A. Antonelli, INAF - Osservatorio Astronomico di Roma (Italy); Andrea A. Bulgarelli, INAF - IASF Bologna (Italy); Ciro Bigongiari, INAF - Osservatorio Astrofisico di Torino (Italy); Pietro Bruno, INAF - Osservatorio Astrofisico di Catania (Italy); Rodolfo Canestrari, INAF - Osservatorio Astronomico di Brera (Italy); Milvia Capalbi, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Enrico Cascone, INAF - Osservatorio Astronomico di Capodimonte (Italy); Osvaldo Catalano, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Andrea Di Paola, INAF - Osservatorio Astronomico di Roma (Italy); Federico Di Pierro, INAF - Osservatorio Astrofisico di Torino (Italy); Valentina Fioretti, INAF - IASF Bologna (Italy); Mauro Fiorini, INAF - IASF Milano (Italy); Stefano Gallozzi, INAF - Osservatorio Astronomico di Roma (Italy); Daniele Gardiol, INAF - Osservatorio Astronomico di Torino (Italy); Fulvio Gianotti, INAF - IASF Bologna (Italy); Enrico Giro, INAF - Osservatorio Astronomico di Padova (Italy); Alessandro Grillo, INAF - Osservatorio Astrofisico di Catania (Italy); Nicola La Palombara, INAF - IASF Milano (Italy); Giuseppe Leto, INAF - Osservatorio Astrofisico di Catania (Italy); Saverio Lombardi, INAF - Osservatorio Astronomico di Roma (Italy); Maria C. Maccarone, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Giovanni Pareschi, INAF - Osservatorio Astronomico di Brera (Italy); Federico Russo, INAF - Osservatorio Astrofisico di Torino (Italy); Pierluca Sangiorgi, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Luca Stringhetti, INAF - IASF Milano (Italy); Vincenzo Testa, INAF - Osservatorio Astronomico di Roma (Italy); Massimo Trifoglio, INAF - IASF Bologna (Italy); Stefano Vercellone, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Andrea Zoli, INAF - IASF Bologna (Italy); Salvo Scuderi, INAF - Osservatorio Astrofisico di Catania (Italy)

The ASTRI mini-array, composed of nine small-size dual-mirror (SST-2M) telescopes, has been proposed to be installed at the southern site of the Cherenkov Telescope Array (CTA), as a set of pre-production units of the CTA observatory. The ASTRI mini-array is a collaborative effort led by the National Institute of Astrophysics INAF (Italy) in partnership with the University of Sao Paulo and FAPESP (Brazil) and the North-West University (South-Africa). We present the main features of the current implementation of the Mini-Array Software System (MASS) now in use for the activities of the ASTRI dual-mirror small-size telescope prototype located at the INAF observing station on Mt. Etna, Italy and the characteristics that make it a prototype for the CTA control software system. CTA Data Management (CTA-DATA) and CTA Data Acquisition and Array Control (CTA-ACTL) requirements and guidelines as well as the ASTRI use cases were considered in the MASS design, most of its features are derived from the Atacama Large Millimeter/sub-millimeter Array Control software. The MASS will provide a set of tools to manage all on-site operations of the ASTRI mini-array in order to perform the observations specified in the short-term schedule (including monitoring and controlling all the hardware components of each telescope and calibration devices), to analyze the acquired data online and to store/retrieve all the data products to/from the on-site repository.

9913-97, Session PS4

Concept study of an observation preparation tool for MICADO

Michael Wegner, Jörg Schlichter, Univ.-Sternwarte München (Germany)

MICADO, the near-infrared Multi-AO Imaging Camera for Deep Observations, will be one of the first light instruments for the European Extremely Large Telescope (E-ELT) of the European Southern Observatory (ESO). It is currently being developed by a consortium of German, French, Austrian, Dutch, and Italian institutes. Optimized to work with the laser guide star multi-conjugate adaptive optics facility MAORY and additionally equipped with a single-conjugated adaptive optics (SCAO) module for operation in a stand-alone mode, MICADO will provide capabilities for astrometric imaging, coronagraphic imaging, and spectroscopy over a large wavelength range at moderate resolution.

As for any other instrument in operation at an ESO observatory, observations with MICADO will have to be prepared in advance. Assuming a similar data flow as for, e.g., the Very Large Telescope (VLT), this will be accomplished by means of a combination of both standard and instrument-specific software tools. In this way the preparation overhead at the telescope can be restricted to a minimum, as well as the particular requirements on the instrument configuration, including plausibility tests and optimizations, can be covered through a custom implementation.

In case of MICADO the observation preparation particularly includes the automatic or manual selection of suitable natural guide stars for adaptive optics as well as of several reference stars for the envisaged secondary guiding through consecutive readouts of small MICADO detector windows. Together with the definition of an offset and dither pattern that is compliant with the selected asterism and depending on the actual AO and observation modes, this is a task which cannot be performed by standard software alone and that requires an optimization for the best possible configuration. In addition, a visual representation of the latter, along with both a dedicated graphical and a scripting interface, would be highly desirable. Finally and as a further option, the MICADO instrument simulator, to be provided by the consortium independently, might eventually be integrated. Therefore, we aim at the development of a flexible, user-friendly, and expandable tool that fulfills the aforementioned requirements and that either enhances or complements the ESO standard observation preparation software.

In the Preliminary Design Phase of the MICADO project we are currently examining different application type options ranging from plug-ins to

stand-alone tools, and we are investigating how the requirements can be reflected in a feasible software design through the prototyping of selected functionalities. We report on the status of our conceptual design study and present a first proof-of-concept implementation of an observation preparation tool for MICADO.

9913-101, Session PS4

Implementation of a distributed system for the PAUCam control system

Otger Ballester, Cristobal Pio, Institut de Física d'Altes Energies (Spain); Nadia Tonello, Port d'Informació Científica (Spain); Santiago Serrano, Institut d'Estudis Espacials de Catalunya (Spain)

The PAU Camera is an instrument equipped with 18 red-sensitive CCDs of 4kx2k pixels with a system of 40 narrow-band (10 nm) filters and 6 wide-band filters which is installed as a visitor instrument at the William Herschel Telescope(WHT).

The PAUCam Camera Control System (CCS) is the software system in charge of the coordination of the several subsystems of PAUCam to acquire exposures, monitor the whole system, check and configure the system and process lists of targets.

The PAUCam CCS is based on a central node (Observation Control System, OCS) and several satellites. The satellites implement interfaces to subsystems of PAUCam or the telescope, while the OCS is in charge of their coordination to execute tasks. The list of satellites includes: Slow Control interface, Data Acquisition interface, On line Quality analysis, Guider, Telescope Control system interface, Storage and Transfer, and buffer.

The PAUCam CCS is a distributed software system which uses "Advanced Messaging Queue Protocol"(AMQP) to implement the communication system. A Shared Variable Engine has been developed on top of AMQP, allowing satellites to share variables in real time. The OCS, by means of Remote Procedure Calls (RPC), sends requests to satellites which are executed on a sandbox environment. OCS also implements the concept of macros which let add functionality to the system easily.

PAUCam can be operated either in manual or in supervised mode. On supervised mode a list of targets are processed sequentially, while in manual mode, the operator has to set each of the tasks to be performed.

9913-105, Session PS4

A 1D spectral extraction software with self learning capabilities for the FOCES spectrograph

Liang Wang, Hanna Kellermann, Anna Brucalassi, Max-Planck-Institut für extraterrestrische Physik (Germany); Frank U. Grupp, Univ.-Sternwarte München (Germany); Ralf Bender, Max-Planck-Institut für extraterrestrische Physik (Germany)

We described a new generation of spectral extraction and analysis software package for the Fibre Optics Cassegrain Echelle Spectrograph (FOCES), which will be attached to the 2-m Fraunhofer Telescope on the Wendelstein Observatory. The package includes a variety of image processing algorithms based on Python language and third party, open source packages Numpy and Scipy. An optimal extraction method was adopted to obtain the one-dimensional spectra with cosmic rays removed. The radial velocities of the multi-order echelle spectra were calculated by minimizing the ?2 with the templates, which were generated either by combining the observed high signal-to-noise spectra, or the synthesis program of the MAFAGS-OS model atmosphere. The package was also optimized for the laser frequency comb, which was used as the wavelength reference to obtain the radial velocity uncertainties down to sub-m/s.

9913-108, Session PS4

Monitoring service for the Gran Telescopio Canarias control system (GCS)

Manuel Huertas, Jordi Molgó Sendra, Francisco Ramos, GRANTECAN S.A. (Spain)

Background

Grantecan is a 10.4 meter Telescope. Grantecan Control System follows a distributed architecture in three tiers, namely equipment real-time control, common services and user interfaces.

The equipment real-time control tier is composed of several embedded systems that connect to the hardware in order to command and to read the telemetry information. These Logical Control Units make use of the common service located in the second tier.

Within the intermediate layer, that aggregates services like: configuration, alarms, logging and so on, it is located the Monitor Manager service, in charge of data collecting, distribution, processing and storage of Telescope and Instruments telemetry. This service decouples real-time streams coming from different subsystems and allow users (Astronomers and Operators) to analyse data at its their own pace while archiving historical data so its availability and performance is key for overall Telescope performance.

Due to several limitations of the former GTC Monitor Manager, a new designed version has been developed and placed in operation recently. This paper presents the innovative design of the new service, which includes more demanding requirements in terms of high availability and fault tolerance, enhanced performance and further scalability for present and future instruments. Latest state-of-art technologies in real time database within distributed system, no single point of failure, easy of integration and maintenance have been among the requisites considered and applied.

Results

Several strategies were adopted, like building a robust set of queues based on Terracota memory management tools, that distributes and buffer telemetry data in parallel streams which can be replicated to achieve scalability at the time that overcome data loss due to unavailability of certain devices. Monitor Manager server was then completely isolated from the Real-Time tier using these queues and a product/consumer architecture which separate producers and consumers data paths. High availability solution was developed based on memory storage shared by different processes and synchronization among them, becoming a cluster with no single point of failure, that provides short term telemetry to user presentation layer. Finally, as a special consumer, a classic MySQL Master Multi-Slave database architecture was selected to provide a Long Term data archive and to facilitate the offline analysis of the data.

Conclusion

This paper presents the architecture of the new GTC System Monitoring, the technical tradeoff taken during design phase, and the alternative paths that were evaluated during its development.

9913-111, Session PS4

ESPRESSO front end guiding algorithms: from design phase to implementation and validation toward the commissioning

Marco Landoni, Marco Riva, INAF - Osservatorio Astronomico di Brera (Italy); Francesco Pepe, Observatoire de Genève (Switzerland); Matteo Aliverti, INAF - Osservatorio Astronomico di Brera (Italy); Alexandre Cabral, Univ. de Lisboa (Portugal); Giorgio Calderone, Roberto Cirami, Stefano Cristiani, Paolo Di Marcantonio, INAF - Osservatorio Astronomico di Trieste (Italy); Matteo Genoni, INAF - Osservatorio Astronomico di Brera (Italy); Denis Mégevand, Observatoire de Genève (Switzerland); Manuele Moschetti, Luca Oggioni, Giorgio Pariani, INAF - Osservatorio Astronomico di Brera (Italy)

In this paper we will review the ESPRESSO guiding algorithm for the Front End subsystem. ESPRESSO, the Echelle SPectrograph for Rocky Exoplanets and Stable Spectroscopic Observations, will be installed on ESO's Very Large Telescope (VLT). The Front End Unit (FEU) is the ESPRESSO subsystem which collects the light coming from the Coud`e Trains of all the Four Telescope Units (UTs), provides Field and Pupil stabilization better than 0.05'' via piezoelectric tip tilt devices and inject the beams into the Spectrograph fibers. The field and pupil stabilization is obtained through a re-imaging system that collects the halo of the light out of the Injection Fiber and the image of the telescope pupil. In particular, we will focus on the software design of the system starting from class diagram to actual implementation. A review of the theoretical mathematical background required to understand the process of simulations needed to achieve the final design is also reported. We will show the performance of the designed algorithm on the actual Front End by adoption of telescope simulator exploring various scientific requirements.

9913-114, Session PS4

HIRES the high resolution spectrograph for the E-ELT: software and hardware solutions for its control

Paolo Di Marcantonio, Veronica Baldini, Giorgio Calderone, Roberto Cirami, Igor Coretti, Guido Cupani, Valentina D'Odorico, Stefano Cristiani, INAF - Osservatorio Astronomico di Trieste (Italy); Alessandro Marconi, Univ. degli Studi di Firenze (Italy)

The current E-ELT instrumentation plan foresees a High Resolution Spectrograph conventionally indicated as HiRes whose Phase A study will start in 2016. Since 2013 however, a preliminary study of a modular E-ELT instrument able to provide high-resolution spectroscopy (R~100,000) in a wide wavelength range (0.37-2.5 ?m) has been already conducted by an international consortium (termed "HiRes initiative"). Taking into account the requirements inferred from this preliminary work in terms of both high-level operations as well as low-level control, we will present in this paper possible solutions for HiRes hardware and software architecture. The validity of the proposed architectural and hardware choices will be eventually discussed based also on the experience gained on a real-working instrument, ESPRESSO, the next generation high-stability spectrograph for the VLT and to certain extent the precursor of HiRes.

9913-117, Session PS4

Monitoring and controlling the SKA telescope manager: a peculiar LMC system in the framework of the SKA LMCs

Matteo Di Carlo, Mauro Dolci, INAF - Osservatorio Astronomico di Teramo (Italy); Riccardo Smareglia, INAF - Osservatorio Astronomico di Trieste (Italy); Matteo Canzari, INAF - Osservatorio Astronomico di Teramo (Italy); Simone Riggi, INAF - Osservatorio Astrofisico di Catania (Italy)

The SKA Telescope Manager (TM) is the core package of the SKA Telescope: it is aimed at scheduling observations, controlling their execution, monitoring the telescope health status, diagnosing and fixing its faults and so on. To do that, TM directly interfaces with the Local Monitoring and Control systems (LMCs) of the various SKA Elements (e.g. Dishes, Low-Frequency Aperture Array, etc.), exchanging commands and data with each of them.

TM in turn needs to be monitored and controlled, in order its continuous and proper operation – and therefore that of the whole SKA Telescope – is ensured. It appears indeed that, while the unavailability of one or more instances of any other SKA element should result only in a degraded operation for the whole telescope, a problem in TM could cause a complete stop of any operation.

In addition to this higher responsibility, a local monitoring and control system for TM has to collect and display logging data directly to operators, perform lifecycle management of TM applications and directly deal - when possible - with management of TM faults (which also includes a direct handling of TM status and performance data).

In this paper the peculiarities presented by the TM monitoring and control and the consequences they have on the design of a related LMC system are addressed and discussed.

9913-120, Session PS4

The software architecture of the camera for the ASTRI SST-2M prototype for the Cherenkov Telescope Array

Pierluca Sangiorgi, Milvia Capalbi, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Renato Gimenes, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy) and Univ. de São Paulo (Brazil); Giovanni La Rosa, Francesco Russo, Alberto Segreto, Giuseppe Sottile, Osvaldo Catalano, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy)

The purpose of this contribution is to present the current status of the software architecture of the ASTRI SST-2M Cherenkov Camera. The ASTRI SST-2M telescope is an end-to-end prototype for the Small Size Telescope of the Cherenkov Telescope Array. The ASTRI camera is an innovative instrument based on SiPM detectors and has several internal hardware components. In this contribution we will give a brief description of the hardware components of the camera of the ASTRI SST-2M prototype and of their interconnections. Then we will present the outcome of the software architectural design process that we carried out in order to identify the main structural components of the camera software system and the relationships between them. We will analyze the architectural model that describes how the camera software is organized as a set of communicating blocks. Finally, we will show where these blocks are deployed in the hardware components and how they interact. We will describe in some detail, the physical communication ports and external ancillary devices management, the high precision time-tag management, the fast data collection and the fast data exchange between different camera subsystems, and the interfacing with the external systems.

9913-129, Session PS4

INO340 telescope control system: middleware requirements, design, and evaluation

Reza Ravanmehr, Hengameh Shalchian, Asghar Jafarzadeh, Iranian National Observatory (Iran, Islamic Republic of)

The INO340 telescope is a 3.4m Alt-Az reflecting optical telescope with a 0.3° field-of-view and the F?ratio of Cassegrain focus is f/11. It is currently in the middle of the detailed design phase. The INO340 Control System (INOCS) is being designed in terms of a distributed real-time architecture comprised of many processors and devices. This system requires a communications layer that provides an efficient and reliable way of exchanging data between its different components. The real-time (soft and firm) nature of many processes inside INOCS causes the communication paradigm very critical and sensitive. Therefore, the middleware shall work at realtime to be able to satisfy INOCS functional and performance requirements.

INOCS high-level middleware is responsible for data transmission among INOCS main subsystems, i.e. the Observation Monitoring System (OMS), the Observation System Supervisor (OSS) and the Telescope Control System Supervisor (TCSS). The middleware must be adaptable to hardware infrastructure and operating system software that may differ between different nodes in INOCS. For this purpose, the Data Distribution Service (DDS) standard has been selected as the communications middleware to distribute information across the entire system. The DDS itself performs based on the well-known publish-subscribe paradigm.

There are several types of middleware and each has its own strong points. The point-to-point messaging type is built on the concept of message queues, senders, and receivers. The client-server model is a distributed application structure in computing that partitions tasks or workloads between the providers of a resource or service, called servers, and service requesters, called clients. The DDS standard is based on a publish-subscribe design pattern. Publish-subscribe applications are typically distributed applications with endpoint nodes that communicate with each other by sending (publishing) data and receiving (subscribing) data anonymously without knowing the destination address.

INOCS is a soft real-time system, therefore, its subsystems need to communicate fast with least possible data loss. After studying and evaluating several major DDS implementations, we have decided to use RTI DDS for INOCS data transmissions. Due to this decision, we shall first determine the feasibility of using RTI DDS as INOCS high level middleware and ensure that it meets our critical expectations and requirements. In order to evaluate RTI DDS, we have performed some analysis considering two important Quality of Service (QoS) factors: the Latency and Sample Loss using different CPU loads, to estimate the performance of INOCS middleware in ordinary and extreme circumstances.

In the first section of this paper we review, survey and compare the main middleware types which are mostly used in distributed real-time applications, and then we illustrate the middleware architecture of INO340 control system and handling the commands based on the use of the DDS standard. We have chosen this design pattern based on our system requirements in terms of functional, design, performance, architectural, operational, interface, reliability and maintainability which are completely discussed in the next section of the paper. These requirements could be served as the reference requirements to the design and evaluation of any middleware for future telescope control systems. In the last section, we present and discuss the different experimental results performed to evaluate the middleware implementation in INOCS based on publish-subscribe paradigm and DDS standards.

9913-132, Session PS4

ASTRI SST-2M data reduction and reconstruction software on low-power and parallel architectures

Michele Mastropietro, INAF - Osservatorio Astronomico di Roma (Italy) and ASI Science Data Ctr. (Italy); Alberto Madonna, INAF - Osservatorio Astronomico di Roma (Italy) and Univ. degli Studi di Padova (Italy); Lucio A. Antonelli, INAF - Osservatorio Astronomico di Roma (Italy) and ASI Science Data Ctr. (Italy); Denis Bastieri, Istituto Nazionale di Fisica Nucleare (Italy) and Univ. degli Studi di Padova (Italy); Saverio Lombardi, INAF - Osservatorio Astronomico di Roma (Italy) and ASI Science Data Ctr. (Italy)

In the framework of the Cherenkov Telescope Array (CTA) International observatory, the Italian National Institute for Astrophysics (INAF) is leading the “Astrofisica con Specchi a Tecnologia Replicante Italiana” (ASTRI) project devoted to the development of a next generation of small-sized dual-mirror (SST-2M) Imaging Atmospheric Cherenkov Telescopes (IACTs). A prototype of the ASTRI SST-2M telescopes has been installed in Italy at the INAF “M. G. Fracastoro” Astronomical Station located at Serra La Nave on Mount Etna, Sicily, and will be operational by the first half of 2016. A mini-array of nine ASTRI SST-2M telescopes has been proposed to be installed at the southern site of the CTA, as an initial seed of the entire observatory. The ASTRI mini-array is a collaborative effort led by INAF (Italy) in synergy with the University of Sao Paulo and FAPESP (Brazil) and the North-West University (South-Africa).

IACTs are typically located in isolated places in order to avoid luminous sky background. In such a remote site, the capability of each telescope to process its own data before sending them to a central acquisition system provides a key advantage: carrying out preliminary data reduction on the telescope would greatly decrease the bandwidth and power required by an array installation.

We implemented the complete analysis chain required by a single ASTRI SST-2M telescope on an NVIDIA Jetson TK1, a development board equipped with an heterogeneous NVIDIA Tegra System-on-Chip. Leveraging its efficient Kepler GPU and the four ARM cores, we show, on Monte Carlo simulation bases, that it can process twice as much of the required data flow (more than 2000 events/s) with a power consumption lower than 10 W. This makes Jetson TK1 a promising embedded processing module for the on-line data analysis of gamma-ray astronomy with Imaging Atmospheric Cherenkov Telescopes.

9913-135, Session PS4

Towards a dynamical scheduler for ALMA: a science-software collaboration

Jorge Avarias, ALMA (Chile) and National Radio Astronomy Observatory (United States); Ignacio Toledo, Daniel Espada, ALMA (Chile); Rafael Hiriart, John E. Hibbard, National Radio Astronomy Observatory (United States); Lars-Åke Nyman, ALMA (Chile)

State-of-the art astronomical facilities are costly to build and operate, hence it is essential that these facilities must be operated as much efficiently as possible, trying to maximize the scientific output and at the same time minimizing overhead times. Over the latest decades the scheduling problem has drawn attention of research because new facilities have been demonstrated that is unfeasible to try to schedule observations manually, due the complexity to satisfy the astronomical and instrumental constraints and the number of scientific proposals to be reviewed and

evaluated in near real-time. In addition, the dynamic nature of some constraints (i.e. the weather parameters and the uncertainty of completing an observation) makes this problem even more difficult.

The Atacama Large Millimeter/submillimeter Array (ALMA) is a major collaboration effort between European (ESO), North American (NRAO) and East Asian countries (NAOJ), under operations on the Chilean Chajnantor plateau, at 5.000 meters of altitude. Currently, it is the largest radio-telescope on Earth, it has 66 antennas of 12-meter and 7-meter diameter, distributed over a wide extension, with up to 16 kilometers of baseline separation. The ALMA interferometer will provide the possibility to be used as a single array, or as up to six minor independent logical arrays or groups of antennas. Over the observing season multiples arrays configurations could be available. This is achieved by moving the antennas from one predefined position to another. During normal operations at least two independent arrays are available, aiming to achieve different types of science. Since ALMA does not observe in the visible spectrum, observations are not limited to night time only, thus a 24/7 operation with little downtime as possible is expected when full operations state will have been reached. However, during preliminary operations (early-science) ALMA has been operated on tied schedules using around half of the whole day-time to conduct scientific observations.

The purpose of this paper is to explain how the observation scheduling and its optimization is done within ALMA, giving details about the problem complexity, its similarities and differences with traditional scheduling problems found in the literature. The paper delves into the current recommendation system implementation and the difficulties found during the road to its deployment in production.

9913-138, Session PS4

Software design and code generation for the engineering graphical user interface of the ASTRI SST-2M prototype for the Cherenkov Telescope Array

Claudio Tanci, INAF - Osservatorio Astronomico di Brera (Italy) and Univ. degli Studi di Perugia (Italy); Gino Tosti, Elisa Antolini, Giorgio F. Gambini, Univ. degli Studi di Perugia (Italy); Rodolfo Canestrari, INAF - Osservatorio Astronomico di Brera (Italy); Vito Conforti, INAF - IASF Bologna (Italy); Saverio Lombardi, INAF - Osservatorio Astronomico di Roma (Italy); Federico Russo, INAF - Osservatorio Astrofisico di Torino (Italy); Pierluca Sangiorgi, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Salvatore Scuderi, INAF - Osservatorio Astrofisico di Catania (Italy)

ASTRI is an on-going project developed in the framework of the Cherenkov Telescope Array (CTA).

An end-to-end prototype of a dual-mirror small-size telescope (SST-2M) has been installed at the INAF observing station on Mt. Etna, Italy. The next step is the development of the ASTRI mini-array composed of nine ASTRI SST-2M telescopes proposed to be installed at the final CTA southern site. The ASTRI mini-array is a collaborative effort led by the National Institute of Astrophysics INAF (Italy) in partnership with the University of Sao Paulo and FAPESP (Brazil) and the North-West University (South-Africa).

To control the ASTRI telescopes, a specific ASTRI Mini-Array Software System (MASS) was designed using a scalable and distributed architecture to monitor all the hardware devices for the telescopes. MASS is built upon the ALMA Common Software (ACS) framework, which provide support in the implementation of monitoring and control of distributed systems, and uses the Open Platform Communication Unified Architecture (OPC-UA) protocol for the interface with the telescope components. MASS is being tested on the ASTRI SST-2M end-to-end prototype.

Using code generation we built automatically from the ASTRI Interface Control Documents a set of communication libraries and extensive Graphical User Interfaces that provide full access to the capabilities offered by the telescope hardware subsystems for testing and maintenance. Leveraging these generated libraries and components we then implemented a human designed, integrated, Engineering GUI for MASS to perform the verification of the whole prototype and test shared services such as the alarms, configurations, control systems, and scientific on-line outcomes.

9913-142, Session PS4

A friction observing and compensating method based on data fusing in telescope controller design

Qiang Wang, Institute of Optics and Electronics (China)

In this paper, a friction identifier and compensator is proposed. Friction is a major disturbance of median or large volume telescope. But the dynamic friction can hardly be measured directly. This paper propose a method to observe the dynamic friction based on data fusing. And used the observed result to identify friction's parameters of LuGre model. A compensator based on these parameters is then designed to compensate the friction. Finally the experiment result is proposed.

9913-146, Session PS4

A real-time prediction system for solar weather based on magnetic nonpotentiality (I)

Xiao Yang, Xin Huang, Ganghua Lin, Yuanyong Deng, National Astronomical Observatories (China)

The Sun is the source of space weather. The influence of the solar-terrestrial space environment on human life has become more and more direct. The characteristics and evolution of the solar active-region magnetic field closely relate to violent solar eruptions such as flares and coronal mass ejections. Vector magnetic-field observation is the observational basis of studying the physical properties of solar atmosphere and the theoretical models of solar activities. The Solar Magnetic Field Telescope in Huairou Solar Observing Station has accumulated numerous vector magnetogram data of solar photospheric active regions (AR) covering nearly 30 years. Utilizing these precious historical data to establish statistical prediction models for solar eruptive events, not only can provide a reference for the timely adjustment of observation mode to specific active regions, but also can offer valuable reference to the monitoring and forecasting departments of solar and space weather. In this part of work, we focus on the Yes/No and occurrence time predictions for AR-related solar flares, and the predictions independently rely on the vector magnetic-filed observation of the solar surface.

9913-148, Session PS4

Use cases to elicit the software requirements analysis within the ASTRI project

Vito Conforti, INAF - IASF Bologna (Italy); Elisa Antolini, Univ. degli Studi di Perugia (Italy); Giacomo Bonnoli, INAF - Osservatorio Astronomico di Brera (Italy); Pietro Bruno, INAF - Osservatorio Astronomico di Catania (Italy); Andrea A. Bulgarelli, INAF - IASF Bologna (Italy);

Milvia Capalbi, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Valentina Fioretti, INAF - IASF Bologna (Italy); Dino Fugazza, INAF - Osservatorio Astronomico di Brera (Italy); Daniele Gardiol, INAF - Osservatorio Astronomico di Torino (Italy); Alessandro Grillo, Giuseppe Leto, INAF - Osservatorio Astrofisico di Catania (Italy); Saverio Lombardi, Fabrizio Lucarelli, INAF - Osservatorio Astronomico di Roma (Italy); Maria C. Maccarone, INAF - Istituto Nazionale di Astrofisica (Italy); Giuseppe Malaguti, INAF - IASF Bologna (Italy); Giovanni Pareschi, INAF - Osservatorio Astronomico di Brera (Italy); Federico Russo, INAF - Osservatorio Astrofisico di Torino (Italy); Pierluca Sangiorgi, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Joseph Schwarz, INAF - Osservatorio Astronomico di Brera (Italy); Salvatore Scuderi, INAF - Osservatorio Astrofisico di Catania (Italy); Claudio Tanci, Gino Tosti, Univ. degli Studi di Perugia (Italy); Massimo Trifoglio, INAF - IASF Bologna (Italy); Stefano Vercellone, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Ricardo Zánmar Sánchez, INAF - Osservatorio Astrofisico di Catania (Italy)

The Italian National Institute for Astrophysics (INAF) is leading the Astrofisica con Specchi a Tecnologia Replicante Italiana (ASTRI) project aimed at the realization of a telescope for one of the small size class of telescopes (SST) for the Cherenkov Telescope Array (CTA). The first goal of the ASTRI project has been the development and operation of an innovative end-to-end telescope prototype using a dual-mirror optical configuration (SST-2M) equipped with a camera based on silicon photo-multipliers. The ASTRI SST-2M prototype has been installed in Italy at the INAF "M.G. Fracastoro" Astronomical Station located at Serra La Nave, on Mount Etna, Sicily. This prototype has been used to test several mechanical, optical, control hardware and software solutions which will be used in the ASTRI mini-array, comprising nine SST-2M telescopes to be placed at the CTA southern site. The ASTRI mini-array is a collaborative effort led by INAF in synergy with the University of Sao Paulo and FAPESP (Brazil) and the North-West University (South-Africa). We present here the use cases, through UML diagrams and text details, that describe the functional requirements of the software that will manage the ASTRI SST-2M prototype, and the lessons learned thanks to these activities. We intend to adopt the same approach for the Mini Array Software System (MASS) that will manage the ASTRI mini-array operations. Use cases are of importance for the whole software life cycle, in particular they provide valuable support to the validation and verification activities. Following the iterative development approach, which breaks down the software development into smaller chunks, we have analysed the requirements, developed and tested the code in repeated cycles. The use case technique allowed us to formalize the problem through user stories that describe how the actor procedurally interacts with the software system. Through the use cases we improved the communication among team members, fostered common agreement about system requirements, defined the normal and alternative course of events, understood better the business process, and defined the system test to ensure that the delivered software works properly.

We present a summary of the ASTRI SST-2M prototype use cases, and how the lesson learned can be exploited for the ASTRI mini-array proposed for the CTA Observatory.

9913-150, Session PS4

M&C Domain Map Maker: an environment complimenting MDE with M&C knowledge ensuring solution completeness

Subhrojyoti R. Choudhury, Tata Consultancy Services, Ltd. (India); Swaminathan Natarajan, Tata Consultancy Services, Ltd. (India); N.R. Mohan, National Ctr. for Radio Astrophysics (India); Amar Banerjee, Tata Research Development and Design Ctr. (India); Puneet Patwari, Tata Consultancy Services, Ltd. (India); Rajiv Banerjee, National Ctr. for Radio Astrophysics (India)

The role of Model Driven Engineering (MDE) as a key driver to reduce development cost of M&C systems is beginning to find acceptance across scientific instruments such as ITER, SKA and other projects. Such projects are adopting it to reduce time to integrate, test and simulate their individual controllers and increase reusability and traceability in the process. Although there is significant tool support with MDE towards the creation of domain-models, there is still gap in the way the models are identified. We argue that the key factors influencing the definition of these models are knowledge about the M&C engineering lifecycle. This knowledge exists not just implicitly but also in silos in the minds of specialist such as M&C architects, engineers, commissioners, operators, maintainers and so on. This is evidenced by our previous works both carried out in the context of Square Kilometer Array (SKA): a) implementation of an integrated M&C design, testing and simulation framework b) development of a framework to capture the running state of the telescope to reason about the telescope status. Both work involved a collection of domain models specific to M&C design, testing and operations. The models supporting the design and testing were interconnected that allowed derivation of much of the input related to testing from the captured design. This reduced effort towards testing and simulation and also enhanced traceability between the design and testing phase. The runtime framework was implemented independently which too pointed towards the need for an integrated M&C domain model since the runtime view of the telescope needed to be in sync with its design view. This strongly indicated the need for an integrated M&C engineering domain model that enabled analysis and verification of the output created across all engineering phases. However, we saw a clear lack of process that enabled the creation of such an integrated domain model.

We feel that this can be done by linking MDE with problem domain knowledge. The complementary domain knowledge will ensure completeness and consistency in the defined domain-models and hence in the final solutions which the current MDE practice does not guarantee. This can be achieved through: a) explicating the domain knowledge b) using it as a basis to define the domain-models and their relations. Although there are environments that allow performing a and b independently, there is no process that connects the two. To mitigate this, we have come up with M&C Domain Map Maker, a set of processes and tools that enables explication of M&C domain knowledge in terms of domain models with mutual consistency relations. This paper discusses this approach.

9913-152, Session PS4

The RTE inversion on FPGA aboard the solar orbiter PHI instrument

Juan Pedro Cobos Carrascosa, Instituto de Astrofísica de Andalucía - CSIC (Spain); Beatriz Aparicio del Moral, J. Luis Ramos, Maria Balaguer, Antonio Lopez, Instituto de Astrofísica de Andalucía (Spain); Jose Carlos del Toro Iniesta, Instituto de Astrofísica de Andalucia (Spain)

SO/PHI (Solar Orbiter Polarimetric and Helioseismic Imager) is a

filtergraph-based, solar magnetograph aimed at mapping the vector magnetic field and the line-of-sight (LOS) velocity of the solar photospheric plasma. It belongs to the scientific payload of the European Space Agency's Solar Orbiter mission which will orbit the Sun at 0.28 astronomical units.

The limited telemetry rate combined with the large amount of scientific information retrieved by the SO/PHI instrument demand a sophisticated on-board data reduction and scientific analysis through the study of the polarization state of a specific spectral line. The main aim is to perform the complicated algorithm needed to translate the polarization state of the light spectrum in terms of some specific solar parameters like the magnetic field vector and velocity. Technically speaking, the inference of the solar physical quantities through a spectropolarimetric study is based on the inversion of the Radiative Transfer Equation (RTE) and these tasks require the processing of a huge quantity of data in parallel.

The RTE inverter is the core of the on-board scientific data analysis and, probably, one of the most innovative parts of the instrument. Due to the unavailability of qualified for space processors, DSPs, or GPGPUs that fulfil the stringent computational requirements with the limited room and power consumption allocated to the instrument, a specifically designed hardware device has been implemented in SO/PHI. This device is in charge of inverting the RTE aboard Solar Orbiter under narrow time and power constraints.

The main aim of this work is to design, build, and test such a hardware device for SO/PHI. With that goal in mind, we propose a high-performance computing architecture for carrying out the RTE inversion using FPGA devices embedded in the SO/PHI instrument.

The computing proposal consists of a SIMD multiprocessor architecture to reach high performance in floating point operations. This architecture on a Virtex-4 FPGA squeezes the FPGA resources in order to reach the time constraints. It is focused in exploiting the data parallelism using several processors working together and using different data streams. One of the most important contributions of this architecture is the ability of saving resources allocating operation cores in a shared operation block, which is accessed by every processor. Some details for extending the architecture to other problems are pointed out.

Using the SIMD architecture, the challenge of carrying out the RTE inversion in less than 15 minutes has been reached. The architecture has not only demonstrated that is able to do it but it is also improves the computing capabilities of ground systems by more than ten times using a relatively slow (and 10 year-old) Virtex-4 FPGA device.

The RTE inverter prototype has been tested using real images taken by another instrument. It is able of working as accurately as usual computers regarding the scientific precision. In addition, it has satisfied the stringent requirements of power consumption and processing time.

9913-154, Session PS4

Knowledge-based engineering of a PLC controlled telescope

Wim Pessemier, Gert Raskin, KU Leuven (Belgium); Philippe Saey, KAHO Sint-Lieven (Belgium); Hans Van Winckel, Geert Deconinck, KU Leuven (Belgium)

As the new control system of the Mercator Telescope is being finalized, we can review some technologies and design methodologies that are advantageous, despite their relative uncommonness in astronomical instrumentation. Particular for the Mercator Telescope is that it is controlled by a single high-end soft-PLC (Programmable Logic Controller). Using off-the-shelf components only, our distributed embedded system controls all subsystems of the telescope such as the pneumatic primary mirror support, the hydrostatic bearing, the telescope axes, the dome, the safety system, and so on. We show how real-time application logic can be written conveniently in typical PLC languages (IEC 61131-3) and in C++ (to implement the pointing kernel) using the commercial TwinCAT 3 programming environment. This software processes the inputs and outputs of the distributed system in real-time via an observatory-wide EtherCAT network, which is synchronized with high precision to an IEEE 1588 (PTP, Precision Time Protocol) time reference clock. Taking full advantage of the ability of soft-PLCs to run both real-time and non real-time software, the same device also hosts the most important user interfaces (HMIs or Human Machine Interfaces) and communication servers (OPC UA for process data, FTP for XML configuration data, VNC for remote control, and HTTP for web-based interfaces). To manage the complexity of the system and to streamline the development process, we show how most of the software, electronics and systems engineering aspects of the control system have been modeled as a set of scripts written in a Domain Specific Language (DSL). When executed, these scripts populate a Knowledge Base (KB) which can be queried to retrieve specific information. By feeding the results of those queries to a template system, we were able to generate very detailed "browsable" web-based documentation about the system, but also PLC software code, Python client code, model verification reports, etc. The aim of this paper is to demonstrate the added value that technologies such as soft-PLCs and DSL-scripts and design methodologies such as knowledge-based engineering can bring to astronomical instrumentation.

9913-157, Session PS4

Aided generation of search interfaces to astronomical archives

Sonia Zorba, Andrea Bignamini, Francesco Cepparo, Cristina Knapic, Marco Molinaro, Riccardo Smareglia, INAF - Osservatorio Astronomico di Trieste (Italy)

Astrophysical data provider organizations nearly always host web portals or web based interfaces providing public or restricted access to the data resources they manage.

Changes in the discovery logic, supported capabilities or data collections, results data formats or data access policies affect interface maintenance.

Each time one such change happens it could be necessary to rewrite search logic in the databases or modify the arrangement or elements of a web form, potentially on different web portals.

This takes time and is also error prone, so a standardized and reliable way to manage this issue was sought for.

It was thus decided to develop a dynamically configurable Java EE web application that can set itself up reading needed information from XML configuration files.

Specification of what information the astronomical archive database has to expose is managed using the TAP_SCHEMA schema from the IVOA TAP recommendation.

The TAP_SCHEMA lists which tables and columns are included in the service but also provides a way to store useful metadata like UCDs (Unified Content Descriptors), descriptions, units and so on.

To improve user experience and to allow tool usage also to people that don't have particular SQL skills a graphical interface has been developed that can be used to create or edit a TAP_SCHEMA instance.

This interface also includes a panel to perform search and validation of UCDs based on Strasbourg astronomical Data Center (CDS) dedicated services.

After setting up and populating the desired TAP_SCHEMA the user can specify what tables and columns should be involved in building the search query, how these elements have to be arranged in a form based web page and if the generated search interface should contain specific auxiliary elements like a text input to perform object name to position resolving, or explicit VO compliant output or other custom tool (e.g. a preview capability for datasets).

The configuration file will store also information about the database connection details, custom portal style elements (background images or

logos), and elements keeping track of which table fields store information concerning users accounts and web service logs.

The user of this tool, managing portal generation, will be able to do all of this directly editing the configuration file but it is also planned to code a wizard helper for generating this file in a graphical way.

When configuration steps are done the tool will build a war file to allow easy deployment of the application in (possibly different) web containers.

The XML configuration file can be saved for future editing and quick re-use.

9913-159, Session PS4

Single sign-on with Shibboleth in the MAST discovery portal

Thomas Donaldson, Anthony Rogers, Space Telescope Science Institute (United States)

The Mikulski Archive for Space Telescopes (MAST) is the official data archive for more than 15 missions, including HST, Kepler, GALEX, FUSE, IUE, EUVE, Swift and XMM. MAST's Discovery Portal is a rich web application for exploring data from all of those missions. The portal can also search and retrieve data from the Virtual Observatory (VO), thus provided one-stop access to a wide variety of other resources such as Spitzer, Chandra, 2MASS, WISE, Simbad and NED. By including search results for multiple missions, the Discovery Portal not only simplifies searching for known data, it facilitates the discovery of data previously unknown to the user.

Most of the MAST and VO data is public, so using the MAST Discovery Portal does not require a login. However, there are two main reasons why the Portal needs to provide a login capability. The first is that some data has access restrictions, such as HST and JWST data still within the proprietary period. Retrieval of such data must require both authentication and authorization of users. The second main purpose for user authentication is to allow search history and preferences to be saved for later use.

Shibboleth is a system that not only enables login to a single web page, but also provides single sign-on (SSO) capabilities for a set of protected web pages and services. That is, once a user logs into one of those web pages, the other pages and services can be accessed without logging in again. SSO will allow MAST Portal users to access other STScI services such as proposal preparation and grants management without needed to manage multiple accounts or logins.

In addition to managing users within an organization, Shibboleth can be configured to recognize users from other organizations. This federating of user identities is potentially a powerful feature for academic web sites such as the MAST Portal since Shibboleth is widely used by academic and scientific organizations.

While the SSO and user federation benefits are clear, Shibboleth is a challenging system to set up and manage. For example, it originally did not support sites that allowed anonymous access, so handling of those sites now is a bit clumsy. Another challenge lies in the complexity of the handshaking sequence required for user authentication. Web browsers hide much of this complexity from users and programmers alike, but when the service access is via Ajax calls from the browser, or from non-browser clients, the complexity cannot be escaped.

By relating our experiences in setting up SSO for the MAST Discovery Portal, we will illustrate several of the challenges facing both web developers and system administrators as they enable single-sign on for their organization.

9913-160, Session PS4

A control system framework for the Hobby-Eberly Telescope

Jason Ramsey, Niv Drory, Randy Bryant, Linda Elliott, James R. Fowler, Gary J. Hill, Martin Landriau, Ronnie Leck, Brian L. Vattiat, The Univ. of Texas at Austin (United States)

We present the development framework for the distributed control systems, scripting frontend, and monitoring facilities of the recently upgraded Hobby-Eberly Telescope (HET). A common flexible control and data acquisition layer in C++, with message passing implemented on top of ZeroMQ, wraps the final designs of each new hardware component including tracking, metrology, instrumentation and calibration equipment. A homogeneous command, response and event layer normalizes the diversity of the lower level software interfaces easing the development of the Telescope Control System (TCS). Applications developed in the framework easily interface to the new tracker and legacy instrumentation of the primary mirror, weather, dome, and tracker support structure. We demonstrate the framework's use in facilitating testing, vetting, and characterization of the telescope and TCS. Examples of the real-time monitoring capabilities and Python scripting methods of various telescope components are given. Lessons learned along the way, future refinements, and anticipated enhancements, are detailed.

9913-162, Session PS4

A user interface framework for the Square Kilometre Array: concepts and responsibilities

Alessandro Marassi, INAF - Osservatorio Astronomico di Trieste (Italy); Mark Nicol, UK Astronomy Technology Ctr. (United Kingdom); Gerhard Le Roux, SKA South Africa (South Africa); Valentina Alberti, INAF - Osservatorio Astronomico di Trieste (Italy); Giorgio Brajnik, Univ. degli Studi di Udine (Italy)

The Square Kilometre Array (SKA) project is responsible for developing the SKA Observatory, the world's largest radio telescope, with eventually over a square kilometre (one million square metres) of collecting area and including a general headquarters as well as two radio telescopes, SKA1-Mid in South Africa and SKA1-Low in Australia. The SKA project consists of a number of subsystems (elements) among which the Telescope Manager (TM) is the one involved in controlling and monitoring the SKA telescopes.

The TM element has three primary responsibilities:

Management of astronomical observations;

Management of telescope hardware and software subsystems;

Management of data to support system operations and all stakeholders (operators, maintainers, engineers and science users) in achieving operational, maintenance and engineering goals.

Operators, maintainers, engineers and science users will interact with TM via proper user interfaces (UI).

The TM G/UI framework envisaged is a complete set of technical solutions (components, technologies and design information) for implementing a generic computing system (GUI platform). Such a system will enable G/UI components to be instantiated, allow for human interaction via screens, keyboards, mouse and implement the necessary logic for acquiring or deriving the information needed for interaction. It will provide libraries and specific Application Programming Interfaces (APIs) to implement operator and engineer interactive interfaces.

This paper will provide a status update of the TM G/UI framework, platform and components design effort, including the technology choices and discuss key challenges in the TM G/UI architecture, and our approaches to addressing them.

User Interface (UI) design is an iterative process that involves close liaisons between users and designers. It covers topics, ranging from usage-centered design during analysis and design, through to testing and validation, in later application lifecycle phases. This involves deriving shared principles, practices, methods and the tools to support the effective participation of different development teams in the design of a well-integrated User Interface to the SKA systems.

Currently the three core activities in this process are:

User and task analysis. Understanding what the users will do with the system;

System prototyping. Develop a series of prototypes for experimentation;

Interface evaluation. Experiment with these prototypes with users.

The TM design activity in general relies on usability prototyping as a core part of defining the design needs for the wider system. It is important to have early users' feedback in the software design and development lifecycle and also to elicit new requirements, validate existing requirements, and highlight possible critical interactions.

Within the TM UI work-stream, prototyping is also a key tool for the evaluation of technologies. Based on the lessons learned, and specific UI analysis conducted by precursor sites (MeerKAT, ASKAP, ALMA, LOFAR), a set G/UI tools has been selected and they are being analyzed against SKA TM requirements. The set includes TANGO tools (e.g. Taurus and Sardana) and general UI frameworks (such as AngularJS, Django, PyQT, PyTango, and TurboGears).

This report summarizes both some of the key principles and stages of this process and the early results from this work.

9913-163, Session PS4

Manipulating SITELLE's data: reduction, extraction, and visualization of huge hyperspectral datasets

Thomas Martin, Laurent Drissen, Univ. Laval (Canada)

We present the latest development and testing results of the data manipulation suite of softwares used to handle SITELLE's data obtained at the Canada-France-Hawaii telescope (CFHT), during the commissioning run (August 2015) and the Science Verification phase (January 2016). SITELLE is an imaging Fourier transform spectrometer (iFTS), designed to obtain the spectrum of extended emission-line sources in a 11x11 arcminute field of view, with a spatial sampling of 0.32 arcsecond/pixel, in selected bandpasses of the visible range (350 - 850 nm). Large hyperspectral datasets of up to 32 Go of various objects have been obtained and successfully reduced with higher than expected speed performances. The software suite primarily used and developed with SpIOMM, a prototype installed at Mont-Mégantic, now adapted to SITELLE and integrated at CFHT is composed of IRIS, a real-time image analysis software designed to compute and display statistical facts during the observations for the CFHT remote observer; ORBS, the data reduction pipeline; ORCS, a data extraction software designed to fit models on interferometric and spectral cubes and 2D/3D viewers for real-time data exploration and analysis. Major improvements are reviewed and discussed for each software. We also show that the success of the integration at CFHT and the synergy between SITELLE's softwares relies on a simple and coherent object-oriented onion-layered architecture based on a carefully designed and versatile core module (ORB).

9913-164, Session PS4

Queue software reuse and implementation at the Large Binocular Telescope Observatory

Igor Suarez Sola, Douglas M. Summers, Joseph A. Astier, Michelle L. Edwards, Christian Veillet, Andrew Cardwell, Jennifer Power, Share Walsh, Large Binocular Telescope Observatory (United States)

In this paper we detail the process the LBTO followed to chose software for reuse and modification to support binocular queue operations. We outline the survey of initial candidate solutions, how and why the final selection was made, and describe our requirements gap analysis for LBTO binocular use. We provide details of our software development approach including a project road-map and phased release strategy. We provide details of added LBTO functionality, discuss issues, and suggest some reuse lessons learned. We conclude with discussion of known desired enhancements to be addressed in future release cycles.

9913-165, Session PS4

The Infrared Imaging Spectrograph (IRIS) for TMT: data reduction system

Gregory Walth, Shelley A. Wright, Univ. of California, San Diego (United States); Jason L. Weiss, James E. Larkin, Univ. of California, Los Angeles (United States); Anna M. Moore, Caltech Optical Observatories (United States); Edward L. Chapin, NRC - Herzberg Astronomy & Astrophysics (Canada); Tuan Do, Univ. of California, Los Angeles (United States); Jennifer S. Dunn, NRC - Herzberg Astronomy & Astrophysics (Canada); Kim Gillies, Thirty Meter Telescope (United States); Yutaka Hayano, Advanced Technology Ctr., NAOJ (Japan); Christopher A. Johnson, Univ. of California, Los Angeles (United States); Daniel Marshall, Univ. of California, San Diego (United States); Luc Simard, NRC - Herzberg Astronomy & Astrophysics (Canada); Ji Man Sohn, Univ. of California, Los Angeles (United States); Ryuji Suzuki, Advanced Technology Ctr., NAOJ (Japan); James E. Wincentsen, California Institute of Technology (United States)

IRIS (InfraRed Imaging Spectrograph) is the diffraction-limited first light instrument for the Thirty Meter Telescope (TMT) that consists of a near-infrared (0.84 to 2.4 micron) imager and integral field spectrograph (IFS). The IFS makes use of a lenslet array and slicer for spatial sampling, which will be able to operate in 100's of different modes, including a combination of four plate scales from 4 milliarcseconds (mas) to 50 mas with a large range of filters and gratings. The imager will have a total field of view of 32.8 x 32.8 arcsec^2 with a plate scale of 4 mas with many selectable filters. We present the preliminary design of the data reduction system (DRS) for IRIS. Reduction of IRIS data will have unique challenges since it will provide real-time reduction and analysis of the imaging and spectroscopic data during observational sequences, as well as advanced post-processing algorithms. The DRS will support three basic modes of operation of IRIS; reducing data from the imager, the lenslet array, and slicer IFS. The DRS will include the following modules: sky/dark subtraction, correction of detector artifacts, correction of cosmic rays, flat fielding, spectral extraction, wavelength solution, cube assembly, residual atmospheric correction, flux calibration, telluric correction, PSF calibration, distortion solutions, and advanced shift and add. The DRS will be written in

Python, making use of the plethora of open-source astronomical packages available. In addition to real-time data reduction, the DRS will utilize real-time visualization tools, providing astronomers with up-to-date evaluation of the target acquisition and data quality. The Quicklook suite of tools will include visualization of the 1D, 2D, and 3D raw and reduced images. We will discuss the overall requirements of the DRS and visualization tools, as well as the necessary calibration data to achieve optimal data quality in order to exploit science cases across all cosmic distance scales.

9913-166, Session PS4

The QuickReduce data processing pipeline for the WIYN one degree imager

Ralf Kotulla, Univ. of Wisconsin-Madison (United States); Daniel R. Harbeck, Wilson M. Liu, WIYN Observatory (United States)

The QuickReduce pipeline for the WIYN One Degree Imager (ODI) started out as a quick-look pipeline to assist with instrument commissioning, and over time evolved into the main instrument pipeline now delivering science-ready data. We will highlight several of its components that were developed especially for ODI, but can now also be applied to other wide-field imagers with one or more detectors: 1) a highly flexible cross-talk correction accounting for variations of cross-talk coefficients between detectors, source area and affected target area; 2) an efficient and effective method to derive fringing amplitude across detectors even in the presence of contaminating sources; 3) a fast, easily parallelized implementation of the la_cosmic algorithm for cosmic ray rejection. 4) a new strategy to derive a pupilghost correction template, compensating for numerous gaps in the focal plane, and powerful enough to compensate for shifts and rotation with respect to the focal plane; 5) a data association framework, allowing to trace each exposure back to its input data, and the input data back to its input data, providing full data provenance for each frame back to all contributing raw data and software components.

Combined with the optimized and highly parallelized implementation of the reduction workflow, written entirely in python, this allows generation of fully calibrated, science-ready data, as well as accompanying and describing data quality information, on a time-scale similar to that between exposures at the telescopes. We will also present changes made to the pipeline to accommodate the upgraded 5x6 detector focalplane. Finally, we illustrate where and how QuickReduce is embedded into the overall ODI dataflow, from providing quick-look data at the telescope to providing data reduction capabilities to both archive operator and archive user via the ODI Portal, Pipeline, and Archive.

9913-167, Session PS4

Key software architecture decisions for the automated planet finder

Kyle Lanclos, W. M. Keck Observatory (United States); William T. S. Deich, Bradford P. Holden, Steve L. Allen, Univ. of California Observatories (United States)

The Automated Planet Finder (APF) at Lick Observatory on Mount Hamilton is a modern 2.4 meter computer-controlled telescope. At one Nasmyth focus is the Levy Spectrometer, at present the sole instrument used with the APF. The primary research mission of the APF and the Levy Spectrometer is high-precision Doppler spectroscopy. Observing at the APF is unattended; custom software written by diverse authors in diverse languages manage all aspects of a night's observing.

This paper will cover some of the key software architecture decisions made in the development of autonomous observing at the APF. The relevance to future projects of these decisions will be emphasized throughout.

9913-168, Session PS4

AVU/BAM: software refurbishment (design and implementation) for the CU3 gaia verification pipeline

Raffaella Buzzi, Alberto Riva, INAF - Osservatorio Astrofisico di Torino (Italy); Marco Pecoraro, Enrico Licata, euriX (Italy); Rosario Messineo, ALTEC SpA (Italy)

AVU/BAM is the Gaia software for the Astrometric Verification Unit devoted to the monitoring of the Basic Angle Monitoring (BAM), one of the metrology instruments onboard of the Gaia Payload.

AVU/BAM is integrated and operative at the Data Processing Center of Turin (DPCT), since the beginning of the Gaia Mission.

The DPCT infrastructure performs the ingestion of pre-elaborated data coming from the satellite and it's responsible of running the code of different Verification Packages.

In this paper we are presenting a structural refactoring of the code.

The new structure of the pipeline consists of three phases: the first is a pre-analysis in which a preliminary study data is performed, with the calculation of quantities needed to the analysis; the second one (configured for a parallel run on multiple nodes) processes the interferograms coming from the two Field of View of the couples of images; the third phase analyzes the data obtained from the previous processing.

Also it has been changed part of the long-term analysis and was added a phase of calibration of the data obtained from the processing.

With this new structure we achieved a significant reduction of processing time, allowing to add new analyses within the time processing constraints.

9913-169, Session PS4

Image X: new and improved image explorer for astronomical images and beyond

Soichi Hayashi, Arvind Gopu, Indiana Univ. (United States); Ralf Kotulla, Univ. of Wisconsin-Madison (United States); Michael D. Young, Indiana Univ. (United States)

The One Degree Imager - Portal, Pipeline, and Archive (ODI-PPA) has included the Image Explorer interactive image visualization tool since it went operational. Portal users were able to quickly open up several ODI images within any HTML5 capable web browser, adjust the scaling, apply color maps, and perform other basic image visualization steps typically done on a desktop client like DS9. However, the original design of the Image Explorer required lossless PNG tiles to be generated and stored for all raw and reduced ODI images thereby taking up tens of TB of spinning disk space even though a small fraction of those images (< 5%) were being accessed by portal users at any given time. It also required a heavy web application to be included within a web portal like ODI-PPA (thereby making it hard to merge in improvements made to a similar deployment in another project's portal), and served the image tiles via the Apache webserver used by the rest of the portal (which was sub-optimal). To address this and other concerns, we redesigned Image Explorer from scratch and came up with Image X, a set of microservices that are part of the Trident software suite, with extensive interactive visualization and analysis capabilities required for ODI data and beyond. We generate a full resolution JPEG image for each corresponding raw and reduced FITS image, one that can be rendered at various sizes as appropriate within the portal (for example: on tabular image listings, views allowing quick perusal of a set of thumbnails, and other initial 'image sifting' activities). Users are also able to request several layers of higher quality lossless PNG tiles similar to the ones used previously by Image Explorer version 1;

backend services pick up such requests, delegate the tile generation to an appropriate microservice while providing portal feedback to the user on the progress of this process. When ready, these tiles can be viewed in a manner similar to how users would on their desktop using a tool like DS9 without having to download Gigabytes of FITS image data. This design allows updates to the tile generation algorithms to be easily applied to any full tileset request. At any given time, only a small subset of images have full tilesets thereby dramatically decreasing the spinning disk requirements. Other improvements related to Image X include use of Docker containers to deploy backend services, use of AngularJS for the client side Model/View code (instead of depending on backend PHP Model/View/Controller code previously used), use of nginx and a lightweight NodeJS application to serve JPG and PNG tiles thereby significantly decreasing the Time To First Byte latency by a few orders of magnitude, and extension of the service for non-FITS images (for example: electron microscopy images).

9913-170, Session PS4

The ExoMars DREAMS scientific data archive

Pietro Schipani, Laurent Marty, Marco Mannetta, Francesca Esposito, Cesare Molfese, INAF - Osservatorio Astronomico di Capodimonte (Italy)

DREAMS is the autonomous surface payload package accommodated on the ExoMars 2016 Schiaparelli Entry and Descent Module (EDM). It is a meteorological station with the additional capability to perform measurements of the electric fields close to the surface of Mars. The EDM will reach Mars during the statistical dust storm season, so DREAMS will characterize the Martian environment in this dust loaded scenario. DREAMS will perform meteorological measurements by monitoring pressure, temperature, wind speed and direction, humidity and dust opacity during a Martian sol at the landing site; characterization of the Martian boundary layer in dusty conditions; hazard monitoring by providing a comprehensive dataset to help engineers to quantify hazards for equipment and human crew: velocity of windblown dust, electrostatic charging, existence of discharges, and electromagnetic. noise potentially affecting communications, intensity of UV radiation; the first ever investigation of atmospheric electric phenomena at Mars. The DREAMS data will be archived and distributed to the scientific community through the ESA's Planetary Science Archive (PSA). All data shall be compliant with NASA's Planetary Data System (PDS4) Standards for formatting and labelling files. This paper describes the format and content of the DREAMS data, including the descriptions of the data products and associated metadata. The generation pipeline to convert raw telemetries to final products for the archive is described as well.

9913-171, Session PS4

Image processing improvement for optical observations of space debris with the TAROT telescopes

Carole Thiebaut, Ctr. National d'Études Spatiales (France); Sebastien Theron, Magellium (France); Pascal Richard, Gwendoline Blanchet, Ctr. National d'Études Spatiales (France); Alain Klotz, Institut de Recherche en Astrophysique et Planétologie (France); Michel Boer, Univ. de Nice Sophia Antipolis (France)

Precise estimation of the satellites and debris trajectories is necessary to improve our knowledge of this population in order to preserve the space environment for the future. As a member of the Inter-Agency Space Debris Coordination Committee (IADC), CNES is involved in the worldwide coordination of activities related to the issues of man-made and natural debris in space. Since 2004, CNES has been observing space debris with a network of two robotic ground based fully automated telescopes called TAROT (Telescopes à Action Rapide pour les Objets Transitoires; Rapid Response Telescopes for Transient Objects). The two TAROT telescopes are fully robotic optical observatories with optimized observation scheduling, automatic data processing and archiving primarily devoted to measure the early optical counterparts of gamma-ray bursts. One of them is located in France and the second at ESO, La Silla, Chile. The system processes the data in real time. Their wide field of view is useful for the discovery, the systematic survey and for the tracking of both catalogued and un-catalogued objects. In 2008, a new image processing algorithm based on morphological mathematic was tested and implemented in the standard pipeline [1]. This method correlates the measurements of the same object on successive images and gives better detection and false alarm rates than the previous one. The overall efficiency and quality of the survey of the geostationary orbit has been drastically improved and debris detection in different orbits was then possible. Nevertheless, as the main target was the geostationary satellites, this processing was limited to the processing of images taken with telescope mount motors turned off. In those images, stars appear as horizontal streaks, geostationary objects as dots and non-geostationary objects as streaks. This algorithm was not adapted for debris observation in debris tracking mode which is the preferred mode when observing debris with a previously known orbit, mainly because of its better detectability. In this last mode, the tracked debris appears to be a point-like object and the stars appear like streaks in a diagonal direction, the direction and the length of the streaks being known. To deal with this debris tracking mode, the image processing algorithm has been recently improved by using method described in [2]. In this paper we present the adaptation to TAROT images of this algorithm composed of different processing steps: background estimation and removal, stars detection and removal, debris detection. Some new steps have been introduced to process TAROT images artefacts due to mechanical problems in the debris tracking mode. We will then present results of the newly implemented algorithm which presents improvement in terms of false detection rate and allows the new track rate mode.

9913-172, Session PS4

The AVU/BAM usage and performances during the Gaia commissioning and early operations

Alberto Riva, Mario Gai, Mario G. Lattanzi, Ronald Drimmel, Raffaella Buzzi, Busonero Deborah, INAF - Osservatorio Astrofisico di Torino (Italy)

Gaia Satellite is the newest astrometric mission financed by Europe. It was launched the 19th of December 2013 and reached L2 in about 1 month. This paper describes the commissioning and early operations outcomes (first six months) of the metrology system dedicated to the Base Angle Variations output, as seen by the Astrometric Verification Unit (AVU), running at the Data Processing Center of Turin (DPCT - Italy).

Metrology results coming from the first six months of mission are slightly different from what expected.

The AVU/BAM software demonstrated to be able to cope with the different scenario.

We will describe the strong and the weak aspects of the AVU/BAM algorithms.

9913-173, Session PS4

DAS-SW: software for the characterization of H2RG detectors in Euclid NSIP instrument

Sylvain Ferriol, Institut de Physique Nucléaire de Lyon (France)

In 2020, the European Euclid satellite used to study the speed up of the universe expansion will carry the Near-Infrared Spectrometer and Photometer (NISP). This instrument is based on an array of 16 Teledyne H2RG detectors. IPNL (Nuclear Physics Institute of Lyon) is responsible to develop and validate the software of the ground characterization workflow for each of these detectors. The workflow has been designed to respect different analyzes such as dark current, noise, low and high flux. These studies must be chained and executed in 21 days per detector, this short timing induces the automatization of all the workflow, from the data acquisition to the pixels maps and characterization reports.

The Data Acquisition System Software (DAS-SW) has been developped to respect all theses requirements and especially to stored acquisition frames, the environment data and context metadata in simple, transportable container. HDF5 technology is a data model and a file format that make possible the management of all these heterogeneous complex data. For the easy way to develop and interface with other low level librairies, Python language has been choosen to manage and controll data flow.

Another major constraint is that DAS-SW must be able to run in different labs, on different characterization setups. They are composed by a cryostat controlled by a Lakeshore devices, an H2RG with its ASIC and warm electronic card associated (Teledyne SAM card or Markury Scientific board), different type of LEDs for illumination and multiple power supplies and sensors. This implies a maximum of genericity in the choice of data transport and protocol in DAS-SW environment. The Internet of Things is the chosen solution. The aim is to view all devices as a physical object connected to a local network using a simple, opened and normalized protocol such as WebSocket. It is a protocol providing full-duplex communication over a single TCP connection. WebSocket is implemented in plenty of languages and directly embedded in most major Web browsers, then it makes things easy to build clients to control, monitor, log data flow.

While WebSocket already is quite awesome, it is low-level. DAS-SW uses instead the Web Application Messaging Protocol (WAMP), which is based on WebSocket and provides two high-level communication patterns: “Remote Procedure Calls” (RPC) and “Publish & Subscribe”. WAMP enable DAS-SW to be distributed freely across process and devices according to characterization workflow functional aspects. WAMP is a routed protocol, so all messages are distributed via a router application and it avoids strong coupling between the Caller and the Callee like a basic client-server model.

On the acquisition part, DAS-SW can communicate with H2RG detector via its associated ASIC and makes a simple user API abstraction, hidding specific Warm Electronic communication and configuration.

DAS-SW Software run under Linux operating system.

9913-174, Session PS4

Thirty Meter Telescope narrow-field infrared adaptive optics system real-time controller preliminary architecture

Daniel A. Kerley, Malcolm Smith, Jennifer S. Dunn, Glen Herriot, Jean-Pierre Véran, NRC - Herzberg Astronomy & Astrophysics (Canada); Luc Gilles, Corinne Boyer, Lianqi Wang, Brent L. Ellerbroek, Thirty Meter Telescope (United States)

The Narrow Field Infrared Adaptive Optics System (NFIRAOS) is the first light AO System for the Thirty Meter Telescope (TMT). NFIRAOS is a laser guide star multi-conjugate AO (MCAO) system that corrects atmospheric and telescope image aberrations over a two arc-minute field of view in the near infrared. It will be located on the Nasmyth platform and will feed light to any one of three selectable instruments. NFIRAOS performs wavefront correction using two deformable mirrors (DM) conjugated to 0km and 11.8km, with one DM mounted on a tip/tilt stage (TTS). Within NFIRAOS are six laser guide star Shack-Hartmann wavefront sensors (LGS WFS) and one high-order natural guide star pyramid wavefront sensor (PWFS). Addition wavefront information is provided to NFIRAOS by up to three Shack-Hartmann wavefront sensors (OIWFS) located in the science instruments, and up to four on-detector guide windows (ODGW) on the science imager. Wavefront information from these detectors is processed by the NFIRAOS Real-Time Controller (RTC) to compute the DM and TTS commands. The National Research Council of Canada Herzberg, Astronomy and Astrophysics Programs (NRC-H) has developed a preliminary design for NFIRAOS RTC.

The NFIRAOS RTC is comprised of several quad-socket Linux-based servers. These servers are assigned various roles including: the High-Order Processing (HOP) servers, the Wavefront Corrector Controller (WCC) server, the Telemetry Engineering Display (TED) server, the Persistent Telemetry Storage (PTS) server, and in addition testing and spare servers.

There are up to six HOP servers that accept LGS WFS or PWFS pixels and perform parallel pixel processing and wavefront reconstruction to produce DM error vectors. The Wavefront Corrector Control (WCC) synchronizes and aggregates DM error vectors from the HOP servers and implements DM and TTS control, as well as performing low-order mode processing of OIWFS and ODGW pixels. The Telemetry Engineering Display (TED) server is the NFIRAOS RTC interface to other TMT sub-systems. The TED server receives all external commands and dispatches them to the rest of the NFIRAOS RTC servers and is responsible for aggregating several offloading and telemetry values that are reported to other sub-systems within TMT. The TED server also provides the engineering GUIs and real-time displays. The Persistent Telemetry Storage (PTS) server contains fault tolerant data storage that receives and stores telemetry data, including data for point-spread function reconstruction.

9913-175, Session PS4

FRIDA’s mechanisms control system structure and tests

Rubén A. Flores-Meza, Gerardo Lara, Beatriz S. Sánchez, Carlos Espejo, Ana Carolina Keiman, José Leonardo Garcés Medina, Salvador Cuevas Cardona, Univ. Nacional Autónoma de México (Mexico); José Javier Díaz García, Instituto de Astrofísica de Canarias (Spain)

FRIDA (inFraRed Imager and Dissector for Adaptive optics) will be a near infrared imager and integral field spectrograph covering the wavelength range from 0.9 to 2.5 microns. FRIDA will work in two observing modes: direct imaging and integral field spectroscopy. In order to comply with a high level of reconfigurability FRIDA will comprise eight cryogenic mechanisms and one room temperature mechanism. Some of these mechanisms require high positioning repeatability to ensure FRIDA fulfills with high astronomical specifications. This paper presents the final design of the FRIDA mechanisms control system structure. Also, some tests performed on the most complex mechanisms in both room and cryogenic environments are described. In order to tuning up the mechanisms positioning control parameters a set of programs have been developed and tested. Programming and tuning up of the embedded control software for most of the FRIDA mechanisms has been performed.

9913-176, Session PS4

A virtual appliance as proxy pipeline for the Solar Orbiter/Metis coronagraph

Maurizio Pancrazzi, INAF - Osservatorio Astrofisico di Arcetri (Italy); Thomas Straus, INAF - Osservatorio Astronomico di Capodimonte (Italy); Mauro Focardi, INAF - Osservatorio Astrofisico di Arcetri (Italy); Gianalfredo Nicolini, INAF - Osservatorio Astrofisico di Torino (Italy); Federico Landini, INAF - Osservatorio Astrofisico di Arcetri (Italy); Marco Romoli, Univ. degli Studi di Firenze (Italy); Vincenzo Andretta, INAF - Osservatorio Astronomico di Capodimonte (Italy); Daniele Spadaro, INAF - Osservatorio Astrofisico di Catania (Italy); SIlvano Fineschi, INAF - Osservatorio Astrofisico di Torino (Italy); Giampiero Naletto, Univ. degli Studi di Padova (Italy); Ester Antonucci, INAF - Osservatorio Astrofisico di Torino (Italy)

Metis is the coronagraph on board Solar Orbiter, the ESA mission devoted to the study of the Sun that will be launched in October 2018. Metis will perform imaging of the solar corona in the visible and in the UV at 121.6 nm and it is equipped with a variable retarder plate that will enable to accomplish polarimetry studies in the visible band.

Due to mission constraints and to the S/C visibility from ground, the telemetry downlink will be limited and the data will be downloaded with different delays that could reach, in the worst case, several months. In order to have a quick overview on how the operations are going on and to check the safety of the 10 on-board instruments, a dedicated downlink channel with a lower latency has been foreseen. Each instrument on board Solar Orbiter can therefore produce a restricted amount of data exploiting this high-priority link and get a feedback on its operations. The so-called Low-Latency Data will be downloaded daily and since they could trigger possible actions they have to be quickly processed on ground as soon as they are delivered.

A proper pipeline has to be developed for each instrument to deal with this data producing a tool that then will be integrated in a single system at the ESA Science Operation Center.

In order to ease the integration of the several tools in a unique system, the different teams involved on Solar Orbiter agreed to develop their tools sharing a common framework that, at the same time, leaves great flexibility to build an instrument-customised software. We chose to develop our processing tool as a Virtual Appliance, i.e. a software application that runs under a common operative system wrapped on a virtual machine. This paper will briefly provide an overview of the on board processing and data produced by Metis and it will describe the proxy-pipeline currently developed to deal with Metis low-latency data.

9913-177, Session PS4

The ALMA snooping project interface (SnooPI)

Alexandros Halevin, CGI Group, Inc. (Germany); A. Maurizio Chavan, Evanthia Hatziminaoglou, European Southern Observatory (Germany)

In order to provide ALMA users with a comprehensive view of their observing projects we developed the ALMA Snooping Project Interface (SnooPI). The simple and intuitive interface allows scientists to follow the status of their projects, broken down into observing unit sets and scheduling blocks. For each scheduling block the list of execution blocks is available, including detailed observational conditions and configuration information, observations and calibration details.

The application itself contains two separate parts: a Java back-end server and a JavaScript front-end client application. The back-end server was written using Spring Boot, Spring Data and Spring Security frameworks. Spring Boot usage significantly simplifies the development process by providing default mechanisms for beans configuring, REST interfaces etc.

The front-end application was developed using small Riot framework (http://riotjs.com/) that supports routing, event management and custom tags. Although we created a so called one-page application, the Riot routing functionality allows to navigate through different views with the possibility to bookmark specific places and a correct use of back button.

At the same time the application interacts with REST interfaces of other ALMA software components to retieve information such as proposal pdf reports, project reports and quality assurance (QA) reports, observations details, as well as an interface of ticketing system to access the statistics of the user's ALMA Helpdesk tickets tickets.

From the main page one can access the list of Projects and the list of Scheduling blocks either via widgets showing the number of items in the list or from the left-hand side navigation panel. The top bar allows switching between the various regimes. By default, the application shows only active projects, i.e. projects that have been approved for observations but have not yet been delivered. Activating 'All projects' allows the user to also access all the delivered projects, from the current as well as previous observing cycles.

The "Contact scientist" mode lists all the projects a user is supporting as a Contact Scientist as well as all the projects supported by other Contact Scientists from the same ALMA Regional Centre (ARC) node (see the Proceeding of SPIE, Volume 9149, id. 91490Y (2014)).

The link behind any project code opens a pane showing the Project Code, full proposal pdf link, project grade, the name of the Contact Scientist and the node at the top. A link to the detail project report is also available.

Each project is represented as a tee-like structure with the following hierarchy: project title, proposal, Science Goal, Group and Member observing unit sets and in the lowest level, the scheduling blocks. The tree structure is identical to that shown in the ALMA Observing Tool (Proceedings of the SPIE, Volume 7019, id. 70190R (2008)). The current state of each of these entities is shown by colour icons to denote "No data taken", "Some data taken", "All data taken", "Timed out", or "Delivered". For each scheduling block the number of successful executions vs. the number of required executions is shown. Project, proposal and scheduling block rows are clickable leading to detailed view.

Each Scheduling Block detailed view contains information about array configuration, band, representative frequency, target coordinates as well as the list of execution blocks with timings, zero level QA flags and links to the QA reports.

In turn, for each execution block information on the system temperature, number of antennas, array configuration, and timings for target observations and calibrations is listed.

All this information allows users to successfully trace their observing programmes at all stages from acceptance through to data delivery.

9913-178, Session PS4

Observatory software for the Mauna Kea Spectroscopic Explorer (MSE)

Tom A. Vermeulen, Sidik Isani, Kanoa K. Withington, Kevin K. Y. Ho, Kei Szeto, Rick Murowinski, Canada-France-Hawaii Telescope (United States)

The Canada-France-Hawaii Telescope is currently in the conceptual design phase to redevelop its facility into the new Maunakea Spectroscopic Explorer (MSE). MSE is designed to be the largest non-ELT optical/NIR astronomical telescope, and will be a fully dedicated facility for multi-object spectroscopy over a broad range of spectral resolutions. This paper

outlines the software and control architecture envisioned for the new facility. The architecture will be designed around much of the existing software infrastructure currently used at CFHT as well as the latest proven open-source software. CFHT plans to minimize risk and development time by leveraging on existing technology.

9913-179, Session PS4

Synchronization of off-centered dome and 3.6 m Devasthal Optical Telescope

Maheswar Gopinathan, Sanjit Sahu, Shobhit Yadava, Purshottam Jangid, Biman Jyoti Medhi, Aryabhatta Research Institute of Observational Sciences (India); Pramesh Rao, National Ctr. for Radio Astrophysics (India); Brijesh Kumar, Amitesh Omar, Wahab Uddin, Aryabhatta Research Institute of Observational Sciences (India)

Most of the optical telescopes are housed within a dome or similar structure, to protect the delicate instruments from the elements. While observing a celestial object through the telescope, the dome slit opening should be suitably positioned so that an unobstructed view of the portion of the sky is always available to the telescope. The 3.6m DOT has a cylindrical dome with a tapered roof. The telescope is placed on a pier structure which is structurally isolated from the telescope housing. The height of the dome is 9.6 m which is measured from the level of the primary mirror. The telescope has an alt-azimuth mount. In normal circumstances, synchronizing the movement of the dome with an alt-azimuth mount telescope is trivial. The dome is said to be synchronized with the telescope when the line of sight (LOS) or the optical axis of the telescope intersects with the center line of the slit at a point defined by the dome azimuth (?D) and the telescope elevation. This is true when the telescope and the dome centers coincide. However, in the case of the DOT, there is a complication to the telescope-dome geometry. The telescope is located at a distance of 1.85 m from the dome centre making an angle of 255 degrees with respect to the celestial north. This was done to facilitate the assembly of the telescope from inside the cylindrical telescope building using two 10 ton capacity cranes. In the case of 3.6 m DOT, because the telescope is off centred toward the south-west of the dome center, the LOS do not coincide. Therefore the dome azimuth corresponding to the telescope azimuth needs to be calculated taking into account the offset. Not only do we need to take into account the offset between the telescope and the dome, but, whether the line of sight is passing through the cylindrical or the roof part of the dome is also needs to be considered. When the line of sight passes through the curved surface of the cylindrical walls, we used the standard equation to get the dome positions. However, when the line of sight passes through the roof of the dome building, the dome azimuth is calculated using a set of parametric equations with the solutions considered in the true range of the dome radius. The above two conditions are combined to get the complete path of the dome when the telescope is in the track mode. An algorithm was written based on the calculations in Python language. The telescope positions are read from the Telescope control system and real time calculations are made to calculate the corresponding dome positions. A GUI has been developed also in Python to interface between the software and the micro-controller based hardware. In this poster we will be presenting the details of the calculations and the scheme that we adopted in the already implemented dome control system.

9913-180, Session PS4

A novel approach to visual rendering of astro-photographs

Daniele L. R. Marini, Cristian Bonanomi, Alessandro Rizzi, Univ. degli Studi di Milano (Italy)

When we perform a visual analysis of a cosmic object photograph the contrast plays a fundamental role. A linear distribution of the observable values is not necessarily the best possible for the human visual system (HVS). In fact HVS has not a linear response, and exploits contrast locally with different stretching for different lightness areas. As a consequence, according to the observation task, local contrast can be adapted to make easier the detection of relevant information. The information collected by a camera sensor for visual photography is fundamentally light energy distributed in a spectral interval limited by the chosen filters. This work proposes a novel approach to render physically meaningful data to make them easily observable. Final results of rendering can be presented on many different devices like monitor, printer or projector. Regardless the fact that each device can be carefully calibrated, each one retains its own characteristic transfer function and consequently potential differences in the resulting appearance.

To render an astro-photograph professional or amateur astronomers normally use Photoshop or similar image editing programs. To solve the tone mapping task of the original picture many cook-books have been proposed that are mainly based on histogram manipulation and masking techniques to modify local contrast, brightness and color. Such methods can be effective but they need a time-consuming trial and error work and the results are cumbersome to reproduce.

The proposed approach is based on Spatial Color Algorithms (SCA) that mimic the HVS behavior. These algorithms compute each pixel value by a spatial comparison with all (or a subset of) the other pixels of the image. The comparison can be implemented as a weighted difference or as a ratio product over given sampling in the neighbor region. A final mapping allows to exploit all the available dynamic range. In the case of color images SCA process separately the three chromatic channels producing an effect of color normalization, without introducing channel cross correlation. This is an important property for many needs e.g. in emission nebulae analysis.

SCA are unsupervised, they have parameters that can be tuned for specific needs, and they have shown an interesting characteristic: since local contrast is adjusted mimicking HVS mechanisms the resulting images have increased visual information content. Our approach does not exclude the use of other imaging tools for pre and/or post processing needs.

The drawback of these algorithms is a potential amplification (or addition) of the noise that has not been completely canceled in the captured images.

We will present very promising results on some images, taken from Digital Sky Survey repository and on amateur photographs of deep sky objects. The results are presented for a qualitative and subjective visual evaluation and for a quantitative evaluation through some measures, in particular to quantify the effect of algorithms on the noise.

9913-181, Session PS4

An enhanced technique for ground-based optical space debris extraction via neural networks algorithm

PEERAPONG TORTEEKA, National Astronomical Observatories of CAS (China)

The ground-based optical telescope equipped with CCD sensor have become an important tool for space debris monitoring and maintain a space debris catalogues, in order to avoid the spacecraft collision in Resident Space objects (RSO). In this paper, we emphasized on an enhancement technique for a small and dimming space object extraction. In general, the static-background subtraction are widely used to extract the moving space object in astronomy field because it is low computation time. However, the main disadvantage of this technique is not robustness with atmosphere effects, illumination changed and etc. In this research, we proposed the enhanced technique for extract the space object under complex background by using the theory of computer vision named running Gaussian average and adaptive it by neural networks algorithm to find the optimal learning rate automatically. The advantage of our propose algorithm is not only to suppress the background noise, low

computation cost but also without a burden or bias from the human, when stellar background has independently changed in image sequences. The performance of proposed algorithm is evaluated by the experimental results with real image, show that our proposed algorithm can achieve a high level of Signal-to-Clutter Ratio (SCR) under a complex or dynamic-background.

9913-45, Session 10

TMT approach to observatory software development process *(Invited Paper)*

Hanne Buur, Kim Gillies, Christophe Dumas, Thirty Meter Telescope (United States); Annapurni Subramaniam, India TMT Coordination Ctr. (India); Ravinder S. Bhatia, Thirty Meter Telescope (United States)

The purpose of the Observatory Software System (OSW) is to integrate all software and hardware components of the Thirty Meter Telescope (TMT) to enable observations and data capture; thus it is a complex software system that is defined by four principal software subsystems: Common Software (CSW), Executive Software (ESW), Data Management System (DMS) and Science Operations Support System (SOSS), all of which have interdependencies with the observatory control systems and data acquisition systems. Therefore, the software development process and plan must consider dependencies to other subsystems, manage architecture, interfaces and design, manage software scope and complexity, and standardize and optimize use of resources and tools. Additionally, the TMT Observatory Software will largely be developed in India through TMT's workshare relationship with the India TMT Coordination Centre (ITCC) and use of Indian software industry vendors, which adds complexity and challenges to the software development process, communication and coordination of activities and priorities as well as measuring performance and managing quality and risk. The software project management challenge for the TMT OSW is thus a multi-faceted technical, managerial, communications and interpersonal relations challenge. The approach TMT is using to manage this multi-faceted challenge is a combination of establishing an effective geographically distributed software team (Integrated Product Team) with strong project management and technical leadership provided by the TMT Project Office and the ITCC partner to manage plans, process, performance, risk and quality, and to facilitate effective communications; establishing an effective cross-functional software management team composed of stakeholders, OSW leadership and ITCC leadership to manage dependencies and software release plans, technical complexities and change to approved interfaces, architecture, design and tool set, and to facilitate effective communications; adopting an agile-based software development process across the observatory to enable frequent software releases to help mitigate subsystem interdependencies; defining concise scope and work packages for each of the OSW subsystems to facilitate effective outsourcing of software deliverables to the ITCC partner, and to enable performance monitoring and risk management. At this stage, the architecture and high-level design of the software system has been established and reviewed. During construction each subsystem will have a final design phase with reviews, followed by implementation and testing. The results of the TMT approach to the Observatory Software development process will only be preliminary at the time of the submittal of this paper, but it is anticipated that the early results will be a favorable indication of progress. TMT is scheduled to achieve first-light in 2024 and start observatory operations soon thereafter.

9913-46, Session 10

Don't get taken by surprise: planning for software obsolescence management at the ALMA Observatory

Erich Schmid, European Southern Observatory (Germany); George Kosugi, Subaru Telescope, National Astronomical Observatory of Japan (Japan); Morgan Griffith, National Radio Astronomy Observatory (United States); Jorge Ibsen, ALMA (Chile)

The ALMA observatory is gearing up for full operations, and while most parts of the ALMA software are still being very actively developed and improved, some of the underlying technologies, third-party tools and hardware, as well as parts of the ALMA software itself are already showing signs of age. This is no big surprise after well over a decade of development in the rapidly changing world of software engineering. But it needs to be managed proactively to avoid small issues becoming big problems in the long run. An obsolescence management plan should come to help.

For hardware to be maintained having a solid obsolescence management plan is very common and many good examples and practices to follow can easily be found. For software this does not seem to be the case. While the core principles of establishing and maintaining a bill of materials, performing risk analysis, prioritization and mitigation can be taken over from hardware in a very similar fashion, many of the considerations to be taken into account for assessing the probabilities and risks are very different for software.

Based on well-established obsolescence management practices for hardware, we present an approach to tackle the problem of software obsolescence management for the ALMA observatory. This is not only important to keep our software maintainable for the lifetime of the ALMA observatory as the environment around us evolves and changes, but also to avoid falling victim to the urge for never-ending rewriting, refactoring and replacement.

We hope that this paper will help others in a similar situation to become aware of the need for software obsolescence management and perhaps benefit from our ideas and findings, and maybe more so to help establishing an active dialog between projects and organizations to mutually benefit from each other.

9913-47, Session 10

Management of the science ground segment for the Euclid mission

Fabio Pasian, Andrea Zacchei, INAF - Osservatorio Astronomico di Trieste (Italy); John Hoar, Guillermo Buenadicha, European Space Astronomy Ctr. (Spain); Christophe Dabin, Ctr. National d'Études Spatiales (France); Anna Gregorio, Univ. degli Studi di Trieste (Italy); Oriana Mansutti, INAF - Osservatorio Astronomico di Trieste (Italy); Marc Sauvage, Commissariat à l'Énergie Atomique (France); Claudio Vuerli, INAF - Osservatorio Astronomico di Trieste (Italy)

Euclid is the second medium-sized mission (M2) of the ESA Cosmic Vision 2015-2025 Plan, aimed at understanding the nature of dark energy and dark matter by accurately measuring the accelerated expansion of the Universe. By measuring two probes (weak lensing and baryon acoustic oscillations) simultaneously, Euclid will constrain dark energy, general relativity, dark matter and the initial conditions of the Universe with unprecedented accuracy. The mission will observe galaxies and clusters of galaxies out to z~2, in a wide extra-galactic survey covering 15 000 deg?,

plus a deep survey covering an area of 40 deg?. The payload is composed of two instruments, an imager in the visible domain (VIS) and an imager-spectrometer (NISP) covering the near-infrared. The launch is planned in Q4 of 2020.

The Science Operations Centre (SOC) operated by ESA and nine Science Data Centres (SDCs), provided by a Consortium composed of 14 European countries (Austria, Belgium, Denmark, Finland, France, Germany, Italy, the Netherlands, Norway, Portugal, Romania, Spain, Switzerland, United Kingdom) plus the United States, are the elements of the Euclid Science Ground Segment (SGS). ESA/SOC and the Euclid Consortium have developed, and are committed to maintain, a tight collaboration in order to design and develop a single, cost-efficient and truly integrated SGS. The distributed nature, the size of the data set, and the needed accuracy of the results are the main challenges expected in the design and implementation of the SGS. In particular, the huge volume of data (not only Euclid data but also ground based data) to be processed in the SDCs will require a distributed storage to avoid data migration across SDCs.

Since data management will be performed in a distributed environment, the Euclid SGS organisation is based on collaborative software development, virtualization, distributed processing and a data-centric approach to the system architecture, implying quite a complexity in the design and implementation of the data handling and processing facilities.

There are therefore a set of management challenges that the Euclid SGS will need to face in dealing with such complexity. The main aspect is related to the organisation of a geographically-distributed software development team. In principle algorithms and code is developed in a large number of institutes, while data is actually processed at fewer centres (the national SDCs) where the operational computational infrastructures are maintained. The effort in designing and implementing the SGS is focussed on the core products and on minimising complexity (with the purpose of minimising risks and costs as well). There is an aim at enforcing commonality wherever needed (mainly at the data structures level, where the need for a common data and information system has been identified). In the few cases where commonality cannot be achieved, interfaces are defined.

In this framework, quality control plays a crucial role. The software produced for data handling, processing and analysis is built within a common development environment defined by an SGS System Team, which has been already active for several years. The code is built incrementally through different levels of maturity going from prototypes, developed mainly by scientists, to production code, engineered and tested at the SDCs. A number of incremental challenges (infrastructure, data processing and integrated) have been included in the Euclid SGS test plan to verify the correctness and accuracy of the developed systems.

9913-48, Session 10

Software collaboration between the observatory and the instrument development teams at the JCMT and UKIRT

Craig A. Walther, Sarah F. Graves, Maren Hauschildt-Purves, East Asian Observatory (United States)

When an instrument team builds a modern, common user, astronomical instrument for an observatory, there are many software issues that need to be settled. Typically there is a need for instrument control software at the hardware-software interface; integration software so that the instrument can be controlled from the observatory's control system (OCS); engineering (control and analysis) software so the instrument can be developed and tested without a full blown OCS; changes to the OCS to accommodate new observing modes to utilize the unique capabilities of the new instrument; perhaps new capabilities to other existing parts of the observatory such as scan patterns for the telescope or the secondary mirror; and, definitely not least, data reduction software that can overcome the drawbacks of the instrument to push it to attain its full potential. Eventually all of this software will be supported by the observatory, so they must supply a set of guidelines for the instrument team to follow. But the instrument team are the ones who know the instrument best, so their input is necessary also. This paper discusses the approach that has been followed by the JCMT and UKIRT telescopes over the past 15 years while accepting new instruments. It discusses what worked, what did not work, the areas in which the required effort was significantly underestimated, and those in which large amounts of time were spent on developing capabilities that were never used. A summary proposes a work breakdown, documentation required from both sides, and the proper amount of (and timing of) collaboration between the instrument team and the observatory.

9913-49, Session 10

Building a world-wide open source community around a software framework: progress, dos, and don'ts

Jorge Ibsen, ALMA (Chile) and European Southern Observatory (Chile); Jonathan A. Antognini, Jorge Avarias, ALMA (Chile); Alessandro Caproni, European Southern Observatory (Germany); Matthias Fuessling, Deutsches Elektronen-Synchrotron (Germany); C. Guillermo Gimenez de Castro, Univ. Presbiteriana Mackenzie (Brazil); Khushbu Verma, Deutsches Elektronen-Synchrotron (Germany); Matias G. Mora Klein, ACS Community Organization (United States); Joseph Schwarz, INAF - Osservatorio Astronomico di Brera (Italy); Tomás Staig, ALMA (Chile)

As we all know too well, building up a collaborative community around a software infrastructure is not easy. Besides recruiting enthusiasts to work as part of it, mostly for free, to succeed you also need to overcome a number of technical, sociological, and, to our surprise, some political hurdles.

The ALMA Common Software (ACS) was developed at ESO and partner institutions over the course of more than 15 years. While it was mainly intended for the ALMA Observatory, it was early on thought as a generic distributed control framework. ACS has been periodically released to the public through an LGPL license, which encouraged around a dozen non-ALMA institutions to make use of ACS for both industrial and educational applications. In recent years, the Cherenkov Telescope Array and the LLAMA Observatory have also decided to adopt the framework for their own control systems.

The aim of the "ACS Community" is to support independent initiatives in making use of the ACS framework and to further contribute to its development. The Community provides access to a growing network of volunteers eager to develop ACS in areas that are not necessarily in ALMA's interests, and/or were not within the original system scope. Current examples are: support for additional OS platforms, extension of supported hardware interfaces, a public code repository and a build farm. The ACS Community makes use of existing collaborations with Chilean and Brazilian universities, reaching out to promising engineers in the making. At the same time, projects actively using ACS have committed valuable resources to assist the Community's work. Well established training programs like the ACS Workshops are also being continued through the Community's work.

This paper aims to give a detailed account of the ongoing (second) journey towards establishing a world-wide open source collaboration around ACS. The ACS Community is growing into a horizontal partnership across a non centralised and diverse group of actors, and we are excited about its technical and human potential.

9913-50, Session 11

The new Gemini Observatory archive: a fast and low cost observatory data archive running in the cloud

Paul Hirst, Ricardo Cardenes, Gemini Observatory (United States)

We have recently developed and deployed a new data archive for the Gemini Observatory.

Focused on simplicity and ease of use, the archive web interface provides a number of powerful and novel features such as complete and automatic association of calibration data with the science data it applies to, and the ability to bookmark searches. More conventional features of note include user authentication and access control over proprietary data, the availability of JPEG data previews within the web interface, and of course searching the data collection by a number of parameters covering instrument configuration, object being observed, and observation details such as the date and time of observation and program and dataset types and identifiers. A simple but powerful API allows programmatic search and download of data. The system is designed to meet the needs of PIs and public archive users as well as remote observers and eavesdropping PIs, with a responsive interface and new data being available for download from the archive typically less than a minute after the readout completes.

By focusing on the most common use cases from our community, and leveraging cloud computing and open-source software, we have implemented a complete facility archive service in a 2-year, 3-FTE development phase, and with an annual operating cost of approximately US$6k + 0.5-FTE. All legacy data has been transferred into the new system, and raw data is ingested in near-real time from both Gemini telescopes. The total compressed data volume is currently a little over 8 TB.

The archive is hosted “in the cloud” on a commercial cloud computing platform (Amazon Web Services), which provides us internet connectivity beyond what we could reasonably achieve locally and also provides us significant cost savings in both operations and development over more traditional deployment options. The code is written in python, utilizing a PostgreSQL database and Apache web server, and is designed such that it can use cloud storage or the file-system to store the content and thus can be deployed either on a commercial cloud computing platform or on a more traditional physical or virtual machine. The same code is deployed at our telescope sites to provide local data management facilities, which includes transferring data to the public archive system in the cloud. This flexibility also provides us with several options to deploy larger scale or multiple servers should the need arise, including the option to deploy archive servers within academic institutions or other user community centers if necessary.

9913-51, Session 11

Petascale cyber infrastructure for ground-based solar physics: approach of the DKIST data center

Steven J. Berukoff, Tony Hays, Kevin Reardon, Daniel Spiess, Fraser Watson, Scott Wiant, National Solar Observatory (United States)

When construction is complete in 2019, the Daniel K. Inouye Solar Telescope will be the most-capable large aperture, high-resolution, multi-instrument solar physics facility in the world. The telescope is designed as a 4-m off-axis Gregorian, with a rotating Coude laboratory housing and supporting five first-light imaging and spectropolarimetric instruments capable of simultaneous operation. At current design, the facility and its instruments will generate data volumes of 5 PB, produce 10^8 images, and 10^10 metadata elements annually. This data will not only forge new understanding of solar phenomena at high resolution, but enhance participation in solar physics and further grow a small but vibrant international community.

The DKIST Data Center is being designed to store, curate, and process this flood of information, while augmenting its value by providing association of science data and metadata to its acquisition and processing provenance. Starting in early Operations, the Data Center will produce quality-controlled and -assured calibrated data sets, closely linked to facility and instrument performance during the Operations lifecycle. These data sets will be made available to the community openly and freely, with software and algorithms made available through community repositories like Github for further collaboration and improvement.

We discuss the current design and key facets of the DKIST Data Center, focusing on the need to provide highly-available and reliable computational and data storage systems on a shoestring, and the underappreciated challenges of calibrating ground-based solar data. We conclude by describing the crucial integration of the Data Center within the larger DKIST Operations lifecycle, and how software and hardware support, intelligently deployed, will enable high-caliber solar physics research and community growth for the DKIST’s 40-year lifespan.

9913-53, Session 11

TRIDENT: scalable compute archive, visualization, and analysis systems

Arvind Gopu, Soichi Hayashi, Michael D. Young, Indiana Univ. (United States); Ralf Kotulla, Univ. of Wisconsin-Madison (United States); Robert Henschel, Indiana Univ. (United States); Daniel R. Harbeck, WIYN Observatory (United States)

The Astronomy scientific community has embraced Big Data processing challenges, e.g. associated with time-domain astronomy, and come up with a variety of novel and efficient data processing solutions. However, data processing is only a small part of the Big Data challenge. Efficient knowledge discovery and scientific advancement in the Big Data era requires new and equally efficient tools: modern user interfaces for searching, identifying and viewing data online without direct access to the data; tracking of data provenance; searching, plotting and analyzing metadata; interactive visual analysis, especially of (time-dependent) image data; and the ability to execute pipelines on supercomputing resources with minimal user overhead and understandable even to novice users. The Trident project at Indiana University offers a comprehensive web- and cloud-based framework of frameworks that can be configured and refactored into customized Scalable Compute Archive (SCA) systems including extensive visualization and analysis capabilities. Trident seamlessly scales up or down in terms of data volumes and computational needs, and the user interface feature sets within the web portal can be quickly adapted to meet individual project requirements. It uses a micro-services architecture, and is made up of light-weight services connected by a message bus; a web portal built using Twitter/Bootstrap, AngularJS, and HighCharts JavaScript libraries, and backend services written in NodeJS, PHP/Zend, and Python. The Trident microservice software suite consists of (1) a Progress service to monitor workflows and sub-workflows (for eg., a complex pipeline data processing job that executes several steps on a set of images) (2) ImageX, an image preview and analysis service that allows interactive image analysis via highly compressed JPEG images for rough perusal and on-demand generation of lossless PNG images for more complex visualization analysis. (3) an authentication service allowing password logins, and hooks to other single sign-on services (4) a Notification service that serves statistical collation and reporting needs of various projects. (5) several others under development. Trident also has built-in frameworks offering: collections for data grouping and sorting, metadata plotting tools, and a Tier-2 workflow system that enables rapid integration of data processing pipelines on an associated compute cluster with customized user interfaces. Trident is an umbrella project, spun off from the One Degree Imager - Portal, Pipeline, and Archive (ODI-PPA) project, and thus far has been deployed toward 1) a powerful analysis/visualization portal for Globular Cluster System (GCS) survey data collected by IU researchers, 2) a data search and download portal for the IU Electron Microscopy Center's data (EMC-PPA), 3) a metadata quality control and analytics portal for DICOM formatted medical imaging data prodoced by the IU Radiology Center's medical imagers, 4) a limited set of components to serve GIS data within the IU GIS web portal, 5) a prototype archive for the Ludwig Maximilian University's Wide Field Imager. Trident SCA systems leverage supercomputing and storage resources at Indiana University but can be configured to make use of any cloud/grid resource, from local workstations/servers to (inter)national supercomputing facilities such as XSEDE.

9913-54, Session 11

The NOAO data lab virtual storage system

Matthew J. Graham, National Optical Astronomy Observatory (United States) and California Institute of Technology (United States); Michael J. Fitzpatrick, Patrick Norris, Knut Olsen, Adam Bolton, Kenneth J. Mighell, Stephen T. Ridgway, Elizabeth B. Stobie, National Optical Astronomy Observatory (United States)

Collaborative research and computing environments are essential for working with the next generations of large astronomical data sets. A key component of them is a cloud storage system to enable data hosting, sharing, and publication. VOSpace is a lightweight interface that provides network access to arbitrary backend storage solutions and is endorsed by the IVOA. Although similar APIs exist, such as Amazon S3, WebDav, and Dropbox, VOSpace has several advantages for research applications. It is designed to be protocol agnostic, it is focused on data control operations, and it supports asynchronous and third-party data transfers, thereby minimizing unnecessary data transfers. It also allows arbitrary computations to be triggered as a result of a transfer operation, a feature known as a Capability. For example, a file can be automatically ingested into a database when put into an active directory, or a data reduction task, such as Sextractor, can be run on it. In this talk, we shall describe the VOSpace implementations that we have developed for the NOAO Data Lab. These offer both dedicated remote storage, accessible as a local filesystem via FUSE, and a local VOSpace service to easily enable data synchronization. We also make extensive use of the Capability mechanism to support data workflows.

9913-119, Session 11

Cloud services on an astronomy data center

Mauricio G. Solar, Mauricio Araya, Univ. Técnica Federico Santa María (Chile); Diego Mardones, Univ. de Chile (Chile); Zhong Wang, Chinese Academy of Sciences South America Ctr. for Astronomy (China)

The research on computational methods for astronomy performed by the first phase of the Chilean Virtual Observatory (ChiVO) led to the development of functional prototypes, implementing state-of-the-art computational methods and proposing new algorithms and techniques.

The ChiVO software architecture is based on the use of the IVOA protocols and standards. These protocols and standards are grouped in layers, with emphasis on the application and data layers, because their basic standards define the minimum operation that a VO should conduct. As momentary verification, the current implementation works with a set of data, with 1 TB capacity, which comes from the reduction of the cycle 0 of ALMA.

This research was mainly focused on spectroscopic data cubes coming from the cycle 0 ALMA's public data. As the dataset size increases when the cycle 1 ALMA's public data is also increasing every month, data processing is becoming a major bottleneck for scientific research in astronomy.

When designing the ChiVO, we focused on improving both computation and I/O costs, and this led us to configure a data center with 424 high speed cores of 2,6 GHz, 1 PB of storage (distributed in hard disk drives-HDD and solid state drive-SSD) and high speed communication Infiniband.

We are developing a cloud based e-infraestructure for ChiVO services, in order to have a coherent framework for developing novel webservices for on-line data processing in the ChiVO. We are currently parallelizing these new algorithms and techniques using HPC tools to speed up big data processing, and we will report our results in terms of data size, data distribution, number of cores and response time, in order to compare different processing and storage configurations.

9913-55, Session 12

Mount control software of the ASTRI SST-2M prototype for the Cherenkov Telescope Array

Elisa Antolini, Univ degli Studi di Perugia (Italy); Marco Bagaglia, Univ. degli Studi di Perugia (Italy); Enrico Cascone, INAF - Osservatorio Astronomico di Capodimonte (Italy); Giorgio F. Gambini, Giuliano Nucciarelli, Univ. degli Studi di Perugia (Italy); Luca Stringhetti, INAF - Osservatorio Astronomico di Brera (Italy); Salvatore Scuderi, INAF - Osservatorio Astrofisico di Catania (Italy); Claudio Tanci, Univ. degli Studi di Perugia (Italy) and INAF-Osservatorio Astronomico di Brera (Italy); Gino Tosti, Univ. degli Studi di Perugia (Italy); Andrea Busatta, Stefano Giacomel, Gianpietro Marchiori, Cristiana Manfrin, Enrico Marcuzzi, EIE Group s.r.l. (Italy)

A mini-array of nine ASTRI telescopes has been proposed to be installed at the southern site of the CTA.

The ASTRI SST-2M telescope is an end-to-end prototype proposed for the Small Size class of Telescopes of the future Cherenkov Telescope Array (CTA).

The prototype is installed in Italy at the INAF observing station located at Serra La Nave on Mount Etna (Sicily) and it was inaugurated on September 2014.

The Mount Control System of the ASTRI SST-2M prototype comprises all hardware and software components devoted to control the drive system, to perform telescope slewing and tracking, to monitor the status of all the devices mounted on the telescope (e.g. the Camera, the Active Mirrors control) and to manage the safety of the system (interlock chain).

The Mount Control Software installed on the ASTRI SST-2M telescope prototype makes use of standard and widely-deployed industrial hardware and software. The state of the art of the control and automation industries was selected, in order to have the highest technological performance with the maximum assembly compactness, high reliability and reduced maintenance. The software package was implemented with the TwinCAT environment for the software Programmable Logical Controller (PLC), while the electronics of control have been chosen in order to maximize the homogeneity and the real-time performance of the system.

From this point of view ASTRI is one of the very few examples where all the functions, including the generation of the tracking trajectory of the telescope, are managed through software PLCs. This choice makes the ASTRI SST-2M telescope an efficient and stand-alone machine, easily integrated in CTA.

The ASTRI SST-2M mount control and security systems have pushed to the limit the cutting-edge technology applied, they allow us to test for the first time a lot of functionality developed by the selected companies, and they serve as prototype for the future Mount Control System of the ASTRI mini-array telescopes proposed to be installed at the CTA southern site.

9913-56, Session 12

Automation and control of the MMT thermal system

J. Duane Gibson, Dallan Porter, William Goble, MMT Observatory (United States)

Automated control of the thermal ventilation system for the MMT Observatory (MMTO) 6.5-meter primary mirror (M1) began in 2009 after years of manual control by the telescope operator. This automated control combines: 1) a simple linear regression control algorithm between the primary chiller setpoint for the glycol/water coolant and the discharge ventilation air temperature into the M1 mirror cell, and 2) a differential air temperature controller for a second methanol-based chiller that trims the final discharge air temperature. The thermal control system attempts to drive the M1 glass temperature towards the ambient air temperature while minimizing thermal gradients within the mirror.

These algorithms are based upon data gathered prior to 2009 during manual control of the thermal system. A rich set of environmental and thermal data has been acquired under automated control over the past six years. The success of the current control algorithms will be evaluated towards the dual goals of minimizing the air/glass temperature contrast at the front face of M1 and reducing thermal gradients within the mirror.

Beginning in 2015, new heating, ventilation, and air conditioning (HVAC) equipment has been installed and brought on?line at the MMTO. This new equipment includes a larger glycol-based chiller, variable frequency drives (VFDs) for the main M1 ventilation blower motor, larger glycol coolant pumps, multiple three-way glycol mixing valves, extensive new coolant plumbing, and numerous status and temperature remote sensors and controllers. This upgraded facilities/building HVAC hardware must be integrated with automated control of the M1 ventilation system. The new HVAC and associated hardware at the MMTO is embedded with electronics, software, sensors and network connectivity that allow these devices to collect and exchange data with each other and with centralized facility automation systems.

The open-source, industry-standard BACnet (Building Automation and Control network) protocol is used to communicate via BACnet objects between devices and computers on different physical data layers. A summary is presented of the BACnet network topology and integration of this protocol into the existing MMTO telemetry and control system, including Redis key-?value stores and MySQL relational databases. The new M1 ventilation and facilities HVAC systems require a more complex and robust approach to automation and control. Instead of control via adjusting chiller setpoints, the ventilation air will be conditioned through the more widely used approach of mixing warm and cold glycol coolant through multiple three-way valves, each associated with an air/glycol heat exchanger. This approach provides better overall system response. Linear regression and other statistical and machine learning approaches as well as proportional-?integral-?derivative (PID) controllers are considered for the revised automated M1 ventilation and facilities HVAC control system.

Finally, new graphical user interfaces (GUI's) have been developed to allow the user to monitor and control the upgraded MMTO thermal system, including the M1 ventilation and facilities HVAC subsystems. These GUI's allow manual control of the thermal system as well as monitoring of automated control of the system. Real-time updates of environmental and thermal data are provided to users using current web-based technologies.

9913-57, Session 12

Software detailed design of INO340 telescope control system

Reza Ravanmehr, Hengameh Shalchian, Iranian National Observatory (Iran, Islamic Republic of)

The INO340 telescope is a 3.4m Alt-Az reflecting optical telescope with a 0.3° field-of-view and the F?ratio of Cassegrain focus is f/11. It is currently in the middle of the detailed design phase. In astronomical projects, software architecture plays an important role because many subsystems and components from different sources with different implementations aspects must work together in a consistent and reliable way. Software architecture deals with the design and implementation of the high-level structure of the software. It shall be designed in a way that it could satisfy the major functionality and performance requirements of the system, as well as some other, non-functional requirements such as reliability, scalability, portability, and availability.

To describe INO340 telescope control system (INOCS) software architecture, we utilize a model called "4+1", composed of multiple views or perspectives. This model has been used with success on many large telescope projects with some local customization and adjustment in terminology. In order to address challenging architectures like ours, the model is made up of five main views:

• The logical view, which is the object model of the design

• The process view, which captures the concurrency and synchronization aspects of the design

• The development view, which describes the static organization of the software in its development environment

• The physical view, which describes the mapping(s) of the software onto the hardware and reflects its distributed aspect

• The scenario view, which binds the previous four views.

We have studied the software architecture model of several telescope control systems including GMT, GTC, DCT, TMT, SOAR, VLT, VST and ATST. We have found that they have also followed the concepts of "4+1" model in their detailed design phase with some customizations. Not all software architecture need the full "4+1" views therefore some of these decided that they do not need to include all of the aforesaid five views in their architecture model.

In INOCS, we have considered all five views in order to obtain a comprehensive software architecture model. The views are used to describe the system from the viewpoint of different stakeholders, such as end-users (observers and operators), developers and project managers. The logical view supports behavioral requirements which are the services the system should provide to INOCS users. The process view takes into account some requirements such as performance and system availability. The development view focuses on the organization of the software modules in the software development environment. The physical view takes into account the system's requirements such as reliability and scalability. We have mapped the views into a set of UML diagrams and some additional visual charts in order to model INOCS software architecture.

In this paper, we review the software architecture of major telescope control systems. Subsequently, we will illustrate the architecture model of INOCS based on the "4+1" view model using the corresponding UML diagrams and other explanatory visual charts such as the class, sequence, component, deployment and use case diagrams respectively. In the last section, we will present a brief description about the INOCS development process in terms of software architecture in detailed design phase.

9913-58, Session 12

Introduction to FAST central control system

Jinghai Sun, Lichun Zhu, Zhiqian Jiang, National Astronomical Observatories (China)

Five-hundred-meter Aperture Spherical Telescope (FAST) will be the largest single dish radio telescope in the world. The construction will be accomplished in September, 2016. During observation, parts of the spherical reflector deforms to a paraboloid of revolution and feed is placed at the instant focal point by 6 parallel cables and fine-tuned by AB rotator and Stewart manipulator. The relative control, measurement and monitor subsystems of active reflector, feed support and receiver should work synchronously, which makes telescope control complicated and inconvenient for operators.

Therefore, an autonomous central control system is designed and implemented to connect and coordinate all subsystems. The main functions are collecting and managing observation tasks, translating the tasks into commands and sending to subsystems, gathering and storing operation data, monitoring facility status and providing time service. In central control room, a large screen display system is employed to show the main status of telescope and can be switched to show a combination of any interested client desktop screens and closed-circuit television signals. Additionally, a friendly web-based user interface is developed for operator, engineer and scientist users. The technique makes it easy to expand the ability of remote operation.

In this paper, the software and hardware architecture of FAST central control system will be presented. The relative infrastructure such as electric power, network and site buildings will be described. Finally, the expansion and upgrades issues will be discussed.

9913-59, Session 12

Prototyping the E-ELT M1 local control system communication infrastructure

Javier Argomedo, Nick Kornweibel, Thomas Grudzien, Martin Dimmler, Pablo J. Barriga Campino, European Southern Observatory (Germany)

The primary mirror of the E-ELT is composed of 798 hexagonal segments of about 1.45 metres across. Each segment can be moved in piston and tip-tilt using three position actuators and therefore can compensate for perturbations, mainly due to temperature, gravity and wind forces. Inductive edge sensors are used to provide feedback for global reconstruction of the mirror shape.

The E-ELT M1 Local Control System will provide a deterministic infrastructure for collecting edge sensor and actuators readings and distribute the new position actuator references while at the same time providing failure detection, isolation and notification, synchronization generation and distribution to segment subunits, power and networking monitoring and configuration management.

The main characteristic of the communication architecture design is the fact that the measurements from each of the 798 segments subunits arrive from the field electronics as individual network packets without relying on intermediate custom data aggregation or pre-processing. The design is based on UDP/IP over switched ethernet communication and relies on multicast addressing, 10Gbps bandwidth and multicore architecture at the computer room.

The prototype mock-up is composed by a server, mirror position data simulator and networking infrastructure replicating the most critical part, in terms of timing and data flow, of the E-ELT M1 control system design.

The simulated M1 segment position measurements are generated using a NI LabVIEW PXI equipped with 6 dual port FPGA based ethernet boards. The measurement messages are triggered by the arrival of the synchronization packet.

The M1LCU was running VxWorks on an Intel multi core server, it implemented the M1 figure loop data flow and generated the synchronization UDP multicast packet at 500 Hz.

The M1 figure loop is implemented as a three pipelined staged algorithm: positions measurements collection, references computation and references distribution.

The present paper describes the prototyping activities carried out to verify the feasibility of the E-ELT M1 control system communication architecture design and assess its performance and potential limitations.

9913-60, Session 12

A new telescope control software for the Mayall 4-meter telescope

Behzad Abareshi, Robert Marshall, Shelby Gott, National Optical Astronomy Observatory (United States); Rolando E. Cantarutti, Cerro Tololo Inter-American Observatory (Chile); Richard Joyce, Doug Williams, Ronald G. Probst, Kristin Reetz, Anthony Paat, Karen Butler, Christian Soto, David Sprayberry, National Optical Astronomy Observatory (United States)

The Mayall 4-meter telescope at Kitt Peak National Observatory, USA, recently went through a major modernization of its telescope control system. We describe MPK (Mayall Pointing Kernel), our new software for telescope control. MPK outputs a 20Hz position-based trajectory with a velocity component, which feeds into Mayall's new servo system over a socket. We wrote a simple yet realistic servo simulator that let us develop MPK mostly without access to real hardware, and also lets us provide other teams with a Mayall simulator as test bed for development of new instruments. MPK has a small core comprised of prioritized, soft realtime threads that handle the critical tasks. Access to the core's services is via MPK's main thread, a complete, interactive Tcl/Tk shell, which gives us the power and flexibility of a scripting language to add any other features, from GUIs, to an API for instrument clients over the network, to interaction with critical subsystems like dome or guider. MPK is designed for long term maintainability: it runs on stock Linux OS and computer, and uses only standard, open source libraries, except for commercial software that comes with source code in ANSI C/C++. Mayall's modernization was based on that of its sister telescope, the Blanco 4-meter at Cerro Tololo Inter-American Observatory, in Chile. MPK uses the same core libraries as its Blanco counterpart: TCSpk/TPK, the commercial libraries for astrometry and pointing by Patrick Wallace and David Terrett, and Reflexxes, an open source trajectory generator. But instead of modifying Blanco's telescope control software, we wrote MPK from scratch, because a thorough, in-house understanding of the control software was crucial for meeting the performance requirements and for being able to quickly add custom, complex features requested by instrument scientists. Besides, although Mayall and Blanco are mechanically similar, their existing, and upcoming, subsystems are different enough to make writing from scratch worthwhile in the long run. We discuss the technical details of how MPK combines Reflexxes with TCSpk/TPK to generically handle any motion request, from slews to offsets to sidereal or non-sidereal tracking. We also discuss our Tpoint modeling strategy.

9913-61, Session 13

Revisiting software specification and design for large astronomy projects
(Invited Paper)

Scott Wiant, Steven J. Berukoff, National Solar

Observatory (United States)

The separation of science and engineering in the delivery of software systems overlooks the true nature of the problem being solved and the organization that will solve it. Use of a systems engineering approach to managing the requirements flow between these two groups as between a customer and contractor has been used with varying degrees of success by well-known entities such as the U.S. Department of Defense. However, treating science as the customer and engineering as the contractor has unfavorable consequences that can be avoided and opportunities that are missed. For example the “problem” being solved is only partially specified through the requirements generation process since it focuses on detailed specification guiding the parties to a technical solution. Equally important is the portion of the problem that will be solved through the definition of processes and staff interacting through them. This interchange between people and processes is often underrepresented and under appreciated.

Indeed, the natural tendency is for requirements to serve as the primary means of communication between parties where changes necessitate reconciliation and typically leave both sides looking out for their own interests. There is another way afforded to an organization that staffs its own engineering team(s) such as those commonly found in astronomy facility development projects such as the DKIST Operations Tools and Data Center project. Such projects face a common theme of highly talented and motivated scientists and engineers that may be insulated from understanding each other’s goals working within constraints in budget and schedule.

By concentrating on the whole problem and collaborating on a strategy for its solution a science implementing organization can realize the benefits of driving towards common goals (not just requirements) and a cohesive solution to the entire problem. The initial phase of any project when well executed is often the most difficult yet most critical and thus it is essential to employ a methodology that reinforces collaboration and leverages the full suite of capabilities within the team. This paper describes a holistic approach to specifying the needs induced by a problem, its solution, and the roles played by the stakeholders during the specification and development of the solution.

9913-62, Session 13

Software requirements flowdown and preliminary software design for the G-CLEF spectrograph

Ian N. Evans, Jamie A. Budynkiewicz, Janet DePonte Evans, Joseph B. Miller, Charles Paxson, David A. Plummer, Harvard-Smithsonian Ctr. for Astrophysics (United States)

The GMT-Consortium Large Earth Finder (G-CLEF) is a fiber-fed optical echelle spectrograph that will be the first light instrument on the Giant Magellan Telescope (GMT). While G-CLEF is general-purpose instrument, with multiple observing modes capable of addressing many fundamental questions in the areas of stellar astrophysics and cosmological studies, the precision radial velocity (PRV) mode (R ~ 110,000) that is designed for exoplanet science drives much of the instrument design. When operating in the PRV mode, G-CLEF will provide unprecedented radial velocity sensitivity, with the capability of making single PRV measurements with a precision of 40-50 cm/sec, and an ultimate PRV sensitivity requirement of 10 cm/sec from multiple observations.

Such PRV sensitivity is achieved by maintaining the G-CLEF optical bench in an ultra-stable environment that is immune to mechanical perturbations, either intrinsically by design (e.g., vibration isolation), or through active control by software (e.g., thermal control, active leveling). These factors drive the flow-down to the software requirements and preliminary design of the instrument device control software (IDCS), and significantly increase the complexity of the latter. In addition to the typical mechanical and detector subsystems, the IDCS must manage an active precision thermal control system that maintains the optical bench temperature to +/- 1 mK, and a precision active leveling system that ensures that the spectrograph assembly is maintained in a gravity invariant orientation with a precision of a few micro-radians. The IDCS must monitor telemetry from several hundred sensors and manage more than one hundred controllable devices. In addition to instrument control, achieving the specified radial velocity precision requires the use of data reduction algorithms that are carefully matched to the instrument operational concept in order to fully eliminate common sources of calibratable errors and minimize the impact of non-calibratable and systematic errors.

To ensure tight integration with the GMT software systems, the G-CLEF software uses a model-based software engineering approach and conforms to a reference architecture developed by the GMT Organization. While model-based development is commonly used for large scale industrial robotics systems, this approach has not been utilized widely in the development of ground-based astronomical instrumentation, where the focus is typically on the hardware. However, in the era of billion-dollar extremely large telescopes, and their concomitant operating costs, expectations for first light performance raise the bar for software development scope and schedule to near space-borne mission standards.

In this paper, we describe the approaches that we have used to identify and flow down the requirements for the G-CLEF IDCS and data reduction pipeline software, and discuss the preliminary designs for key components. Since this phase of the G-CLEF software effort is being conducted in parallel with both the internal G-CLEF hardware design work and also with the GMT’s own software requirements and design effort, we discuss how we handle revisions to driving requirements that impact our software requirements and preliminary design process. Finally, we identify a number of lessons learned that have general applicability to the development of software for ground-based instrumentation under similar circumstances.

9913-63, Session 13

Software framework for automatic learning of telescope operation

Jose Antonio A. Rodríguez Losada, Jordi Molgó Sendra, Dailos Guerra Ramos, Instituto de Astrofísica de Canarias (Spain)

The “Gran Telescopio de Canarias” (GTC) is an optical-infrared 10-meter segmented mirror telescope at the ORM observatory in Canary Islands (Spain). The GTC Control System (GCS) is a distributed object and component oriented system based on RT-CORBA and it is responsible for the operation of the telescope, including its instrumentation. The current development state of GCS is mature and fully operational. On the one hand telescope users as PI’s implement the sequences of observing modes of future scientific instruments that will be installed in the telescope and operators, in turn, design their own sequences for maintenance. On the other hand engineers develop new components that provide new functionality required by the system. This great work effort is possible to minimize so that costs are reduced, especially if one considers that software maintenance is the most expensive phase along the software life cycle. Could we design a system that allows the progressive assimilation of sequences of operation and maintenance of the telescope, through an automatic self-programming system, so that it can evolve from one Component oriented organization to a Service oriented organization? One possible way to achieve this is to use mechanisms of learning and knowledge consolidation to reduce to the minimum expression the effort to convert the specifications of the different telescope users to the operational deployments. This article presents the key to make this process a reality: refactoring based on value, Self-Organizing Maps, Service Oriented Architectures, Adaptive software and evolutionary algorithms.

9913-64, Session 13

Can your software engineer program your PLC?

Alastair J. Borrowman, Philip Taylor, Observatory Sciences Ltd. (United Kingdom)

The use of Programmable Logic Controllers (PLCs) in the control of large physics experiments is biquitous. The programming of these controllers is normally the domain of engineers with a background in electronics, this paper introduces PLC program development from the software engineer's perspective.

LC programs provide the link between control software running on PC architecture systems and physical hardware controlled and monitored by digital and analogue signals. The higher-level oftware running on the PC is typically responsible for accepting operator input and from this deciding when and how hardware connected to the PLC is controlled. The PLC accepts demands from the PC, considers the current state of its connected hardware and if correct to do so (based upon interlocks or other constraints) adjusts its hardware I/O signals appropriately for the PC's demands. A published ICD (Interface Control Document) defines the PLC memory locations available to be written and read by the PC to control and monitor the hardware. Historically the method of programming PLCs has been ladder diagrams that closely resemble circuit diagrams, however, PLC manufacturers nowadays also provide, and promote, the use of higher-level programming languages.

Based on techniques used in the development of high-level PC software to control PLCs for multiple telescopes, this paper examines the development of PLC programs to operate the hardware of a medical cyclotron beamline controlled from a PC using the Experimental Physics and Industrial Control System (EPICS), which is also widely used in telescope control. The PLC used is the new generation Siemens S7-1200 programmed using Siemens' Pascal based Structured Control Language CL). The approach described is that from a software engineer's perspective, utilising Siemens' Totally Integrated Automation (TIA) Portal development environment to create modular PLC programs based upon reusable functions capable of being unit tested without the PLC connected to hardware. Emphasis has been placed on designing an interface between EPICS and SCL that enforces correct operation of hardware through stringent separation of EPICS accessible PLC memory and hardware I/O addresses used only by the PLC. The paper also introduces the method used to automate the creation, from the same source document, the PLC memory structure (tag) definitions defining memory used to access hardware I/O and that accessed by EPICS) and creation of EPICS database records used to access the PLC addresses. From direct experience this paper demonstrates the advantages of PLC program development being shared between electronic and software engineers, to enable use of the most appropriate processes from both the perspective of the hardware and the higher-level software used to control it.

9913-65, Session 13

A lightweight set of frameworks for the implementation of state analysis in the GMT control system

José M. Filgueira, Marti Pi, Chien Y. Peng, Matthieu D. Bec, GMTO Corp. (United States)

The Giant Magellan Telescope (GMT) requires the implementation of complex behaviors to perform observations in both seeing limited and adaptive optics modes. GMT is developing a set of software frameworks that facilitate the specification and development of the required behaviors. The frameworks are the embodiment of a state analysis control architecture, the design and implementation of which is enabled by a model based development process and a set of Domain Specific Languages (DSL).

The behaviors needed to achieve the required image quality in each observing mode will involve complex target acquisition sequences of multiple wavefront and metrology sensors and the coordination of complex nested control loops. The robust execution of these behaviors and a visual representation of the system that can be understood intuitively by the telescope operators are both paramount to the accurate and efficient operation of the observatory.

The implementation of the frameworks leverages existing open-source third party packages, and remain implementation independent following an adapter pattern.

The design of these frameworks addresses several concerns related to distribute communication, goal based sequencing, data product provenance, and complex behavior visualization. A common core framework implements a distributed communication design pattern to establish temporal bindings of arbitrary duration between goals and state variables. This communication pattern provides a higher level abstraction than publish-subscribe or command-reply patterns and simplifies the implementation of complex distributed goal networks. Observations will be specified with a goal-based sequencing DSL that represents the desired behavior of the system. A goal engine will execute the sequences and record the relevant state variables. The sampled data will provide evidence of past behavior of the system and will enable the reenactment of that behavior for diagnostics purposes. The record of sampled data will also provide the foundation to establish data product provenance as well as temporal and causal dependencies to facilitate the understanding of state variable telemetry. Finally, a visualization framework that facilitates the navigation and monitoring of complex goal networks enables telescope operators to understand and anticipate the behavior of the system.

9913-66, Session 14

Integrated data analysis in the age of precision spectroscopy: the ESPRESSO case

Guido Cupani, Valentina D'Odorico, Stefano Cristiani, INAF - Osservatorio Astronomico di Trieste (Italy); Jonai Isai González Hernández, Instituto de Astrofísica de Canarias (Spain); Christophe Lovis, Observatoire de Genève (Switzerland); Sérgio Sousa, Univ. do Porto (Portugal); Giorgio Calderone, Roberto Cirami, Paolo Di Marcantonio, INAF - Osservatorio Astronomico di Trieste (Italy); Denis Mégevand, Observatoire de Genève (Switzerland)

The Echelle SPectrograph for Rocky Exoplanets and Stable Spectral Observations (ESPRESSO) is an ultra-stable spectrograph for the coudé-combined focus of the VLT. With its unprecedented capabilities (resolution up to ~200,000, wavelength range from 380 to 780 nm; centimeter-per-second accuracy in wavelength calibration), ESPRESSO is a prime example of the now spreading "science machine" concept: a fully-integrated system carefully designed to perform direct scientific measurements on the data, in a matter of minutes from the execution of the observations. This approach is motivated by the very specific science cases of the instrument (search for terrestrial exoplanets with the radial velocity method; measure of the variation of fundamental constants using the spectral signatures of the inter-galactic medium) and is achieved by a dedicated tool for spectral analysis, the data analysis software (DAS), targeted to both stellar and quasar spectra. In this paper, we describe characteristics and performances of the DAS, with particular emphasis on the novel algorithms for quasar analysis (continuum fitting and interpretation of the absorption features), and its relevance for future instrumentation (like the high-resolution spectrograph for the E-ELT).

9913-67, Session 14

Fast and flexible big data processing at LSST data rates using existing, shared-use hardware

Ralf Kotulla, Univ. of Wisconsin-Madison (United States); Arvind Gopu, Indiana Univ. (United States)

Processing astronomical data to science-readiness was and remains a challenge, in particular in the case of multi-detector instruments such as wide-field imagers. One such instrument, the WIYN One Degree Imager, is available to the astronomical community at large, and, in order to be scientifically useful to its varied user-community on a short timescale, provides its users fully calibrated data in addition to the underlying raw data. However, time-efficient re-processing of the often large datasets with improved calibration data and/or software requires more than just a large number of CPU-cores and disk space. This is particularly relevant if all computing resources are general purpose and shared with a large number of users in a typical university setup. Our approach to address this challenge is a flexible framework, combining the best of both high performance (large number of nodes, internal communication) and high throughput (flexible/variable number of nodes, no dedicated hardware) computing. Based on the Advanced Message Queuing Protocol, we a developed a Server-Manager-Worker framework. In addition to the server directing the workflow and the worker executing the actual work, the manager maintains a list of available worker, adds and/or removes individual workers from the worker pool, and re-assigns worker to different tasks. This provides the flexibility of optimizing the worker pool to the current task and workload, improves load balancing, and makes the most efficient use of the available resources. We present performance benchmarks and scaling tests, showing that, today and using existing, commodity shared-use hardware we can process ODI data with data throughputs (including data reduction and calibration) approaching that expected in the early 2020s for future observatories such as the Large Synoptic Survey Telescope.

9913-68, Session 14

GAVIP: a platform for Gaia data analysis

Daniel Vagg, Derek O'Callaghan, Parameter Space (Ireland)

Gaia is a major ESA mission currently in orbit around L2. Its main scientific objective is to survey one billion stars in the Milky Way in order to make a 3-D map of unprecedented accuracy, thereby answering fundamental questions about the origin and evolution of our Galaxy. The distances of about 10 million stars will be determined to better than 1% accuracy.

In the course of its survey, Gaia also observes tens of thousands of other objects, such as asteroids, brown dwarfs and extra-solar planets. With its unique combination of wide field of view, sensitivity, simultaneous source colours/spectra and multi-epoch observations, Gaia's archive will undoubtedly become a transformational resource across many branches of astronomy in the years and decades to come. The first Gaia data release is scheduled for mid-2016.

Although Gaia has a 1 billion pixel focal plane instrument, the Gaia archive will primarily be in the form of a catalogue, rather than image-based. Even so, the final Gaia archive will ultimately be of the order of 1 PetaByte in size. As Gaia data becomes publicly available and reaches a wider audience, there is therefore an increasing need to facilitate the further use of Gaia products without needing to download large datasets over the net.

The Gaia Added Value Interface Platform (GAVIP) is designed to address this need by providing an innovative platform for scientists to re-use and deploy, close to the data, their own existing code - packaged as "Added Value Interfaces" (AVIs).

AVIs, when hosted in GAVIP, comprise a set of processing elements that can be shared and combined into more complex scientific workflows. GAVIP hosts these AVIs using Docker containers, which provide a lightweight form of virtualisation. The container itself is created using one of many Docker images, referred to as 'AVI templates', which are created to support different types of development. For example, a Java runtime may be installed in a template to enable the use of Java within an AVI pipeline.

Each AVI is developed within a Python framework which integrates a rich toolkit that astronomers are familiar with, including Jupyter and libraries such as astroquery, numpy and scipy.

In addition to hosting user-contributed AVIs, GAVIP will provide features including search and retrieval of products from the Gaia archive, management of user-specified processing tasks, management and storage of processing outputs and provision of services to integrate resources using VOSpace, TAP and SAMP.

GAVIP leverages technologies including OS-level virtualization (via Docker) and pipelines defined by code (via Luigi).

This paper will describe the capabilities of GAVIP, focussing on the features affecting users of the GAVIP platform. A demonstration of GAVIP can be provided.

GAVIP is designed to provide flexible and innovative capabilities for scientists and others to remotely engage with the Gaia archive, and is therefore to be deployed initially close to the primary data-products (i.e. Gaia data products), at the European Space Astronomy Centre (ESAC), near Madrid. This platform may also provide a useful baseline for future 'big astronomy' projects such as LSST.

Conference 9914: Millimeter, Submillimeter, and Far-Infrared Detectors and Instrumentation for Astronomy VIII

Tuesday - Friday 28–1 July 2016

Part of Proceedings of SPIE Vol. 9914 Millimeter, Submillimeter, and Far-Infrared Detectors and Instrumentation for Astronomy VII

9914-1, Session 1

The NIKA 2 commissioning campaign: performance and first results

Andrea Catalano, Lab. de Physique Subatomique et de Cosmologie de Grenoble (France)

New challenges in millimetre wave astronomy require high sensitivity and high resolution instruments. To achieve such a goal, the development of a new generation of array of detectors is needed, because current detectors such as high impedance bolometers are already photon noise limited both for space and for ground observations. One of the proposed technological solution is the use of Lumped Element Kinetic Inductance Detectors (LEKID) that allow for a large multiplexing factor (up to 400 pixels) frequency domaine read-out and an accessible manufacturing. This technological solution has been selected for the NIKA project that aims at constructing a dual-band millimetre camera for observation at 30 m IRAM telescope (Pico Veleta, Spain).

Within this context, the NIKA 2 camera is a kilo-pixels arrays instrument and it represents a one step further with respect the NIKA pathfinder instrument which has already shown state-of-the-art detectors and photometric performance. The camera has been permanently installed at the IRAM 30m telescope in October 2015, and it will be open to public observations at the end of 2016. The targets of the NIKA2 camera are to perform simultaneous observations in two millimetre bands (1.15 mm and 2.0 mm) of sub-mJy point sources as well as to map extended continuum emission up to about 6.5 arcmin scale with diffraction limited resolution and background limited performances. Such observational requirements will lead the NIKA2 camera to be a science driver in several astrophysical fields as the follow-up of Planck satellite clusters via the Sunyaev-Zel'dovich effect, high redshift sources and quasars, early stages of star formation and nearby galaxies emission. In addition, The NIKA 2 instrument hosts polarisation capability in the 1.15 mm arrays. The adopted solution is the use of an rotating warm Half-Wave-Plate to modulate the astrophysical polarised signal and a polariser mounted at the 100 mK stage to analyse the linear polarisations on the two 1.15 mm arrays.

9914-2, Session 1

POL-2: a polarimeter for the James-Clerk-Maxwell Telescope

Per Friberg, East Asian Observatory (United States); Pierre Bastien, Univ. de Montréal (Canada); Giorgio Savini, Univ. College London (United Kingdom); David S. Berry, East Asian Observatory (United States)

A polarimeter for SCUBA-2 has been under commissioning at the JCMT for some time. We will describe some recent results and the behavior of the instrument. The instrument consists of a spinning achromatic lambda/2 plate followed by a wire-grid analyzer in front of the SCUBA-2 bolometer camera. Observations are done by scanning the telescope. The polarization signal is dominated by the background polarized by the optical components and the wind blind protecting the telescope. We will discuss the removal of this polarized background as well as its relation to the instrumental polarization. Reflections between the analyzer and wave plate generate a modulation with twice the wave plate rotation rate which overshadows the polarization modulation at four times the wave plate rotation rate. The instrumental polarization is due to the wind screen and oblique reflections in the optical train. These and other artifacts due to the SQUID readout in SCUBA-2 are discussed as well as the data reduction.

9914-3, Session 1

ZEUS-2 at APEX: science results and performance

Amit Vishwas, Cornell Univ. (United States); Carl Ferkinhoff, Winona State Univ. (United States) and Max-Planck-Institut für Astronomie (Germany); Thomas Nikola, Stephen C. Parshley, Justin P. Schoenwald, Gordon J. Stacey, Cornell Univ. (United States); Sarah J. U. Higdon, James L. Higdon, Georgia Southern Univ. (United States); Axel Weiss, Rolf Guesten, Karl M. Menten, Max-Planck-Institut für Radioastronomie (Germany)

We present recent science results from the second generation Redshift (z) and Early Universe Spectrometer (ZEUS-2) deployed at the Atacama Pathfinder Experiment (APEX) Telescope. ZEUS-2 is a long slit, direct detection, grating spectrometer for submillimeter wavelengths. The detector consists of two TES bolometer arrays designed for use between 200-850um. It is optimized for observations of faint molecular and atomic emission lines (R~1000) that can be used to characterize the physical conditions of both nearby and highly redshifted galaxies.

ZEUS-2 has demonstrated background limited performance in both, 350um and 450um bands at the telescope enabling extremely sensitive ground based sub-mm spectroscopy. Most of the star formation in the early Universe is highly obscured by dust in the interstellar medium of the host galaxy. A large population of such dusty star forming galaxies (DSFGs) in the early Universe has been discovered through their far-IR continuum (redshifted to sub-mm bands). Spectral line studies can help reveal the mode of star formation and characterize the energy source powering the starburst in individual sources. We present first results of our survey of the bright [OIII] 88um line studying the young stellar populations in such DSFGs, during the epoch of maximum star formation rate density in the Universe. We also present the first high redshift (z>2) detection of the [OI] 63um line from a galaxy at z=4.6.

We will also report on the lab characterization of the new 215/645um array to be deployed simultaneously with the 400um array in ZEUS-2 for the next observing run at APEX. The sensitivity of ZEUS-2's TES bolometer arrays, filters tuned to various grating orders and 7 atmospheric telluric windows combined with the 12-m APEX telescope at the best accessible site for sub-mm astronomy provides a powerful combination for studying galaxy formation and evolution near and far. ZEUS-2 observations will provide a stepping stone for detailed studies of high-z galaxies with ALMA in the near future.

9914-4, Session 1

The ArTeMiS wide-field submillimeter camera: on-sky performances at 350 and 450 microns

Vincent Révéret, Philippe André, Yannick-Jean Le

Pennec, Michel Talvard, Patrick Agnèse, Laurent Clerc, Commissariat à l'Énergie Atomique (France); Carlos De Breuck, European Southern Observatory (Germany); Cyrille Delisle, Eric Doumayrou, Lionel Duband, Didier Dubreuil, Luc Dumaye, Eric Ercolani, Pascal Gallais, Vera Konyves, Commissariat à l'Énergie Atomique (France); Bruno Maffei, The Univ. of Manchester (United Kingdom); Michel Lortholary, Jérôme Martignac, Wilfried Rabaud, Johan Relland, Louis R. Rodriguez, Aurélie Vandeneynde, François Visticot, Commissariat à l'Énergie Atomique (France)

ArTeMiS is a wide-field submillimeter ground-based camera with simultaneous imaging capabilities in two atmospheric transmission bands (350 and 450 microns), and a radiometric mode in the 200 microns band. It benefits from the exceptional conditions at the APEX telescope site (Chile, 5100m above sea level), in term of low atmospheric opacity in the submillimeter range. ArTeMiS is developed by CEA (Saclay and Grenoble, France), IAS (France) and the University of Manchester (UK) in collaboration with the European Southern Observatory (ESO). The camera has been previously tested at APEX during two technical runs in 2013 and 2014, with detectors operating in the 350 microns atmospheric window only. The paper reports on the installation of the full capacity ArTeMiS instrument during the first half of 2016 in the Cassegrain cabin of the APEX telescope.

The first part of the paper gives an overview of the updated hardware of ArTeMiS. We present several improvements in the mechanical and optical parts compared to the previous version. We describe the addition of the new optical bands, in particular the 200 μm band to be used to reduce atmospheric noise. The updated cryogenic system is also presented: we describe the thermal regulation system that improves the overall stability of the detectors during observations. This new feature is of particular interest when we perform skydips (measurement of the atmospheric emission at different airmasses). During these phases, the telescope rapidly moves along the elevation axis and this sudden change in orientation can affect the performances of the ArTeMiS pulse tubes (and therefore the temperatures of the whole thermal chain). The thermal regulation can actively compensate the variations of temperatures of certain thermal interfaces inside the camera.

We also describe the characteristics of the focal plane units: pixel yield, spatial arrangement of the pixels, optical alignment, dynamical range, flatfield. The ArTeMiS detectors consist in resistive high impedance bolometers arranged in 16 x 18 sub-arrays operating at 300 mK. These detectors are similar to the ones developed for the Herschel PACS photometer but they are adapted to the high optical load encountered at APEX site.

In the last section, we give details on the on-sky commissioning run made at APEX. Performances on sky are given and compared to the results obtained during the previous runs. The mapping speed of the previous version of ArTeMiS was already 3 times better than the previous 350 microns instrument installed at APEX. We give the updated value and show preliminary scientific results.

9914-5, Session 1

MUSTANG2: on-sky performance and first results

Simon R Dicker, The Univ. of Pennsylvania (United States); Peter A. R. Ade, Cardiff Univ. (United Kingdom); James Aguirre, The Univ. of Pennsylvania (United States); Justus A. Brevik, National Institute of Standards and Technology (United States); Hsiao-Mei Cho, Stanford Univ. (United States); Rahul Datta, Univ. of Michigan (United States); Mark J. Devlin, Bradley J. Dober, The Univ. of Pennsylvania (United States); Dennis Egan, National Radio Astronomy Observatory (United States); John M. Ford, National Institute of Standards and Technology (United States); Pam Ford, National Radio Astronomy Observatory (United States); Gene C. Hilton, Johannes Hubmayr, National Institute of Standards and Technology (United States); Kent D. Irwin, Stanford Univ. (United States); Paul Marganian, Brian S. Mason, Melinda Mello, National Radio Astronomy Observatory (United States); Jeff J. McMahon, Univ. of Michigan (United States); Anthony K. Mroczkowski, European Southern Observatory (Germany); Johnathan Sievers, Univ. of KwaZulu-Natal (South Africa); Sara M. Stanchfield, The Univ. of Pennsylvania (United States); Carole E. Tucker, Cardiff Univ. (United Kingdom); Steven White, Mark Whitehead, National Radio Astronomy Observatory (United States); Alex H. Young, The Univ. of Pennsylvania (United States)

MUSTANG2 is a 215 element focal plane array that operates between 75 and 105 GHz on the 100 meter Green Bank Telescope (GBT). It shares many of the science goals of its predecessor, MUSTANG, which operated between 2007 and 2013. However, with over 10 times the sensitivity and an increase in the field-of-view (fov) of over a factor of 25, MUSTANG2 will greatly expand on what MUSTANG has been able to do. For example, MUSTANG was able to resolve substructure in selected galaxy clusters via the Sunyeav-Zel'dovich effect but with 100 times the mapping speed MUSTANG2 will be able to do the same on a statistically significant sample. In addition MUSTANG2's larger fov (4.3 arcminute) will recover angular scales from 9" to 6' with high fidelity providing a unique and larger overlap between high resolution instruments such as ALMA and lower resolution single dish telescopes such as ACT or SPT.

MUSTANG2 will have a background limited performance. Smooth walled feeds with monotonically decreasing profiles control the illumination of the telescope and planar OMTs couple each polarization into superconducting microstrip. To simplify readout and to make detector noise targets easier to meet, the two polarizations are combined onto a single TES bolometer. To read out the detectors, MUSTANG2 uses microwave SQUID multiplexers and is the first astronomical instrument to do so. In this multiplexing scheme the TES bias current runs through an RF SQUID which forms part of a resonator. Changes in incident power on the TES change the self-inductance of the SQUID, which in turn causes small shifts in the frequency of the resonator. These shifts can be measured by a matching RF frequency tone. Each resonator in the array has a slightly different frequency so large numbers of detectors can be read out using a comb of tones sent into the cryostat using a single pair of coaxial lines.

Because of the large size of the GBT, the optimal feed horn pitch is 15.5mm which is large compared to the size of the silicon wafers used to manufacture TES detectors. Consequently MUSTANG2 uses a modular approach with individual detectors mounted on the end of each feed and connected to the multiplexers via a superconducting circuit board. This has the advantage that a completely functioning array can be achieved and new detector recipes tested simply by swapping out modules.

9914-22, Session 1

SPACEKIDS: kinetic inductance detectors for space applications

Matthew J. Griffin, Cardiff Univ. (United Kingdom)

Superconducting detectors operating at sub-kelvin temperatures are currently the most sensitive detectors of far infrared and submillimetre radiation. Instruments using transition edge superconducting (TES) sensors and kinetic inductance detectors (KIDs) are already in use in ground-based

astronomical instruments, but have yet to be flown in space. SPACEKIDS, a recently completed European Union FP-7 project, has focussed on developing advanced KID arrays and demonstrating their suitability for space applications in both astronomy and Earth observing.

SPACEKIDS has included the following activities: (i) review and analysis of the scientific requirements for future astrophysics observatories, cosmic background polarisation experiments, and Earth observing missions, to derive key requirements for different applications and to specify the design of laboratory demonstration systems and the performance parameters of prototype arrays; (ii) development and evaluation of various pixel and array designs using both antenna-coupled and lumped-element KID architectures; (iii) design and manufacture of 2-GHz bandwidth readout electronics suitable for use with kilo-pixel KID arrays; (iv) fabrication and comprehensive testing, in representative laboratory test-beds, of prototype kilo-pixel arrays operating in both low and high photon background, to demonstrate key performance parameters relevant to future space missions; (v) conceptual studies of space-borne KID-based instruments and formulation of a technology development roadmap outlining future work needed to develop space-qualified KID array systems.

Following an in-depth study of future mission requirements, detailed performance specifications were defined for two demonstrator systems (one low-background, representative of a cold-aperture space astrophysics mission) and one high-background (representative of Earth-observing applications), including electromagnetic radiation bandwidth, background power levels, sensitivity (NEP), 1/f noise, speed of response, cosmic ray susceptibility, crosstalk rejection, dynamic range and linearity. There has been a wide range of modelling and experimental work, with good progress made in all respects. Modelling of KID-KID cross-coupling has quantified the degree to which it depends on inter-pixel distance and on the differences in resonant frequency, leading to the development and verification of a method to minimise the effects, and showing that KID arrays can be made with negligible cross coupling. KIDs based on aluminium films have been shown to meet the sensitivity and other requirements, with photon noise limited performance down to background power levels of 0.1 fW and ability to achieve high-efficiency broadband optical coupling. Methods of reducing the susceptibility of the detectors to cosmic ray impacts have been modelled and experimentally proven. Both antenna-coupled and lumped-element KID array designs have been developed, manufactured and successfully tested in dedicated high- and low-background test facilities, using the FPGA-based readout electronics developed and built for the project.

We will present an overview of the SPACEKIDS project and a summary of its main results and conclusions.

9914-6, Session 2

Optical performance of prototype horn-coupled TES bolometer arrays for SAFARI

Michael D. Audley, Gert de Lange, SRON Netherlands Institute for Space Research (Netherlands); Jian-Rong Gao, SRON Netherlands Institute for Space Research (Netherlands) and Technische Univ. Delft (Netherlands); Pourya Khosropanah, Richard A. Hijmering, Marcel L. Ridder, SRON Netherlands Institute for Space Research (Netherlands)

The next generation of far-infrared space-based astronomical observatories will require extremely sensitive detectors. To meet the challenge of testing such sensitive detectors we constructed an ultra-low background test facility based on a cryogen-free high-capacity dilution refrigerator, paying careful attention to stray-light exclusion, shielding, and vibration isolation. This test facility has been used for optical testing of ultra-sensitive prototype horn-coupled TES bolmeters for SAFARI, the grating spectrometer on board the proposed SPICA satellite. SAFARI's three bolometer arrays, coupled with a diffraction grating, will make spectroscopic observations over the wavelength range 34—210 μm.

Each of SAFARI's prototype bolometers consists of a transition edge sensor (TES), with a transition temperature close to 100 mK, and a tantalum absorber on a thermally-isolated silicon nitride membrane. The nitride membrane sits behind a few-moded feedhorn and in front of a hemispherical backshort. SAFARI requires extremely sensitive detectors (NEP<0.2 aW/rtHz), with correspondingly low saturation powers, to take advantage of SPICA's cooled optics.

For optical measurements the SAFARI Detector Test Facility contains internal cold (3—35 K) and hot (up to ~300 K) black-body calibration sources, a light pipe for external illumination, and a broad-band reference detector for characterising the spectral content of the calibration sources. Following a long programme of optimization and characterization the test facility is in routine use, measuring the electrical and optical characteristics of ultra-sensitive TES bolometers with NEP as low as 0.5 aW/rtHz.

We measured the broad-band response of prototype detectors for SAFARI's short-wave band (34--60 μm) under DC bias and obtained a thorough understanding of how the detectors couple to the modes supported by the feedhorn. We have also used an external Fourier transform spectrometer with the light pipe to measure the spectral response of the detectors.

We have added reimaging optics to the test bed in order to facilitate array optical measurements. We are now using the SAFARI Detector Test Facility for optical testing of prototype detector arrays read out with frequency-domain multiplexing. We present our latest measurements of the optical performance of prototype arrays, compare them with simulations, and discuss them in terms of the instrument performance.

9914-7, Session 2

Optical characterization of a camera module developed for ultra-low NEP TES detector arrays at FIR wavelengths

Dmitry V. Morozov, Rashmikant V. Sudiwala, Peter A. R. Ade, Cardiff Univ. (United Kingdom); David J. Goldie, Dorota M. Glowacka, Stafford Withington, Univ. of Cambridge (United Kingdom); Neil A. Trappe, National Univ. of Ireland, Maynooth (Ireland)

A unique camera architecture is proposed for future FIR low background instruments using ultra-low noise TES detectors. It consists of using profiled wall pyramidal horns in a square array feeding an array of TES detectors on a single silicon chip with an appropriate back-short. Important factors which drive this design are the need for a compact form with robust structure and tight tolerances <5?m which creates a Faraday cage around the detectors and guards against stray light. Here we report on the optical design and on the spectral-spatial characterisation of a small 16 pixel camera. The prototype uses TES detectors with NEPs ~10-16 W/Hz0.5 which have been fabricated with near identical optical coupling structures to mimic their much lower NEP counterparts (~10-19 W/Hz0.5). This modification, which is achieved through changing only the pixel thermal conductance, G, has allowed us to perform spectral/spatial cryogenic testing using a 100mK Adiabatic Demagnetisation Refrigerator to view room temperature thermal sources. The measurements show a flat spectral response across the waveband and minimal side lobe structure in the antenna patterns down to 30dB.

In addition, to separate coupling efficiency issues attributable to either the detector or the horn plate we have devised a scheme that enables spectral and spatial measurements of the horn plates alone to be made at ambient temperature. These results are also reported here.

Performance of horn-coupled transition edge sensors for L- and S-band optical detection on the SAFARI instrument

David J. Goldie, Dorota M. Glowacka, Stafford Withington, Univ. of Cambridge (United Kingdom); Peter A. R. Ade, Dmitry V. Morozov, Rashmi V. Sudiwala, Cardiff Univ. (United Kingdom); Neal A. Trappe, National Univ. of Ireland, Maynooth (Ireland); Orlando Quaranta, Univ. of Cambridge (United Kingdom)

We describe the geometry, architecture, dark- and optical performance of ultra-low-noise transition edge sensors as THz detectors for the SAFARI instrument. The TESs are fabricated from superconducting Mo/Au bilayers coupled to impedance-matched superconducting beta-phase Ta thin-film absorbers. The detectors have phonon-limited dark noise equivalent powers of order 0.5-1 “aW”⁄√(“Hz”) and saturation powers of order 20-40” fW.” The low temperature test configuration incorporating micro-machined backshorts is also described, and construction and typical performance characteristics for the optical load are shown. We report preliminary measurements of the optical performance of these TESs for two SAFARI bands; L-band at 110-210 “?m” and S-band 34-60 “?m” .

9914-9, Session 2

Ultra-low noise TES bolometer arrays for SAFARI instrument on SPICA

Pourya Khosropanah, SRON Netherlands Institute for Space Research (Netherlands); Toyoaki Suzuki, Japan Aerospace Exploration Agency (Japan); Richard A. Hijmering, Marcel L. Ridder, SRON Netherlands Institute for Space Research (Netherlands); Jian-Rong Gao, SRON Netherlands Institute for Space Research (Netherlands) and Technische Univ. Delft (Netherlands); H. Akamatsu, Luciano Gottardi, Jan van der Kuur, Brian D. Jackson, SRON Netherlands Institute for Space Research (Netherlands)

SPICA (SPace Infrared telescope for Cosmology and Astrophysics) is a future space mission for mid- and far-infrared (IR) astronomy. By having a large (2.5 m) and cooled (< 8 K) telescope combined with ultra-sensitive IR detectors, SPICA provides an opportunity to make natural background-limited observations over the wavelength range from 17 to 230 μm. One of the instruments aboard SPICA is SAFARI (SpicA FAR-infrared Instrument), which is a grating spectrometer covering the full 34-230 μm wavelength range. SAFARI detectors are transition edge sensor (TES) bolometers for three wavelength bands: S-band for 34-60 μm, M-band for 60-110 μm, and L-band for 110-230 μm. Each band requires a large number of pixels (~ 600-2000 pixels) and an extremely-high sensitivity (electrical Noise Equivalent Power, NEPel ~ 2?10^-19 W/√Hz at frequencies below ~ 100 Hz). SRON is developing ultra-low noise TESs based on a superconducting Ti/Au bilayer on a suspended SiN island with SiN legs. The pixel size is ~ 800x800 μm^2. Three types of TESs were fabricated on SiN islands with different sizes and with and without optical absorbers. These TESs have thin (0.20 μm), narrow (0.5-0.7 μm), and long (340-460 μm) SiN legs, and show Tc of ~ 93 mK and Rn of ~ 158 m. They were characterized under AC bias using a Frequency-Division Multiplexing readout (1-3 MHz) system. The TESs without absorber show NEPs as low as 1.1?10^-19 W/√Hz with response time of below 1 ms,. For the TESs with absorber, we confirmed a higher NEPel (~ 5?10^-19 W/√Hz) than that of TESs without the absorber, due to the stray light.

9914-10, Session 2

Development and performance of the microwave SQUID multiplexed TES array for MUSTANG-2

Sara M. Stanchfield, Alex H. Young, The Univ. of Pennsylvania (United States); Mark Whitehead, Steven White, National Radio Astronomy Observatory (United States); Leila R. Vale, National Institute of Standards and Technology (United States); Carole E. Tucker, Cardiff Univ. (United Kingdom); Charles Romero, Univ. of Virginia (United States) and IRAM-Domaine Univ. de Grenoble (France); Anthony K. Mroczkowski, U.S. Naval Research Lab. (United States); Jeff J. McMahon, Univ. of Michigan (United States); Melinda Mello, National Radio Astronomy Observatory (United States); John A. B. Mates, National Institute of Standards and Technology (United States); Brian S. Mason, Paul Marganian, National Radio Astronomy Observatory (United States); Kent D. Irwin, Stanford Univ. (United States); Gene C. Hilton, Johannes Hubmayr, National Institute of Standards and Technology (United States); Pam Ford, Dennis Egan, National Radio Astronomy Observatory (United States); Bradley J. Dober, Simon R. Dicker, Mark J. Devlin, The Univ. of Pennsylvania (United States); Rahul Datta, Univ. of Michigan (United States); Hsiao-Mei Cho, Stanford Univ. (United States); Justus A. Brevik, National Institute of Standards and Technology (United States); James Aguirre, The Univ. of Pennsylvania (United States); Peter A. R. Ade, Cardiff Univ. (United Kingdom)

MUSTANG-2 is a 90 GHz feedhorn-coupled, microwave SQUID-multiplexed TES bolometer array, with 215 unpolarized pixels. MUSTANG-2 operates with background-limited performance and 9” resolution on the 100-meter Robert C. Byrd Green Bank Telescope in Green Bank, WV. The sensitivity and mapping speed provided by MUSTANG-2 on the GBT will allow detailed study of a myriad of astrophysical phenomena including galaxy cluster mergers, active galactic nuclei, and star formation. In addition, MUSTANG-2 will enable detailed follow-up of galaxy clusters detected by Planck, ACT-Pol, and others in order to better constrain the scaling relationship between cluster mass and flux from the Sunyaev-Zel’dovich effect. The microstrip-coupled detector technology utilized for MUSTANG-2 was developed by a collaboration consisting of NIST, Princeton, the University of Chicago, the University of Colorado, and the University of Michigan. The collaboration has already produced detectors that have been thoroughly tested and deployed on SPTpol, ACTpol, and ABS. The microwave SQUID readout system developed for MUSTANG2 will eventually allow thousands of detectors to be read out with a single pair of coaxial cables. This microwave SQUID multiplexer combines the proven abilities of millimeterwave TES detectors with the multiplexing capabilities of KIDs with no degradation in noise performance of the detectors. In this system each TES is coupled to an RF-SQUID. A change in TES current (caused by the TES absorbing incident photons) induces a change in the magnetic flux of the SQUID, which then shifts the resonant frequency of resonator inductively coupled to that SQUID. The chain of resonators is then interrogated with a comb of probe tones whose transmitted amplitude and phase trace the power incident on the TES. Each multiplexing device is read out using warm electronics consisting of a commercially available ROACH board, a DAC/ADC card, and an Intermediate Frequency mixer circuit. The hardware was originally developed by the UC Berkeley Collaboration for Astronomy Signal Processing and Electronic Research (CASPER) group, whose primary goal is to develop scalable FPGA-based hardware with the flexibility to be used

in a wide range of radio signal processing applications. We present on the design and performance of the MUSTANG-2 array, including the microwave SQUID multiplexed devices as well as the readout system and results from commissioning of MUSTANG2.

9914-11, Session 2

Silicon-based antenna-coupled polarization sensitive millimeter-wave bolometer arrays for cosmic microwave background instruments

Karwan Rostem, Aamir Ali, John A. Appel, Charles L. Bennet, Johns Hopkins Univ. (United States); David T. Chuss, Villanova Univ. (United States); Felipe A. Colazo, Kevin L. Denis, NASA Goddard Space Flight Ctr. (United States); Thomas Essinger-Hileman, Tobias A. Marriage, Johns Hopkins Univ. (United States); Samuel H. Moseley, Kongpop U-Yen, NASA Goddard Space Flight Ctr. (United States); Edward J. Wollack, Johns Hopkins Univ. (United States)

We are developing feedhorn-coupled polarization-sensitive detector arrays that utilize monocrystalline silicon as the dielectric material for the on-chip microwave circuitry. Monocrystalline silicon has a low-loss tangent and repeatable dielectric constant, characteristics that allow efficient and uniform superconducting microwave circuits to be realized. An additional advantage of this material is its low specific heat that is well defined by the Debye equation. In a detector pixel, two Transition-Edge Sensor (TES) bolometers are antenna-coupled to in-band radiation via a symmetric planar orthomode transducer (OMT). The orthogonal linear polarizations are coupled to superconducting microstrip transmission lines. On-chip filtering is employed to both reject out-of-band radiation from the upper-band edge to the gap frequency of the niobium superconductor, and to flexibly define the bandwidth for each TES to meet the requirements of the application. The full-waveguide bandwidth of the OMT can be divided with a diplexer to achieve high-fidelity multichroic operation when desired. Metalized silicon platelets are used to define the quarter-wave backshort for the symmetric waveguide probes. This micro-machined structure is also used to mitigate the coupling of out-of-band radiation to the microwave circuit. At 40 GHz, the detectors achieve ~90% coupling efficiency with a linear TES response to in-band radiation. In this paper, we describe the development of the 90 GHz detector arrays that will soon be demonstrated using the Cosmology Large Angular Scale Surveyor (CLASS) ground-based telescope.

9914-12, Session 3

Development of digital sideband separating receivers for YTLA

Chao-Te Li, Jen-Chieh Cheng, Derek Y. Kubo, John T. Kuroda, Kim Guzzino, Ming-Tang Chen, Institute of Astronomy and Astrophysics - Academia Sinica (Taiwan)

This report presents a digital sideband separating method of upgrading the heterodyne receivers of the Yuan-Tseh Lee Array (YTLA) to a two-sideband receiver system. As observations of the Sunyaev-Zeldovich (SZ) clusters tapered off, a new initiative was taken for the YTLA, formerly the Array for Microwave Background Anisotropy (AMiBA), to map CO intensity to trace the large scale structure of star forming galaxies in the early universe. Since the analog correlator for the SZ observations doesn't have enough frequency resolution, the array is being retrofitted with a digital correlator for molecular line detection. Digital sideband separating receivers were also developed to double the processing bandwidth to probe more space volume. The receiver has a MMIC HEMT front-end operating at 3mm wavelength, and outputs signals at intermediate frequencies(IF) of 2-18 GHz. Our sideband separation scheme utilizes an analog RF hybrid followed by mixers as down-converters. The IF hybrid is implemented using high-speed analog?to?digital converters (ADC) and field?programmable gate arrays (FPGA). The ADC is capable of sampling up to 5 giga-sample-per-second (Gsps) and designed to interface with the Re-configurable Open Architecture Computing Hardware (ROACH), a stand-alone FPGA processing board developed by the Collaboration for Astronomy Signal Processing and Electronics Research (CASPER). The design samples up to 4 Gsps and thus produces two sidebands, each with 2 GHz bandwidth. This 2 x 2GHz band can be tuned within the 2-18 GHz IF of the array. By equalizing power and delay between the in-phase and quadrature (I/Q) signals, the sideband rejection ratios (SRR) are above 20 dB across the 4 GHz bandwidth. SRRs above 30 dB can be achieved when calibration is applied.

9914-13, Session 3

A wideband 240 GHz receiver for the submillimeter array

Edward C. Tong, Paul K. Grimes, Steve P. Leiker, Harvard-Smithsonian Ctr. for Astrophysics (United States)

Over the past few years, the Submillimeter Array (SMA) has offered 3 receiver bands for observation: the 200 GHz receiver covers 200 – 245 GHz; the 300 GHz receiver covers 260 – 350 GHz; and the 400 receiver covers 330 – 420 GHz. While the SIS mixers at the heart of these receivers can be operated over much wider bandwidth, the above listed useful bandwidth is dictated by the lowestt common denominator of frequency of operation of the Gunn oscillators powering the individual receivers in each antenna of the SMA.

Recently, a new receiver band has been introduced at the SMA. This new 240 GHz receiver is operated by a YIG-based Local Oscillator which is continuously tunable between 210 and 270 GHz. The new receiver is part of the wideband upgrade effort of the SMA, undertaken since 2011, in which the 8 element interferometer targets to increase its digital processing bandwidth from 4 GHz DSB to 2 x 8 GHz DSB for its 28 baselines of observation. For this, the SMA has expanded its IF bandwidth from 4 – 8 GHz to 4 – 12 GHz, while offering dual band and dual polarization observation capabilities. As a result, the SMA-240 receiver can be tuned to receive any sky frequency covering 198 – 282 GHz.

Apart from the wide IF bandwidth, the receiver features a low cost local oscillator module based on commercial components, built around an 8 – 18 GHz YIG oscillator and a 23 – 30 GHz medium power amplifier. No further high frequency power amplification is used. The SIS mixer is a scaled version of other SMA receivers. By using a 3 junction series connected SIS mixer, the receiver can provide low noise IF to beyond 12 GHz. The performance of this new receiver is comparable to that of the SMA-200 receiver already in operation. Including all the SMA receiver optics, typical receiver noise temperatures of 40 – 50 K are readily achieved across the whole receiver bandwidth. The noise measurement also demonstrates that the YIG-based LO does not degrade the receiver sensitivity.

One key mission of the SMA-240 receiver is to operate in conjunction with the SMA-200 receiver, by means of a wire grid polarizer at ambient temperature, to provide dual polarization observations. It is therefore important that the beams from the two receivers are co-aligned. During the commissioning phase of the SMA-240 receiver, we have employed a compact scanner built around a multiplied noise source to perform in situ amplitude beam mapping of the two receivers at the first focal plane of the SMA optics train. This set up allows quick alignment of the receiver beams.

In this paper, we will report on the construction of the SMA-240 receiver and its local oscillator module, it's on- telescope performance and the procedure used to align the receiver beams.

9914-14, Session 3

A new high-performance sideband-separating mixer for 650 GHz

Ronald Hesper, Univ. of Groningen (Netherlands); Andrey Khudchenko, SRON Netherlands Institute for Space Research (Netherlands); Andrey M. Baryshev, Univ. of Groningen (Netherlands); F. Patricio Mena, Univ. de Chile (Chile); Jan Barkhof, Univ. of Groningen (Netherlands)

In the past we successfully demonstrated a sideband-separating mixer for the frequency range of 600-720 GHz (ALMA Band 9). This mixer is based on the classical quadrature hybrid architecture, micromachined into a modular waveguide split-block. This mixer fulfilled the ALMA specifications with respect to noise temperature and image rejection.

However, based on the performance of the individual mixer devices, the performance was expected to be better. The main issues were a general excess of noise temperature, and a marked anti-correlation of the noise temperature and image rejection between mixer blocks of different materials and surface finish.

We report on the mechanisms responsible for these effects, and conclude the following. In the first place, the anti-correlation of the noise temperature and the image rejection is explained by the presence of standing waves. Based on simulations, we know the rejection ratio to be very sensitive to those. In principle, all potential round-trip paths should be terminated in matched loads, so no standing waves can develop. In practice, imperfect loads and non-negligible input/output reflections of the other components give many opportunities for standing waves. Since we can attribute almost all loss of rejection to the presence of standing waves, the anti-correlation with the noise temperature becomes obvious: when there is excess loss in the structure, the waveguides start acting like distribured loads, reducing the standing waves, and thereby improving the rejection ration. At the same time, however, the noise temperature suffers.

For the observed excess loss, two main contributions were identified: material properties and waveguide geometry. On the side of material properties, the gold plating that is customarily applied to waveguide blocks appeared to be detrimental to the waveguide transmission. In contrast, we found the noise performance of unplated copper blocks (even when alloyed with a few percent of tellurium for machinability) to be much better. The second important loss mechanism turned out to be the geometry of the waveguides. These were rather small (310 x 145um), which put the lower edge of the band close to the waveguide cutoff.

While functionally excellent, what was not taken into account at the time was the behaviour of the losses as function of waveguide size. A run of simulations we performed shows that this is close to the cutoff, losses rise significantly even with high-conductivity waveguide walls.

Based on these experiences, we designed a completely new waveguide structure, with a basic waveguide size of 400 x 200um and improved loads. As mentioned before, a strong emphasis was placed on low input and output reflections, in some places at the cost of phase or amplitude imbalance, for which there is ample marging in the design, however. Apart from further details of the design, we present the first results of the new mixers, tested in a modified production-level ALMA band 9 receiver.

9914-16, Session 3

Sideband-separating MMIC receivers for observation in the 3mm band

James W. Lamb, Kieran A. Cleary, Rohit S. Gawande, California Institute of Technology (United States); Jacob W. Kooi, California Institute of Technology (United States) and Jet Propulsion Lab. (United States); Michael P. Laxen, California Institute of Technology (United States); Richard L. Plambeck, Univ. of California, Berkeley (United States); Rodrigo A. Reeves, Univ. de Concepción (Chile); Pekka P. Kangaslahti, Jet Propulsion Lab. (United States); Mikko Varonen, Aalto Univ. School of Electrical Engineering (Finland)

Until April, 2015, CARMA, the Combined Array for Research in Millimeter-wave Astronomy, provided observational facilities in the 1-cm, 3-mm, and 1-mm bands. The receivers in the 3-mm band were single-polarization, double-sideband SIS mixers with cooled MMIC IF amplifiers, delivering 8 GHz of instantaneous bandwidth. During the final proposal funding period, we developed a new generation of receiver based on 3-mm MMIC amplifiers followed by image separating mixers capable of delivering 17 GHz of bandwidth in each sideband in each of two polarizations, or 68 GHz total instantaneous bandwidth per antenna. We present the design and results for the prototype receiver.

The goal was to develop low-noise receivers covering the 3-mm band from 80-116 GHz. To convert the signal down to a usable band, a side-band separating mixer is used after the amplifiers. Its function is to separate the noise from the two sidebands at a level of > 10 dB for improved sensitivity; much higher separation of the signal is achieved by phase-switching the LO in the interferometer.

Each amplifier is an integrated block incorporating three MMIC chips, waveguide input and output probes, and gain slope equalizers, as well as an integrated bias protection circuit. Using measured s-parameters for the MMICs and an EM model of the blocks, the equalizer parameters were adjusted for optimum amplifier performance. Measurements of the first demonstration blocks show an amplifier noise temperature between 25 and 45 K across the 75-116 GHz band, with 45-55 dB gain.

The amplifier is followed by a sideband-separating mixer designed for this receiver. It uses a waveguide quadrature hybrid to split the input signal, which is then fed to a pair of balanced mixers. LO to the mixers is supplied to the two mixers in the two polarizations through a 4-way splitter. The custom-design wideband quadrature hybrid splitter uses a septum with milled slots, and was qualified for amplitude and phase balance on a VNA. Following successful testing, a production quantity of 50 was made. To allow good integration and tight LO phase match, a 4-way splitter was machined in a split-block design that mates directly to the mixers on the quadrature hybrid.

Measurements of phase and amplitude matching of an ensemble commercial broadband solid-state mixers were made to confirm their suitability and enable selection of matching pairs. Commercial strip-line hybrids are used to combine the IF signals. One IF has a delay adjuster inserted to optimize phase balance, and both IFs have fixed pads with attenuations chosen to optimize amplitude balance.

A complete prototype with dual-circular polarization has been tested in the lab. Measured noise for the receiver, including the OMT and polarizer varies between ~45 and ~70 K. Typically, sideband separation is < 10 dB, but at some frequencies drops to 6 dB. On-the-sky tests were conducted with CARMA, and for line observations the improvement in sensitivity relative to the DSB SIS receivers was ~60%. With dual polarization this will yield a total sensitivity increase of ~2.3.

9914-68, Session PTue1

Development of a new tri-chroic antenna coupled bolometer for measurements of the polarization of the cosmic microwave background and foregrounds in a space environment

Benjamin Westbrook, Aritoki Suzuki, Adrian T. Lee, Oliver Jeong, Ari Cukierman, Univ. of California, Berkeley (United States); Kam S. Arnold, Univ. of Wisconsin-

Madison (United States); Nils W. Halverson, Univ. of Colorado Boulder (United States); Johannes Hubmayr, National Institute of Standards and Technology (United States)

We present the development of a tri-chroic antenna coupled transition edge sensor (TES) bolometer optimized for precision measurements of the polarization of the Cosmic Microwave Background (CMB) and galactic foreground in space environment. These devices employ a polarization sensitive broadband self-complementary sinuous antenna to feed on-chip band defining filters before delivering the power to load resistors coupled to a TES on a released bolometer island. They were originally developed by UC Berkeley for POLARBEAR-2 and SPT-3G and are now being considered as a candidate detector for the LiteBIRD mission, which is designed to measure B-modes from cosmic inflation and to robustly characterize the cosmic foreground from a satellite platform. We present the status of a prototype detector, which will have bands centered on 100, 145, 190 GHz with a fractional bandwidths of 23%, 30%, and 30% respectively. In addition, we present work on tailoring noise properties of these devices to meet the specifications of the experiment by reducing the Tc to 180 mK and thermal conductance of the bolometers to ~10 pW/K in all three bands.

9914-67, Session PTue2

Results of using permanent magnets to suppress Josephson noise in the KAPPa SIS receiver

Caleb H. Wheeler, Marko Neric, Matthew Underhill, Hamdi Mani, Arizona State Univ. (United States); Sander Weinreb, California Institute of Technology (United States); Damon S. Russell, Jet Propulsion Lab. (United States); Arthur W. Lichtenberger, Univ. of Virginia (United States); Jacob W. Kooi, California Institute of Technology (United States); Christopher K. Walker, Craig A. Kulesa, The Univ. of Arizona (United States); Christopher E. Groppi, Arizona State Univ. (United States)

We present the results of an investigation with the Kilopixel Array Pathfinder project (KAPPa) instrument. The KAPPa instrument is a THz heterodyne receiver using a Superconducting-Insolating-Superconducting (SIS) mixer that requires a magnetic field to improve performance. The KAPPa instrument can house an electromagnet that can be tuned to optimize the applied field, but it is also capable of accommodating a permanent magnet that applies a fixed field. Our permanent magnet design uses off-the-shelf neodymium permanent magnets and then reshapes the magnetic field using machinable iron concentrators. These concentrators allow the use of an unmachined permanent magnet in the back of the detector block while two small posts provide the required magnetic field across the SIS junction in the detector cavity. The KAPPa test instrument is uniquely suited to compare the permanent magnet and electromagnet receiver performance. The current work includes our design of a 'U' shaped permanent magnet, the testing and calibration procedure for the permanent magnet, and the overall results of the performance comparison between the electromagnet and the permanent magnet counterpart.

SIS mixers in THz heterodyne receivers allow for the down-conversion of high frequency signals (RF) to lower frequency signals (IF) that can be transmitted and analyzed by commercially available components. Efficient down-conversion requires the suppression of Josephson Noise, or Cooper pairs tunneling across the SIS junction, by biasing the junction with a magnetic field. Electromagnets allow for precise tuning of the bias field but are too large and consume too much power to be used in future, densely-packed SIS array receivers. Our strategy to solve the issue of power consumption and packing density for future THz arrays is to replace a tunable electromagnet with an off-the-shelf fixed permanent magnet to create the required magnetic field.

The KAPPa instrument was designed to house either an electromagnet or a permanent magnet. The magnet flexibility allows for the electromagnet and permanent magnets to be installed interchangeably from the backside of KAPPa instrument's detector block without the need to open the detector block and disturb the SIS device or supporting electronics. This feature provides a direct comparison of the same system's performance and an unambiguous test-bed for different magnetic field biasing techniques.

We present results for the KAPPa instrument over the dynamic range of the electromagnet coil tuning compared to the performance with the fixed field strength of the permanent magnet. Our methods for accounting for the hysteretic nature of the magnetic field strength for the optimal suppression of Josephson Noise for both systems are discussed.

Despite not machining our magnets, there is considerable room for changing field strength through magnet selection due to the variety of magnets available and the flexibility of the KAPPa permanent magnet platform. We present techniques for a lab bench measurement of the electromagnet and permanent field strengths. Additionally, we outline our process for selecting permanent magnets that will provide a magnetic field most similar to that of the optimal electromagnet tuning.

9914-69, Session PTue2

Band-1 receiver front-end cartridges for Atacama Large Millimeter/submillimeter Array (ALMA): design and development toward production

Yuh-Jing Hwang, Chau Ching Chiong, Yau-De Huang, Institute of Astronomy and Astrophysics - Academia Sinica (Taiwan); Chi-Den Huang, Ching-Tang Liu, National Chung-Shan Institute of Science and Technology (Taiwan); Yue-Fang Kuo, National Taipei Univ. (Taiwan) and Institute of Astronomy and Astrophysics - Academia Sinica (Taiwan); Shou-Hsien Weng, Chin-Ting Ho, Po-Han Chiang, Hsiao-Ling Wu, Chih-Cheng Chang, Shou-Ting Jian, Chien-Feng Lee, Yi-Wei Lee, Institute of Astronomy and Astrophysics - Academia Sinica (Taiwan); Marian W. Pospieszalski, National Radio Astronomy Observatory (United States); Doug W. Henke, National Taipei Univ. (Canada); Ricardo Finger, Univ. de Chile (Chile); Alvaro González, National Astronomical Observatory of Japan (Japan)

The ALMA Band-1 receiver front-end prototype cold and warm cartridge assemblies, including the system and key components for ALMA Band-1 receivers have been developed and two sets of prototype cartridge were fully tested based on the initial development presented in [1] – [3]. Based on the cryogenically cooled broadband low-noise amplifiers provided by NRAO and the cascode MHEMT mixers developed in ASIAA, the receiver noise temperature can be as low as 15 – 28K for pol-0 and 17 – 34K for pol-1. Other key testing items are also measured. The receiver beam pattern is measured, the results is well fit to the simulation and design. The pointing error extracted from the measured beam pattern indicates the error is 0.1 degree along azimuth and 0.15 degree along elevation, which is well fit to the specification (smaller than 0.4 degree). The power compression is measured, with 380 -436K hot load the compression is less than 4%, which fit to the specification of 5% with 373K input thermal load. The image band suppression is higher than 30 dB typically and the worst case is higher than 10 dB for 34GHz RF signal and 38GHz LO signal, which is all higher than 7 dB required specification. The cross talk between orthogonal polarization is 37 dB based on present prototype LO. The amplitude stability is below 2.0 x 10-7 , which is fit to the specification of 4.0 x 10-7

for timescales in the range of 0.05 s ≤ T ≤ 100 s. The signal path phase stability measured is smaller than 10fs, which is smaller than 22 fs for Long term (delay drift) 20 s ≤ T < 300 sec. The IF output phase variation is smaller than 2.5° rms, and the specification is less than 4.5° rms. The measured IF output power level is -28dBm with 300K input load. The measured IF output power flatness is less than 6 dB for 2GHz window, and 1dB for 31MHz window. All the above items are well fit to the specifications. At the moment of abstract submission, two sets of prototype cartridges have been successfully testes and the other two sets are under assembling, target to be tested in spring 2016 to collect more performance data. The first batch of prototype cartridges will be installed on site for further commissioning before the end of 2016.

Quantum-limited parametric amplifiers for coherent detection and the readout of superconducting detector arrays

Saptarshi Chaudhuri, Stanford Univ. (United States); Jiansong Gao, National Institute of Standards and Technology (United States); Kent D. Irwin, Stanford Univ. (United States)

Quantum-limited parametric amplifiers are promising for readout of large superconducting detector arrays, as well as coherent detection and spectroscopy of astronomical signals. The physics of parametric amplifiers based on superconducting kinetic inductance thin films and Josephson junctions is explored. We provide new insights into four-wave mixing and analyze the effects on amplifier noise performance due to heating, loss, and phase fluctuations. We also illustrate constraints on designing amplifiers using three-wave mixing. We discuss experimental progress toward realizing an amplifier with quantum-limited noise performance, high gain-bandwidth, and large dynamic range. Prospects for readout of large arrays of superconducting detectors, as well as detailed single pixel studies, with quantum-limited amplifiers is discussed. We also explore the possibility of using these amplifiers for coherent detection of astronomical signals.

We report the development of the new 4-beam, 2-polarization, 2-sideband, 100 GHz band SIS receiver "FOREST" (FOur beam REceiver System on the 45-m Telescope) and the results from commissioning and observations on the Nobeyama 45-m Telescope operated by Nobeyama Radio Observatory, a branch of National Astronomical Observatory of Japan. FOREST aims to add new capabilities of large-area mapping and simultaneous multi-line observation at 80 - 116 GHz band to the Nobeyama 45-m Telescope, which is one of the largest millimeter radio telescopes in the world.

The configuration of the four beams is a quadrate of 2 x 2 with the separation between adjacent beams of ~ 50". Beam size of each beam is ~ 15" at 115 GHz. Receiver noise temperature is as low as that of ALMA receivers, so that mapping speed is more than four times as high as that of the other 100 GHz band receivers on the 45-m Telescope. The IF bandwidth is 8 GHz (4 - 12 GHz) realizing simultaneous 12CO, 13CO, and C18O J=1-0 observations. Cooled components inside of cryostat are modularized per beam that includes one corrugated horn, one ortho-mode transducer, two sideband-separating SIS mixers (2SB mixers), two IF quadrature hybrids, four IF isolators, and four CLNAs. IF signals from the cryostat are processed by the room temperature IF system, and then passed to spectrometers.

We have installed the FOREST receiver into the Nobeyama 45-m Telescope, evaluated its performance, and made large area mapping observations. Beam pattern is measured by observing SiO masers, and we obtain beam separations of ~ 50" and beam sizes of ~ 20" at 86 GHz, which are consistent with the optics design. The system noise temperature including atmosphere is ~ 200 K, which is slightly higher than we expected. This is mainly because the SIS mixers are not optimized for such wide IF bandwidth. We are updating the design of SIS junctions and evaluating SIS mixers in laboratory, and we obtain a good candidate that shows DSB receiver noise temperature of ~ 30K at 4 - 12 GHz IF band. We will replace present SIS mixers to new ones next summer. Although FOREST shows an insufficient performance at this moment, its mapping capability, especially with the J=1-0 transitions of 12CO, 13CO, and C18O, is spectacular. We simultaneously achieved rms noise levels of 0.8 K, 0.4 K and 0.4 K at 1 km/s velocity resolution over the 1 deg x 1 deg area with a 5-hour observation for 12CO, 13CO and C18O J=1-0 transitions, respectively. This shows that the mapping efficiency is more than six times higher than that of the previous 25-beam SIS receiver, BEARS.

The FOREST receiver is used for the legacy projects of Nobeyama Radio Observatory, surveying nearby star-forming regions, nearby galaxies ("COMING": CO Multiline Imaging of Nearby Galaxies), and the Galactic plane ("FUGIN" = the Japanese Wind God: FOREST Ultra-wide Galactic plane survey In Nobeyama). Studies based on these surveys are on-going.

Extremely low noise UHF-band amplifier for square kilometer array

Frank Nianhua Jiang, Dominic Garcia, Pat Niranjanan, Mark Halman, Ivan Wevers, National Research Council Canada (Canada)

I. INTRODUCTION

In radio astronomy scientists always demand state-of-the art low noise and wideband receivers. With technology advancing and design tools improving, RF engineers can speed up the design cycle and realize the optimal design and ultimate best receiver performance. The Square Kilometer Array (SKA) project is an international effort to build the world's largest radio telescope, with a square kilometer of signal collecting area. The SKA will be the most powerful, sensitive and largest radio telescope ever constructed. Low noise amplifiers dominate the receiver's sensitivity. Most of low noise amplifiers published by far is operating above 1 GHz. A UHF-band cryogenic low noise amplifier was developed for SKA-mid telescope band-1 receiver with a record low noise temperature of 1.5 K and wide bandwidth from 350 to 1100 MHz.

II. DESIGN

It is a challenge to RF engineers to design cryogenic low noise amplifiers with a compact size and low power dissipation at the frequency of 350 MHz and wideband ratio (3:1). As the frequency band moves down to below 1000 MHz, The LNA design needs higher component values, and the circuits get larger in size. MMIC foundry processing has limitations on the fabrication of large value inductors and capacitors. Larger component values have a larger footprint on wafer and larger substrate loss. The large value components fabricated on wafer would compromise Q-factors. Hybrid circuit configuration is not subject to these limitations and is best adapted for a low noise design in the low frequency range. Discrete passive components with high-Q and large values can be selected to integrate with the best low noise transistors to optimize the LNA performance. The cryogenic LNA design for radio astronomy telescope comprises at least 8 parameters, such as low noise temperature, good S11 and S22, high gain, gain flatness, gain stability, gain compression, and unconditional stability beyond the entire operational frequency range. A considerable challenge in LNA design is to simultaneously achieve low noise temperature and good S11. They have complicated correlation and do not always work in each other's favor. Hybrid circuitry has flexibility on circuit layout and component placement. This facilitates minimizing the electromagnetic coupling and interference among the components, which can improve the stability, and reduce the noise from the unwanted feedback in circuit. InP HEMTs exhibit very low noise, high gain, and excellent performance especially at cryogenic temperature. For operating at this very low frequency, the transistors with large gate width and moderate gate length are preferred.

III. LNA PERFORMANCE

A UHF-band cryogenic LNA has been developed and fully tested at cryogenic temperature of 15 K. The cold attenuator method was used to measure the noise temperature and gain of the LNA in cryostat. The LNA was completely tested with 50 Ohm, open and short terminations at the LNA input port to confirm that the LNA was unconditionally stable at cryogenic operation. The LNA achieved an extremely low noise temperature of 1.5 K. The return losses (S11 & S22) were measured ≤ -12 dB at 15 K from 350 to 1100 MHz. The low S11 is preferred for improving the system efficiency and reducing the standing wave between feed and LNA. Given the good S11, this LNA doesn't need an isolator between OMT and LNA input port. Consequently, the receiver can achieve lower noise temperature than the one using an isolator.

Strategies on solar observation of Atacama Large Millimeter/submillimeter Array (ALMA) band-1 receiver

Chau-Ching Chiong, Po-Han Chiang, Yuh-Jing Hwang, Yau-De Huang, Institute of Astronomy and Astrophysics - Academia Sinica (Taiwan)

ALMA covering 35-950 GHz is the existing largest telescope array in the world. Among the 10 receiver bands, Band 1, which covers 35-50 GHz, is the lowest. For solar observation, which is identified as one of the main scientific goals of ALMA, a solar filter with 6-12 dB attenuation is already installed for the other bands. It is equipped with Amplitude Calibration Device (ACD) located between the secondary and the cryostat in the ALMA receiver cabin. However, there are at least two drawbacks when it is applied to Band 1. First, the current solar filter is only 94mm in diameter, and with current Band 1 receiver layout, the beam size is 52mm at the position of the solar filter when observing at 35 GHz. Spillover contributes high noise level in the final data. Second, the solar filter degrades the signal-to-noise ratio due to high attenuation. To overcome this problem, strategies for direct observation toward the Sun are investigated. At millimeter regime, the radiation comes mainly from the chromosphere with brightness temperature of 6000 to 10000 K, it is more than 15 dB stronger in power compared with room temperature load. For active regions, another 15 dB margin is needed. To reduce the system gain, to minimize the impact on noise performance, and to maintain the power compression budget, we thus investigate the de-tuning biasing technique for the RF amplifiers in the system. In current Band 1 system, the cryogenic and room temperature amplifiers are multi-stage HEMT-based amplifiers. The biasing points of transistor in the middle (typically the third stage and the fourth stage) are de-tuned. Preliminary testing at room temperature shows de-tuning one stage can reduce 10 dB gain without degradation in output power compression level. Further gain reducing is possible with de-tuning fourth stage without hurting power compression level. Impact of the noise performance of the amplifier is little with one stage de-tuned. Changing of input/output return loss is also minimal. The total system gain can be fined-tuned by the following tunable attenuator to comply ALMA output power level requirement. With the strategies, solar observation with HEMT-based receiver shows its superior to SIS-mixer receiver for little degradation in system noise performance. System level testing will be performed in early 2016.

The 7 beams S-band cryogenic receiver for the Sardinia Radio Telescope primary focus: status of project

Giuseppe Valente, Adelaide Ladu, Pasqualino Marongiu, Alessandro Navarrini, Tonino Pisanu, INAF - Osservatorio Astronomico di Cagliari (Italy)

The Sardinia Radio Telescope (SRT) is a general purpose fully steerable 64-m diameter radio telescope capable of operating whit high efficiency from 300 MHz up to 115 GHz. The SRT optical design is based on a classic symmetrical Gregorian configuration where both primary and secondary surfaces are shaped in order to remove the stationary wave bouncing between the two mirrors, improving consequently the antenna efficiency. The main reflector consists of a back up structure (bus) which supports the quasi-parabolic active surface. The primary reflector is composed by 1008 aluminum panels. The sub-reflector consists of 49 aluminum panels and along with the prime focus positioner and the associated instrumentation, it's supported by the quadrupod structure connected to the bus. One of the peculiar characteristics of SRT is the availability of three different focal positions, to operate in different frequency ranges: Primary (F1), Gregorian

(F2) and Beam-Wave Guide (F3), with F/D ratio and frequency ranges respectively of: 0.33 (0.3-20 GHz), 2.35 (7.5-115 GHz), and 1.37 & 2.84 (1.4- 35 GHz). The primary focus has a feed edge illumination of 74°, while for the Gregorian focus the half aperture angle is 12°. At this moment on SRT there are three receivers installed, one for each focus. In the primary focus there is a dual frequency LP receiver, which operates simultaneously in both bands P (0.305-0.410 GHz) and L (1.3-1.8 GHz). In the BWG focus there is a mono-feed C-Band receiver (5.7-7.7 GHz). In the Gregorian focus there is a multi beam K-band receiver (18-26,5 GHz). For the second generation of the receiver for the ST, the Observatory of Cagliari (INAF-OAC) is designing a superhetoryne cryogenic array receiver with seven pixel and dual polarization, operating at S-band, 3.0-4.5 GHz. This new instrument will offer large science capabilities forpulsar observations and mapping of radio sources. The main specification of the receiver are as follow:

RF (Radio Frequency) Band: 3.0-4.5 GHz;

Size of the array: seven pixel;

Polarization: two linear polarization for each pixel;

IF (Intermediate Frequency) Band: 0.1-1.6 GHz;

Noise Temperature: < 15 Kelvin for each pixel;

The RF signal path is completely cooled down at 20 Kelvin. It consist of a simple broadband circular feed, a double ridged orthomode transducer (OMT) that divide the signal into the horizontal and vertical polarization. Finally, each polarization is amplified with a commercial low noise amplifier (LNA). The RF chain is repeated identically seven time because the finally configuration of the Focal Plane Array is composed by seven beams. The design of the waveguide passive components, like feed and OMT, were constrained by the available space along the optical axis direction, (1 m) inside the focal cabin of the telescope.

In this paper, we describe the new architecture of the 7-Beams S-band cryogenic receiver, the final electromagnetic simulations of the overall front end RF chain, the thermal design and the final measurement of the down conversion section.

9914-75, Session PTue2

The control system and the new cryogenics of the 3 mm band SIS receiver for the Sardinia Radio Telescope

Adelaide Ladu, Pierluigi Ortu, Andrea Saba, Pasqualino Marongiu, Giuseppe Valente, Tonino Pisanu, Enrico Urru, Alessandro Navarrini, INAF - Osservatorio Astronomico di Cagliari (Italy); Giuseppe Mazzarella, Univ. degli Studi di Cagliari (Italy)

The Sardinia Radio Telescope (SRT), a challenging scientific project of the Italian National Institute for Astrophysics (INAF), is a new general purpose fully steerable 64 m diameter radiotelescope designed to operate with high efficiency across the 0.3-116 GHz frequency range. The technical and scientific commissioning of the telescope has recently been completed and a call for proposal for an early science program released.

We present the status of development of a 3 mm band cryogenic receiver, one of the new Front-Ends planned for installation in SRT, which will join the already commissioned telescope instrumentation (P-, L-, C- and K-band receivers). The instrument is an old-generation receiver designed and built at IRAM (Institut de RadioAstronomie Millimétrique) which was deployed at the Plateau de Bure Interferometer until 2006. Following its decommissioning, it was purchased from INAF with the goal of testing the performance of the active surface of SRT at its highest operational frequencies of approximately 100 GHz. In particular, the receiver will cover the 84-116 GHz frequency range and will be installed at the secondary (Gregorian) focus of SRT. The Front-End is based on a backshort-tuned Single Side Band (SSB) SIS (Superconductor-Insulator-Superconductor) mixer which was cryogenically cooled at 4 K by thermalizing it to a liquid helium vessel located inside a three-stage cryostat, where a CTI 350CP cold head provided the ≈20 K and ≈80 K cooling stages.

In order to allow integration of the receiver in SRT, three important modifications were made to the original design: a) to the cryogenics; b) to the local oscillator; c) to the control system.

a) We changed the receiver liquid helium cryogenics and adopted a cold head from Advanced Research Systems (ARS, model DE-204SF) which is mechanically compatible with the pre-existing CTI350CP model and can be mounted on the cryostat (from Infrared Lab). The ARS cold-head has two cryogenic stages, one at ≈20K (delivering 8 W of cooling power) the other ≈4 K (delivering 0.2W of cooling power), thus allowing a liquid helium-free solution, which much facilitate the receiver maintenance and is compatible with the telescope operation. The choice of this cold head imposed a change both internal and external of this receiver;

b) Rather than using the traditional Gunn-based local oscillator employed at IRAM for pumping the SIS mixer, we utilize an electronically tuned Local Oscillator (LO) based on an Active Multiplied Chain (AMC) and Power Amplifier (PA), developed at NRAO (National Radio Astronomy Observatory) for the ALMA (Atacama Large Millimeter Array) project;

c) The control system is based on a single-board computer from Raspberry, on microcontrollers from Arduino and on a Python program for communication between the receiver and the SRT antenna control software, which remotely controls the backshort-tuned SIS mixer, the receiver calibration system and the local oscillator.

In addition to a detailed description of the points in a), b), c) above, we will present the receiver laboratory test results and comparison with expected performance.

9914-76, Session PTue2

Next generation receivers for the submillimeter array

Paul K. Grimes, Edward C. Tong, Raymond Blundell, Scott N. Paine, Lingzhen Zeng, Smithsonian Astrophysical Observatory (United States)

The Submillimeter Array (SMA) is an 8 element mm/sub-mm interferometer, operated on the summit of Mauna Kea by SAO and ASIAA. After 11 years of operation, the time has come for an overhaul of the array's cryogenics, receivers and other systems in order to enhance the science capabilities of the array.

Currently the SMA can simultaneously operate two DSB, single polarization receivers, with 2 GHz of IF bandwidth per receiver, or 4 GHz bandwidth for a single receiver. Ongoing upgrades will increase the bandwidth to 2x 8GHz DSB. Either the 200 (200–245 GHz) or 300 (260–350 GHz) receiver can be used on one polarization, while either the 240 (198–282 GHz) or 400 (330–420 GHz) receiver is used on the other. This allows either dual frequency observing on orthogonal polarizations or dual polarization observing within the overlap frequency ranges of orthogonal receivers.

The next generation receiver for the SMA features a new pulse-tube cooled cryostat, which houses cooled receiver selection optics and dual polarization receiver cartridges at 230 GHz and 345 GHz. The selection optics will allow dual polarization observing with either receiver, single polarization/dual frequency observing using a wire grid and one channel of both receivers, or dual polarization/dual frequency observing using a dichroic plate.

Both receiver cartridges will use a single dual polarization feedhorn feeding an orthomode transducer. The use of a single feedhorn will simplify the alignment of the beams for each polarization, while the use of identical mixers in a single receiver assembly for both polarizations should reduce gain fluctuations between the two polarizations.The two wideband receivers are powered by two Local Oscillator modules continuously tunable between 210-270 GHz and 280-360 GHz. These LO signals will be brought into the cryostat in waveguide, and coupled via waveguide directional couplers. The SIS mixers will be developments of the existing

SMA wideband SIS mixers, each providing at least 14 GHz (4-18 GHz) of DSB IF bandwidth.

Given that the new receivers will provide a total instantaneous bandwidth of 4 x 14 = 56 GHz, transporting this IF bandwidth to the correlator will require a number of changes to the SMA signal transport scheme, with the deployment of a 1550 nm WDM system over the existing optical-fibers. The SMA is committed to further develop the ultra-wideband digital backend (SWARM), which it pioneers, to handle the bandwidth of the new receiver systems.

The simplification of the receiver optics and use of a smaller cryostat for the main receiver bands will allow space in the receiver cabin for a "guest receiver" position that will be able to accommodate a variety of interchangeable receiver systems that could be developed for specific large scale observing programs or to provide new observing capabilities. Examples of possible guest receivers include high frequency receivers for the 650 or 800 GHz bands, dual frequency receivers targeting the 492 GHz and 806 GHz ionized carbon lines and small multibeam array receivers.

9914-77, Session PTue2

Status of the radio receiver system of the Sardina Radio Telescope

Giuseppe Valente, Tonino Pisanu, Alessandro Navarrini, Istituto Nazionale di Astrofisica (Italy); Alessandro Orfei, Istituto Nazionale di Astrofisica (Italy) and INAF - Istituto di Radioastronomia (Italy)

The Sardinia Radio Telescope (SRT, www.srt.inaf.it) is a general purpose fully steerable 64-m diameter antenna, capable of operating at high efficiency from 300 MHz up to 115 GHz. The SRT optical design is based on a classic Gregorian configuration, where both primary (M1) and secondary (M2) reflector surfaces are shaped in order to remove the stationary standing wave bouncing between the two mirrorsThe main reflector consists of a back-up structure which supports the quasi-parabolic active surface. The M1 and M2 are made respectively of 1008 and 49 aluminum panels, are and supported by a back-up and a quadripod structure. SRT has been designed to observe from six focal positions and to be equipped with up to twenty seventeen receivers: Primary focus (F1), Gregorian focus (F2) and Beam-Wave Guide foci (F3-F5 and F4-F6), with focal length to diameter ratio (F/D) and frequency ranges respectively equal to 0.33 (0.3-20 GHz), 2.35 (7.5-115 GHz), and 1.37 & 2.84 (1.4- 35 GHz). At the moment on SRT there are installed 3 radio receivers, one for each focus. A dual linear polarization coaxial receiver, that covers two frequency bands, the P band (305-410 MHz) and the L band (1.3-1.8 GHz) is arranged in the primary foci (F1). A double circular polarization mono-feed, that covers the High C band (5.7-7.7 GHz) is installed in the beam waveguide (BWG) foci (F3). Finally, a multi-beam (seven beams) double circular polarization K band Receiver (18-26.5 GHz) is installed in the Gregorian foci (F2). The typical schematic diagram of the receiver for the antenna is a superheterodyne configuration. The radiofrequency (RF) reflected from the mirrors is coupled with the feed antenna and then amplified with by a cryogenic LNA (low noise amplifier), mixed with a strong amplitude local oscillator in order to generate the intermediate frequency band proportional to the RF signal. The K and C band are based on a superheterodyne configuration, instead the LP band, due to its low RF band, is transported inside the standard intermediate frequency range of the system (IF range: 0.1-2.1 GHz) and doesn't has because it is not provided of a down convertion section. The RF chain between the three receivers are quite different and we will show these differences into this paper. Another fundamental aspect of our receivers is that they operate at cryogenic temperature (typically below 20 Kelvin) to improve the total noise temperature noise of the system. In conclusion in this paper, we describe each single configuration of the receivers, showing the most important performances like system temperature (Tsys), half power beam width (HPBW), stability. In the last part of the document we will anticipate the second generation of the radio receivers for the SRT.

9914-78, Session PTue2

Wideband millimeter and submillimeter-wave parametric amplifiers based on kinetic inductance

Peter K. Day, Henry G. LeDuc, Jet Propulsion Lab. (United States); Byeong-Ho Eom, California Institute of Technology (United States); Christopher E. Groppi, Arizona State Univ. (United States); Roger C. O'Brient, Jet Propulsion Lab. (United States); Philip D. Mauskopf, Arizona State Univ. (United States)

We will discuss progress toward superconducting traveling-wave kinetic inductance parametric amplifiers for the millimeter and submillimeter bands. Microwave frequency versions of these amplifiers, which exploit four-wave mixing in an NbTiN coplanar waveguide transmission line, have demonstrated wide band gain and near quantum limited noise at several GHz. Their simple design is easily scalable to higher frequency, potentially allowing for operation up to about 1 THz, close to the gap frequency of NbTiN. Use of a quantum limited, wide band amplifier at the front end of a sub/millimeter band heterodyne receiver would allow for a much wider instantaneous bandwidth than is achievable with SIS mixers.

We have designed and fabricated waveguide-coupled parametric amplifiers for W-band. Integrated matched filters prevent self-oscillations that may result from out of band reflected power. The results of preliminary measurements on these devices will be described.

9914-79, Session PTue2

Traveling wave parametric amplifiers for millimeter wave heterodyne systems

Roger C. O'Brient, Peter K. Day, Henry G. Leduc, Jet Propulsion Lab. (United States); Christopher E. Groppi, Arizona State Univ. (United States)

We are developing superconducting traveling wave parametric amplifiers for millimeter waves to act as front-end low noise amplifiers for spectroscopy and interferometry applications. We have fabricated W-band amplifiers as NbTiN CPW lines on Silicon substrates with integrated waveguide probes that couple power between split-block waveguide feeds. This design draws on our teams success with microwave frequency amplifiers, but with appropriate modifications for high-frequency operation. We will describe this design and comment on on-going cryogenic tests of noise performance and spectral features performed with a VNA test-bed. In principle, these amplifiers can operate at the quantum noise limit, which could provide substantial sensitivity benefits if used in conjunction with traditional SIS heterodyne systems.

9914-80, Session PTue2

New instrumentation for the 1.2m Southern Millimeter Wave Telescope (SMWT)

Nicolás Reyes, Pablo Vásquez, Rafael Rodriguez, Pablo Astudillo, Ricardo Finger, F. Patricio Mena, Leonardo Bronfman, Univ. de Chile (Chile)

Here we describe the upgrade of the Southern 1.2?m mm? Wave Telescope. The telescope was relocated from Cerro Tololo to Santigo (Chile) allowing for aesier use of the facility by our students and faculties. To compensate for the atmospheric opacity of the new site the front/end was upgraded to

include a sideband separation system. This reduces the noise contribution of the atmosphere by a factor of two. The new LO system and receivers are designed to cover an extended frequency range from 85 to 116 GHz. The receiver is based on low noise amplifier using HEMT technology and two sub-harmonic Schottky mixers for down conversion. The complete receiver is cooled to 80 K by liquid nitrogen. The old back-end based on a filter bank was replaced by a new digital spectrometer, based on the Reconfigurable Open Architecture Computing Hardware (ROACH). This new back-end increases the spectral resolution by a factor of 4 and incorporates digital calibration of the sideband rejection mixer, achieving values of rejection larger than 30 dB across the whole band. Future plans for the instruments include capabilities for simultaneous observations of the 12CO, 13CO and C18O lines. The new telescope control system is under development and the complete system will start scientific observation on 2016/2.

9914-17, Session 4

GISMO-2: a two-color millimeter bolometer camera for the JCMT

Johannes G. Staguhn, NASA Goddard Space Flight Ctr. (United States) and Johns Hopkins Univ. (United States); Elmer H. Sharp III, NASA Goddard Space Flight Ctr. (United States) and Global Science & Technology, Inc. (United States); Dominic J. Benford, NASA Goddard Space Flight Ctr. (United States); Dale J. Fixsen, NASA Goddard Space Flight Ctr. (United States) and Univ. of Maryland (United States); Gene C. Hilton, National Institute of Standards and Technology (United States); Kent D. Irwin, Stanford Univ. (United States); Attila Kovacs, California Institute of Technology (United States); Samuel Leclercq, IRAM-Domaine Univ. de Grenoble (France); Stephen F. Maher, NASA Goddard Space Flight Ctr. (United States) and Science Systems and Applications, Inc. (United States); Samuel H. Moseley, Edward J. Wollack, NASA Goddard Space Flight Ctr. (United States)

The GISMO 2 mm bolometer camera at the IRAM 30m telescope has been available to the astronomical community for many years. GISMO provides observational capabilities across a wide range of astronomical targets, including observations of galactic dust and free-free emission, the characterization of the SEDs of nearby galaxies, detecting dusty galaxies at high redshifts, and measurements of the Sunyaev–Zel'dovich decrement in the Cosmic Microwave Background Radiation, which traces the evolution of massive galaxy clusters throughout the history of the universe. The 2 mm band is well suited to trace the first dusty galaxies in the universe, since their redshifted SEDs peak close to GISMO's observing frequency, whereas the medium redshift galaxy foreground is almost invisible in this band. This effect makes GISMO's deep field observations a valuable complement, rather than a redundancy, to the HERSCHEL far-infrared and sub-mm surveys.

The GISMO-2 camera, which will enhance GISMO's observational capabilities significantly by utilizing larger detector arrays in two bands at 1.2mm and 2 mm, is planned to start operations at the JCMT in late 2016. A warm dichroic will enable simultaneous observations with SCUBA-2, which will allow for synchronized 4 color observations between 0.45 mm and 2 mm. This capability will not only allow to obtain simultaneous multi-color images of astronomical objects/fields, but will also enable better calibration.

We will describe the expected performance of GISMO-2 at the JCMT and summarize the scientific capabilities enabled by its simultaneous operation together with SCUBA-2.

9914-18, Session 4

Instrumental performance and results from testing of the BLAST-TNG receiver, submillimeter optics, and MKID detector arrays

Nicholas Galitzki, The Univ. of Pennsylvania (United States); Peter A. R. Ade, Cardiff Univ. (United Kingdom); Francesco E. Angilè, The Univ. of Pennsylvania (United States); Peter Ashton, Northwestern Univ. (United States); Jason Austermann, National Institute of Standards and Technology (United States); Tashalee Billings, The Univ. of Pennsylvania (United States); George Che, Kristina Davis, Arizona State Univ. (United States); Hsiao-Mei Cho, SLAC National Accelerator Lab. (United States); Mark J. Devlin, Simon R. Dicker, Bradley J. Dober, The Univ. of Pennsylvania (United States); Laura M. Fissel, Northwestern Univ. (United States); Yasuo Fukui, Nagoya Univ. (Japan); Jiansong Gao, National Institute of Standards and Technology (United States); Samuel Gordon, Christopher E. Groppi, Arizona State Univ. (United States); Seth N. Hillbrand, The Univ. of Pennsylvania (United States); Gene C. Hilton, Johannes Hubmayr, National Institute of Standards and Technology (United States); Kent D. Irwin, Stanford Univ. (United States); Jeffrey M. Klein, The Univ. of Pennsylvania (United States); Zhi-Yun Li, Univ. of Virginia (United States); Nathan P. Lourie, The Univ. of Pennsylvania (United States); Hamdi Mani, Arizona State Univ. (United States); Peter G. Martin, Univ. of Toronto (United States); Philip D. Mauskopf, Arizona State Univ. (United States); Christopher M. McKenney, National Institute of Standards and Technology (United States); Federico Nati, The Univ. of Pennsylvania (United States); Giles Novak, Northwestern Univ. (United States); Enzo Pascale, Giampaolo Pisano, Cardiff Univ. (United Kingdom); Douglas Scott, The Univ. of British Columbia (Canada); Adrian Sinclair, Arizona State Univ. (United States); Carole E. Tucker, Cardiff Univ. (United Kingdom); Matthew Underhill, Arizona State Univ. (United States); Michael Vissers, National Institute of Standards and Technology (United States)

Polarized thermal emission from interstellar dust grains can be used to map magnetic fields in star forming molecular clouds and the diffuse ISM. The Balloon-borne Large Aperture Submillimeter Telescope for Polarimetry (BLASTPol) flew from Antarctica in 2010 and 2012 and has produced degree scale polarization maps of several nearby molecular clouds with arcminute resolution. The success of BLASTPol has motivated a next-generation instrument, BLAST-TNG, which will use ~3000 linear polarization sensitive Microwave Kinetic Inductance Detectors (MKIDs) combined with a 2.5 m diameter carbon fiber primary mirror to make diffraction limited observations at 250, 350, and 500 microns. With 16 times the mapping speed of BLASTPol, sub-arcminute resolution, and a longer flight time, BLAST-TNG will be able to examine nearby molecular clouds and the diffuse galactic dust polarization spectrum in unprecedented detail. The cryogenic receiver and detector arrays have been integrated and are undergoing extensive testing prior to deployment to establish the optical and polarization characteristics of the instrument. Progress on BLAST-TNG offers insight into the effectiveness of kilopixel

MKID arrays for application in submillimeter astronomy. BLAST-TNG is scheduled to fly from Antarctica in December 2016 for 28 days and will be the first balloon-borne telescope to offer a quarter of the flight for "shared risk" observing by the community.

9914-19, Session 4

An upgraded SCUBA-2 for JCMT

Daniel Bintley, Jessica T. Dempsey, Per Friberg, East Asian Observatory (United States)

SCUBA-2 is a state of the art wide field camera for the JCMT. SCUBA-2 has been fully operational for over 4 years, producing a wide range of science results, including a unique series of survey programs. A new large survey programme has just commenced and for the first time, we offer polarisation sensitive measurements using POL-2, the polarimeter ancillary instrument. We present plans and discuss the science case for upgrading SCUBA-2 with new detector arrays, that will keep SCUBA-2 and the JCMT at the forefront of continuum submillimetre science.

9914-20, Session 4

Detector modules and spectrometers for the TIME-Pilot [CII] intensity mapping experiment

Jonathon Hunacek, California Institute of Technology (United States); James J. Bock, C. Matt Bradford, Bruce Bumble, Jet Propulsion Lab. (United States); Tzu-Ching Chang, Institute of Astronomy and Astrophysics - Academia Sinica (Taiwan); Yun-Ting Cheng, California Institute of Technology (United States); Asantha R. Cooray, Univ. of California, Irvine (United States); Abigail T. TIME-Pilot is a new mm-wavelength grating spectrometer array that will study the Epoch of Reionization (the period of time when the first stars and galaxies ionized the intergalactic medium) by mapping the fluctuations of the redshifted 157.7 ?m emission line of singly ionized carbon ([CII]) from redshift z ~ 5.2 to 8.5. As a tracer of star formation, the [CII] power spectrum can provide information on the sources driving reionization and complements 21 cm data (which traces neutral hydrogen in the intergalactic medium). Intensity mapping provides a measure of the aggregate population without the need to resolve and detect faint sources individually. We target a 1 degree by 0.35 arcminute field on the sky and a spectral range of 199-305 GHz, creating a spatial-spectral slab which is 140 Mpc by 0.9 Mpc in x and y by 1230 Mpc in z. With careful removal of intermediate-redshift CO sources, we anticipate a detection of halo-halo clustering in [CII] consistent with current models for star formation history in 240 hours on the JCMT.

TIME-Pilot will use two stacks of 16 parallel-plate waveguide spectrometers (one stack per polarization) with a resolving power R ~ 100 and a spectral range of 183 to 326 GHz. The range is divided into 60 spectral channels, of which 16 at the band edges on each spectrometer serve as water vapor monitors. These monitor channels have a total water vapor sensitivity greater than that in the science band. The diffraction gratings are curved to produce a compact instrument, each focusing the diffracted light onto an output arc sampled by the 60 bolometers. The bolometers are built in 1D buttable dies of 8 or 12 spectral channels x 8 spectrometers and are mated to the spectrometer stacks. Detectors consist of gold micro-mesh absorbers and titanium transition edge sensor (TES) thermistors. The detectors (1920 total) are designed to operate from a 250 mK base temperature in an existing cryostat with a photon-noise-dominated NEP of ~1e-17 W/Hz^1/2. A set of flexible superconducting cables connect the detectors to a time-domain multiplexing SQUID readout system. This talk will give an update on the current TIME-Pilot instrument design and status with a focus on the close-packed modular detector arrays and spectrometers. Results of laboratory tests with prototype detectors and spectrometers will be discussed.

9914-21, Session 4

Performance of backshort-under-grid kilopixel TES arrays for HAWC+

Johannes G. Staguhn, NASA Goddard Space Flight Ctr. (United States) and Johns Hopkins Univ. (United States); Dominic J. Benford, NASA Goddard Space Flight Ctr. (United States); Charles D. Dowell, Jet Propulsion Lab. (United States); Dale J. Fixsen, NASA Goddard Space Flight Ctr. (United States) and Univ. of Maryland (United States); Gene C. Hilton, National Institute of Standards and Technology (United States); Kent D. Irwin, Stanford Univ. (United States); Christine A. Jhabvala, Stephen F. Maher, Timothy M. Miller, Samuel H. Moseley, NASA Goddard Space Flight Ctr. (United States); Marcus C. Runyan, Jet Propulsion Lab. (United States); Elmer H. Sharp III, Edward J. Wollack, NASA Goddard Space Flight Ctr. (United States)

HAWC+ was selected as the second generation instrument for the Stratospheric Observatory for Infrared Astronomy (SOFIA). It is a far-infrared wide-field camera and polarimeter with general capability for the observatory with deployment anticipated in early 2016. In order to provide high mapping speeds, the camera utilizes kilopixel Backshort Under Grid (BUG) TES-based detector modules, provided by NASA/GSFC. These modules consist of planar 32x40 pixel arrays of close-packed TES bolometers with a separate optical back-termination wafer inserted into the grid. The detector array is bump bonded to a 32x41 pixel time domain multiplexer from NIST/Boulder. The arrays are designed to provide background-limited sensitivity in all of the instrument's five selectable FIR bands (ranging from 53 to 215 ?m). In order to provide for differential polarimetry, the camera employs two separate focal plane arrays, with the final goal of each a mosaic with two modules abutted to produce a nearly-filled 64x40 pixel active area (at this time three of possible four arrays are installed). We present a summary of the detector characterization in the laboratory and discuss the derived performance parameters. These measurements provide the first demonstration of kilopixel BUG arrays.

9914-23, Session 5

Lumped element kinetic inductance detectors for space applications

Alessandro Monfardini, Alain Benoit, Andrea Catalano, Martino Calvo, Antonio D'Addabbo, Johannes Goupy, Helene Le Sueur, Olivier Bourrion, Ctr. National de la Recherche Scientifique (France); SPACEKIDS collaboration, NIKA2 collaboration, CNRS (France)

Kinetic Inductance Detectors (KIDs) are now routinely used on ground-based telescopes. These large arrays, deployed in formats up to several kilopixels, exhibit state-of-the-art performance at millimeter (e.g. 120-300 GHz, NIKA and NIKA2) and sub-millimeter (e.g. 350-850 GHz, AMKID) wavelengths. KID technology has many distinct advantages compared to bolometers, among which is that the detectors are deposited directly on a solid mono-crystalline substrate. Thus the complications and difficulties associated with micro-machined suspended structures is avoided. These fine structures are necessary in the case of bolometric detectors to realise the extremely low thermal conductivity that must exist between the thermistor/absorber and the thermal bath. Their geometry can have the added advantage of reducing cosmic-ray collisional cross-section. One as-yet unquantified issue with KID technology for space applications has been potential susceptibility to cosmic ray hits. To investigate this we have studied in detail the interaction of ionizing particles (muons, alphas, x-rays) with KID arrays of hundreds of pixels designed for Cosmic Microwave Background observations. We have developed for this purpose a dedicated system of read-out electronics with which we are able to sample at MHz frequencies a number of pixels and thus follow in real time the propagation of a-thermal phonons across the array substrate. We have also set up a dedicated cryostat in which we reproduce typical observing conditions of a space-borne CMB observation. In these conditions we irradiate the KID arrays with alpha particles and X-rays. We confirm that the rate of hits is larger in KIDs compared to bolometers. However, KIDs not only have a much faster response time constant but also are less sensitive to base temperature variations. We conclude that the KID arrays used in this study would behave a factor of ten better than Planck detectors. In addition we have found other ways to further reduce the physical region of the KID array that is affected by a cosmic ray event. We have characterized the influence of the ground plane filling factor and composition in limiting the propagation of the Cooper-pair-breaking phonons over large distances across the substrate, and shown that the effects of cosmic ray hits can be confined to a small region around the position of impact. We will report the details and conclusions from a large number of measurements.

9914-24, Session 5

Dual polarization LEKIDs for millimeter wavelengths

Heather McCarrick, Glenn E. Jones, Bradley R. Johnson, Maximilian H. Abitbol, Columbia Univ. (United States); Peter A. R. Ade, Cardiff Univ. (United Kingdom); Sean A. Bryan, George Che, Arizona State Univ. (United States); Peter K. Day, Jet Propulsion Lab. (United States); Daniel Flanigan, Columbia Univ. (United States); Henry G. LeDuc, Jet Propulsion Lab. (United States); Michele Limon, Columbia Univ. (United States); Philip D. Mauskopf, Arizona State Univ. (United States); Amber D. Miller, Columbia Univ. (United States); Anthony K. Mroczkowski, U.S. Naval Research Lab. (United States); Carole E. Tucker, Cardiff Univ. (United Kingdom); Jonas Zmuidzinas, Jet Propulsion Lab. (United States)

We discuss the design considerations and the measured performance of arrays of dual-polarization, lumped-element kinetic inductance detectors (LEKIDs) nominally designed for cosmic microwave background studies. The detectors are horn-coupled, and each array element contains two single-polarization LEKIDs, which are made from thin-film aluminum and optimized for a single spectral band centered on 150 GHz. We are developing two array architectures, one based on 160 micron thick silicon wafers and the other based on silicon-on-insulator (SOI) wafers with a 30 micron thick device layer. The SOI architecture promises enhanced performance at the cost of added fabrication complexity, so we are investigating the tradeoffs between these two approaches. Our 20-element test arrays (40 LEKIDs) are characterized with both a linearly-polarized electronic millimeter wave source and a thermal source. We present (i) measurements of the noise-equivalent power and noise-equivalent temperature, (ii) the low-frequency noise properties, and (iii) measurements of the polarization selectivity of these dual-polarization devices.

9914-25, Session 5

A study of novel superconducting material systems for use in microwave kinetic inductance detectors

Paul Szypryt, Benjamin A. Mazin, Univ. of California, Santa Barbara (United States); Bruce Bumble, Jet Propulsion Lab. (United States); Gerhard Ulbricht, Matthew J. Strader, Seth R. Meeker, Alex B. Walter, Clint Bockstiegel, Giulia Collura, Univ. of California, Santa Barbara (United States)

We report on the effects of using new superconducting materials in the fabrication of microwave kinetic inductance detectors (MKIDs). The main motivation for this work is to search for a replacement for the TiN superconductors used in the majority of current MKID devices. Although TiN MKIDs have already shown photon counting capabilities with moderate energy resolution, they suffer from spatial non-uniformities in the TiN superconducting critical temperature across a wafer. In large MKID arrays, these variations in critical temperature cause resonators to shift away from their designed frequency, and collisions in frequency space render the resonators unusable by the readout. To counter this shortcoming, we explored superconducting materials that are inherently more uniform than TiN.

To begin testing materials for their potential as MKID superconductors, we developed a simple one layer test mask with a multitude of structures that could test films spanning a wide range of sheet inductance. The test mask could be used to probe a variety of important MKID resonator properties such as critical temperature, internal quality factor, surface impedance uniformity, quasiparticle lifetime, energy resolution, and quantum efficiency. The material we have spent the majority of our time investigating, and the one that currently shows the most promise, is platinum silicide. We measured a critical temperature of 900mK for thin PtSi films, which is in an ideal range for use in adiabatic demagnetization or dilution refrigerators. Resonators structured from PtSi films show high internal quality factors (>150,000) and energy resolution similar to that of TiN (>10). The quantum efficiency is also comparable to that of TiN, but begins to exceed that of TiN for longer wavelengths. Most importantly, we find that the uniformity in surface impedance is about an order of magnitude better in the PtSi films than it is in the standard TiN films.

We examine a few other materials including niobium silicide, tungsten silicide, and osmium using one layer test structures. We then compare the resonators created with these materials and describe the types of instruments and applications most suited for a particular material. For example, most MKIDs benefit from long quasiparticle lifetimes which improve energy resolution, but for higher energy detectors in which a membrane structure is required, it may be more advantageous to have quasiparticle lifetimes be short compared to thermal timescales.

9914-26, Session 5

Photon noise limited performance over an octave of bandwidth of kinetic inductance detectors for sub-millimeter astronomy

Juan Bueno, SRON Netherlands Institute for Space Research (Netherlands); Ozan Yurduseven, Technische Univ. Delft (Netherlands); Stephen J. C. Yates, SRON Netherlands Institute for Space Research (Netherlands); Nuria Llombart, Technische Univ. Delft (Netherlands); Vignesh Murugesan, SRON Netherlands Institute for Space Research (Netherlands); David J. Thoen, Technische Univ. Delft (Netherlands); Andrey M. Baryshev, SRON Netherlands Institute for Space Research (Netherlands) and Kapteyn Astronomical Institute (Netherlands); Andrea Neto, Technische Univ. Delft (Netherlands); Jochem J. A. Baselmans, SRON Netherlands Institute for Space Research (Netherlands) and Technische Univ. Delft (Netherlands)

We present the development of background limited kinetic inductance detectors (KIDs) for sub-millimeter (sub-mm) astronomy applications to be used in space based observatories. The sub-mm radiation is coupled to the KID via a leaky wave antenna covering the frequency range from 1.4 to 2.8THz. We have developed a hybrid niobium titanium nitride/aluminium (NbTiN/Al) KID, fabricated on a silicon (Si) substrate, in which the leaky wave antenna and absorbing section of the KID are fabricated on a suspended silicon nitride (SiN) membrane. The radiation is coupled to the leaky wave antenna with a Si lens placed on top of it at a distance of 3?m. We observe photon noise limited performance both in the phase and amplitude readout simultaneously, with a good optical efficiency at a frequency of 1.55THz. The Fourier Transform Spectroscopy (FTS) measurements showing the broadband radiation coupling for an octave of bandwidth, and the beam pattern measurements at 1.55THz are also presented. In summary, we have developed a new fabrication route that assures photon noise limited performance, and a scalable assembly method that provides the 3?m gap space between the antenna and the lens. These developments assure background limited performance with a broad frequency coupling over an octave of bandwidth for sub-mm radiation. Given these results, hybrid NbTiN/Al leaky wave antenna coupled KIDs will enable astronomically usable kilopixel arrays for sub-mm imaging for future space missions.

9914-27, Session 5

Antenna coupled kinetic inductance detectors for multi-band CMB instruments

Erik D. Shirokoff, Ryan McGeehan, The Univ. of Chicago (United States)

To make continued progress in studies of the cosmic microwave background (CMB), multiple telescopes with at least 10^5 polarization sensitive detectors operating at multiple wavelengths will be required. The scientific potential for such an instrument is significant: a Stage-IV CMB experiment will measure the absolute mass of neutrinos to four-sigma, constrain the number of neutrino species at an unprecedented level and rule out (or confirm) the presence of non-interacting sterile neutrino species. It will also extend the search for primordial B-mode polarization, the smoking gun evidence for inflation in the early universe, at a level two orders of magnitude lower than present limits and test a large class of theoretically favored models. However, the technical challenges are daunting: such an instrument will require square meters of focal plane covered in background limited cryogenic detectors, and a dramatic scaling up of existing readout hardware.

A promising technology is the kinetic inductance detectors (KID), which will allow for more robust fabrication and naturally multiplexed readout. We will present an update on the development of a novel KID detector optimized for studies of the CMB. Our design employs titanium-nitride (TiN) lumped element KIDs (LEKIDs) operating at a readout frequency of hundreds of MHz. Broad-band, planar, dual polarization antennas with Si lenses deliver mm-wave radiation to band defining microstrip structures which then deposit power on the inductor of each LEKID. The detectors include a novel broad-band coupling scheme for delivering power from a symmetric Nb microstrip to a single-layer TiN meander located on the ground-plane layer. Prototype designs feature five dual-pol spectral channels covering the telluric windows above 70 GHz.

We will present an overview of the detector design, simulations of the mm-wave and microwave features, and performance estimates based on measured material properties. We will also discuss ongoing progress toward the fabrication of optical devices, including microwave characterization and dark noise measurements of locally fabricated TiN resonators and process verification of test structures that will enable mm-wave coupling.

9914-28, Session 6

BICEP3 performance overview and future prospects for a multi-receiver array

BICEP3 is a 520-mm aperture compact two-lens refractor designed to observe the polarization of the cosmic microwave background (CMB) at 95 GHz. Its focal plane consists of modularized tiles of antenna-coupled transition edge sensors (TESs), similar to those used in BICEP2 and the Keck Array. The increased per-receiver optical throughput compared to BICEP2/Keck Array, due to both its faster f/1.7 optics and the larger aperture, will more than double the combined mapping speed of the BICEP/Keck program. The BICEP3 receiver was recently upgraded to a full complement of 20 tiles of detectors (2560 TESs), and is now beginning its second year of observation at the South Pole. We report on its current performance and observing plans. Given its high per-receiver throughput while maintaining the advantages of a compact design, BICEP3-class receivers are ideally suited as building blocks for a 3rd-generation CMB experiment, consisting of multiple receivers spanning 35 GHz to 220 GHz with total detector count in the tens of thousands. We present preliminary plans for such an array, including design optimization, frequency coverage, and deployment/observing strategies.

9914-29, Session 6

Second year detectors performance of BICEP3

Howard Hui, California Institute of Technology (United States)

BICEP3 is the newest telescope in the BICEP/ Keck collaboration, started its observation at the South Pole in April 2015. It is a 550mm aperture refractive telescope observing the polarization of the cosmic microwave background at 95GHz at degree-angular scales. We upgraded from 9 detector tiles to fully-populated 20 tiles, 1280 dual-polarization pixels during the austral summer of 2015-16. We will show the focal plane design and detector performance, including near and far-field beam, spectral response, magnetic pickup, optical efficiency and sensitivity of the upgraded BICEP3.

9914-30, Session 6

A report on the in-flight performance of Spider: a sub-orbital mm-wavelength CMB polarimeter

William C. Jones, Princeton Univ. (United States)

We report on the in-flight performance of Spider, a sub-orbital mm-wavelength polarimeter designed to measure the polarization of the Cosmic Microwave Background on angular scales from 20 to 0.5 degrees. Spider has produced polarized surveys covering ~10% of the full sky in the southern Galactic hemisphere at 94 and 150 GHz, with the instrument having the highest instantaneous sensitivity ever achieved at these frequencies. We report on the instrument and in-flight performance of the system, which uses wide format arrays of time-division multiplexed superconducting transition edge sensors.

9914-31, Session 6

Development of 285 GHz feedhorn-coupled TES arrays for the balloon-borne polarimeter SPIDER

Johannes Hubmayr, National Institute of Standards and Technology (United States); On Behalf of the SPIDER collaboration, NIST (United States)

We describe bolometric detector arrays under development for the second flight of the balloon-borne instrument SPIDER. In the 2015 flight, SPIDER made large angular scale measurements of CMB polarization at band centers near 90 GHz and 150 GHz. The second flight will have expanded frequency coverage, including three arrays of feedhorn-coupled TES polarimeters, fabricated at NIST and optimized for detection at 285 GHz in order to characterize polarized dust foregrounds. The silicon-platelet, feed-coupled detector architecture has been used in ground-based instruments SPTpol and ACTPol. Here we describe design changes required to scale up in frequency and optimize for the balloon environment. We present the focal plane design, which consists of a 16x16 array of conical, corrugated feeds with ~5? horn diameter apertures to match the telescope optics. By fabrication and measurement of single horns of this design, we demonstrate near Gaussian-shaped beams with a beam waist that matches the design and < 1% ellipticity in a 30% fractional bandwidth centered on 285 GHz. A feedhorn array couples to a monolithic detector array, fabricated on a 150mm diameter substrate. Each pixel of the array is comprised of a dual-polarization sensitive antenna coupled to two transition edge sensor bolometers, one for each polarization. Each bolometer is operated from a 300mK bath

temperature, has a designed saturation power of 3 pW to take advantage of the low background photon loading, and is read out with a time-division SQUID multiplexer. In addition to the detailed design description, we present the results of a SiN leg-isolated bolometer study used to realize the low thermal conductivity bolometers required for SPIDER.

9914-32, Session 6

In-flight performance of the PILOT balloon borne experiment

Jean-Philippe Bernard, Institut de Recherche en Astrophysique et Planétologie (France)

Measuring precisely the faint polarization of the Far-Infrared and sub-millimetre sky is one of the next observational challenges of modern astronomy and cosmology. I will describe the concept and science goals of the PILOT balloon-borne experiment project, dedicated to measuring the linear polarization of the faint interstellar diffuse dust emission in the Far-Infrared in our Galaxy and nearby galaxies. I will present the in-flight performance of the experiment as observed during the successful first flight of PILOT from Timmins, Canada in September 2015.

9914-82, Session PWed1

SHARP: a super-sized 345GHz heterodyne array for JCMT

Jessica T. Dempsey, Paul T. P. Ho, Per Friberg, East Asian Observatory (United States); Ming-Tang Chen, Institute of Astronomy and Astrophysics - Academia Sinica (Taiwan); Craig A. Walther, East Asian Observatory (United States)

As part of the JCMT Future Instrumentation Project, the EAO looks to optimise the premier niche of the facility as the go-to telescope for fast, deep wide-field mapping of the universe at 345GHz (850um). SHARP (Super-HARP) will be designed to provide deep ultra-fast mapping capabilities that takes advantage of the full field-of-view available to the telescope, and an array of 100+ SIS mixers. The preliminary design options will be discussed, as well as the critical science drivers for the project.

9914-81, Session PWed2

Design of corrugated-horn-coupled MKID focal plane for LiteBIRD

Yutaro Sekimoto, National Astronomical Observatory of Japan (Japan); Masakazu Sekine, Shigeyuki Sekiguchi, Shibo Shu, The Univ. of Tokyo (Japan); Takashi Noguchi, Wenlei Shan, Agnes Dominjon, National Astronomical Observatory of Japan (Japan); Tom Nitta, Univ. of Tsukuba (Japan); Masato Naruse, Saitama Univ. (Japan); Akihira Miyachi, Makoto Mita, Shigeo Kawasaki, Institute of Space and Astronautical Science (Japan)

A focal plane based on MKID has been designed for the cosmic microwave background (CMB) polarization observation satellite, LiteBIRD.

The LiteBIRD measures the polarization of the CMB with sigma (r) of 0.001, and explores physics of the inflation before the Big Bang.

The satellite is planned to be launched by JAXA in the 2020s.

The superconducting sensors (TES or MKID) of the focal plane are cooled to a temperature of 100mK and observe 50 GHz - 300 GHz, and make whole sky polarization map with 5 ?K · arcmin.

We are designing and developing a focal plane with broadband corrugated horn array, planar OMT, 180 degree hybrid, bandpass filters, and MKIDs. The focal plane consists of 3 octave bands (55 – 108 GHz, 80 – 160 GHz, 160 – 320 GHz), 10 hexagonal modules. Broadband corrugated horn-array has been directly machined from an Al block and measured to have a good beam shape which is consistent with electromagnetic field simulations in octave bands (120 - 270 GHz, 80 - 160 GHz). The horn array is designed to be low standing-wave, light weight, and electromagnetic shield. The broadband 4 probes ortho-mode transducer (OMT) is fabricated on Si membrane of an SOI wafer. An 180 degree hybrid made with coplanar waveguide (CPW) is used to reduce higher modes of the circular waveguide. Two bandpass filters of each polarization are patterned with Nb microstrip. Al-MKID achieved dark NEP of 2 ? 10^(-18) W / rHz and has been demonstrated to be no degradation after the 10 krad proton irradiation which corresponds to a total dose during 5 years at L2 orbit. We report system design of the focal plane, the sensitivity forecast, and prototype measurements.

9914-84, Session PWed2

Responsivity boosting in FIR TiN LEKIDs using phonon recycling

Adalyn Fyhrie, Jason Glenn, Univ. of Colorado Boulder (United States); Peter K. Day, Jet Propulsion Lab. (United States); Christopher M. McKenney, National Institute for Science and Technology (United States); Henry G. LeDuc, Jet Propulsion Lab. (United States)

To further characterize the cosmic star formation history at high redshifts, a large-area survey by a cryogenic 4-6 meter class telescope with a focal plane populated by tens of thousands of far-infrared detectors is needed. With a primary aperture cooled to 4 Kelvin and equipped with sufficiently sensitive detectors, the sensitivity of such a surveyor would be limited by astrophysical backgrounds. Broadband detector noise equivalent powers (NEPs) on the order of 3e-19 W/sqrt(Hz) are required to be photon noise limited. Kinetic inductance detectors (KIDs) show great promise for a mission such as this because of their intrinsic frequency multiplexability and simple cryogenic amplification requirements.

KIDs are high quality factor superconducting resonators — their superconducting current is carried by Cooper pairs. When photons of sufficient energy are absorbed by KIDs, the Cooper pairs are broken up into individual electrons — quasiparticles. When quasiparticles recombine, they emit phonons which propagate through the substrate and are lost to the low-temperature bath. However, if phonons can be confined to the KID substrate, they can break additional Cooper pairs, thereby increasing responsivity and reducing NEP. We refer to this mechanism as “phonon recycling”.

We present the design and initial characterization data of an array of 96 350 micron phonon-recycling KIDs. Our KID array is fabricated with TiN deposited on a silicon-on-insulator (SOI) wafer, which is a 2 micron thick layer of silicon bonded to a thicker slab of silicon by a thin oxide layer. The backside thick slab is etched away underneath the absorbers so that the detectors are suspended on just the 2 micron membrane. The intent is that quasiparticle recombination phonons are trapped in the thin membrane, thereby increasing their likelihood of being re-absorbed by the KID to break additional Cooper pair and boost responsivity.

9914-86, Session PWed2

Development of octave-band planar ortho-mode transducer with MKID for LiteBIRD

Shibo Shu, Shigeyuki Sekiguchi, Masakazu Sekine, The Univ. of Tokyo (Japan); Yutaro Sekimoto, National Astronomical Observatory of Japan (Japan); Tom Nitta, Univ. of Tsukuba (Japan); Agnes Dominjon, Takashi Noguchi, National Astronomical Observatory of Japan (Japan); Masato Naruse, Saitama Univ. (Japan); Wenlei Shan, National Astronomical Observatory of Japan (Japan)

LiteBIRD is a next-generation satellite mission for measuring the primordial B-modes polarization signals of CMB [1]. We describe a design of octave-band corrugated horn coupled planar ortho-mode transducer (OMT) [2,3] with Microwave Kinetic Inductance Detector (MKID) [4] as a candidate detection technology for LiteBIRD.

In our design, each single pixel contains 90 and 150 GHz two frequency bands, covering the maximum power part of CMB polarization signal. Through a 2.4 mm diameter circular waveguide, polarization signal are coupled to the 4-probe planar OMT structure silicon membrane, below which a backshort structure with quarter wavelength is fabricated by deep reaction-ion etching from the backside of silicon on insulator wafer.

After planar OMT, a broadband coplanar waveguide (CPW) 180-degree hybrid [5] is used to cancel higher modes from circular waveguide. An Al/Ti center strip acts as absorber to absorb higher modes signal and TE11 signal is transmitted to a CPW-to-microstrip (MS) transition structure for connecting MS 5-element Chebyshev diplexer and following MKID. For coupling signal to MKID, the center strip of MKID acts as ground of MS and absorber to generate quasi-particle [6]. For testing, a 4-pixel model is designed, containing 16 MKIDs and 4 dark MKIDs. MKIDs are designed with Nb ground plane and Al/Ti bilayer center strip line to achieve low frequency response and high sensitivity.

The 4-pixel broadband corrugated horn array is fabricated with high accuracy direct machining. Measurement shows that S11 parameter is lower than -10 dB from 80 GHz to 170 GHz and agree well with simulation. After calibration and testing, this prototype will be installed on Nobeyama 45-m telescope.

Responsivity and noise in TiN/Ti/TiN kinetic inductance detectors

Yiwen Wang, Southwest Jiaotong Univ. (China); Johannes Hubmayr, Michael Vissers, National Institute of Standards and Technology (United States); Jason Austermann, Univ. of Colorado Boulder (United States); Dale Li, Hsiao-Mei Cho, Kent D. Irwin, Stanford Univ. (United States); Mark J. Devlin, Bradley J. Dober, The Univ. of Pennsylvania (United States); Christopher E. Groppi, Philip D. Mauskopf, Arizona State Univ. (United States); Daniel T. Becker, David P. Pappas, James Beall, Jeff Van Lanen, Leila R. Vale, Gene C. Hilton, National Institute of Standards and Technology (United States); Lianfu Wei, Southwest Jiaotong Univ. (China); Jiansong Gao, National Institute of Standards and Technology (United States)

We are developing TiN/Ti/TiN trilayer and multilayer films for feedhorn-coupled polarization-sensitive kinetic inductance detectors (KID) for the balloon-borne instrument BLAST. We have found unique properties of the TiN/Ti/TiN films in both responsivity and noise that differ significantly from conventional superconductors such as Al. On one hand, TiN/Ti/TiN films exhibit linear frequency response over a wide range of loading power and bath temperature. Interestingly, in TiN films, quasiparticles generated either optically or thermally do not seem to directly combine with each other. This also suggests that the responsivity increases as 1/V when the absorber volume V is reduced. On the other hand, we find that the detector dark noise at low frequency is dominated by inductor noise (or kinetic inductance fluctuations), rather than two-level system (TLS) noise from the capacitors. The inductor noise level does not depend on the microwave power or bath temperature, but only upon the inductor width w as 1/w^2. Combining the 1/V scaling of responsivity and the 1/w^2 scaling of noise level, the noise equivalent power (NEP) scales as w. This suggests that lower NEP can be achieved by reducing the absorber volume while keeping the aspect ratio fixed and the impedance matching condition unchanged. Using absorber narrower than 2-micron wide, detector NEP below 10^-17 W/(Hz)^0.5 at 1 Hz may be achieved.

9914-94, Session PWed2

Fabrication of TiN MKID polarimeter arrays for the BLAST-TNG telescope

Michael Vissers, National Institute of Standards and Technology (United States); For the BLAST-TNG collaboration, NIST (United States)

We describe the fabrication and performance of the prototype detector arrays for the Balloon LAunched Submillimeter Telescope – The Next Generation (BLAST-TNG), a suborbital mapping experiment designed to study the role magnetic fields play in star formation and bridge the angular scales between Planck's low resolution all-sky maps and ALMA's ultra-high resolution narrow fields. BLAST-TNG is scheduled to launch from Antarctica in 2016. This experiment will utilize 8 times as many polarization sensitive detectors and will have 16 times greater mapping speed compared to the previous BLAST telescopes.

BLAST-TNG will employ three arrays of microwave kinetic inductance detectors (MKIDs) at 250, 350, and 500 microns. Each spatial pixel consists of a pair of polarization-sensitive resonators fabricated from a Titanium Nitride/Titanium multilayer on a silicon-on-insulator (SOI) wafer. After micromachining each wafer, the device silicon layer of the SOI wafer forms a quarter wavelength backshort optimized for efficient coupling in each band. The TiN/Ti multilayers combine high responsivity, high uniformity, low loss, and a tunable superconducting Tc. The Tc is chosen to balance responsivity with loss from thermal quasiparticles. In single pixel laboratory experiments, the detectors have been shown to be photon noise limited [Hubmayr et al, Applied Physics Letters, 2015] and have excellent polarization sensitivity.

The BLAST-TNG arrays are fabricated on 100 mm Si wafers with a different wafer for each detection band. Each array is read out using several microwave feedlines. Each microwave feedline addresses as many as 600 frequency-multiplexed resonators in 300 spatial pixels, and has been created using a semi-automated layout scheme to make a stepper-

compliant lithography process. The layout and design of the detectors must minimize crosstalk between the resonators as well reduce the number of frequency collisions between resonators. Preliminary results on the array performance will be reported.

Kinetic inductance detectors for far-infrared spectroscopy

Alyssa Barlis, James Aguirre, The Univ. of Pennsylvania (United States); Thomas R. Stevenson, NASA Goddard Space Flight Ctr. (United States)

The star formation mechanisms at work in the early universe remain one of the major unsolved problems of modern astrophysics. Many of the luminous galaxies present during the period of peak star formation (between redshifts 1 and 3) were heavily enshrouded in dust, which makes observing their properties difficult at optical wavelengths. However, many spectral lines exist at far-infrared wavelengths that serve as tracers of star formation during that period, in particular fine structure lines of nitrogen, carbon, and oxygen, as well as the carbon monoxide molecule. Using an observation technique known as intensity mapping, it would be possible to observe the total line intensity for a given redshift range even without detecting individual sources. Here, we describe a detector system suitable for a balloon-borne spectroscopic intensity mapping experiment at far-infrared wavelengths. The experiment requires an "integral-field" type spectrograph, with modest spectral resolution (R~100) for each of a number of spatial pixels spanning several octaves in wavelength. The detector system uses lumped-element kinetic inductance detectors (LEKIDs), which have the potential to achieve the high sensitivity, low noise, and high multiplexing factor required for this experiment. We detail the design requirements and considerations, fabrication process, and preliminary performance results for a prototype LEKID array of 1600 pixels. The pixel design is driven by the need for high responsivity, which requires a small physical volume for the LEKID inductor. In order to minimize two-level system noise, the resonators include large-area interdigitated capacitors. High quality factor resonances are required for a large frequency multiplexing factor. Detectors were fabricated using both trilayer TiN/Ti/TiN recipes and thin-film Al, and are operated at base temperatures near 250 mK.

9914-96, Session PWed2

Performance verification of double-slot antenna and elliptical silicon lens for large format KID arrays

Lorenza Ferrari, SRON Netherlands Institute for Space Research (Netherlands); Ozan Yurduseven, Nuria Llombart, Technische Univ. Delft (Netherlands); Stephen J. C. Yates, SRON Netherlands Institute for Space Research (Netherlands); Andrey M. Baryshev, SRON Netherlands Institute for Space Research (Netherlands) and Univ. of Groningen (Netherlands); Juan Bueno, Jochem J. A. Baselmans, SRON Netherlands Institute for Space Research (Netherlands)

Large format imaging arrays are now a reality due to the recent improvements in detectors performance. In the next decade submm and mm astronomy will benefit enormously from the mapping capability of these instruments followed up with the high spatial and spectral resolution of ALMA (Atacama Large Millimeter/ submm Array). The realization of imaging cameras has been made possible by detectors that combine background limited sensitivity, high optical efficiency and high multiplexing ratio. Microwave Kinetic Inductance Detectors (MKIDs) have shown to satisfy all these requirements, thus becoming a promising candidate for next generation instruments. A MKID consist of a superconducting resonator coupled to a feed-line used for the readout, with radiation coupling, here achieved using antenna coupling. The antenna is placed in the focus of an elliptical lens to increase the filling factor. In this paper we present the design and the optical performance of MKIDs optimized for operation at 850 GHz. The detailed device design takes into account the properties of the substrate material, the Kinetic Inductance of the superconducting metals, the effect of the metal thickness and the exact shape of the Si dielectric lens. We have measured a device consisting of 4 pixels. We have characterized the detector coupling efficiency, antenna-lens frequency response and beam pattern and compared these to theoretical simulations. The optical efficiency has been measured by means of a black body radiator mounted in an ADR cryostat; through the variation of the black body temperature a variable illumination of each pixel (from 0.1 fW to 2 pW) is achieved. The frequency response and beam pattern have been measured in a He3 cryostat directly via the cryostat window and without the use of intermediate optics.

9914-97, Session PWed2

Development of focal plane detectors for GroudBIRD experiment

Satoru Mima, RIKEN (Japan); Jihoon Choi, Korea Univ. (Korea, Republic of); Thushara Damayanthi, RIKEN (Japan); Makoto Hattori, Tohoku Univ. (Japan); Masashi Hazumi, High Energy Accelerator Research Organization, KEK (Japan); Hikaru Ishitsuka, The Graduate Univ. for Advanced Studies (Japan); Hiroki Kutsuma, Tohoku Univ. (Japan); Makoto Minowa, The Univ. of Tokyo (Japan); Makoto Nagai, Univ. of Tsukuba (Japan); Takeo Nagasaki, Shugo Oguri, High Energy Accelerator Research Organization, KEK (Japan); Chiko Otani, RIKEN (Japan); Yutaro Sekimoto, National Astronomical Observatory of Japan (Japan); Osamu Tajima, High Energy Accelerator Research Organization, KEK (Japan); Nozomu Tomita, The Univ. of Tokyo (Japan); Eunil Won, Korea Univ. (Korea, Republic of); Tomohisa Uchida, Mitsuhiro Yoshida, High Energy Accelerator Research Organization, KEK (Japan)

Observation of the Cosmic Microwave Background radiation (CMB) polarization provide us knowledge how the Universe was born. The Inflation, accelerated expansion of space-time metric at early stage of the Universe, generated primordial gravitational waves. The primordial gravitational waves can be observed as odd-parity patterns, B-modes, on the CMB polarization map. GroundBIRD a ground based experiment for observing the CMB polarization aims to measure B-modes at large angular scale based on its unique experiment approach. Our instrumental features are high speed rotation scan, cold optics, and Microwave Kinetic Inductance Detector (MKID). Our focal plane consists of corrugated horn coupled MKIDs arrays. We will present its design simulation, hybrid approach of fabrication (usage both mask aligner and stepper), and performance evaluation.

The MKID is one of cutting-edge superconducting detectors. It is easy to readout by frequency domain multiplexing. This is advantage to reduce heat loads from the read-out wires to cold stage. Moreover, fast time response of the MKID is well matched with our scan strategy, the high speed rotation scan to reduce effects of 1/f noise.

Our focal plane consists of seven hexagonal corrugated horn coupled MKID arrays; six hexagon units are for 145 GHz bands (55 pixels/unit), and one unit is for 220 GHz (109 pixels). Each pixel consists of corrugated horn, planner OMT, millimeter wave circuits for transmission of dual-polarization

signals with suppression of crosstalk modes, and two MKIDs for each polarization. The corrugated horn which has the 1/4 lambda wave length structure, makes the beam shape sharp. It has also mode conversion area which is convert form the linear polarization to TE01 mode of the circular waveguide. We make the corrugated horn array and a jig which holds MKIDs array by direct machining.

The OMT consists of two probe antenna pairs on the silicon membrane structure made by deep etching machine. The radio wave is captured by the probe and transport to the MKID through a crossover and a 180 degree hybrid. Between Cross over and hybrid there are two types of impedance transformer, exponential tapered line and second chebyshev transformer. Each resonator of the MKID consists of Niobium films and Aluminum (or Titanium Nitride) films which is sensing parts. the millimeter wave brake the cooper pair in the sensing material and detect the change of MKID resonance parameter.

9914-138, Session PWed2

Fabrication and performance verification of a 961 pixel Kinetic Inductance Detector system for future space borne observatories

Jochem J. A. Baselmans, Juan Bueno, SRON Netherlands Institute for Space Research (Netherlands); Ozan Yurduseven, Technische Univ. Delft (Netherlands); Stephen Yates, SRON Netherlands Institute for Space Research (Netherlands); Nuria Llombart, Technische Univ. Delft (Netherlands); Vignesh Murugesan, SRON Netherlands Institute for Space Research (Netherlands); David J. Thoen, Technische Univ. Delft (Netherlands); Andrey Baryshev, SRON Netherlands Institute for Space Research (Netherlands) and Univ. of Groningen (Netherlands); Andrea Neto, Technische Univ. Delft (Netherlands)

We present the development of a system demonstrator for a future far infrared/sub-millimeter observatory. The system consists of a monolithic detector array of 31 x 31 = 961 antenna coupled microwave kinetic inductance detectors, MKIDs, operating in a 825 – 925 GHz band. The array is read-out using frequency division multiplexing. We use a single pair of coaxial cables, one cryogenic amplifier and a single back-end to read-out al 961 detectors. The back-end consists of a digital/analog readout system capable of reading out up to 4000 MKIDs in a 2 GHz readout bandwidth at a datarate up to 1.2 kHz. The MKID array design is done explicit-ly to achieve a good match with the readout electronics, high pixel yield and high dynamic range.

The performance of the system is tested by placing the detector array in a light tight box and cooling this assembly to 100 mK. A 3-30 K black body radiator, coupled to the central part of the detector array by a 20 mm aperture equipped with band-pass filters, is used to illuminate a part of the array. We find that 85% of the pixels can be used (818 out of 961) and yield an average dark NEP = 4?10-19 W/√Hz, calculated from the measured noise and temperature response of the devices. This sensitivity is not affected by the readout electronics but limited only by the MKID performance.

9914-83, Session PWed3

Improving ALMA’s calibration of atmospheric spectral features: development of high spectral resolution system temperature measurement

Neil M. Phillips, European Southern Observatory (Chile); Todd R. Hunter, National Radio Astronomy Observatory (United States); Dominique Broguière, Institut de Radio Astronomie Millimétrique (France)

ALMA visibility spectra are calibrated for atmospheric transmission and sky brightness effects by scaling by a system temperature spectrum determined from auto-correlation spectra of the sky and two calibration loads. Up to ALMA Cycle-3 observations, these system temperature spectra have been limited to resolution of around 30 MHz (15.625 MHz channel widths), which whilst sufficient in many cases, insufficiently sample narrower atmospheric emission lines, leading to uncorrected residual errors in higher resolution science spectra. The limited resolution is due to the need for linear autocorrelation response, which is only satisfied in the Baseline correlator’s low resolution “TDM” mode. Extra processing by filter banks in the higher resolution “FDM” mode results in an inability to apply numerical correction for signal quantisation, which is required for linear response. In this paper we present the work of an ALMA Development Study to produce system temperature spectra at full science resolution, including for FDM mode observations. The effects of insufficiently resolved narrow atmospheric lines on science data calibration, and proof of concept demonstrations of measuring system temperature spectra at full science resolution are presented. To achieve meaningful system temperature measurement in FDM mode, without significant hardware and low level software modification in the correlator, we show the results of combining FDM autocorrelations with data from square law detectors in the receiver backends -- a technique which can be implemented in ALMA’s online calibration software. Performance and storage implications of the higher spectral resolution calibration are discussed, as well as downstream implications in the CASA and ALMA Pipeline offline software.

9914-85, Session PWed3

A compact cryogenic calibrator for mm-wave detector characterization

David T. Chuss, Villanova Univ. (United States); Karwan Rostem, NASA Goddard Space Flight Ctr. (United States) and Johns Hopkins Univ. (United States); Marco Sagliocca, Villanova Univ. (United States); Felipe A. Colazo, Edward J. Wollack, NASA Goddard Space Flight Ctr. (United States)

We describe the construction of a cryogenically-compatible quasioptical source designed to be used for measurements of cryogenic detector arrays operating at millimeter waves. The source is constructed using a carbon-loaded epoxy mixture that is molded into a tiled pyramidal structure. The mold is fabricated using a hardened steel template produced via a wire EDM process. The full angle of the pyramid is 20 degrees, and the measured size of the apex of the pyramid produced by this technique is less than 10 microns. The carbon-loaded epoxy used as the absorbing material has a measured dielectric constant of 6.3+0.47i. A copper backplane is embedded in the epoxy mixture to provide thermalization of the absorbing layer. We present the design and fabrication of this structure. We discuss the thermal design, including the heat capacity and resulting time constant and residual thermal gradients in the structure. Additionally, we discuss the thermal survivability. Finally, we describe the radiometric performance of the structure, including the performance as a function of the angle of incidence.

9914-87, Session PWed3

Analysis of antenna position measurements and weather station network data during the ALMA long baseline campaign of 2015

Todd R. Hunter, National Radio Astronomy Observatory (United States); Robert Lucas, Institut de Planétologie et d'Astrophysique de Grenoble (France); Dominique Broguiere, Institut de Radio Astronomie Millimétrique (France); William R. Dent, Joint ALMA Observatory (Chile); Edward B. Fomalont, National Radio Astronomy Observatory (Chile); Neil M. Phillips, David Rabanus, Joint ALMA Observatory (Chile); Catherine Vlahakis, National Radio Astronomy Observatory (United States)

In a connected element radio interferometer, the determination of accurate geometrical antenna positions relies on accurate calibration of the dry and wet delay of the atmosphere. For the Atacama Large Millimeter/Submillimeter Array (ALMA), with baseline lengths up to 15 kilometers, the geography of the site forces the height of the more distant antenna pads to be significantly lower than the central array.

Thus, both the ground level meteorological values and the total water column can be quite different between antennas in the extended configurations. During 2015, a network of six additional weather stations was installed to monitor pressure, temperature, relative humidity and wind velocity, in order to test whether inclusion of these parameters could improve the repeatability of antenna position determinations in these configurations. We present an analysis of the data obtained during the long baseline campaign of October through November 2015. The repeatability of antenna position measurements typically degrades as a function of antenna distance. Also, the scatter is more than three times worse in the vertical direction than in the local tangent plane, suggesting that a systematic effect is limiting the measurements. So far we have explored correcting the delay model for deviations from hydrostatic equilibrium in the measured air pressure and separating the partial pressure of water from the total pressure using water vapor radiometer (WVR) data. Correcting for these combined effects still does not provide a good match to the residual position errors in the vertical direction. One hypothesis is that the current model of water vapor may be too simple to fully remove the day-to-day variations in the wet delay. We are now exploring new avenues of improvement, which include recalibrating the baseline measurement datasets using the contemporaneous measurements of the water vapor scale height and temperature lapse rate from the oxygen sounder, and applying more accurate measurements of the sky coupling of the WVRs.

9914-89, Session PWed3

Managing the cryogenic systems of SCUBA-2 for long term operations

Jamie L. Cookson, Daniel Bintley, East Asian Observatory (United States)

SCUBA-2 has been operational on JCMT producing excellent science for over 4 years. We describe the strategy and methods that we have evolved to keep one of the worlds first “dry dilution refrigerators” and the other cryogenic systems working effectively at the summit of Mauna Kea, keeping the instrument functioning at peak efficiency for extended periods (over 12 months at a time), with minimum downtime. We discuss new plans to reduce day to day operational costs and to add remote management of the gas handling systems, as we look to the future and envisage another ten years of SCUBA-2 science.

9914-91, Session PWed3

The QUIJOTE TGI cryomechanics

Vicente Sánchez-de-la-Rosa, Instituto de Astrofísica de Canarias (Spain)

The QUIJOTE (Q-U-I JOint Tenerife) CMB Experiment is operating at the Teide Observatory with the aim of characterizing the polarization of the CMB and other processes of Galactic and extragalactic emission in the frequency range of 10–40GHz and at large and medium angular scales. QUIJOTE consists of two telescopes installed inside a single enclosure, and three instruments, the MFI (multi-frequency 10–30GHz), the TGI (26-36 GHz) and the FGI (37-47 GHz). The first QUIJOTE telescope, together with the MFI instrument, is already operative at the Observatory since November 2012. The second telescope was accepted on site in January 2015.

In this paper we present the TGI cryo-mechanics. The TGI is a 30 pixel polarimeter array with a modular design. This feature permits the assembly and dissasembly of each pixel individually. Each pixel is cooled by three automatic thermal links based in the concept of ALMA cartridge-type cryostat. We designed a crown-like monolithic thermal link with 12 fingers. The thermal link is made of high conductivity oxygen free copper and the clamp belt is made of Teflon©. The cryostat is cooled by a two stage GM cryocooler Leybold COOLPOWER 10 MD. Horns, low noise amplifiers, 20K cold plates and 20K radiation shield are cooled on the 12 K second stage. R22 waveguides, 50K cold plate and 50K radiation shield are cooled on the 50K second stage. To reduce the mechanical vibration an antivibration mount is used as interface between the coldhead and the cryostat and high conductivity oxygen free copper flexibles links are used between the cold head stages and the cold plates. The vacuum vessel, with a cylindrical shape and two diameters, is made of Al6061-T6 to reduce the weight. The cryostat window is a single Mylar© piece of 600mm supported in the 31 holes of the front flange and secured by two PVC© pieces. These PVC© pieces also contains a dry air system to prevent window condensation. Also included is the development of the automatic thermal link, the mechanics of the calibration system as well as the instrument manufacturing, assembly, integration and tests. The TGI instrument is currently undergoing the commissioning phase and will be operating in the second telescope.

9914-93, Session PWed3

Artificial calibration source for ALMA radio interferometer

Hitoshi Kiuchi, National Astronomical Observatory of Japan (Japan); Richard Hills, Univ. of Cambridge (United Kingdom); Nicholas D. Whyborn, ALMA (Chile); Shin'ichiro Asayama, Seiichi Sakamoto, Satoru Iguchi, National Astronomical Observatory of Japan (Japan); Stuartt A. Corder, ALMA (Chile)

The ALMA (Atacama Large Millimeter/submillimeter Array) radio interferometer has some different types of antennas which have a variation of gain and leakages across the primary beam of an individual antenna. We have been developing an artificial calibration source which is used for compensation of individual difference of antennas. In a high-frequency antenna, using astronomical sources to do calibration measurement would be extremely time consuming, whereas with the artificial calibration source becomes a realistic possibility. Photonic techniques are considered to be superior to conventional techniques based on electronic devices in terms of wide bandwidth and high-frequency signals. Conversion from an optical signal to a millimeter/sub-millimeter wave signal is done by a photo-mixer.

We will place a small low-powered millimeter/submillimeter wave source on one of the mountain peaks overlooking ALMA operations site (5000m above sea level).

This will serve several purposes:

(1) to provide a signal for interferometric holography measurements of the antenna surfaces,

(2) to provide a source of known and preferably changeable polarization so we can measure the polarization properties of the antenna/receiver system,

(3) to provide a source with high signal-to-noise ratio to help measure things like coherence, phase stability, switching timing and perhaps stability and sideband ratio.

The artificial calibration source consists a wide-bandwidth noise source, a comb (or a continuous wave) generator, a photo-mixer, and a polarization controller.

The polarization calibration is the most difficult hurdle. Since ALMA has a 0.1 % polarization requirement we certainly need to know what is being produced to this sort of level. The ALMA receivers have two nominal linear polarization channels.

There are two important cases to consider:

(1) the polarization properties of the array of dishes.

(2) the variation of the gains and leakages across the primary beam of an individual antenna, we can make accurate polarization maps of extended sources.

Measurement of the polarization properties of the ALMA receiver system is more complicated than it was assumed. The patterns are quite different for the different antennas. The effect is thought to be due to multi-path propagation in the optics. Although we were expecting the leakage terms, as a function of three parameters (frequency, azimuth offset and elevation offset), to be a function of the position of the source in the primary beam, the assumption was that the pattern would only vary slowly with frequency.

An arrangement of wire grids, including at least one that rotates about an axis perpendicular to the plane of the grid, should be used to produce a pure linear polarization signal at a controlled orientation.

We made a laboratory test with an ALMA receiver. The main purpose of these tests was to confirm that the source produces signals which will be easy to use for calibrating the ALMA system. We will report the performance of the artificial calibration source.

9914-33, Session 7

Polarization sensitive multichroic MKIDs for CMB studies

Bradley R. Johnson, Columbia Univ. (United States); Peter A. R. Ade, Cardiff Univ. (United Kingdom); Sean A. Bryan, George Che, Arizona State Univ. (United States); Hsiao-Mei Cho, Stanford Univ. (United States) and SLAC National Accelerator Lab. (United States); Peter K. Day, Jet Propulsion Lab. (United States); Rahul Datta, Univ. of Michigan (United States); Simon M. Doyle, Cardiff Univ. (United Kingdom); Daniel Flanigan, Columbia Univ. (United States); Kent D. Irwin, Stanford Univ. (United States); Glenn E. Jones, Columbia Univ. (United States); Dale Li, Stanford Univ. (United States); Philip D. Mauskopf, Arizona State Univ. (United States); Heather McCarrick, Columbia Univ. (United States); Jeff J. McMahon, Univ. of Michigan (United States); Amber D. Miller, Columbia Univ. (United States); Giampaolo Pisano, Cardiff Univ. (United Kingdom); Sarah A. Stokes Kernasovskiy, Stanford Univ. (United States); Harshad Surdi, Arizona State Univ. (United States)

We report on the status of an ongoing effort to develop 20-element prototype arrays of horn-coupled, polarization-sensitive microwave kinetic inductance detectors (MKIDs) that are each sensitive to two spectral bands between 130 and 280 GHz. These multi-chroic MKID arrays are tailored for experiments that are designed to simultaneously characterize the polarization properties of both the cosmic microwave background (CMB) and Galactic dust emission. We present the device design and show results from initial laboratory-based characterization measurements. Our device design builds from successful transition edge sensor (TES) bolometer architectures that have been demonstrated to work in instruments on the ACT and SPT telescopes. Therefore, our research program focuses on (i) developing the microstrip-to-CPW coupling between the TES-based on-chip millimeter-wave polarimeter circuit and the distributed MKID and (ii) demonstrating that the performance of theses arrays is competitive with arrays of similar TES-based devices. The 20-element prototype arrays we are building allow us to test the full bandwidth of our ROACH-2-based readout system, which should ultimately allow multiplexing factors of approximately 500. Our prototype array design is directly scalable to 331 elements, and seven of these arrays can be tiled into a 9268 detector array.

9914-34, Session 7

MKID detector development for large scale far-infrared arrays

Christopher M. McKenney, Jiansong Gao, Jason Austermann, Johannes Hubmayr, Michael Vissers, Gene C. Hilton, James Beall, Daniel T. Becker, National Institute of Standards and Technology (United States); Hsiao-Mei Cho, SLAC National Accelerator Lab. (United States); Mark J. Devlin, Bradley J. Dober, The Univ. of Pennsylvania (United States); Christopher E. Groppi, Arizona State Univ. (United States); Kent D. Irwin, Dale Li, SLAC National Accelerator Lab. (United States); Philip D. Mauskopf, Arizona State Univ. (United States); David P. Pappas, Jeff Van Lanen, National Institute of Standards and Technology (United States); Yiwen Wang, National Institute of Standards and Technology (United States) and Southwest Jiaotong Univ. (China); Joel N. Ullom, National Institute of Standards and Technology (United States)

We are developing Microwave Kinetic Inductance Detectors (MKIDs) for sub-millimeter through millimeter wave focal planes. Development is focused on improving sensitivity, array size, and multiplexing density to achieve large scale arrays for future far infrared and millimeter wave missions. Current MKID detector design, fabrication and testing efforts are geared toward developing focal planes for BLAST-TNG, which will require approximately 3000 total detectors operating with photon noise sensitivity and polarization sensitivity at 250, 350, and 500 microns. The fundamental design is a feedhorn coupled to two separate MKID resonators with inductors which are orthogonal to each other acting as independent absorbers in the two linear polarizations. Photon noise operation under ~ pW loading has been demonstrated in lab. Various designs of the absorber geometry have been developed to couple the radiation; predictions and lab testing for the optical efficiency, optical and polarization sensitivity, and cross talk for inductors fabricated using various approaches to separate the polarizations will be presented.

Ti/TiN/Ti trilayer and multilayer films offer a high kinetic inductance relative to other materials such as Aluminum and is used as the absorbing element and inductor allowing the resonators to achieve the desired LC frequencies < 1 GHz to meet electronic readout requirements. Additionally the Tc uniformity of these films allows for resonators to behave both uniformly and be close to the designed frequency. BLAST-TNG is being fabricated on 100 mm wafers using two layers of lithography to define the resonators and quarter wave backshorts. The designs are made with consideration toward upgrading the design and process to 150 mm wafers.

We are also exploring the use of TiN for 90 GHz detectors; the ability to reach these longer wavelengths coupled with larger wafer scale fabrication would make the attractive for cosmological application. Preliminary results on detectors at 90 GHz will also be reported.

9914-35, Session 7

Low-volume Al and Al/TiN bilayer LEKIDs for far-infrared astronomy

Jason Glenn, Adalyn Fyhrie, Jordan D. Wheeler, Univ. of Colorado Boulder (United States); Peter K. Day, Byeong-Ho Eom, Henry G. Leduc, Jet Propulsion Lab. (United States)

Next-generation far-infrared astronomical telescopes, such as the Far Infrared Surveyor that is intended to have a T ~ 4 Kelvin, 4 – 6 meter aperture, require detector NEPs of approximately 3e-19 W/sqrt(Hz) and 3e-20 W/sqrt(Hz) for imaging and spectroscopy, respectively. Such NEPs will match the expected photon background limit of astrophysical sources and hence maximize the capability of the Surveyor for astrophysics. Kinetic inductance detectors (KIDs) are a promising detector technology because they can be multiplexed with minimal cryogenic amplification complexity. Very encouraging progress has been made in KID sensitivities in recent years; however, additional progress remains to be made in sensitivity and in demonstration of many-pixel arrays.

We present the design and characterization of low-volume Al/TiN bilayer and Al-only lumped-element kinetic inductance detectors (LEKIDs) meant to demonstrate NEPs approaching the requirements of applications such as the FIR Surveyor. The LEKIDs are comprised of meandered inductors that serve as radiation absorbers in parallel with interdigitated capacitors, forming high quality factor resonators. Resonance frequencies are in the range of 190 to 360 MHz, with quality factors of 1e4 to 1e5. The interdigitated capacitor architecture is designed to mitigate two-level system noise by lowering electric fields in the substrate (Si) dielectric. Low inductor volumes lead to low NEPs by raising quasiparticles densities, and hence responsivities, with respect to larger volumes. Low volumes are achieved with thin (20 nm), narrow (150 micron) lines. The TiN layer on top of the Al serves as a protective layer, but complicates the superconducting properties compared to Al-only devices. Detector performance properties, including yields, responsivities, NEPs, and noise contributions for 350 um arrays are reported under various optical loading conditions, along with an optical coupling analysis and a comparison of Al/TiN versus Al-only LEKIDs.

9914-36, Session 7

Ultrasensitive kinetic inductance detectors for far-infrared space telescopes

Omid Noroozian, NASA Goddard Space Flight Ctr. (United States) and Univ. of Maryland, College Park (United States); Emily M. Barrentine, Ari Brown, Vilem Milkula, Thomas R. Stevenson, Edward J. Wollack, Kongpop U-Yen, Samuel H. Moseley, NASA Goddard Space Flight Ctr. (United States)

We are developing ultra-sensitive Kinetic Inductance Detectors (KIDs) suited for the next-generation of far-infrared space instruments and in particular for NASA's notional far-IR surveyor mission. These instruments especially the moderate resolution spectrometers will require either photon counting capability or power detection sensitivity of order 10^-20 W/rt Hz.

We are exploring KIDs made from thin aluminum (10 – 100 nm) and NbTiN (100 nm) films on single-crystal silicon and SOI substrates. We have achieved internal quality factors as high as Qi ~ 7 x 10^6 for 25 nm Al on Si and 2.5 x 10^6 for 100 nm Al on Si resonators. We have also obtained quasi-particle lifetimes of ~ 1 ms for 100 nm Al. Our cryogenic testbed was optimized for ultra low stray radiation, which we confirmed by measurement comparisons. Furthermore, with SOI parallel-plate capacitors we hope to minimize two-level system resonator noise by confining the electric fields inside the crystalline dielectric. Ultimately we will maximize sensitivity by using very small volume kinetic inductors.

We report on dark and optical measurements of single- and double layer resonator KIDs made from these films, and our plans to implement these into optically coupled ultrasensitive KIDs.

9914-37, Session 7

Phonon recycling for low-NEP kinetic inductance detector

Roger C. O'Brient, Hein T. Nguyen, Charles D. Dowell, Henry G. Leduc, Jet Propulsion Lab. (United States); Jonas Zmuidzinas, Jet Propulsion Lab. (United States) and California Institute of Technology (United States)

We are developing released Kinetic Inductance Detectors (KIDs) that may boost sensitivity through a process known as phonon recycling. The responsivity of KIDs increases with the life-time of excited quasiparticles,, typically limited to ~100us by decay back into cooper pairs with emissions of a phonon. Our released KIDs on high-purity HF-dipped SOI substrates attempt to "trap" these phonons in a thin 2um films and reflect them back to the KID where they can be re-excite quasiparticles. This should dramatically increase the effective quasiparticle lifetime and thus sensitivity of the device by at least an order of magnitude. Early tests showed such a large responsivity differences between released and un-released KIDs, but there was ambiguity since the release can also alter the optical coupling efficiency. In this study, we address this ambiguity by releasing all devices but altering the perimeter of some devices to change the fraction of phonons that can escape into the surrounding substrate. We will comment on the status of these tests in these talks and discuss measured differences in responsivity as well as detector time constants.

9914-38, Session 8

Next generation sub-millimeter wave focal plane array coupling concepts: an ESA TRP project to develop multichroic focal plane pixels for future CMB polarization experiments

Neil A. Trappe, National Univ. of Ireland, Maynooth (Ireland); Martin Bucher, AstroParticule et Cosmologie (France); Paolo De Bernardis, Sapienza Univ. di Roma (Italy); Jacques Delabrouille, AstroParticule et Cosmologie (France); Prafulla Deo, The Univ. of Manchester (United Kingdom); Marco DePetris, Sapienza Univ. di Roma (Italy); Leonid S. Juzmin, Chalmers Univ. of Technology (Sweden); Bruno Maffei, The Univ. of Manchester (United Kingdom); Silvia Masi, Sapienza Univ. di Roma (Italy); Anthony Murphy, Marcin L. Gradziel, Créidhe O'Sullivan, National Univ. of Ireland, Maynooth (Ireland); Luca Pagano, Francesco Piacentini, Sapienza Univ. di Roma (Italy); Michel R. Piat, AstroParticule et Cosmologie (France); Giampaolo Pisano, Cardiff Univ. (United Kingdom); Matthew Robinson, The Univ. of

Manchester (United Kingdom); Radek Stomper, Andrea Tartari, AstroParticule et Cosmologie (France); Maarten van der Vorst, European Space Research and Technology Ctr. (Netherlands)

The main objective of this ESA funded activity is to develop new focal plane coupling array concepts and technologies that optimise the coupling from reflector optics to the large number of detectors required for next generation sub millimetre wave telescopes targeting B Mode detection in the cosmic microwave background (CMB). B mode observations will detect or set an upper bound on the primordial gravitational waves (tensor mode fluctuations) predicted by theories of cosmic inflation. The B mode signal associated with gravitational waves have not yet been detected from the ground or via balloon borne instruments and a space mission may offer the best opportunity to observe these weak inflationary signals.

To reach the sensitivity levels required many thousands of polarisation sensitive detectors are required in the focal plane of a large telescope. This leads to challenges in the optical design of the system. The traditional horn arrays used in CMB missions are heavy and difficult to cool so a new planar focal plane technology is desirable for such a future B mode mission. The development of multichroic operation will allow the reduction in size of the potential focal plane area. In light of these requirements a multichoic planar pixel design was developed as part of a European Space Agency (ESA) TRP programme. After a detailed scientific and technical review of existing technology, the consortium were tasked with designing, manufacturing and the experimentally verifying a prototype multichroic pixel which would be suitable for the large focal plane arrays required to reach the sensitivity levels to detect CMB B modes. The proposed pixel is based on a planar mesh lens focusing incident radiation to detector via a multichoic planar antenna. The mesh lens operates by achieving the appropriate transmission and phase delays across the lens surface using a sub wavelength size metal mesh or grid in a thin dielectric layer. The technology is very robust, and can be used cryogenically as well as in space environments as normal mesh filters.

A number of different planar antenna configurations were investigated including a wideband sinuous antenna and a configuration of slot antennas referred to a seashell antenna. The detector chosen for the prototype design is a CEB bolometer but this coupling concept can also be used with other detector types. For the prototype pixel only dual frequency operation will be demonstrated at 75 and 105 GHz in the w band close to the peak CMB signal. In order to fully verify the operation of the pixel a number of room and cryogenic measurements were planned. The optical behaviour of the mesh lens and antenna are carefully measured along with the spectral response of the antenna coupled detector to allow accurate characterisation for each pixel component.

9914-39, Session 8

Optical characterization and analysis of multi-mode pixels for use in future far-infrared telescopes

Darragh N. McCarthy, Neil A. Trappe, Anthony Murphy, Stephen Doherty, Marcin L. Gradziel, Créidhe O'Sullivan, National Univ. of Ireland, Maynooth (Ireland); Michael D. Audley, Gert de Lange, SRON Netherlands Institute for Space Research (Netherlands); Maarten van der Vorst, European Space Research and Technology Ctr. (Netherlands)

In this paper we present the development and verification of feed horn simulation code based on the mode-matching technique to simulate the electromagnetic performance of waveguide based structures of rectangular cross-section. This code is required to model multi-mode pyramidal horns which may be required for future far infrared (far IR) space missions where wavelengths in the range of 30 to 200 ?m will be analysed. Multi-mode pyramidal horns can be used effectively to couple radiation to sensitive superconducting devices like Kinetic Inductance Detectors (KIDs) or Transition Edge Sensor (TES) detectors. These detectors could be placed in integrating cavities (to further increase the efficiency) with an absorbing layer used to couple to the radiation. The developed code is capable of modelling each of these elements, and so will allow full optical characterisation of such pixels and allow an optical efficiency to be calculated effectively.

As the signals being measured at these short wavelengths are at an extremely low level, the throughput of the system must be maximised and so multi-mode systems are proposed. To this end, the focal planes of future far IR missions may consist of an array of multi-mode rectangular feed horns feeding an array of, for example, TES devices contained in individual integrating cavities. Such TES arrays have been fabricated by SRON Groningen and are currently undergoing comprehensive optical, electrical and thermal verification. In order to fully understand and validate the optical performance of the receiver system, it is necessary to develop comprehensive and robust optical models in parallel.

We outline the application of this developed rectangular mode-matching technique to the experimental testbed used at SRON Groningen in the optical testing of the TES arrays with multi-mode pyramidal horns. This testbed makes use of a blackbody source to illuminate the pixels both together and individually, and returns the power output from each of the TES detectors. The extension to the mode-matching technique to allow for the excitation of a pixel using the blackbody source is outlined, in addition to the method used in order to predict the power measured by the TES detectors from the mode-matching technique and the optical efficiency of the pixel. The simulated results are compared to the SRON measurements.

SAFARI (SPICA FAR infrared Instrument) is a far infrared imaging grating spectrometer, to be proposed as an ESA M5 mission. It is planned for this mission to be launched on board the proposed SPICA (SPace Infrared telescope for Cosmology and Astrophysics) mission, in collaboration with JAXA. SAFARI is planned to operate in the 1.5-10 THz band, focussing on the formation and evolution of galaxies, stars and planetary systems. The test pixel discussed in this paper is typical of one option that could be implemented in the SAFARI focal plane, and so the ability to accurately understand and characterise such pixels is critical in the design phase of the next generation of far IR telescopes.

9914-40, Session 8

Development of the multi-mode horn-lens configuration for the LSPE-SWIPE B-mode experiment

Stephen Legg, The Univ. of Manchester (United Kingdom); Luca Lamagna, Paolo de Bernardis, Sapienza Univ. di Roma (Italy); Gabriele Coppi, The Univ. of Manchester (United Kingdom); Grazia Giuliani, Riccardo Gualtieri, Tommaso Marchetti, Silvia Masi, Sapienza Univ. di Roma (Italy); Giampaolo Pisano, Cardiff Univ. (United Kingdom); Bruno Maffei, The Univ. of Manchester (United Kingdom)

The information contained within the B-mode component of the cosmic microwave background polarisation has the potential to constrain theories of cosmic inflation in the early universe. The extremely weak nature of the B-mode signal necessitates a measuring instrument with a high sensitivity and well controlled systematics. Furthermore, observations must be made over a wide frequency range in order to discriminate against the strong galactic foregrounds which contaminate the B-mode signal.

The Large Scale Polarisation Explorer (LSPE) is a balloon-borne experiment aiming to measure the B-mode at large angular scales. The Short Wavelength Instrument for the Polarisation Explorer (SWIPE) is a bolometric polarimeter observing in three bands centred at 140, 220 and 240 GHz. The telescope is a single large 480 mm diameter plano-convex

high density polyethylene lens. Polarisation sensitivity is achieved by means of a large metal-mesh rotating half-wave plate and a fixed wire grid polariser; feeding orthogonal polarisations onto two focal planes of back-to-back feed horns. Instrument sensitivity is boosted by allowing the feed horns to couple many higher order waveguide modes onto the bolometer. The main drawback of the multi-mode design is an increased complexity in the measurement and simulation of the optics and detector assembly. Thinking of the detector as a transmitter, the propagating electric fields produced by each modal excitation at the throat of the horn act incoherently and therefore must be simulated separately through the system, leading to long simulation times. Furthermore, each of these modal excitations is associated with a different coupling efficiency to the bolometer, which must be taken into account. Combining this with the large electrical size of the lens in SWIPE makes it a very challenging system to simulate.

Simulations have been performed to predict the multi-mode optical response (intensity and polarisation) of the horn-lens system for centre and off-axis pixels pertaining to each frequency band. The horn is simulated to a high accuracy using the full-wave simulation technique, the Method of Moments (MoM). Using the horn as a source, the optical response of the lens is examined using the more approximate simulation technique, Ray-Launching Geometrical Optics (RL-GO). Solution accuracy and simulation time depend heavily on the choice of RL-GO simulation parameters including: mesh size, maximum number of ray interactions and the angle between adjacently launched rays. Individual convergence studies are performed for each of these parameters and a final model is obtained as a compromise between simulation time and accuracy.

Another key factor in the design of the horn-lens system is the position of the telescope focus relative to the horn. For a single mode horn, the telescope focus is placed at the horn phase centre in order to optimise gain and angular resolution. The situation is more complicated for a multi-mode system since each modal excitation can produce a different location of phase centre. The optimal location of 'phase centre' has been investigated and compared using several techniques including: backwards propagation of the horn aperture field; and the translation of the lens in the full simulation.

9914-41, Session 8

Systematics of ambient temperature rapidly rotating half-wave plates

Thomas Essinger-Hileman, Johns Hopkins Univ. (United States); Akito Kusaka, Lawrence Berkeley National Lab. (United States); John A. Appel, Johns Hopkins Univ. (United States); Steven K. Choi, Kevin T. Crowley, Norman Jarosik, Lyman A. Page, Princeton Univ. (United States); Lucas P. Parker, Johns Hopkins Univ. (United States); Srinivasan Raghunathan, Univ. de Chile (Chile); Sara M. Simon, Suzanne T. Staggs, Katerina Visnjic, Princeton Univ. (United States)

We present an evaluation of the systematic errors associated with a rapidly-rotating, ambient-temperature half-wave plate (HWP) based on two seasons of data from the Atacama B-Mode Search (ABS) experiment located in the Atacama Desert of Chile. The HWP allows for rejection of unpolarized atmospheric fluctuations and ground pickup, as well as clear separation of celestial polarization from intensity. We present our in-field evaluation of celestial (CMB plus galactic foreground) temperature-to-polarization leakage and estimate its contribution to the systematic error budget of the ABS experiment. We decompose the leakage into scalar, dipole, and quadrupole terms. We report a scalar leakage of ~ 0.01%, which is consistent with model expectations and an order of magnitude smaller than any other CMB experiment. No significant dipole or quadruple terms are detected; we constrain each to be < 0.06% (95% confidence level). The upper limit on possible systematic error from these effects corresponds to a tensor-to-scalar ratio r ~ 0.01 with no mitigation due to scan strategy, including boresight rotation. This demonstrates that ABS is not systematic-error limited from the HWP at this level and shows the promise of fast polarization modulation with ambient-temperature HWPs for precision microwave polarization measurements.

9914-42, Session 8

The design and characterization of wideband spline-profiled feedhorns for Advanced ACTPol

Sara M. Simon, Princeton Univ. (United States)

Advanced ACTPol (AdvACT) is an upgraded camera for the Atacama Cosmology Telescope that will measure the Cosmic Microwave Background in both temperature and polarization over a wide range of angular scales and five frequency bands from 28-230 GHz with unprecedented resolution and sensitivity. AdvACT's sensitivity, resolution, wide frequency coverage, and large sky coverage will enable it to simultaneously probe inflation at large angular scales while using small angular scale measurements to constrain the mass and number of neutrinos, dark energy, and dark matter. AdvACT will employ three arrays of feedhorn-coupled, polarization-sensitive multichroic detectors that are designed to maximize the focal plane area through minimizing the spacing between pixels on the array. To achieve this higher packing density, we have developed and optimized wideband spline-profiled feedhorns for the AdvACT multichroic arrays that maximize coupling efficiency while carefully controlling polarization systematics. The feedhorns are optimized via Markov chain Monte Carlo (MCMC) simulations to minimize the difference between the calculated E-plane and H-plane beams of the feedhorn over twenty frequencies within the multichroic observation bands while estimating the beam coupling efficiency. By using parallel MCMC optimizations, we have decreased the design time to a few days. To validate the feedhorn design before fabrication, we simulate the beams of each feedhorn in HFSS (an electromagnetic finite element method solver) then calculate the beam coupling efficiency, cross-polarization, return loss, far field beams including the instrument Lyot stop, and the polarization leakages in the power spectra assuming a pair differenced detector pair. This represents an extreme test of the performance since in AdvACT the half-wave plates will eliminate the need for pair differencing orthogonal pairs of detectors to gain polarization sensitivity and will provide significant extra mitigation of systematics. Once the monolithic Si feedhorn arrays are fabricated by the National Institute of Standards and Technology, we measure the feedhorn beams and return loss with an ambient-temperature vector network analyzer. We will present the design, fabrication, and testing of wideband spline-profiled feedhorns for the multichroic arrays on AdvACT.

9914-43, Session 8

Antireflection and gradient index layers for silicon optical elements utilizing deep reactive ion etch processing

Matthew I. Hollister, California Institute of Technology (United States); Goutam Chattopadhyay, Jet Propulsion Lab. (United States); Sunil R. Golwala, California Institute of Technology (United States); Cecile Jung-Kubiak, Jet Propulsion Lab. (United States); Simon J. Radford, Jack Sayers, Arjun Bose, Hiroshige Yoshida, California Institute of Technology (United States)

A broad range of applications in millimeter and submillimeter astronomy have benefited from the use of silicon optical elements, and silicon is likely to continue to be important in future applications both from the

ground and in space. The high refractive index and low loss of silicon at these wavelengths make it an ideal material for focusing optics, while the mechanical properties are suitable for constructing large diameter but low-loss vacuum windows. Antireflection treatment of silicon optics is essential, however, and has proven a major challenge for the 150 to 1000 millimeter diameter optics required for current and future applications. Moreover, multilayer antireflection treatments are necessary for wide spectral bandwidths, with wider bandwidths requiring more layers. It is difficult to find low-loss dielectrics with the correct refractive index and thermophysical properties to work well with silicon. Considerable success has been achieved at longer wavelengths by cutting matched layers into silicon surfaces with dicing saws, however, obtaining progressively larger bandwidths requires cutting of progressively more and deeper layers with thinner grooves, and the utility of this approach at higher frequencies is limited by the minimum feature size that a dicing saw can produce. While smaller features can be produced by deep reactive ion etch processing, this method is limited in the depth and aspect ratio of the produced features, and is unsuitable for use on thick and/or curved substrates.

We are investigating an alternative approach in which a silicon optic is produced by stacking multiple patterned wafers. The resulting optic is designed with an axial gradient in the refractive index for antireflection purposes, combined with a radial index gradient for focusing. Individual wafers are patterned with holes or pillars to achieve the required refractive index gradient, and multiple wafers are bonded together to produce the finished optic.

In this paper, we discuss the current status of the development program. The design, fabrication and performance of individual optical layers are presented, and the progress towards the production of the overall stacked optic is described.

9914-44, Session 9

Large arrays of dual-polarized multichroic TES detectors for CMB measurements with the SPT-3G receiver

Chrystian M. Posada, Argonne National Lab. (United States); Peter A. R. Ade, Cardiff Univ. (United Kingdom); Adam Anderson, Fermi National Accelerator Lab. (United States) and Kavli Institute for Cosmological Physics (United States); Jessica Avva, Univ. of California, Berkeley (United States); Zeeshan Ahmed, Stanford Univ. (United States); Kam S. Arnold, Univ. of Wisconsin-Madison (United States); Jason Austermann, National Institute of Standards and Technology (United States); Amy N. Bender, Argonne National Lab. (United States); Brad A. The cosmic microwave background (CMB) is remnant radiation from the early universe that provides a unique window for exploring fundamental physics. CMB detectors have evolved to the point where their sensitivity is limited by photon noise. Increasing the sensitivity of CMB experiments requires fabricating focal planes with orders of magnitude more detectors than current instruments. Large arrays of multichroic pixels constitute an economic approach to increasing the number of CMB detectors within a given focal plane area. Here, we present the fabrication of large arrays of dual-polarized multichroic transition-edge sensor (TES) bolometers for CMB measurements. These detectors will be used for the South Pole Telescope third generation CMB receiver (SPT-3G). Deployment of the SPT-3G receiver to the South Pole is planned for the end of 2016. The complete SPT-3G receiver will have ~2690 pixels. Each pixel has six detectors, allowing for individual measurement of three spectral bands (centered at 95 GHz, 150 GHz and 220 GHz), each in two orthogonal polarizations. In total, the SPT-3G focal plane will have 16140 detectors. Each pixel is comprised of a broad-band sinuous antenna coupled to a niobium microstrip transmission line. In-line filters are used to define the different band-passes before the millimeter-wavelength signal is fed to the respective Ti/Au TES sensors. The overall microfabrication involves a total of 16 processes, including reactive and magnetron sputtering, reactive ion etching, inductively coupled plasma etching and chemical etching. Patterns are defined using a combination of stepper and contact lithography. Together with the fabrication process, results on the pre-deployment cryogenic characterization of the fabricated detectors are presented.

9914-45, Session 9

Characterization of the first high density sub-mm multichroic array for the Atacama Cosmology Telescope

Shuay-Pwu Patty Ho, Princeton Univ. (United States); ACT Collaboration, ACT Collaoration (United States)

The Advanced Atacama Cosmology Telescope Polarimeter (Advanced ACTPol) is a polarization sensitive receiver upgrade to the 6 m Atacama Cosmology Telescope. Advanced ACTPol adds new frequency bands on denser arrays to make measurements of the small angular scale polarization anisotropies in the Cosmic Microwave Background (CMB), and simultaneously constraining foregrounds. The improved sensitivity of the upgrade will permit new cosmological constraints on topics including the sum of the neutrino masses, dark energy parameters, and alternate models of gravity. The new receiver will comprise multichroic arrays, each covering two frequency bands spanning 30 GHz and 220 GHz. The receiver will be operated at 100 mK continuously using a dilution refrigerator. The first detector array is composed of 2024 feedhorn-coupled AlMn TES bolometers, fabrcated on a single 150 mm wafer; and read out through a 2-stage SQUID-based time division multiplexing scheme. We will present the optimization and characterization of the first detector array for the receiver, sensitive to both 220 GHz and 150 GHz frequency bands simultaneously.

A highlight of this work is that the detectors are fabricated for the first time on a 150-mm wafer. The wafer is then assembled with readout components, which all fit in a 12-inch diameter area. The resulting assembly is compact and dense. The use of 100 mK cryogenics improves the sensitivity significantly. High-density sensitive multichroic arrays are a critical component of proposed future CMB experiments, including the ground-based CMB Stage IV effort.

We will focus on first the design of the detectors which is driven by optimization of the detector performance. Next, we describe the characterization of the detectors using the novel ultra dense readout scheme, and conclude with projections of the detector on-site performance. We will cover the detector parameters tested in the laboratory and prediction of the achieved performance under different loading conditions on the telescope at the high-altitude site. The parameters presented will include the overall detector yield, the critical temperatures, thermal conductivities, saturation power, time constants and efficiencies and their uniformity across the 150-mm wafer.

9914-46, Session 9

Fabrication of 150/230 GHz multichroic polarimeter arrays for Advanced ACTPol

Shannon M. Duff, National Institute of Standards and Technology (United States); On Behalf of the Advanced ACTPol Collaboration, NIST (United States)

Advanced ACTPol (AdvACT) is a third-generation cosmic microwave background (CMB) polarization-sensitive receiver that will be deployed as a multi-stage upgrade to the Atacama Cosmology Telescope (ACT) in Chile. Spanning five frequency bands from 25 GHz to 280 GHz and having just over 5600 transition-edge sensor (TES) bolometers, this receiver will provide increased sensitivity, increased mapping speed, and improved CMB foreground rejection compared to previously fielded ACT instruments. AdvACT, like the currently fielded ACTPol instrument, will employ the proven combination of silicon platelet feedhorns coupled to polarization-sensitive TES detectors. This technology provides repeatable band edges, excellent noise performance, fast time constants, excellent beam properties, and high coupling efficiencies. The AdvACT detectors build upon the ACTPol 90/150 GHz polarimeter architecture, with the same key components in each pixel – the feedhorns couple radiation via the orthomode transducer to orthogonally polarized Nb transmission lines, which connect to in-line stub filters that define two passbands prior to the signals being routed to a hybrid tee, which passes the lowest order mode to a thermally isolated AlMn TES. Each pixel consists of four TESs, allowing for individual measurements of two frequency bands, each in x- and y-polarizations.

With a goal of densely packed detectors on a monolithic substrate, we have migrated our traditional 3 inch diameter wafer array fabrication process to 150 mm diameter wafers. The 150/230 GHz AdvACT array, scheduled for deployment in early 2016, consists of 2012 individual AlMn-based TES bolometers. Many fabrication process improvements were specifically developed to increase array yield and uniformity and were required to meet the design specifications and desired performance improvements. The process has been streamlined by decreasing the total wafer count for a single focal plane from five 3 inch wafers to one 150 mm wafer and decreasing the total number of fabrication steps by 25%. By utilizing repeating rhombus-shaped pixels and wiring tracks, every front-side layer is patterned with non-contact stepped lithography in a close-packed arrangement. A partially automated layout code allows straightforward modification of pixel size, wiring width and pitch, and bond pad placement. An AlMn-alloy TES material has been developed with a uniform Tc (160 mK) across 150 mm, coarsely set by Mn concentration and fine-tuned by a post-deposition anneal. The dielectric loss has been reduced by switching to an optimized SiNx film from SiOx, resulting in a projected 10% increase in overall detection efficiency. A microwave cross-under structure has been designed and implemented that minimizes reflections and crosstalk between adjacent channels and also simplifies the fabrication process by eliminating the need for a third wiring layer. All of these improvements have been tested by fabricating and measuring prototype 150/230 GHz single pixels, which exhibit well-formed single-moded beams, good optical efficiency, and multichroic passband distinction that is well-matched to simulation. In addition to describing the process improvements and details of the 150/230 GHz HF array fabrication, we will present an update on the ACT instrument status that reflects the installation of the HF array.

9914-47, Session 9

Multimode bolometer development for the PIXIE instrument

Peter C. Nagler, NASA Goddard Space Flight Ctr. (United States); Kevin T. Crowley, Princeton Univ. (United States); Archana Devasia, Kevin L. Denis, Dale J. Fixsen, Alan J. Kogut, George Manos, Thomas R. Stevenson, NASA Goddard Space Flight Ctr. (United States)

The Primordial Inflation Explorer (PIXIE) is an Explorer-class mission concept designed to measure the polarization and absolute intensity of the cosmic microwave background [1]. In this work, we report on the design, fabrication, and performance of the multimode polarization-sensitive bolometers for PIXIE, which are based on silicon thermistors. In particular we focus on several recent advances in the detector design, including the implementation of a tensioning scheme to greatly raise the frequencies of the internal vibrational modes of the large-area, low-mass optical absorber structure consisting of a grid of micromachined, ion-implanted silicon wires. With ~30 times the absorbing area of the spider-web bolometers used by Planck, the tensioning scheme enables the PIXIE bolometers to be robust in the vibrational and acoustic environment at launch of the space mission. More generally, it could be used to reduce microphonic sensitivity in other types of low temperature detectors. We also report on the performance of the PIXIE bolometers in a dark cryogenic environment.

9914-48, Session 9

Beam pattern optimization for the primordial inflation explorer (PIXIE)

Dale J. Fixsen, NASA Goddard Space Flight Ctr. (United States) and Univ. of Maryland (United States); Alan J. Kogut, Robert S. Hill, Peter C. Nagler, Lenward T. Seals III, Joseph M. Howard, NASA Goddard Space Flight Ctr. (United States)

Measuring the B-mode polarization of the CMB radiation requires a detailed understanding of the projection of the detector onto the sky. The Primordial Inflation Explorer (PIXIE) uses a polarizing Fourier transform spectrometer to difference two co-pointed beams on the sky. We show a detailed analysis of the full PIXIE instrument including the telescope, FTS, and non-imaging concentrator. Small deviations from conic sections can significantly improve the beam shape in polarization. We discuss the importance of the m=2 mode for polarization and show how it can be improved for the full instrument response.

Both the details of the overall beam shape and the details of the polarization efficiency are important, however the operation of PIXIE allows separation and correction for all non m=2 modes. So the beam optimization concentrates on reducing the m=2 mode, while retaining the overall through-put of the instrument.

9914-99, Session PThu1

Design and measurement of a direct-drillable smooth walled feedhorn at 1.2 THz for the next generation BLASTPol experiment

Christopher E. Groppi, Philip D. Mauskopf, Arizona State Univ. (United States); Peter A. R. Ade, Cardiff Univ. (United Kingdom); Matthew Underhill, Arizona State Univ. (United States)

We present the design and measurement of a direct-drillable smooth walled feedhorn for the Next Generation BLASTPol balloon experiment. The 1.2 THz (250 micron) band Next Generation BLASTPol has over 600 dual polarization kinetic inductance detectors, each requiring a high performance, broad band dual polarization feed. The design presented here, based on a scaled version of a horn developed by Tan et al. (2012), is directly drillable with a custom single flute milling cutter. The horn is a modified Pickett-Potter type horn with three conical steps mated to a circular waveguide. Simulations show a high quality Gaussian beam with a bandwidth of approximately 30%. Custom milling cutters were obtained commercially and used to fabricate a two feedhorn structures with UG-387 flanges, each with a ? wavelength section of circular waveguide. These horns were then mated at the flange to produce a back to back feedhorn coupled by 1 wavelength of circular waveguide. These horns were then tested at Cardiff University using a rotation stage scanner to measure E and H plane cuts of the horn with a Fourier transform spectrometer operating in the band 840 GHz-1050 GHz. The measurements show good agreement in both the beam FWHM and sidelobes as compared to HFSS simulations of the horn. Scaled versions of the same horn will also be used for the 500 micron and 350 micron bands of the Next Generation BLASTPol instrument.

Tan, B-K, Leech, J., Yassin, G., Kittara, P., Tacon, M., Wangsuya, S., Groppi, C., A High Performance 700 GHz Feed Horn, Journal of IR, MM and THz Waves, v. 33, no. 1, pp. 1-5, 2012.

Simulations of far sidelobes produced by panel gaps in the Atacama Cosmology Telescope (ACT) and their effect in CMB power spectrum measurements

Pedro Antonio Fluxa Rojas, Rolando Dünner Planella, Pontificia Univ. Católica de Chile (Chile); Rahul Datta, Jeff J. McMahon, Univ. of Michigan (United States)

The Atacama Cosmology Telescope is a 6 m diameter CMB telescope located at 5200 meters in the Chilean desert, producing maps of the sky's intensity and polarization at 150 and 90 GHz with arcminute resolution. These observations have led to precise measurements of the fine angular power spectrum of the CMB fluctuations in temperature and polarization. One of ACT's goals is to search for the B- mode polarization signal from primordial gravity waves, and thus to extend ACT's data analysis to larger angular scales. This goal presents new challenges in the control of systematic effects, including better understanding of far sidelobe effects that might contaminate the power spectrum at degree angular scales. Here we study the effects of the $\approx$ 2 mm gaps between panels comprising the ACT primary and secondary mirrors in the worst case scenario in which the gaps remain open. We produced numerical simulations of the optics using GRASP that extended up to 15 degrees away from the main beam, revealing the asymmetrical and polarized nature of the far sidelobes, which are also highly attenuated below the main beam. To understand their effects, a simulated CMB map was de-projected onto ACT-like detector time-streams using the simulated beam, together with the true angle and position information obtained from real observations. The time-streams where then re-mapped, averaging down the asymmetries of the beam in a realistic manner. The resulting maps where then analyzed, quantifying the systematic effects produced by the far sidelobes on the temperature and polarization angular power spectra.

9914-108, Session PThu1

Modeling multimode feed-horn coupled bolometers for millimeter-wave and terahertz astronomical instrumentation

Eimante Kalinauskaite, Anthony Murphy, Ian McAuley, Neil A. Trappe, Colm P. Bracken, Darragh N. McCarthy, Stephen Doherty, Marcin L. Gradziel, Creidhe O'Sullivan, National Univ. of Ireland, Maynooth (Ireland); Bruno Maffei, The Univ. of Manchester (United Kingdom); Jean-Michel A. Lamarre, Observatoire de Paris (France); Peter A. R. Ade, Cardiff Univ. (United Kingdom); Giorgio Savini, Univ. College London (United Kingdom)

Multi-mode horn antennas can be utilized as high efficiency feeds for bolometric detectors, providing increased throughput and sensitivity over single mode feeds, while also ensuring good control of beam pattern characteristics. Multimode horns were employed in the highest frequency channels of the European Space Agency Planck Telescope, and have been proposed for future terahertz instrumentation, such as SAFARI for SPICA.

What differentiates a multimode horn from a single mode horn is the larger size of the waveguide feeding it, which allows higher order modes to propagate carrying extra power to the detector. If diffraction limited resolution is not required, as when observing extended faint sources, then the full increase in sensitivity of multimode horns can be utilized, otherwise a cold stop can be used to provide the required resolution.

Clearly, the efficiency with which the individual modes couple to the bolometer in the cavity will influence the overall beam pattern shape, as well as the aperture efficiency of the horn. It is usually assumed that a cavity mounted bolometer is a perfect black body absorber (as was done for the HFI 857 GHz and 545 GHz channels on Planck). However, this is an approximation and in this paper we present how this approach can be extended to actually include the cavity coupled bolometer, now modelled as a thin absorbing film. Generally, this is a big challenge in that the structures are typically electrically large. In this case the radiation pattern of multi-mode horns can be most efficiently simulated using mode matching, typically with smooth walled waveguide modes as the basis and computing an overall scattering matrix for the horn-waveguide-cavity system.

As well as predicting the horn beam pattern more precisely, we are also of course interested in investigating the cavity configuration for optimizing power absorption. Therefore, in the paper, as an example, the effects of offsetting the axis of a cylindrically symmetric absorbing cavity from that of a circular waveguide feeding it are discussed. This allows for the extra possibilities of power scattering between modes of different azimuthal orders, as well as also between the degenerate orthogonal pairs of modes (with the same radial field distributions) of a given azimuthal order. Another issue is the effect on the optical efficiency of the detectors of the presence of any gaps, through which power can escape. To model these effects requires that existing in-house mode matching software 'CylindricalSCATTER', which currently calculates the scattering matrices for axially symmetric waveguide structures, be further developed to be able to handle offset junctions and free space gaps ('OffsetSCATTER'). Results of the application of the 'OffsetSCATTER' software for various detector cavity offsets, feed waveguide lengths, detector sizes, surface resistances and detector positions within the cavity are also presented, along with the resulting multimode beam patterns. We will show how the approach can be applied to proposed terahertz systems, such as SPICA-SAFARI, and how multi-mode horns are also possible as feeds for CMB arrays for B-polarization experiments.

9914-112, Session PThu1

Optical design and modeling of the QUBIC instrument: a next-generation quasi-optical bolometric interferometer for cosmology

Stephen P. Scully, Donnacha Gayer, David Burke, National Univ. of Ireland, Maynooth (Ireland)

The expansion of the universe has redshifted and therefore cooled the remnant radiation from the earliest epoch in the universe so that today it has a blackbody spectrum at a temperature of 2.73 K. It is known as the Cosmic Microwave Background (CMB). Hot Big Bang cosmologies predict that the CMB contains faint temperature and polarisation anisotropies imprinted in the early universe. Temperature measurements are effectively complete with the PLANCK satellite measuring exquisite detail out to multipole l=2500 (Ade, et al., 2013). The next logical step, albeit ambitious, is to map the primordial polarisation signatures which are expected to be several orders of magnitude lower than those of the temperature anisotropies. A suitable decomposition for this type of observation is into E-modes (curl-free) and B-modes (divergence-free). Using this decomposition, scalar sources (producing E-modes) and tensor sources (producing E- and B-modes) can be distinguished. Their relative amplitudes are described by, r, the tensor-to-scalar ratio. E-modes, a couple of orders of magnitude lower than the temperature anisotropies, were first detected by DASI (Leitch, et al., 2002) and by several follow-up missions. Primordial B-modes have to-date avoided detection as their magnitude is lower again. Their magnitude is unknown but PLANCK has placed an upper limit on, $r \leq 0.11$. Inflation theory predicts large scale (>1°) B-mode patterns in the CMB and their detection is a "smoking-gun" for Inflation. Detection of B-modes will require a sensitive telescope with exceptional control over systematics. The ground-based QUBIC (Q and U Bolometric Interferometer for Cosmology) instrument aims to provide this. It is based on the novel concept of bolometric interferometry in conjunction with synthetic imaging. Cryogenically cooled bolometers provide the sensitivity at the image plane. Fizeau interferometry with the aid of a novel auto-calibration technique exploiting the equivalent-baseline structure inherent in the aperture array will give the required control over systematics. Beams from an array of feed horns observing the sky will be combined quasi-optically. The optical-combiner is an off-axis compensated Gregorian operating in a dual band (150 and 220 GHz with 25% bandwidth) mode. Stokes parameters will be extracted directly from the synthetic image and the dual band nature will allow for foreground removal and detection of a tensor-to-scalar ratio, $r \geq 0.05$ with two years of data or $r \geq 0.04$ if PLANCK data are also used.

In this paper we outline the optical modelling of the QUBIC beam combiner. Beams from an array of 400 back-to-back ultra-Gaussian feed horns that observe the sky are combined. Modelling was carried out with a range of techniques, to account for the non-negligible diffraction effects and large component sizes at these frequencies. The techniques included ray-tracing, a Gaussian-beam-mode analysis and physical-optics. The modelling was implemented in the commercial package GRASP (TICRA, 2005) and MODAL (White, 2006; Gradziel, et al., 2008) which is software developed in-house by Maynooth University, Ireland. We describe the expected performance of the combiner and modelling work envisaged for the future.

9914-116, Session PThu1

Optical modeling and polarization calibration for CMB measurements with the ACTPol and advanced ACTPol

Brian Koopman, Cornell Univ. (United States)

The Atacama Cosmology Telescope Polarimeter (ACTPol) is a polarization

sensitive upgrade to the Atacama Cosmology Telescope, located at an elevation of 5190 m on Cerro Toco in Chile. ACTPol utilizes transition edge sensor bolometers coupled to orthomode transducers to measure both the temperature and polarization of the cosmic microwave background (CMB). Calibration of the detector angles is a critical step in producing polarization maps of the CMB. Polarization angle offsets in the detector calibration can cause leakage in polarization from E to B modes and induce a spurious signal in the EB and TB cross correlations.

We calibrate the ACTPol detector angles by raytracing the designed detector angle through the entire optical chain to determine the projection of each detector angle on the sky. These per detector calibrated polarization angles are consistent with a global offset angle of zero when compared to the EB-nulling offset angle, the angle required to null the EB cross correlation power spectrum. Here we present the optical modeling process which uses the commercial optical design software CODEV.

The calibrated design angles can be cross-checked through observations of known polarized sources, whether this be a galactic source or a man-made source. To cross-check the ACTPol detector angles we use a fine wire grid placed in front of the receiver of the telescope, after the primary and secondary mirrors. Making use of the Advanced ACTPol rapidly rotation half wave plate (HWP) hardware we spin the polarizing grid at a constant speed, polarizing and rotating the incoming atmospheric signal. The resulting sinusoidal signal is used along with angular position data from the HWP hardware to determine the detector angles.

The optical modeling calibration technique was shown to be consistent with a global offset angle of zero when compared to EB nulling in the first ACTPol results and will continue to be a part of our calibration implementation. The first array of detectors for Advanced ACTPol, the next generation upgrade to ACTPol, will be deployed in 2016. We plan to continue using both techniques and comparing them to astrophysical source measurements for the Advanced ACTPol polarization calibration.

9914-120, Session PThu1

Design and development of a room-temperature continuously rotating achromatic half wave plate for CMB polarization modulation on POLARBEAR-2

Charles Hill, Shawn Beckman, Neil Goeckner-Wald, Univ. of California, Berkeley (United States); Masashi Hazumi, High Energy Accelerator Research Organization, KEK (Japan); Brian G. Keating, Univ. of California, San Diego (United States); Akito Kusaka, Lawrence Berkeley National Lab. (United States); Adrian T. Lee, Univ. of California, Berkeley (United States); Frederick Matsuda, Univ. of California, San Diego (United States); Richard L. Plambeck, Aritoki Suzuki, Univ. of California, Berkeley (United States); Satoru Takakura, High Energy Accelerator Research Organization, KEK (Japan)

The POLARBEAR-2 (PB2) experiment will study polarization fluctuations in the Cosmic Microwave Background (CMB) from the Atacama Desert in Chile starting in early 2017. In order to suppress 1/f noise due to unpolarized atmospheric turbulence and allow for study of degree-angular-scale CMB fluctuations, where the inflationary gravitational wave signal is thought to exist, polarization modulation is needed. The PB2 system projects a 365mm-diameter focal plane of 7588 dichroic, 95/150GHz transition edge sensor (TES) bolometers onto a 3-arcminute beam that scans at 1 degree per second. This system necessitates a large-aperture, low-thermal-emission, broadband modulator that can provide 100 seconds of detector stability. We present the development of a room-temperature continuously rotating achromatic half wave plate (HWP) as a polarization modulator for PB2. We first acknowledge promising experiences from third season PB1 HWP noise analysis. We then present the design requirements for the PB2 HWP, the results of our integration and evaluation of the HWP birefringent sapphire substrate, anti-reflection coating, and rotation mechanism, and the prospective impact of the HWP on PB2 noise performance, beam systematic mitigation, and galactic foreground subtraction. We conclude with a discussion of planned improvements for HWP instrumentation on future Simons Array receivers.

9914-123, Session PThu1

Optical design and verification of a 4mm receiver for the 20m telescope at Onsala Space Observatory

George Walker, Eimante Kalinauskaite, Darragh N. McCarthy, Neil A. Trappe, Anthony Murphy, National Univ. of Ireland, Maynooth (Ireland); Leif Helldner, Miroslav G. Pantaleev, Jonas Flygare, Onsala Space Observatory (Sweden)

The work of this research is the design, analysis and verification of the optical performance of a 4 mm receiver channel for the 20 m telescope at Onsala Space Observatory, Onsala, Sweden. This work was carried out at Maynooth University in collaboration with Onsala Observatory Onsala Space Observatory is the Swedish National Facility for Radio Astronomy. The 20 m and 25 m telescopes are used for studies of the formation of stars, and of molecules in the Milky Way and other galaxies.

The 4 mm (75 GHz) receiver is a newly proposed channel designed to be installed parallel to the existing 3 mm (100 GHz) channel targeting new science at that longer wavelength. The 4 mm receiver is designed to operate over the bandwidth between 67 GHz and 86 GHz. In order to have constant aperture efficiency over the band of interest, the optical layout is designed to be wavelength independent over this band. This is achieved by developing a two mirror system to image the horn antenna aperture to the secondary mirror of the telescope ensuring a constant beam size is achieved. As the receiver is contained within a cryostat unit, there are severe mechanical restrictions, which also have to be accounted for in the proposed optical design.

In the initial design, Gaussian beam mode analysis is used to produce the fundamental optical design of the system, as it is a computationally efficient method which provides all critical beam characterization through the optical train. Ray transfer matrix analysis is used to model beam transformation due to optical components. This method, also commonly known as ABCD matrix analysis, is adapted from geometrical analysis and makes use of the paraxial approximation. It is used to determine important parameters associated with the beam at certain planes in the system such as first order beam truncation and beam clipping.

The design is then analysed more accurately with the physical optics approximation. This allows a full aberration analysis to be included for the off-axis ellipsoidal mirror designs, as well as a full optical efficiency calculation when the propagated beam at the secondary mirror is coupled with an ideal beam from the sky. This technique allows full characterization of the system and the best design mechanically fitting into the cryostat was realized. Experimental verification of the realized optical design was carried out at Onsala Space Observatory allowing full verification of the simulations to be carried out. Near field measurements were used in the verification which can be compared with simulations directly due to the accurate mechanical testing and placement of scanning antennae. We report on the comparison of simulation and measurement and verification of the system design.

9914-126, Session PThu1

Submillimeter and far-infrared dielectric properties of thin films

Giuseppe Cataldo, Edward J. Wollack, NASA Goddard Space Flight Ctr. (United States)

High-performance circuits and optical coatings play an important role in submillimeter and far-infrared astronomical instrumentation. In practice, vapor-deposited thin film dielectrics find widespread use because of their nearly ideal insulation, electromagnetic propagation and compatibility in fabrication. The complex dielectric function enables the study of the refractive and absorption properties of these materials as a function of frequency and not only provides important insights into the consistency of the derived optical properties but can be used to inform the suitability of candidate materials for service in their intended application.

An analysis approach will be presented and used to derive the complex dielectric function from observed transmittance spectra to within an accuracy of 4%. The underlying model will be shown to satisfy the requirements, causality and passivity, as set by the Kramers-Kronig relations. Dielectric functions found in the literature based on different profile line shapes, such as the Lorentzian, the Gaussian, the Voigt and the Classical Damped Harmonic Oscillator, will be briefly surveyed. While only the latter meets all of the above-mentioned criteria, the first three do not; however, their use is widespread due to their relative simplicity of implementation and generally acceptable accuracy in the infrared, but can lead to spurious long-wavelength spectral artifacts. A model based on the classical harmonic oscillator with a frequency-dependent damping will also be considered. This simple model meets all the requirements and suitably describes amorphous dielectric materials. The application of this dielectric function to the measured transmission spectra between 1 ?m and 300 ?m for low-stress silicon nitride and silicon oxide films will be presented.

9914-129, Session PThu1

An ultra-broadband optical system for ALMA band 2+3

Valeria Tapia, Univ. de Chile (Chile); Renzo Nesti, INAF - Osservatorio Astrofisico di Arcetri (Italy); Álvaro González, National Astronomical Observatory of Japan (Japan); Ignacio Barrueto, F. Patricio Mena, Nicolás Reyes, Univ. de Chile (Chile); Fabrizio Villa, Francesco Cuttaia, INAF - IASF Bologna (Italy); Pavel Yagoubov, European Southern Observatory (Germany)

The Atacama Large Millimeter Array (ALMA) is the largest millimeter and submillimeter radio telescope in the world. It combines an array of 66 classical Cassegrain antennas providing high sensitivity between 35 and 950 GHz. This frequency range is divided in 10 bands with fractional bandwidths between 19 and 36%. Having a lifespan of at least 50 years, ALMA is carrying out a permanent upgrading program for every one of its subsystems. Regarding its receivers the program focuses on achieving better sensitivity and larger bandwidths at the RF and IF level.

Due to the lack of good amplifiers above 80 GHz astronomical receivers, including those of ALMA, use superconductor-insulator-superconductor (SIS) mixers as the first element in the receiving chain. However, nowadays, low-noise amplifiers based on high-electron-mobility transistors (HEMTs), combined with Schottky diodes, have the potential to achieve similar noise levels of traditional SIS mixers at the W Band. Moreover, HEMT amplifiers are inherently easier to use, have a wider bandwidth and are more stable than SIS mixers, promising, thus, a new generation of broadband receivers. For these reasons an international consortium has been formed to demonstrate this technology in a prototype receiver covering current Bands 2 and 3 of ALMA (67 to 116 GHz) corresponding to a fractional bandwidth of 54%. Such receiver may allow to perform new astronomical measurements not achievable by receivers covering the two bands independently. Moreover, it could vacate space inside the cryostat for new instrumentation.

Here we present the design, implementation and characterization of an optical system covering the full range of ALMA Band 2+3. Since the optics is the first subsystem of any receiver, low noise figure and maximum aperture efficiency are fundamental for best sensitivity. However, a conjunction of several factors as the large bandwidth, truncation set by existing cryostat apertures, dielectrical couplings, losses in the materials, construction constraints and cost limitations, makes extremely challenging achieving these goals. To overcome these problems, several options have been studied including reflective and refractive optics. So far, the most promising, complying with all constraints, is the latter. It consists of a corrugated horn, a modified Fresnel lens and an ortho-mode transducer (OMT).

Two corrugated horns, implemented using different methods of construction, were studied. One is a horn whose profile was optimized for best performance and ease of fabrication using a single-piece manufacturing process in a lathe. The other is a more classical corrugated horn implemented using a series of concentric rings. To minimize the noise contribution of the optical system a one-step zoned lens was selected. The parameters of the lens were carefully optimized to maximize the frequency coverage and reduce losses. Simulations indicate that the systems implemented with these elements have aperture efficiencies better than 81% and the lens, the mayor contributor to the noise, adds less than 5K to the receiver noise temperature. As OMT we have studied two designs based on a turnstile junction.

Two versions of the system were constructed and characterized. The results indicate an excellent performance in good agreement with simulations.

9914-133, Session PThu1

FreeCAD visualization of realistic 3D physical optics beams within a CAD system model

Donnacha Gayer, Créidhe O'Sullivan, Stephen P. Scully, National Univ. of Ireland, Maynooth (Ireland); Claude Chapron, AstroParticule et Cosmologie (France); David Burke, National Univ. of Ireland, Maynooth (Ireland)

The facility to realise the shape and extent of optical beams within a telescope or beamcombiner can aid greatly in the design and layout of optical elements within the system. Beyond the realm where raytracing is applicable however, it becomes much more difficult to realise accurate 3D beam representations which incorporate diffraction effects. It then is another issue to incorporate this into a CAD model of the system.

A novel method is proposed which has been used to aid with the design of an optical beam combiner for the QUBIC experiment operating at 150GHz and 220GHz. The method combines calculation work in GRASP, a commercial physical optics modelling tool from TICRA, geometrical work in Mathematica, and post processing in MATLAB. Finally, the python console of the open source package FreeCAD is exploited to realise the 3D beams in a complete CAD system-model of the QUBIC optical beam combiner.

GRASP is used to measure the beam at sample grids which are perpendicular to the axis of propagation, these grids are spaced regularly along the beam path with positions chosen by trading off between calculation time and the detail necessary.

The individual grids are then analysed in MATLAB and the extent of the beam to be realised can be chosen. The footprint of the beam on each grid can be determined as that enclosed by a contour of a particular level where each grid is normalised to the peak power level on the grid. Alternatively the footprint on each grid can be determined as a circle which encloses a certain specific fraction of the initial beam power. The

percentage power method has the disadvantage that it returns circular beams however the contour method breaks down in quite distorted beams as 3D Beams cannot be constructed by this method from grids that return more than one independent contour of the chosen level.

The 2D locations of the chosen footprint on grids are then realised into a 3D beam by "stitching" the footprints appropriately from successive grids into a 3D mesh object through creating trigonal facets from the points. This mesh is then transformed to the reference frame used in the CAD system-model. Finally the python console in FreeCAD allows these 3D beams to be visualised within the CAD system-model.

In the analysis of the QUBIC beam combiner presented here, 3D beams of chosen footprints are shown in situ in the CAD system-model for various different horns of the 400 horn design, the -3dB and -13dB contour envelope is shown as well as envelopes enclosing 80% and 95% of the power of the beam. In an ideal Gaussian, the -3dB and -13dB contours enclose 50% and 95% of the Gaussian beam power. It is shown how the ability to see these beams in situ with all the other elements of the combiner such as mirrors, cold stop, beam splitter and cryostat widows etc. greatly simplified the design for these elements and facilitated communication of element dimension and location between different subgroups within the QUBIC group.

9914-137, Session PThu1

Silicon metamaterial optical elements for measurement of the cosmic micro-wave background

Kevin Coughlin, Charles D. Munson, Rahul Datta, Jeff J. McMahon, Univ. of Michigan (United States)

Precision measurements of the polarization of the Cosmic Microwave Background (CMB) are a promising avenue for advancing our knowledge of the cosmos, putting constraints on the scalar to tensor ratio as well as the sum of the neutrino mass. In order to put meaningful constraints on these cosmological parameters, a wide range of frequencies are needed for foreground removal. Next generation instruments require broadband antireflection (AR) coated lenses to accommodate multichroic detectors and half-wave plates (HWPs) to suppress 1/f noise and telescope systematics. We describe progress on metamaerial AR coatings and a novel approach to broadband HWPs.

The AR coatings are realized by cutting subwavelength features into the silicon using a custom dicing saw. We have already created several such AR coated silicon lenses, which are currently deployed on the Atacama Cosmology Telescope (ACT) mid-frequency (90-150 GHz) band, and planned for their high frequency (150-220 GHz) and low-frequency (20-40 GHz) bands. The band average reflection for these three layer structures is less than 0.3%, and can be fabricated with high yield. Our designs can be extended to higher frequency in the THz range by cutting thinner features. We can also extend to very broadband coatings by increasing the number of layers. We have fabricated a prototype coating which is expected to reduce reflection below 1.5% over a 5:1 bandwidth.

Metmaterial HWPs are realized by cutting anisotropic features into single crystal silicon to create low loss birefringent metamaterial layers. Using this technique, we created a novel broadband polarization modulator by forming a three layer Pancharatnam structure realized by three cutting half-wave plates into two silicon wafer and gluing them together. A novel birefringent silicon AR coating optimized to minimize differential reflection was created on the two outer surfaces. We describe a design optimized for 2.2:1 bandwidth, covering both the 90 and 150 GHz CMB bands.

BICEP3 is a small-aperture refracting cosmic microwave background (CMB) telescope designed to make sensitive polarization maps in pursuit of a potential B-mode signal from inflationary gravitational waves. It is the latest in the BICEP/Keck Array series of CMB experiments located at the South Pole, which has provided the most stringent constraints on inflation to date. For the 2016 observing season, BICEP3 was outfitted with a full suite of 2500 detectors operating at 95 GHz. In these proceedings we report on the far-field beam performance using calibration data taken during the 2015-2016 summer deployment season in situ with a thermal chopped source. We characterize the differential beam response between co-located, orthogonally polarized detectors, which contributes to the leading systematic in pair differencing experiments. The magnitude and distribution of BICEP3's differential beam mismatch -- and the level to which temperature-to-polarization leakage may be marginalized over or subtracted in analysis -- will inform the design of next-generation CMB experiments with many thousands of detectors.

9914-105, Session PThu2

Data-driven electothermal and noise modeling of TES detectors in multichroic arrays for Advanced ACTPol

Kevin T. Crowley, Steve K. Choi, Princeton Univ. (United States); Advanced ACTPol Collaboration, Advanced ACTPol Collaboration (United States)

The future of the Atacama Cosmology Telescope (ACT) is the Advanced ACTPol (AdvACT) upgrade, featuring three types of dual-frequency, polarization-sensitive focal-plane arrays for a total of five observing frequency bands. The detectors at the heart of these arrays will be manganese-doped aluminum transition edge sensors (TESes). Currently, the first fielded dual-frequency array is observing as part of the ACTPol mission, with bilayer MoCu TES detectors in the focal plane. Understanding the detector response in situ, under instrumental loading conditions in the ACTPol cryostat, is crucial both to ACTPol and the AdvACT arrays which will use the same cryogenics.

Here we report on a campaign of dedicated data acquisition to create a detailed electrothermal picture of the MoCu superconducting bilayers. The data sets used include high sample-rate complex impedance and detector noise data. The last two complement each other and allow exploration of the fine details of detector response throughout the superconducting transition. Specifically, electrothermal model parameters estimated from complex impedance data at various TES resistances can be used to map detector parameters on the transition and to predict the expected noise spectra.

This method is equally applicable in the laboratory and the field, and thus the report includes early laboratory results on the electrothermal modeling of the AlMn TESes being fabricated for inclusion in AdvACT's high-frequency array. We plan a program of evaluating the noise characteristics of these AlMn TESes across the transition at bath temperatures chosen to mimic the anticipated field conditions. The measurements can be compared to the expected noise level calculated from the thermal properties of the detectors as measured with other datasets. Combined with a measurement of the detector optical efficiency using a cold blackbody load and the simulated model of the detector bandpass, these data can be extrapolated to predict the array sensitivity under observing conditions at the telescope.

Taken together, the field and laboratory high-frequency noise data in concert with more direct probes allow us to determine the detailed response of both types of detectors. In the case of AlMn TESes, this information may lead to ways to improve their design for future arrays. Finally, we intend to compare the electrothermal response of the doped superconductor (AlMn) and bilayer (MoCu) TESes.

9914-110, Session PThu2

The QUIJOTE TGI control system

María Francisca Gómez-Reñasco, Yolanda Martín-Hernando, Marta Aguiar-González, Juan Cózar-Castellano, Noemí González-Cobos, Roger J. Hoyland, Miguel Núñez-Cagical, Maria Rosario Ángeles Pérez-de-Taoro, Vicente Sánchez-de la Rosa, Afrodisio Vega-Moreno, Teodora Aleida Viera-Curbelo, Instituto de Astrofísica de Canarias (Spain)

The QUIJOTE TGI (Therty GHz) instrument is currently being installed and commissioned at the Izaña Observatory in Tenerife. The TGI is a 30 pixel 26-36 GHz polarimeter array designed to be mounted at the focus of the second QUIJOTE telescope which has already been commissioned during the first months of 2015. This follows a first telescope and multi-frequency instrument (MFI) that have now been observing for more than 3 years. The polarimeter design is based on the QUIET polarimeter scheme implementing phase switches of 90º and 180º to generate 4 states of polarisation. The TGI control system acquires the scientific signal of the 4 channels for each of the 30 polarimeters, sampled at 160KHz; it controls the commutation of the 30 phase switches; it performs the acquisition and monitoring of the health of the complete instrument acquiring housekeeping from the different subsystems and also controls the different operational modes of the telescope. It finally, implements a queue system which allows to automatize the observations allowing the programming of several days of observations with a minimum human intervention. The telescope is a replica of the first telescope that hosts the MFI, but it has been improved by the inclusion of some safety boards as well as important mechanical issues. The operational modes are the movement around the azimuth axis at a constant velocity while the elevation axis is held at a fixed elevation; tracking of a sky object; and raster of a rectangular area both in horizontal and sky coordinates. The acquisition system is based on a PXI-RT host from NI which performs the acquisition, processing and transfer of the scientific data. A PXI-FPGA subsystem, also from NI, performs the commutations of the phase switches and a PC receives and stores data from the different subsystems, monitor the health of the instrument and implements the user interface. The 120 channels are sampled at 160KHz at the RT host and a real time processing is performed which allows to decrease the final transfer and storing rate to 4K Samples/sec. The FPGA subsystem generates the signal to commutate each of the 30 phase switches at 16KHz or 8KHz commutation producing 16 different states which are also averaged to obtain scientific measurements at 0º, 90º, 180º and 270º. Both the signal sampling and the commutation are synchronized with an external GPS system through NTP. The same clock is used to synchronize the telescope, providing the mechanism to reference the scientific signal with the sky to provide polarization maps. Two separate PCs provides the user interface, the first one receives and stores the scientific signal as well as the telescope positions; it also acquire and monitor the housekeeping of all subsystems. A second PC allows to

automatize observations by commanding both the acquisition system and the telescope. The control system software have been implemented mainly in LabVIEW with the support of some C dlls and Python has been used for the implementation of the observations queues.

9914-114, Session PThu2

Measurement concept of the PILOT instrument, pre-flight optical characterization, and optimization performed during end-to-end ground tests

Ruka Misawa, Institut de Recherche en Astrophysique et Planétologie (France)

Future cosmology space missions will concentrate on measuring the polarization of the Cosmic Microwave Background (CMB), which potentially will bring invaluable information about the early universe. In particular, detection of the B-mode polarization may reveal the inflationary periods in the very early universe. Such measurements will require very high sensitivity and very low instrumental systematic effects. As for measurements of the CMB intensity, sensitive measurements of the CMB polarization will be made difficult by the presence of foreground emission from our own Milky Way. Such foreground emission will have to be understood very accurately and removed from cosmological measurements. This polarized emission is also interesting in itself, since it brings information relevant to the process of star formation and about the orientation of the magnetic field in our Galaxy through the alignment of dust grains. For measuring the foreground, we have developed the PILOT balloon borne experiment, which measures the linear polarization of diffuse interstellar medium in far-infrared in our Galaxy and nearby galaxies.

PILOT has a large field of view about 0.8°?1° and maps the galactic plane and deep fields during a 24 hrs flight at 40 km altitude. The instrument is composed of a 1 m diameter telescope and a Helium 4 dewar accommodating the rest of the optics and 2 focal plane arrays with a total of 2048 individual bolometers cooled down to 300 mK, developed for the PACS instruments on board Hershel satellite. It operated in one photometric band centered at 240 ?m (1.2 THz) in the first flight with an angular resolution of 2 arcminutes. Polarization is measured using a step and stare half-wave plate. The system is designed in order to reduce instrumental systematic effects. End-to-end calibration tests were performed between 2012 and 2014 in order to prepare the first scientific flight in September 2015 from Timmins, Canada.

Firstly, I will summarize briefly our current knowledge in this field, on the basis of extinction and emission measurements from the ground and airborne experiments and in the context of the recent measurements with the Planck satellite which PILOT will be able to complement for short wavelength. Then, I will describe the concept and science goals of the PILOT. After, I will focus on the ground calibration results to characterize the optical performance of PILOT including image quality control over the extended focal plane, defocus tests, focal plane geometry, and identification of internal straylight.

(United States) and Kavli Institute for Particle Astrophysics & Cosmology (United States)

The BICEP2 and Keck Array telescopes measure(d) CMB polarization with orthogonal Transition Edge Sensor-coupled antennas. An uncertainty in the polarization axis of the detectors leads to a mixing of E-to-B mode power. Because temperature fluctuations and E-mode polarization are correlated, this uncertainty also leads to a false correlation between temperature and B-modes. If the goal is only to measure B-mode power, one option is to rotate the polarization angles of the focal plane in order to minimize EB and TB correlation. However, this minimization prevents us from measuring or putting upper limits on any possible cosmic birefringence. We aim to measure the polarization angles of our detectors to better than 0.1 degrees.

With a rotating polarized source in the far-field and a Dielectric Sheet Calibrator (DSC) in the near-field, we measure the polarization angles of our detectors. In these proceedings we focus on the DSC, which is a thin beam-filling plastic film that acts as a beam splitter. Most of the beam is transmitted to the cold sky while a portion is reflected to a warm forebaffle. When rotating the DSC, the detectors see polarized signals, modulated at 360 degrees, that depend on the polarization axes of the detectors and the incident angles of the beams on the dielectric film. We present the design of the DSC for use with the Keck Array telescope. We also show how uncertainties in the measurement process propagate to uncertainties of the polarization angle calibration.

9914-121, Session PThu2

Assembly and integration process of the first high density detector array for Atacama Cosmology Telescope

Yaqiong Li, Princeton Univ. (United States)

The Advanced Atacama Cosmology Telescope Polarimeter (Adv ACTPol) is an upgrade of the Atacama Cosmology Telescope (ACT) using Transition Edge Sensor (TES) detector arrays to measure CMB polarization anisotropies in multiple frequencies. The whole detector array consists of several major parts, including the feed horn and detector wafer stack, mux chips which serve as time division multiplexer and shunt chips for mux's bias tuning, series array board which contains SQUID module for signal amplification, printed circuit board (PCB) which connects chips to series array board through cables and wire bonding, and the flexible circuitry (flex) which connects detector wafer stack to PCB.

AdvACTPol will implement a new type of multiplexer chips (mux-13c) to achieve higher Multi-Channel Electronics (MCE) utilization efficiency and twice the number of total transition-edge sensors (TES) as compared to ACTPol. However, the consequent change of the readout PCB's design and the smaller size of the new mux chips, create significant challenges for finding practical detector array assembly processes. One major challenge concerns the success rate of wire bonding and the strength of wires, since the total number of wires is on the scale of 20,000 and each single wire is associated with 32 or 64 TESes. Mounting silicon wiring chips, on which mux chips and shunt chips are held by Stycast epoxy, to the PCB with rubber cement simultaneously solves the issue caused by differential thermal contraction of the chips and the PCB in a cryogenic environment and the wire-bonding problem. Additionally, jigs to secure the PCB while bonding, as well as new gluing methods of chips and the flex are also invented to improve the wire bonds' performance. Another challenge is the need for accurate alignment between the detector wafers, the PCB, and other affiliated parts including wiring chips and flexes. A displacement of several tenths millimeter would cause severe misalignment since the PCB and flex bond pad widths are on the scale of 100 micron. Vacuum wafer jig, wafer transfer jig, copper ring which holds the entire PCB, and flex gluing jig are all designed as a consequence of the higher requirement of alignment accuracy. These jigs vacuum-hold their corresponding parts in order to align all array components with each other through L-brackets and dowel pins. The aforementioned assembly process and methods would be advantageous for even denser detector assembly in the future.

9914-124, Session PThu2

Multi-band millimeter-wave polarimeters for advanced ACTPol

Jason Austermann, On Behalf Of Advanced ACTPol Collaboration, National Institute of Standards and Technology (United States)

We describe the designs and performance of prototype feedhorn-coupled, multi-chroic polarimeters of the third-generation camera for the Atacama Cosmology Telescope (ACT), referred to as Advanced ACTPol. Recently, the Planck and BICEP/KECK experiments have established that measurements of the Cosmic Microwave Background (CMB) polarization signal is limited, in part, by polarized foreground emission. In particular, polarized emission from galactic dust has been found to dominate and obscure potential signals of cosmic inflation, even in regions of the sky specifically identified as having relatively low galactic emission. Advanced ACTPol aims to address the foreground contamination by conducting observations of half the sky with broad spectral coverage spanning 25--280 GHz. Utilizing five discrete bands within this frequency range, the spectral coverage will allow differentiation within the measured signal between foreground sources of polarization and that of the CMB, which have different spectral characteristics. To cover such a large spectral range, the NIST-fabricated multi-chroic polarimeter arrays of Advanced ACTPol will comprise three different designs, each sensitive to a different pair of frequencies bands: a low-frequency (LF) polarimeter with bands centered at 28 and 41 GHz; a mid-frequency (MF) polarimeter at 90 and 150 GHz; and a high-frequency (HF) design operating at 150 and 230 GHz. Here we present the detailed mm-wave pixel design. Incoming radiation is coupled through a beam-forming feedhorn and waveguide to an orthomode transducer (OMT) that separates the radiation to two orthogonally polarized signal paths. A diplexer consisting of in-line microstrip filters further separates each polarization state into two frequency bands. A microstrip hybrid tee is used to reject undesired modes before the radiation is deposited on an AlMn transition edge sensor (TES) detector. In total, each pixel comprises four TES devices that together provide simultaneous sensitivity to two orthogonal polarization states in two frequency bands. We also present up-to-date characterization of the latest prototypes and/or final architecture (HF pixel development is complete). Measured performance qualities to be discussed include optical efficiency, polarization response, passband response, differential beam properties, and TES electrothermal properties. The three focal planes of Advanced ACTPol will each consist of monolithic NIST-fabricated polarimeter arrays fabricated on 150 mm silicon wafers and coupled to the ACT optics via silicon-platelet feedhorn arrays. Advanced ACTPol will be deployed as staged upgrades to the existing ACTPol camera, beginning with the new HF array to be installed in the second quarter of 2016.

9914-127, Session PThu2

Mechanical designs and development of TES bolometer detector arrays for the Advanced ACTPol experiment

Jonathan T. Ward, Univ of Pennsylvania on behalf of the Advanced ACTPol Collaboration (United States)

The Atacama Cosmology Telescope (ACT) is a six-meter diameter telescope located at 17,000 feet (5,200 meters) on Cerro Toco in the Andes Mountains of northern Chile. The next generation Advanced ACTPol (AdvACT) experiment is currently underway and will consist of four multichroic TES bolometer arrays operating together, totaling ~5800 detectors on the sky. Each array will be sensitive to two frequency bands: a high frequency (HF) array at 150 and 230 GHz, two middle frequency (MF) arrays at 90 and 150 GHz, and a low frequency (LF) array at 28 and 41 GHz. The AdACT detector arrays will feature a revamped design when compared to ACTPol, including a transition to 150mm wafers equipped with multichroic pixels, allowing for a more densely packed focal plane. Each set of detectors consists of a feedhorn array of stacked silicon wafers which form a corrugated profile leading to each pixel. This is then followed by a four-piece detector stack assembly of silicon wafers which includes a waveguide interface plate, detector wafer, backshort cavity plate, and backshort cap. Each array is housed in a custom designed structure manufactured out of gold-plated, high purity copper. In addition to the detector array assembly, the array package also encloses the majority of our readout electronics. We present the full mechanical design of the AdvACT HF and MF detector array packages along with a detailed look at the detector array assemblies. This experiment will also make use of extensive hardware and software previously developed for ACT, which will be modified to incorporate the new AdvACT instruments. Therefore, we discuss the integration of all AdvACT arrays with pre-existing ACTPol infrastructure.

9914-132, Session PThu2

Systematic error mitigation for the PIXIE instrument

Alan J. Kogut, Dale J. Fixsen, Peter C. Nagler, NASA Goddard Space Flight Ctr. (United States); Gregory S. Tucker, Brown Univ. (United States)

The Primordial Inflation Explorer (PIXIE) uses a nulling Fourier Transform Spectrometer to measure the absolute intensity and linear polarization of the cosmic microwave background and diffuse astrophysical foregrounds. PIXIE will search for the signature of primordial inflation and will characterize distortions from a blackbody spectrum, both to precision of a few parts per billion. Rigorous control of potential instrumental effects is required to take advantage of the raw sensitivity. PIXIE employs a highly symmetric design using multiple differential nulling to reduce the instrumental signature to negligible levels. We discuss the systematic error budget and mitigation strategies for the proposed PIXIE mission.

9914-135, Session PThu2

Calibration techniques for the primordial inflation explorer (PIXIE)

Dale J. Fixsen, NASA Goddard Space Flight Ctr. (United States) and Univ. of Maryland (United States); David T. Chuss, Alan J. Kogut, Paul Mirel, Edward J. Wollack, NASA Goddard Space Flight Ctr. (United States)

The Primordial Inflation Explorer (PIXIE) compares the sky to an external blackbody calibrator to search for distortions in the blackbody spectrum of the cosmic microwave background at the 10 parts-per-billion level.

Achieving this goal requires accurate transfer of an absolute calibration standard from the time-ordered data to the final sky maps and spectra. The PIXIE calibration is based on a full-aperture blackbody calibrator.

The calibrator is similar to a compact blackbody flown on the ARCADE-2 balloon instrument but with improved optical and thermal performance. We discuss the PIXIE blackbody calibrator and the methods used to transfer the calibration from the raw time-ordered data to the final sky maps and spectra.

A significant improvement comes from allowing the either the calibrator or the sky on either input of the instrument. This allows a factor of 2 reduction of uncertainty in comparing the sky to the calibrator. It also eliminates systematic differences between the sky data and the calibration data as the measurements and the calibration use the same data.

9914-98, Session PThu3

The initial characterization of a revised 10-Gsps analog-to-digital converter board for radio telescopes

Homin Jiang, Institute of Astronomy and Astrophysics - Academia Sinica (Taiwan)

In this study, the design of a 4 bit, 10-gigasamples-per-second analog-to-digital converter (ADC) printed circuit board assembly (PCBA) was revised, manufactured, and tested. It is used for digitizing radio telescopes. Two model of Adsantec flash ADC chips were used, ANST7120-KMA as in the original design and a just released ANST7120A-KMA. Associated with the field-programmable gate array platform developed by the Collaboration for Astronomy Signal Processing and Electronics Research (CASPER) community, the developed PCBA provides data acquisition systems with a wider bandwidth and simplifies the intermediate frequency(IF) section. The current version of the PCBA exhibits an analog bandwidth of up to 10 GHz (3 dB loss), and the chip of ANST7120-KMA exhibits an analog bandwidth of up to 18 GHz. The just released chip ANST7120A-KMA exhibits an analog bandwidth of up to 20 GHz . This facilitates second, third Nyquist and fourth Nyquist sampling. The following worst-case performance parameters were obtained from the revised PCBA with the chip of ANST7120-KMA at over 5 GHz: spurious-free dynamic range of 12 dB, signal-to-noise and distortion ratio of 2 dB, and effective number of bits of 0.7. The design bugs in the ADC chip of ANST7120-KMA caused the poor performance. The worst-case performance parameters from the revised PCBA with the chip of ANST7120A-KMA at over 5 GHz: spurious-free dynamic range of 27 dB, signal-to-noise and distortion ratio of 23 dB, and effective number of bits of 3.3. The chip of batch ANST7120A-KMA is the new version inherited from the ANST7120-KMA with bugs removed, thus it outperforms the original batch, and all the performance is reasonable to the standard of a four bits ADC.

By acquiring hardware from the CASPER community scientific institutes can save resources. Various ADC boards, with sampling rates ranging from a couple hundred MHz to 3 gigasamples per second (Gsps), are available through CASPER. The fastest sampling rate was 3 Gsps before the authors fabricated a 5 Gsps ADC board in 2012. After the success of the 5-Gsps ADC PCBA, a 10-Gsps ADC chip manufactured by Adsantec (ANST7120A-KMA) was selected as the key component in this study.

The architecture of the revised PCBA is highly similar to the original design, except for the input signal layout and a few minor modifications. The board comprises four key components: one 10-Gsps ADC chip, two demultiplexing chips (ANST2032-MBL), and one clock buffer. The ASNT5020-PQD high-speed analog clock buffer (Adsantec) was replaced with the NB6L11M buffer (ON Semiconductor). The performance of the new clock buffer met the study requirements at a lower cost.

With the wide bandwidth up to fourth Nyquist zone of the PCBA and the chips, the IF and Local Oscillation (LO) section can be further simplified.

That allows only the low pass and bandpass filters needed for the IF/LO system. The usual down-converting scheme in radio telescope to manipulate the radio frequency (RF) to the baseband frequency will not be necessary.

9914-104, Session PThu3

Detecting anomalies in astronomical signals using machine learning algorithms embedded in a FPGA

Alejandro Saez, Daniel E. Herrera, ALMA (Chile)

Taking a large interferometer for radio astronomy, such as the ALMA telescope, where the amount of stations (64 in the case of the ALMA main array) produces a huge amount of data in a short amount of time (visibilities every 16msec or total power information every 1msec), it is becoming more difficult to detect problems in the signal produced by each antenna in a timely manner (one antenna producing 4 x 2GHz spectral windows x 2 polarizations, meaning a 16 GHz bandwidth signal, which is digitized using 3-bits samplers).

Under this context there is a wide range of possible issues which may cause corruption, or no sense data. Among these problems we can list:

- Big DC component introduced during the digitization step
- Reflections in the IF signal
- Unexpected spectral features (discontinuities or spikes)
- Harmonics
- Loss of coherence

The aforementioned signal inconveniences are not always detected promptly and the troubleshooting process can be a cumbersome task for scientists, especially during critical observation campaigns under a tight schedule or array constraints. Detecting those kinds of problems can take a considerable amount of time and the inability to detect them sooner can cause data losses during the subsequent observations.

This work presents an approach for detecting the previously listed types of problems in a real time manner. The already available logic resources (FPGA) will be the foundation for this new feature. Therefore no new hardware will be deployed for implementing this feature and, in addition, the software infrastructure will be marginally changed (the idea is to only add 16 monitor points and provide an alarm system to be used by the telescope operators).

Our proposal includes the use of machine learning algorithms for classifying and detecting signals which are presenting problems like the ones listed previously. The proposed algorithm will access a set of collected results from the correlator output and according to the method to be defined, a trained response will be able to recognize if the output at a certain instant is accepted, or whether it belongs to the list of acknowledged signal errors. As this work continues to grow, this tool will be able to detect more problems related to any antenna or correlator subsystem.

This work will present an approach which can be implemented using the information provided by the correlation function. Methodologies for extracting signal statistical features will be analyzed. Methodologies for validating the detection of signal problems will be analyzed. Performance of the classification engine will be tested.

The aim of this work is to produce a non invasive sub-system which can provide real time alerts if a signal were to show problems. In addition, one of the objectives is to reduce the usage of logical resources as much as possible.

The preventive alert system proposed in this work will allow astronomers to promptly flag a certain antenna and, according to the results given by this tool, follow up the problem immediately with instrumentation experts avoiding the offline analysis done as today and to dramatically speed up the troubleshooting process.

9914-109, Session PThu3

The FDM readout system for the TES bolometers of the SWIPE instrument of the balloon-borne LSPE experiment

Giovanni Signorelli, Alessandro M. Baldini, Istituto Nazionale di Fisica Nucleare (Italy); Fabrizio Cei, Istituto Nazionale di Fisica Nucleare (Italy) and Univ. di Pisa (Italy); Luca Galli, Giovanni Gallucci, Marco Grassi, Marco Incagli, Istituto Nazionale di Fisica Nucleare (Italy); Alessandro Iezzi, Donato Nicolò, Istituto Nazionale di Fisica Nucleare (Italy) and Univ. di Pisa (Italy); Franco Spinella, Istituto Nazionale di Fisica Nucleare (Italy); Marco Venturini, Istituto Nazionale di Fisica Nucleare (Italy) and Scuola Normale Superiore (Italy); Davide Vaccaro, Istituto Nazionale di Fisica Nucleare (Italy) and Univ. degli Studi di Siena (Italy)

The LSPE balloon-borne experiment aims at measuring the linear polarization of the Cosmic Microwave Background at large angular scales to find the imprint of inflation on the B-mode CMB polarization by means of a 15-days circumpolar flight in the northern hemisphere during the 2017 polar night (see P. de Bernardis et al, contribution at this conference).

The Short Wavelength Instrument for the Polarization Explorer (SWIPE) onboard the LSPE balloon is composed of two facal planes hosting 170 TES Au/Mo spiderweb bolometers each, cooled at 0.3K for the detection of microwave frequencies of 140, 220 and 240 GHz to disentangle the contribution given by dust foregrounds.

To readout all the detectors a 16 channel frequency domain multiplexing readout system has been devised. It consists of a set of cold LC resonators composed of custom Nb superconducting inductances and SMD capacitors with a resonance frequency range between 200 kHz and 1.6 MHz, grouped in set of 16, each set being readout by a single SQUID amplifier. The tuned filter limits the bandwidth of the current noise of the TES and allows multiple detectors to be biased and read-out with a single pair of wires. The TES biasing, modulation and demodulation of the signals are managed by a readout system built around a MicroSemi SmartFusion2 system-on-chip model M2S150 that includes a powerful FPGA core with 150K LUT and an ARM processor with 167 MHz speed coupled to the necessary ADC and DACs to sinthesize the multiple sinusoids and read-out the signals modulated by the change in resistance of the TES bolometers induced by the physical signal.

The chosen DAC (LTC1668) was selected for its low noise and low power properties, while the ADC will be an AD9266 with a sampling speed of 20 MHz.

We will present the design of the system and tests of a partial set-up consisting of a sub-set of LC resonators driven by a prototype FDM board and read-out by a single SQUID showing that the packing factor and the necessary line-widths can be achieved, together with a preliminary firmware for the generation and read-out of the biasing frequency comb.

The superconducting inductances have been designed after suitable simulations at INFN Pisa and realized in NEST SNS Pisa facilities. They are assembled in the 4K readout chain in INFN Pisa clean-rooms. The circuits are tested in a cryogenic facility at INFN Pisa composed of a cryostat equipped with a 4K pulse tube refrigerator.

The roadmap towards the assembly and integration of the readout chain using the TES bolometers produced at INFN Genova (see M. Biasotti et al. contribution at this conference) will be discussed.

9914-113, Session PThu3

A real-time KLT implementation for radio-SETI applications

Andrea Melis, Raimondo Concu, INAF - Osservatorio Astronomico di Cagliari (Italy); Claudio Maccone, INAF - IASF Milano (Italy); Stelio Montebugnoli, Pierpaolo Pari, INAF - IRA Bologna (Italy); Giuseppe Valente, Carlo Migoni, Alessio Trois, Delphine Perrodin, Andrea Possenti, INAF - Osservatorio Astronomico di Cagliari (Italy); Francesco Schillirò, INAF - Osservatorio Astronomico di Catania (Italy); Massimo Barbaro, Maria Ilaria Lunesu, Univ. degli Studi di Cagliari (Italy); Jader Monari, INAF - IRA Bologna (Italy); Alessandro Navarrini, Matteo Murgia, Tonino Pisanu, Valentina Vacca, INAF - Osservatorio Astronomico di Cagliari (Italy)

The Search for ExtraTerrestrial Intelligence (SETI) is a project whose goal is to find possible life signatures emitted (intentionally or unintentionally) by possible civilizations from other habitable planets.

Historically, the narrow-band FFT approach has been used to detect intentionally-transmitted signals, since a quasi-monochromatic signal is expected to be among the probable ones to be used for sending a message to another distant world.

Nevertheless, we could receive an unintentionally-transmitted signal as well. In that case, it would most certainly not be a quasi-monochromatic signal, but would probably be similar, with a wider bandwidth, perhaps of the order of MHz, to the signals that we use for conventional communications on Earth.

The Kahrunen-Loeve Transform is a powerful algorithm for such a kind of research. To see why the KLT can, in some areas, be better than FFT, we consider an analogy with mechanics. Let us take as an example a book and a reference system composed of three Cartesian axes. In accordance with classic mechanics, all of the book's properties concerning the rotational dynamics can be described by a symmetric 3x3 matrix called the "inertia matrix". As is well known, computing the autocorrelation is a good method for extracting a signal immersed in noise.

Let us consider the autocorrelation to be the book itself; the eigenvectors of the autocorrelation matrix can then be calculated so as to find the best data representation. This is the idea behind the KLT.

However, a real-time implementation of the KLT has thus far not worked due to a lack of technological resources.

In this paper, we describe a hardware-software infrastructure at the new 64-m diameter Sardinia Radio Telescope (SRT) that makes it possible. Currently, the three receivers available at the telescope are: the dual-frequency L-P band (305-410 MHz, 1300-1800 MHz), the mono-feed high-C band (5.7-7.7 GHz) and, finally, the seven-feed K-band (18–26.5 GHz) receivers; other receivers (mono-feed low-C band (4.2-5.6 GHz), seven-feed S-band(3-4.5 GHz)) are under development.

Since SETI research is often conducted in piggyback mode only, a dedicated conditioning module was developed at the level of the intermediate frequencies. In particular, it acts as a frequency compensation mechanism that is necessary for keeping the chosen bandwidth stable even when a Doppler tracking system is activated, or in case the chosen bandwidth changes completely during the observation.

The data processing is distributed among FPGA-based boards developed by CASPER (Collaboration for Astronomy Signal Processing and Electronics Research) and named ROACH (Reconfigurable Open Architecture and Computing Hardware), and some GPU-based nodes. The first stage, implemented on the ROACH board, consists in splitting up the entire bandwidth into smaller pieces using the polyphase filter bank technique. In the second stage, a particular sub-band is sent to the GPU-based host in which the KLT runs.

We also show some results achieved during laboratory tests and on data acquired at the SRT.

9914-119, Session PThu3

Inflight characterization and correction of the Planck HFI analog to digital converter nonlinearity

Alexandre Sauvé, Institut de Recherche en Astrophysique et Planétologie (France) and Observatoire Midi-Pyrénées (France); François Couchot, Lab. de l'Accélérateur Linéaire (France) and Institut National de Physique Nucléaire et de Physique des Particules (France); Guillaume Patanchon, AstroParticule et Cosmologie (France) and Univ. Paris 7-Denis Diderot (France); Ludovic Montier, Institut de Recherche en Astrophysique et Planétologie (France) and Observatoire Midi-Pyrénées (France)

The Planck satellite is a space astronomical mission developed by ESA, launched in May 2009, with as scientific primary goal the study of the Cosmic Microwave Background (CMB) anisotropies: the Big Bang relic radiation. Its two instruments, High Frequency Instrument (HFI) and Low Frequency Instrument (LFI), have made an all-sky survey from centimeter to sub-millimeter wavelengths, during more than 3 years, covering about five times the whole sky area at a resolution of 5 to 30 arcmin.

While the CMB radiation, with a temperature of 2.75 K, is very isotropic and homogeneous on the sky, a 1E-5 relative accuracy is required to map the CMB anisotropy fluctuations. The 54 sub-millimeter bolometer detectors of the HFI instrument were cooled at 0.1K and associated to an electronic readout chain presenting an unprecedentedly low noise level to reach such a requirement. Unfortunately the Analog to Digital Converters (ADC) was not properly characterized on ground. This critical component, added nonlinear effect up to 2% of the primary signal fluctuations while a goal of 0.01% bias level had to be achieved to reach the most challenging science analyses in temperature and polarization at large angular scales. I will present how we have performed inflight characterization of the ADC nonlinear response at very high accuracy. This has been achieved in two steps. A ground campaign on spare chips allowed us to build constraints on the generic design of the ADC response. Then a specific inflight acquisition campaign has been designed to gather data for chips characterization. There were 54 channels with individual ADC chip and as many different nonlinear response.

I will describe the several problematics interacting with the nonlinear response and making its correction very difficult. First, the science telemetry sent to Earth consists in a sum of 40 samples over each half-period of raw signal and singularly affected by the nonlinear response of the ADC. Its correction then requires an accurate modeling of the electronic response of the detectors at high sampling. Second, the most problematic effect comes from the 4 Kelvin cooler stage which consist in a mechanical 40Hz coupled pair of compressors leaking signal on the acquired data. This spurious signals varying on a minute basis, is entangled with detector response and is only sampled at the low telemetry rate. This makes the reconstruction of all components of the signal extremely difficult. I will show how we proceed to overcome these major issues and produce the best correction of the ADC systematics, which allowed us to reach the main science goals.

While ADC nonlinearity is a usual systematic effect, I will discuss how to optimize the technical design of the readout electronics in order to avoid such similar issues for future experiments, taking into account all interdependent parameters of the global architecture of the upcoming high sensitivity CMB experiments, such as CORE+, or LiteBIRD.

9914-100, Session PThu4

A zero-bias ultrasensitive far-IR hot-electron bolometer with large dynamic range

Boris Karasik, Theodore J. Reck, Jet Propulsion Lab. (United States)

As more powerful instruments are being planned for the next generation of submillimeter telescopes (e.g., the Far-IR Suveyor mission), the need for better detectors is becoming more urgent. Several advanced concepts have been pursued in the recent years with the goal to achieve a detector Noise Equivalent Power (NEP) of the order of 1E-20 - 1E-19 W/sqrt(Hz) that corresponds to the photon noise limited operation of the future space borne far-IR spectrometers under an optical load ~ 1E-19 W. Our recent work was focusing on the hot-electron nanobolometer (nano-HEB), a Transition-Edge Sensor (TES) where a very low thermal conductance was achieved due to the weak electron-phonon (e-ph) coupling in a micron- or submicron-size device. Using this approach, the targeted low NEP values have been confirmed recently via direct optical measurements. The kinetic inductance detector and the quantum capacitance detector demonstrated recently a similar sensitivity.

We see nevertheless the possibility to advance the state-of-the-art even further. Increase of the operating temperature and the saturation power, and simplification of the array architecture are believed to be the important areas of improvement not only for the ultrasensitive detectors but also for far-IR detectors intended for use in photometers and polarimeters where the background is higher (NEP = 1E-18 - 1E-16 W/sqrt(Hz)). Our recent paper (Karasik et al, IEEE Trans. THz Sci.&Technol. 5, 16 (2015)) analyzed the sensitivity of a normal metal nano-HEB, which uses the Johnson Noise Thermometry (JNT) to read an increase of the electron temperature caused by the absorbed far-IR radiation. Such a detector does not require any bias lines and just needs to be connected to a low-noise microwave amplifier (LNA) via a narrowband filter defining the noise bandwidth. By using a filter bank channelizer, a ~ 1000 detectors can be multiplexed using a single amplifier. The use of normal metal eliminates the need in detector material development (like, e.g., for TES) and provide a ~100 dB dynamic range. The NEP depends on the noise temperature of the readout amplifier and is not very sensitive the e-p coupling strength. An NEP < 1E-19 W/sqrt(Hz) can be achieved with commercially available LNA.

In this paper, we will present an initial experimental study of a normal metal HEB made from a 1-square-micron normal metal patch coupled to a planar twin-slot microantenna. A SQUID-rf LNA with the noise temperature Ta < 1 K followed by a HEMT LNA with Ta ≈ 5 K and a large gain are for readout. Electrical NEP is measured by sending a dc current through the device and measuring a change of output noise power caused by the heating. At 50 mK, the NEP is ~ 1E-19 W/sqrt(Hz). The data are obtained as function of bath temperature and the filter passband and compared with the model. An on-going effort to design a 1000-element bank of narrowband (few MHz) filters needed to array multiplexing will be presented too. We will also discuss various options of LNA (HEMT, parametric superconducting amplifiers, etc.) and associated sensitivity and dynamic range trade-offs.

9914-107, Session PThu4

Developments towards the terahertz intensity interferometry

Hajime Ezawa, Hiroshi Matsuo, National Astronomical Observatory of Japan (Japan); Masahiro Ukibe, Go Fujii, Shigetomo Shiki, National Institute of Advanced Industrial Science and Technology (Japan)

High angular resolution is one of the key demand in modern astronomy. Recently VLTI and ALMA successfully demonstrated their capability for high angular resolution in optical and radio astronomy, respectively, while high angular resolution observation at terahertz wavelengths are yet to be realized. In order to fill this “terahertz gap”, we are considering a terahertz intensity interferometer to realize high angular resolution, which may be deployed either with ground based telescopes or space-borne missions. The presentation will discuss the concept of terahertz intensity interferometry, as well as its sensitivity, and the progress of necessary technical developments.

Intensity interferometer for astronomy observation was first realized by Hanbury-Brown and Twiss, where they successfully determined the radius of compact objects, however synthesis imaging was not possible due to the absence of the delay information at that time. We have introduced a new method to determine the delay time by making use of the intensity fluctuation, or photon bunches, governed by Bose-Einstein statistics. This new method makes synthesis imaging possible even with intensity interferometers, where direct detectors may be applied, instead of heterodyne receivers, to gain the sensitivity. Recently we have demonstrated this method at 17 GHz with Nobeyama Radioheliograph (NoRH), where we have successfully determined the delay within 5 ps, even with the electromagnetic phase information being smeared out from the signal time stream. The key to the success was the capability to fast sample the time stream data with 1.25 GS/s.

Following this success, we started to study the possibility to expand this method into terahertz region. Current developments are focused on the detector and the readout circuit. Considering a typical case of observing a 1 Jy source with a 10-m telescope at 1 THz and 100 GHz bandwidth, approximately 100 M photons/s is expected; the detector is required to respond as fast as 1 GHz or to realize NEP<10^(-17) W/Hz^(1/2). This can be achieved by an SIS photon detector with low leakage current of 1 pA, while other direct detection techniques such as TES or KIDs are too slow for this purpose. The SIS photon detector with Nb/Al/AlOx/Al/Nb is being developed to meet this specification. Preliminary results indicate that this goal would be achievable by realizing a small junction as 1 um x 1 um. Another key development is the cryogenic readout circuit, especially the first stage amplifier. This involves some specific requirements, such as gate capacitance as small as 1 fF, gate leakage current less than 1 pA, or electrical bandwidth larger than 1 GHz. The readout electronics is expected to operate at cryogenic temperature, since it should be mounted close to the SIS detector operating at 0.8 K. For this, we expect JPHEMT (Junction Pseudomorphic High Electron Mobility Transistor) to provide a breakthrough for the first stage FET.

The basic concept of terahertz intensity interferometer, details of the design and the results from the latest evaluation experiment will be presented in the talk.

9914-102, Session PThu5

A full circuit model and hybrid simulation scheme for SuperSpec filter bank spectrometers

George Che, Arizona State Univ. (United States); Steven Hailey-Dunsheath, California Institute of Technology (United States); C. Matt Bradford, Jet Propulsion Lab. (United States); Sean A. Bryan, Arizona State Univ. (United States); Jason Glenn, Univ. of Colorado Boulder (United States); Philip D. Mauskopf, Arizona State Univ. (United States); Corwin Shiu, California Institute of Technology (United States); Erik D. Shirokoff, The Univ. of Chicago (United States); Jordan D. Wheeler, Univ. of Colorado Boulder (United States); Jonas Zmuidzinas, California Institute of Technology (United States)

SuperSpec is a novel spectrometer technology designed to provide the requisite resolution (R ~ 100-500), bandwidth (~1.65:1), and sensitivity

(<10^-17 W/sqrt(Hz)) to investigate star formation and galaxy evolution during the Epoch of Reionization. Since much of the optical and ultraviolet light emitted by stars and black holes throughout the history of the universe has been absorbed and reradiated by interstellar dust, understanding star formation and galaxy evolution requires precise observations in the mm and submm regimes, which are unaffected by dust obscuration. Spectroscopic measurements are especially useful because atomic and molecular lines, such as the 158 um [CII] line, provide powerful probes for interstellar medium physics. Existing grating spectrometers and heterodyne interferometers are well-suited for studying small numbers of individual galaxies, but respectively lack the architecture and bandwidth required to conduct broadband spectral surveys over large areas of the sky.

SuperSpec integrates a broadband transmission line filter bank and hundreds of kinetic inductance detectors (KIDs) on a single chip only a few square cm in size, enabling construction of multi-pixel, focal-plane spectrometer arrays. Covering an instantaneous bandwidth of 50% or more in the 100-500 GHz range, each filter bank is comprised of a series of spectral channels realized in superconducting half-wave resonant filters coupled to a main transmission line. Each channel is terminated by a KID and the channel's spectral resolution R is equal to the quality factor Q of the loaded resonator.

Currently, our main goal is to deploy an on-sky demonstrator instrument employing this technology on a major ground-based telescope in 2017. While initial modeling has enabled a basic demonstration of the resonator operation and detector sensitivity, developing an optimized filter bank for scientific use requires a realistic circuit simulation capability which includes higher order electromagnetic effects such as non-Lorentzian channel profiles and off-resonance standing wave patterns.

We have developed a microwave network model, which assembles a full filter bank by cascading together its constituent spectral channels and transmission lines, taking into account all internal reflections. Representing each channel as a 3-port lumped-element resonator, our model agrees with full-wave Sonnet simulations of a filter bank with 5 well-separated channels and a Nyquist-spaced, 6-channel filter bank with oversampling of three. Ongoing work to fit model spectra to measured spectra will investigate the discrepancy between design and measured resonant frequency and quality factor of each channel, fully describing filter bank behavior and informing future designs.

A science-grade filter bank requires ~100 channels, which is prohibitively memory-intensive for a full-wave simulation. To drastically reduce memory requirements for accurately simulating large filter banks, we are developing a hybrid simulation scheme, which entails performing full-wave analyses on individual channels and cascading them together using our network model. This scheme agrees with our full-wave analysis of the Nyquist-spaced, 6-channel filter bank.

9914-106, Session PThu5

Low-cost Ku band interferometer for educational purposes

Daniel E. Herrera, Alejandro Saez, ALMA (Chile)

The latest discoveries on the astronomy field have been associated to the development of extremely sophisticated instruments. In the case of the radio-astronomy the instrumentation has evolved to higher processing data rates and a continuous performance improvement, in the analog and digital domain. Developing, maintaining and using such a kind of instruments, especially in the radio-astronomy field, requires to understand complex processes which are plenty of subtle details. The above has inspired the engineering and astronomy community to design low-cost instruments, which can be easily replicated by the non-scientist people who possess a basic technical background.

The final goal is to provide the means to build an affordable tool for teaching radiometry sciences. In order to give a step further in this way, we introduce a design of a basic interferometer (two elements) intended to become in a handy tool for learning the basic principles behind the interferometry technique and radiometry sciences.

The first approach to present here was made by an array of two LNBs (the same models used for satellite TV) which are especially modified in order to get the timing reference from an external oscillator. As digital back end a ROACH I board was the choice due to its flexibility and short time to get it operative, allowing us to study and prepare the technical system requirements according to the phenomenon we want to capture and present in an educational setting. A description of the instruments setup will be given, in addition of the signal diagram, the implementation details and the programmed software to process the signal coming from the ROACH board.

One of the pedagogical experiences using this tool will be the measurement of the sun's angular diameter, using these two Ku band receptor, we aim to capture the solar radiation in the 11-12Ghz frequency range, the power variations at the earth spin, with a proper phase-lock of the receptors will generate a cross-correlation power oscillation where we can obtain an approximation of the angular sun's diameter. Variables of interest in the calculation of this angular diameter is the declination of the sun (which depends on the capture date and location), the relation between maximal and minimal power within a fringe cycle.

This work also presents a survey of future works focused in enhance the instruments capabilities, as can be the measurement of the sun's temperature using known-temperature loads in the calibration process in the LNB, the characterization of the antenna beam analyzing the power trends over time in a sun observation, and the usage of basic boards for data capture and correlation with the purpose of reduce the implementation costs, enabling a broader amount of students to be in touch with science and engineering.

9914-115, Session PThu5

A 4 K FTS demonstrator for future cooled space telescopes

David A. Naylor, Ian T. Veenendaal, Brad G. Gom, Univ. of Lethbridge (Canada); Peter A. R. Ade, Cardiff Univ. (United Kingdom)

The next generation of far infrared space observatories are being designed to address outstanding questions in astrophysics and cosmology, in topics ranging from the formation and evolution of galaxies in the early universe, to the formation of stars and planets in the milk way. Early missions such as IRAS, ISO and Spitzer paved the way for more sensitive telescopes such as Herschel and JWST. While these missions represent significant advances in angular resolution and sensitivity, it is widely recognized that the next generation missions will require cooled telescopes and instruments, with extremely high angular resolution and sensitivity across the full far-IR band.

One such mission, SPICA, aims to achieve an increase in sensitivity of between 10 to 100 times that of Herschel, in order to reach sky limited sensitivity between 5 and 210 μm. While the telescope aperture and thus spatial resolution will be similar to that provided by Herschel, the application of an actively cooled primary mirror will reduce the telescope photon noise by two orders of magnitude at the critical longer wavelengths. The SAFARI instrument on SPICA will provide imaging spectroscopy from 30 to 210 μm with resolving powers between 300 and 3,000. The baseline design is a cryogenic FTS operating at ~4K in order to reach the ambitious low thermal background requirements.

Another proposed mission, the Far Infrared Interferometer (FIRI), combines stellar interferometry with Fourier transform spectroscopy to provide an unprecedented combination of high spatial resolution with extremely sensitive spectroscopy between 25 and 300 μm.

The SAFARI spectrometer, and both the interferometry and spectroscopy aspects of FIRI, rely on accurate delay lines. For accurate spectroscopic phase retrieval and ghost line suppression, studies have shown that position metrology sampling accuracy better than 0.1% of the shortest wavelength is required. Meeting this requirement through optical design and the control of the linear stage is relatively simple on the ground at room temperature, but becomes a substantial challenge in space at cryogenic temperatures.

This paper presents the design, testing and performance of a demonstrator 4 K interferometer delay line operated within a cryogenic test facility, intended for testing optical components at temperatures down to 4 K and for evaluation of metrology techniques for application in future 4 K interferometer mechanisms such as those proposed for FIRI and SPICA. We have modified a commercial FTS delay line mechanism for cryogenic operation. When installed in the 4 K test facility cryostat with a multiple component blackbody calibration source and a 0.3 K detector, the system enables the evaluation of metrology options, scanning and data compression techniques, and the performance of critical optical components such as beam splitters and filters at their intended operating temperatures.

The ongoing activities at the University of Lethbridge in testing of cryogenic delay lines will prove fundamental in identifying key issues in interferometer designs such as those proposed for SPICA and FIRI. The integrated test bed also allows us to investigate the potential role for Canada in delivering a cryogenic FTS mechanism for future space missions, particularly SPICA/SAFARI.

9914-118, Session PThu5

SuperSpec: design and device testing

Jordan D. Wheeler, Univ. of Colorado Boulder (United States); Peter S. Barry, Cardiff Univ. (United Kingdom); C. Matt Bradford, Jet Propulsion Lab. (United States); Scott C. Chapman, Dalhousie Univ. (Canada); George Che, Arizona State Univ. (United States); Jason Glenn, Univ. of Colorado Boulder (United States); Steven Hailey-Dunsheath, Matthew I Hollister, Attila Kovacs, California Institute of Technology (United States); Henry G. LeDuc, Jet Propulsion Lab. (United States); Philip D. Mauskopf, Arizona State Univ. (United States); Christopher M. McKenney, California Institute of Technology (United States); Roger C. O'Brient, Jet Propulsion Lab. (United States); Stephen Padin, California Institute of Technology (United States); Theodore J. Reck, Jet Propulsion Lab. (United States); Erik D. Shirokoff, The Univ. of Chicago (United States); Corwin Shiu, California Institute of Technology (United States); Carole E. Tucker, Cardiff Univ. (United Kingdom); Ross Williamson, Jet Propulsion Lab. (United States); Jonas Zmuidzinas, California Institute of Technology (United States)

SuperSpec is an on-chip spectrometer being developed for multi-object, moderate resolution (R = 100?500), large bandwidth submillimeter and millimeter survey spectroscopy of high-redshift galaxies. The heart of the SuperSpec spectrometer is a microstrip filter bank that employs kinetic inductance detectors (KIDs) to detect astrophysical radiation on each filter. KIDs are superconducting series inductor and capacitor (LC) circuits, whose inductance changes when incident radiation is absorbed. The natural multiplexability and small physical size of KIDs allow for the fabrication of a wide band spectrometer that can be lithographically patterned on only a few cm2 of silicon. We will detail some of the results of our current device designs and testing. This includes investigation into both SuperSpec's optical coupling and the device noise properties.

The first astronomical application of SuperSpec targets atomic and molecular line emission from, e.g. CII and CO in external galaxies and is designed to cover the atmospheric transmission window between 180 and 320 GHz water lines, which necessitates wideband optical coupling from free space. The main design drivers for the optical coupling are high coupling efficiency and ease of fabrication. We examine both horn coupling with waveguide-to-microstrip transitions and lens-coupled antennas with wideband microstrip baluns. Coupling efficiency and beam patterns of the systems are simulated. The design solutions are evaluated in terms of bandwidth, coupling efficiency, directivity, and complexity of fabrication.

In addition we present an analysis of the noise properties of our current prototype devices. Noise contributions for Kinetic Inductance Detectors consist of Two Level System noise (TLS), generation and recombination noise, amplifier noise, and photon noise. TLS noise is the result of atoms or groups of atoms in the dielectric substrate tunneling between energy levels, resulting in a varying capacitance in the KID. Generation-recombination noise is the result of the random thermal generation of quasiparticles, and the recombination of both thermal and optical quasiparticles into Cooper pairs. Along with these noise sources we see additional low frequency noise not explained by these components. We examine each of these noise sources, their correlation between detectors, and their dependencies on operating conditions for our current prototypes.

9914-125, Session PThu5

Measurements and analysis of optical crosstalk in a microwave kinetic inductance detector array

Laura Bisigello, Stephen Yates, Lorenza Ferrari, Andrey Baryshev, SRON Netherlands Institute for Space Research (Netherlands)

In the last decades, larger and larger blank surveys have been carried out in astronomy in order to study populations of galaxies in a more statistical way and to analyze rare classes of astronomical objects. For this reason is important to develop large and fast cameras also at infrared wavelengths. For example, A-??MKID is a large sub-??millimeter camera for the APEX telescope in Chile based on the kinetic inductance technology. This camera is particularly suitable for large surveys thanks to its large field-??of-??view, its huge number of pixels and therefore highmapping speed.

9914-128, Session PThu5

A general purpose terahertz camera based on kinetic inductance detectors for commercial/industrial applications

Sam Rowe, Simon M. Doyle, Enzo Pascale, Cardiff Univ. (United Kingdom); Ken Wood, QMC Instruments Ltd. (United Kingdom)

Kinetic inductance detectors have come into prominence in the field of far-infrared, sub-millimetre and millimetre-wave astronomy by virtue of their high sensitivity and the ease of fabrication and electronic readout of large format arrays. Beyond astronomy, there are a range of disciplines that can benefit from these advances, including biomedical sensing, process control in manufacturing, hidden object detection, security screening, etc.

In collaboration with QMC Instruments Ltd., we are developing a general purpose imaging system based on focal plane arrays of lumped element KIDs operating at terahertz frequencies. We aim to have a fully functioning and versatile camera that is ready to enter the commercial marketplace within the next two years.

Here we present our progress so far, in particular, on the design and construction of the cryogenic cooling platform and cold imaging optics system; the development and fabrication of detector array architectures suited for a range of optical bands -- including options for simultaneous multi-band observations; the development and assembly of a multiplexing

readout system based on ROACH-2 electronics; the development and testing of intuitive and simple-to-operate control software; and concepts for

9914-131, Session PThu5

Development of instrumentation for differential spectroscopic measurements for the millimeter wavelengths

Giuseppe D'Alessandro, Sapienza Univ di Roma (Italy); Alessandro Schillaci, Sapienza Università di Roma (Italy) and Sapienza Univ di Roma (Italy); Paolo de Bernardis, Sapienza Univ di Roma (Italy) and Sapienza Università di Roma (Italy); Silvia Masi, Sapienza Università di Roma (Italy)

The Sunyaev-Zel'dovich (SZ) effect is a powerful tool for studying clusters of galaxies and cosmology. Large mm-wave telescopes are now routinely detecting and mapping the SZ effect in a number of clusters, measure their comptonisation parameter and use them as probes of the large-scale structure and evolution of the universe.

By using accurate simulations of observations, we show that estimates of the physical parameters of clusters obtained from multi-band SZ photometry can be significantly biased, owing to the reduced frequency coverage, to the degeneracy between the parameters and to the presence of a number of independent components larger than the number of frequencies measured. By demonstrating that low-resolution spectroscopic measurements of the SZ effect that are effective in removing the degeneracy.

We describe an imaging, efficient, differential Fourier transform spectrometer (FTS), optimized for measurements of faint brightness gradients at millimeter wavelengths.

The instrument is based on a Martin-Puplett interferometer (MPI) configuration. We combined two MPIs working synchronously to use the whole input power. In our implementation the observed sky field is divided into two halves along the meridian, and each half-field corresponds to one of the two input ports of the MPI. In this way, each detector in the FTS focal planes measures the difference in brightness between two sky pixels, symmetrically located with respect to the meridian. Exploiting the high common mode rejection of the MPI, we can measure low sky brightness gradients over a high isotropic background.

This unique feature makes the MPI an optimal zero instrument, able to detect small brightness gradients embeddend in a large common background. We investigate experimentally the common-mode rejection achievable in the MPI at mm wavelengths, and discuss the use of the instrument to measure the spectrum of cosmic microwave background (CMB) anisotropy.

9914-134, Session PThu5

Development of an R=256 μ-Spec: an integrated spectrometer for submillimeter spectroscopy

Emily M. Barrentine, Ari D. Brown, Giuseppe Cataldo, Negar Ehsan, Omid Noroozian, Thomas R. Stevenson, Kongpop U-Yen, Edward J. Wollack, Samuel H. Moseley, NASA Goddard Space Flight Ctr. (United States)

μ-Spec is a compact submillimeter (350-700 GHz) spectrometer which uses low loss superconducting niobium microstrip transmission lines and a single-crystal silicon dielectric to integrate all of the components of a grating-analog spectrometer onto a single chip. The instrument components include a slot antenna with a silicon lens for optical coupling, a phase delay transmission line network, a parallel plate waveguide interference region, and aluminum microstrip transmission line kinetic inductance detectors (KIDs). ?-Spec provide orders of magnitude reduction in size and mass from the current state of the art and will enable high-performance spectroscopy from space for observation of IR-obscured galaxies at redshifts from z~2-8.

We have already successfully evaluated the performance of a prototype ?-Spec, with spectral resolving power, R = ?/?? = 64. Here we present our progress towards developing a higher resolution version of μ-Spec (R=256/512) which would enable the first science returns for ?-Spec in a balloon flight version of this instrument. We describe our modifications to the overall design in scaling from an R=64 to an R=256 instrument, including the operation of the spectrometer in higher order using broadband order-sorting filters, and a scaling of our KID design to achieve increased sensitivity. We also describe the path for scaling this instrument to our ultimate resolution goal of R~1500 in terms of instrument size, efficiency, and configuration.

9914-136, Session PThu5

W-band planar antennas for next generation sub-millimeter focal plane arrays

Prafulla Deo, Matthew Robinson, Bruno Maffei, The Univ. of Manchester (United Kingdom); Giampaolo Pisano, Cardiff Univ. (United Kingdom)

Measurement of the B-mode polarization of the Cosmic Microwave Background remains elusive. This calls for increased instrument sensitivity and more sophisticated foreground subtraction. Due to the noise of modern day detectors, such as bolometers and KIDs, being at the fundamental photon noise limit, further increase in instrument sensitivity is achieved either by employing multi-moded components or by increasing the total detector count. In this work, the approach of increasing instrument sensitivity by increasing the number of detectors is followed. The Planck spacecraft utilized 52 detectors in its High Frequency Instrument. The demands of the next generation focal planes call for arrays consisting in excess of 1000 pixels. The scalability of feed horn coupled pixels for focal plane arrays consisting of this number of pixels is restrictive given the size, weight, and manufacturing cost associated with each pixel. In this work, two alternative pixel designs based on planar antenna technology are presented. The pixels are smaller than classic horn antennas, are more lightweight and can be mass-produced using common lithographic techniques leading to reduced manufacturing costs.

Two multichroic planar antenna designs have been developed at W-band; a seashell antenna and a sinuous antenna. Each antenna supports two sub-bands and two polarisations, leading to four detectors per pixel. This doubles the number of detectors per pixel compared to classic single-band horn antennas. The antennas will ultimately be used to feed a planar mesh lens, which will define the beam on the telescope optics. Simulation results are presented for the seashell and sinuous antennas at W-band frequencies. Measurements of scale models of each antenna have been planned.

The seashell antenna consists of four dual-slot antennas. Each slot pair is excited with a microstrip transmission line. Analysis of the antenna on a thin substrate of polypropylene shows that it has highly elliptical beams (>40%) and narrow sub-bands (<10% bandwidth). The high beam ellipticity is corrected by confining the propagation of the near-field with a metallic aperture. This aperture has been optimized to minimize the beam ellipticity in each sub band.

The sinuous antenna is printed on the underside of a cylinder of polypropylene. The thickness and diameter of this polypropylene substrate has been optimized to maximize forward gain and minimize the backlobe power. The antenna has broad -10 dB impedance bandwidth (>60%) and has moderately elliptical beam performance (between 5% to 9%). The

effects of an additional matching layer have also been investigated. The antenna demonstrates symmetric beams and broadband performance leading to the extraction of two or more sub-bands.

9914-49, Session 10

Readout of a 176 pixel FDM system for SAFARI TES arrays

Richard A. Hijmering, Roland H. den Hartog, Marcel L. Ridder, Ton van der Linden, Jan van der Kuur, SRON Netherlands Institute for Space Research (Netherlands); Jian-Rong Gao, SRON Netherlands Institute for Space Research (Netherlands) and Kavli Institute of Nanoscience Delft (Netherlands); Brian D. Jackson, SRON Netherlands Institute for Space Research (Netherlands)

SAFARI is one of the focal-plane instruments for the Japanese/European far-IR SPICA mission proposed for the ESA M5 selection. It is based on three arrays with in total 3550 TES-based bolometers with noise-equivalent powers (NEP) of 2 E-19 W/?Hz. The arrays are operated in three wavelength bands: S-band for 30-60 μm, M-band for 60-110 μm and L-band for 110-210 μm, and have background-limited sensitivity and high efficiency. SRON is developing Frequency Domain Multiplexing (FDM) for read out of large AC biased TES arrays for both the SAFARI instrument, and the XIFU instrument on the X-ray Athena mission. In FDM for SAFARI, the TES bolometers are AC biased and readout using 24 channels. Each channel contains 160 pixels of which the resonance frequencies are defined by in-house developed cryogenic lithographic LC filters. FDM is based on the amplitude modulation of a carrier signal, which also provides the AC voltage bias, with the signal detected by the TES. To overcome the dynamic range limitations of the SQUID pre-amplifier baseband feedback (BBFB), is applied. BBFB attempts to cancel the error signal in the sum-point, at the input coil of the SQUID, by feeding back a remodulated signal to the sum-point, and therefore improving the dynamic range of the SQUID pre-amplifier.

Previously we have reported on the successful low-noise read-out of 38 bolometer TES and a detailed study on the effects of electrical crosstalk using our first iteration of a prototype of the full 160 pixel FDM experiment. Using the obtained knowledge, a second generation prototype with a 176 pixel FDM experiment is developed in which the crosstalk due to carrier leakage, mutual inductance and common impedance are minimized. The cold part of the experiment consists of a detector chip with 176 pixels with a designed NEP of 7E-19 W/?Hz and two matching LC filter chips, each of which contains 88 carefully placed high-Q resonators, with in total 176 different resonance frequencies, and a single-stage SQUID. The warm electronics consist of a low-noise amplifier (LNA) and a digital board on which the generation of the bias carriers, the demodulation of the signal and remodulation of the feedback signal are performed. Compared to the previous experiment, the effect of carrier leakage has been reduced by a factor two and the effects of mutual inductance have been removed. The common impedance has been reduced by design to 4nH, of which 3nH is from the input coil of the SQUID. This has successfully been further reduced to below 1 nH by implementing screening of the input coil. By connecting the pixels in stages, corresponding to a quarter, a half and a full array, the complexity of the experiment increased in steps, which allowed us to resolve intermediate technical issues more efficiently. Number of In this paper we will report on the results obtained with this 176 pixel FDM experiment.

The South Pole Telescope third generation receiver, SPT-3G, will make extremely deep, arcminute-resolution maps of the temperature and polarization of the Cosmic Microwave Background. The SPT-3G maps will enable studies of the B-mode polarization signature, constraining primordial gravitational waves as well as the effect of massive neutrinos on structure formation in the late universe. The SPT-3G receiver will achieve exceptional sensitivity through a focal plane of sim16,000 transition-edge sensor bolometers, an order of magnitude more than the current SPT receiver. SPT-3G uses a frequency domain multiplexing (fMux) scheme to readout the focal plane, combining the signals from 64 bolometers onto a single pair of wires. The fMux readout facilitates the large number of detectors in the SPT-3G focal plane by limiting the number of wires dissipating heat on the ultracold cryogenic stage. The fMux system also allows optimized operation of each bolometer. In addition to the benefits, the fMux readout introduces new challenges into the design and operation of the receiver. The bolometers are operated at a range of frequencies up to 5 MHz, requiring control of stray reactances over an expanded bandwidth. Additionally, crosstalk between multiplexed detectors will inject large false signals into the data if not adequately mitigated. SPT-3G is scheduled to deploy to the South Pole telescope in late 2016. Here, we present the pre-deployment performance of the fMux readout system with the SPT-3G focal plane.

9914-51, Session 10

FPGA-based digital signal processing for the next generation radio astronomy instruments: ultra-pure sideband separation and polarization detection

Ricardo Finger, Andrés Alvear, Roberto Fuentes, Raul Sapunar, Univ. de Chile (Chile); Tom Geelen, Technische Univ. Eindhoven (Netherlands); Franco Curotto, Rafael Rodriguez, David Monasterio, Nicolás Reyes, F. Patricio Mena, Leonardo Bronfman, Univ. de Chile (Chile)

Field Programmable Gate Arrays (FPGAs) capacity and Analog to Digital Converters (ADCs) speed have largely increased in the last decade. Nowadays we can find one million or more logic blocks (slices) as well as several thousand arithmetic units (ALUs/DSP) available on a single FPGA chip. We can also commercially procure ADC chips reaching 10 GSPS, with 8 bits resolution or more.

This unprecedented power of computing hardware has allowed the digitalization of signal processes traditionally performed with analog components. In radio astronomy the clearest example has been the development of digital sideband separating receivers which, by replacing the IF hybrid and calibrating the system imbalances, have exhibited a sideband rejection above 40dB; this is 20 to 30 dB better than traditional analog sideband separating receivers.

In Rodriguez et al.[1], and Finger et al.[2], we have demonstrated very high digital sideband separation at 3mm and 1mm wavelengths, using laboratory setups. We here show the first implementation of such technique with a 3mm receiver integrated in a telescope, where the calibration was performed by optical injection of the test tone at the secondary mirror of the Cassegrain antenna.

We also report progress in digital polarization synthesis, particularly in the implementation of a calibrated Digital Orthomode Transducer (DOMT) based on the Morgan et al. proof of concept [3]. They showed off-line synthesis of polarization with isolation better than 40dB. We plan to implement a digital polarimeter in a real-time FPGA based (ROACH-2) platform, to show ultra-pure polarization isolation in a non-stop integrating spectrometer.

9914-52, Session 10

GPU-based readout for kinetic inductance detectors

Attila Kovacs, California Institute of Technology (United States); Jonas Zmuidzinas, California Institute of Technology (United States) and Jet Propulsion Lab. (United States); C. Matt Bradford, Charles D. Dowell, California Institute of Technology (United States) and Jet Propulsion Lab. (United States); Pradeep Bhupathi, California Institute of Technology (United States)

The growth of submillimeter and far-infrared (FIR) detectors arrays beyond the thousands of pixels/channels today is limited primarily by two factors: (i) the per-detector cost, and (ii) the number of channels that can be multiplexed on a single readout. Kinetic inductance detectors (KIDs) offer a step forward in both areas, combining a simple low-cost lithographic process with high multiplexing density in frequency domain. KIDs are therefore well-positioned to meet the needs of the next-generation large FIR arrays, on the ground and in space, with 100k or more pixels/channels, at low (below $1 per pixel/channel) cost. KIDs can also be used as fast optical or X-ray detectors, enabling time-resolved optical/X-ray imaging in photon-counting mode.

However, the optimal extraction of signals from a large number of frequency-multiplexed KIDs remains a challenge. Most current readout systems use FPGAs and rely on a tone-based readout approach, in which each KID resonator is excited by one or more fixed-placed tones. Changes (e.g. frequency shifts) in the detector response are characterized by those select tones alone.

We present an alternative readout system that uses commercial components (ADCs and DACs) and a graphical processing unit (GPU) to process up to 125 MHz full bandwidth instantaneously. We use broad-band excitation of the detectors, which allows for a more complete characterization of the detector response (such as resonator frequency shift, line width, amplitude, or line-shape) in real time. Our readout does not require explicit resonance search or calibration preceding a measurement, and can keep track of resonators even when these move by much more than a line-width, with no sensitivity trade-off. The full-spectrum approach also provides faster sampling than tone-based readout. E.g. for Q~10^5 resonators in the 125--250 MHz range, sampling up to ~4 kHz rates is possible.

The GPU-based readout system was successfully demonstrated in May 2015, using the MAKO camera at the Caltech Submillimeter Observatory (CSO). Its noise performance was comparable to the ROACH-based readout system. We will report these results and will present improvements to the system we implemented since. These include a new method of targeted spectral excitation, a more optimal algorithm for the extraction of frequency shifts, and improved electronic noise performance.

Ultimately, such GPU-based resonator readout, can provide an easy-to-use, and low-cost readout solution for both KIDs, and other frequency-domain multiplexed, detectors.

9914-53, Session 10

Readout of two-kilopixel transition-edge sensor arrays for advanced ACTPol

Shawn W. Henderson, Jason Stevens, Michael D. Niemack, Cornell Univ. (United States)

Advanced ACTPol is an instrument upgrade for the six-meter Atacama Cosmology Telescope (ACT) designed to measure the cosmic microwave background (CMB) temperature and polarization with arcminute-scale angular resolution. Advanced ACTPol requires a higher multiplexing factor than any previous CMB experiment to achieve its science goals by incorporating approximately two thousand transition-edge sensor (TES) bolometers into each 150 mm detector wafer. We present the implementation and testing of the Advanced ACTPol time-division multiplexing readout architecture with a 64-row multiplexing factor. This includes testing of individual multichroic detector pixels and superconducting quantum interference device (SQUID) multiplexing chips, as well as testing and optimization of the integrated readout electronics. In particular, we will describe the new automated multiplexing SQUID tuning procedure we have developed to select and optimize the thousands of SQUID parameters required to read out each Advanced ACTPol array. The multichroic detector pixels in each array use separate channels for each polarization and each of the two frequencies, such that four TESes must be read out per pixel. Challenges addressed include doubling the number of detectors per multiplexed readout channel compared to ACTPol as well as optimizing the Nyquist inductance to minimize aliasing of detector and SQUID noise.

The Simons Array is a next generation cosmic microwave background (CMB) polarization experiment whose science targets are precision measurements of the B-mode polarization pattern produced both by inflation and by gravitational lensing. As a continuation and extension of the successful POLARBEAR experimental program, Simons Array will consist of three cryogenic receivers each featuring multichroic bolometer arrays mounted onto separate 3.5m telescopes. The first of these, also called POLARBEAR-2, will be the first to deploy in early 2017 and has a large diameter focal plane consisting of dual-polarization dichroic pixels sensitive at 95 GHz and 150 GHz. The focal plane of POLARBEAR-2 will utilize a total of 7,588 antenna-coupled superconducting transition edge sensor (TES) bolometers read out with SQUID amplifiers using frequency domain multiplexing techniques. The next two receivers that will make up the Simons Array will be nearly identical in overall design but will feature extended frequency capability. The combination of high sensitivity, multichroic frequency coverage and large sky area available from our mid-latitude Chilean observatory will allow Simons Array to produce high quality polarization sky maps over a wide range of angular scales and to separate out the CMB B-modes from other astrophysical sources with high fidelity. The Simons Array will constrain the inflationary B-mode signal down to a tensor-to-scalar level of $r = 0.01$ (2 sigma) and will constrain the sum of neutrino masses to 40 meV (1 sigma including foreground separation residuals) when Simons Array data is cross-correlated with galaxy surveys. We present the current status of this funded experiment, its future, and discuss its projected science return.

9914-55, Session 11

POLARBEAR-2: an instrument for CMB polarization measurements

POLARBEAR-2 (PB-2) is a ground-based CMB polarization experiment with a large detector array that consists of 7588 dual-band antenna-coupled Al-Mn bilayer transition edge sensor (TES) bolometers for simultaneous measurements at 95 and 150 GHz. The main goal of PB-2 is to detect degree scale odd-parity (B-mode) polarization patterns. The B-mode is created by primordial gravitational waves generated during the inflation. Its discovery is a smoking gun signature of inflationary universe. The PB-2 experiment expects to achieve the sensitivity of tensor to scalar ratio, r~0.01 (95% C.L.). PB-2 also plans to measure the sub-degree scale B-mode from gravitational lensing, with that the sum of neutrino masses, ?m?, will be constrained at 90meV (68 % C.L.). The receiver will be mounted on a telescope with a ~3.5m primary mirror, corresponding to the angular resolution of 3.5 arc minutes at the 150 GHz band. The receiver is being developed in the laboratory and has been tested, and we plan to start the scientific observation from early 2017. To achieve the large field of view over 4.8 degrees with high Strehl ratios, large reimaging lenses made of high purity alumina are adopted to realize the focus tele centric over the whole 365mm-diameter focal plane. The focal plane is filled with 7 wafers. Each wafer has 271 dual linear polarized pixels sensitive in 95 GHz and 150 GHz bands. A silicon lenslet with epoxy-based two-layer anti-reflection coating is placed on each pixel. Incoming radiation is coupled with a sinuous antenna. Micro-strip filters on the pixel split the signal onto two detection bands. Intensity of each signal is detected by a TES bolometer. The entire focal plane is cooled to ~250mK by a helium sorption cooler. The signal from each bolometer is amplified by a Quantum Interference Device (SQUID) and readout by multiplexed readout system based on the digital implementation of the frequency domain technique. The increase of the number of detectors requires an increase in the multiplexing factor. Therefore the number of detectors read out per SQUID is 40 at PB-2, which is larger than 8 that is achieved at PB-1. Characterizations of the PB-2 receiver system have been carried out in the lab. First of all, we measured temperatures of the optical elements and estimated the total loading to obtain expected sensitivities. We also measured positions and shapes of the lenses to model the optical system and obtained expected optical performance. The simulated side lobe levels are -20 and -25 dB at 95 and 150 GHz. These results meet our requirements. In this talk, we explain the overview of POLARBEAR-2 experiment and results of validation tests for the large optics and detector system.

The Primordial Inflation Polarization ExploreR (PIPER) is a balloon-borne telescope designed to measure polarization of the Cosmic Microwave Background (CMB) on large angular scales. It will observe at 200, 270, 350, and 600 GHz on subsequent Northern and Southern-hemisphere flights, and cover 85% of the sky. PIPER's resolution permits measurement of E and B modes to l~300, and polarization modulation and stable float environment are expected to allow constraint on CMB polarization anisotropy from reionization. The instrument resides in an LHe bucket dewar, which becomes superfluid at float. Superfluid pumps permit cooling and cryogenic operation of the modulator and optics. Helium vapor from boiloff avoids the need to use a warm vacuum window. These factors allow sensitivity limited by the sky background, and competitive B-mode sensitivity from conventional balloon flights. Ultimately 8 flights provide sensitivity to the tensor-to-scalar ratio r~0.007. PIPER will spin in azimuth with a ten-minute period, at 55 degrees off zenith. Earth's rotation allows 55% of the sky to be mapped in the nighttime segment of the flight. In the day, the scan will be limited to a 20-degree strip in the anti-solar direction. The first science flight will use two 32x40 arrays of backshort-under-grid free-space absorbers and Transition Edge Sensors. Superconducting vias connect to indium bump bonds of a NIST 2D SQUID MUX. The array is multiplexed in the time domain and read with the UBC Multi-Channel Electronics. Detectors are maintained at 100 mK with a compact Continuous Adiabatic Demagnetization Refrigerator. The PIPER instrument comprises two parallel telescopes whose polarization analyzers are offset by 45 degrees about the boresight. Each telescope measures Stokes Q and V (modulated) and I (unmodulated) in its frame using a cryogenic Variable-delay Polarization Modulator (VPM). The two telescopes together yield instantaneous sensitivity to Stokes Q and U in the instrument frame. Modulation between Stokes Q and V eliminates Q to U leakage, and Stokes V is expected to be negligible at the observed angular scales and frequencies. The VPM is the first optical element. This allows the detectors to lock in on the modulation and reject instrumental polarization and 1/f drifts of the data, facilitating recovery of large angular scales. Silicon lenses follow the reflective optics and are cut with a broadband AR metamaterial layer. The band-defining filter stack, VPM throw, and some of the AR coatings will be changed between flights to survey one of each of the four bands per flight. Use of a common detector array in all frequencies is facilitated through a backshort spacing that is optimized for science bands but is less efficient at 350 GHz and 600 GHz, where loading is higher. Additionally the fractional bandwidth is reduced, to keep detector loading ~0.5 pW. PIPER's first flight will be from the Northern hemisphere, and overlap with the CLASS survey at lower frequencies. I will describe the current status of the PIPER instrument.

9914-57, Session 11

The Cosmology Large Angular Scale Surveyor (CLASS)

Kathleen Harrington, Aamir Ali, Johns Hopkins Univ. (United States); Mandana Amiri, The Univ. of British Columbia (Canada); John A. Appel, Charles L. Bennett, Johns Hopkins Univ. (United States); Matthew Berkeley, NASA Goddard Space Flight Ctr. (United States); Fletcher Boone, Univ. of Michigan (United States); David T. Chuss, Villanova Univ. (United States); Felipe A. Colazo, NASA Goddard Space Flight Ctr. (United States); Sumit Dahal, Johns Hopkins Univ. (United States); Kevin L. Denis, NASA Goddard Space Flight Ctr. (United States); Rolando Dünner Planella, Pontificia Univ. Católica de Chile (Chile); Joseph R. Eimer, Thomas Essinger-Hileman, Johns Hopkins Univ. (United States); Pedro Fluxa, Pontificia Univ. Católica de Chile (Chile); Dominik Gothe, Johns Hopkins Univ. (United States); Gene C. Hilton, National Institute of Standards and Technology (United States); Mark Halpern, The Univ. of British Columbia (Canada); Gary F. Hinshaw, The Univ. of British Columbia (Canada); Johannes Hubmayr, National Institute of Standards and Technology (United States); Jeffrey Iuliano, David Larson, Tobias A. Marriage, Johns Hopkins Univ. (United States); Jeff J. McMahon, Univ. of Michigan (United States); Nathan J. Miller, Johns Hopkins Univ. (United States); Samuel H. (United States); Zhilei Xu, Johns Hopkins Univ. (United States); Lingzhen Zeng, Harvard-Smithsonian Ctr. for Astrophysics (United States)

The Cosmology Large Angular Scale Surveyor (CLASS) is a four telescope array designed to detect and characterize relic primordial gravitational waves from inflation and the optical depth to reionization through a measurement of the polarized cosmic microwave background (CMB) on large angular scales. The frequency bands of the CLASS telescopes, one at 38 GHz, two at 93 GHz, and one dichroic system at 145/217 GHz, are chosen to avoid regions of high atmospheric emission and span the minimum of the polarized galactic foregrounds: synchrotron emission at lower frequencies and polarized dust emission and higher frequencies. Low noise transition edge sensor detectors and a rapid front-end polarization modulator provide a unique level of high sensitivity, stability, and control of systematics. The CLASS site, at high altitude in the Chilean Atacama

desert, allows for daily mapping of up to 70% of the sky and enables the observation of the largest angular scales. Using this combination of a broad frequency range, large sky coverage, control over systematics, and high sensitivity, CLASS will observe the reionization and recombination peaks of the CMB E- and B-mode power spectra. CLASS will make a cosmic variance limited measurement of the optical depth to reionization and will measure or place upper limits on the tensor-to-scalar ratio, r, down to a level of 0.01 (95% C.L.).

9914-58, Session 12

Development of far-IR sensors based on superconducting MgB2

Boris Karasik, Daniel Cunnane, Jet Propulsion Lab. (United States); Narendra Acharya, Matthaeus Wolak, Teng Tan, Temple Univ. (United States); Jonathan H. Kawamura, Jet Propulsion Lab. (United States); Xiaoxing Xi, Temple Univ. (United States)

Terahertz range is rich with molecular lines important for understanding of the chemistry associated with evolution of star-forming molecular clouds. High-resolution spectroscopy of such clouds greatly relies on hot-electron superconducting bolometric (HEB) mixers. Current state-of-the-art receivers use mixer devices made from ultrathin (~ 3-5 nm) films of NbN with critical temperature ~ 9-11 K. Such mixers have been deployed on a number of ground based and suborbital (SOFIA, STO, TELIS) platforms, and have been used in HIFI instrument on the Hershel Space Observatory. Despite its good sensitivity and well-established fabrication process, the NbN HEB mixer suffers from the narrow intermediate frequency (IF) bandwidth ~ 2-4 GHz and is limited to operation at liquid Helium temperature. As an interest in high-resolution spectroscopy of high THz frequency lines (e.g., [HD] 2.68 THz, [OIII] 3.39 & 5.79 THz, [OI] 4.75 THz, [NIII] 5.23 THz, etc.) is growing the need in larger IF bandwidth becomes more pressing.

A possibility to increase both the operating temperature and the IF bandwidth of HEB mixers lies with the use of superconducting MgB2 with critical temperature of 39 K. Realization of a receiver operating at 20 K would allow for the use of relatively low-cost mechanical cryocooling in space. This would be a big impact on the cost reduction and lifetime increase of an associated space mission.

Recently, thin films of this superconductor have become achievable, which opened a door for development of various detectors. Our current work focuses on the development of practical HEB mixers using ultrathin (8-20 nm) MgB2 films. We prepare films using the Hybrid Physical-Chemical Vapor Deposition (HPCVD) process in combination with ion mill yielding high-quality ultrathin films with critical temperature ~ 37-39 K on THz-transparent SiC substrates. The combination of small film thickness, large sound velocity, high acoustic phonon transparency at the interface with the substrate, and short electron-phonon relaxation time results in an IF bandwidth ≈ 9 GHz, which has been measured in 15-nm thick HEB devices. Even larger IF bandwidth is expected in thinner (5-10 nm) films, which have been already achieved. Micron- and submicron-sized spiral-antenna coupled HEB mixers have been fabricated in order to minimize the local oscillator (LO) power requirements. Preliminary measurements yielded a double-sideband noise temperature of ≈ 2,500 K weakly dependent on temperature between 4 and 20 K. This indicates that, indeed, mixer operation may be possible using a cryogen-free cooling system. An on-going material development work focuses on achieving disordered films (but still with high critical temperature) where the intrinsic quantum efficiency is expected to be high. An additional benefit of the high resistivity will be better rf and IF impedance match of HEB devices.

We will report on experimental results to date as well as on the progress in development of a cryocooler based 4.7 THz HEB receiver using a Quantum Cascade Laser (QCL) as an LO source. We will also discuss other potential applications of MgB2 films to far-IR sensors. Promising devices include tunnel-junction mixers, kinetic inductance detectors and parametric amplifiers, and flux-flow oscillators.

9914-59, Session 12

SHASTA: a high resolution 2 THz spectroscopic imaging array 3rd generation instrument for SOFIA

Paul F. Goldsmith, Jet Propulsion Lab. (United States)

The Stratospheric Heterodyne Array System for Terahertz Astronomy (SHASTA) is a 3rd generation facility instrument for the SOFIA airborne observatory, which has been selected by NASA for an Instrument Concept Study. SHASTA will have 64 heterodyne pixels with HEB mixers cooled to 4K. Each pixel will have an individually adjustable local oscillator (LO) power to yield minimum noise temperature. The LO is based on frequency multiplication in a sequence of cascaded frequency doublers and triplers derived from a common reference oscillator. This technology is derived from successful JPL work on the Herschel HIFI instrument and has been extended for use in the submillimeter receiver of the NASA APRA balloon project, STO2 (C. Walker, Univ. of Arizona, PI).

SHASTA's 1.9-2.1 THz frequency range includes two of the most important species in the interstellar medium – ionized carbon (C+) and atomic oxygen (OI) via their fine structure lines. These will undoubtedly continue to be the targets of large mapping projects for which SOFIA's 16" angular resolution will be particularly valuable. SHASTA will also be able to observe highly-excited transitions of CO, other molecules including CH, and the potentially very interesting molecular ion HeH+. SHASTA's sensitivity and pixel count will enable mapping clouds in the Milky Way and nearby galaxies dramatically more rapidly than is now possible. Previous work with Herschel/HIFI and SOFIA GREAT show that studying C+ and other fine structure lines with high velocity resolution gives critical information about the source's location in the Milky Way and the possible effect of absorption by line of sight clouds, in addition to detailed information about the structure of the source itself. SHASTA's rapid mapping capability combined with high spectral resolution will open up important new capability of understanding how molecular clouds are formed and evolve from the more diffuse interstellar medium, and how this regulates star formation.

The array pixels will be in a close-packed 8x8 square configuration, permitting high efficiency coupling through the SOFIA optics. The local oscillator signals are produced in an 8x8 array which ends with feedhorns. The 64 LO beams are then coupled into the 64 horn/mixer pixels via a Gaussian Beam telescope and dichroic beam splitter. The frontend is cooled by a closed-cycle cooler as already proven in use by the upGREAT instrument on SOFIA. The first IF stages are cooled, and after further amplification, the signal for each pixel is sent to a digital spectrometer based on a CMOS ASCI VLSI chip being developed by JPL and UCLA. The spectrometer will cover 3 GHz bandwidth, corresponding to 480 km/s at the 1900.5 GHz frequency of C+. This is adequate for covering even the Galactic Center and nearby galaxies in a single integration. The spectrometer will have 8K spectral channels, giving a resolution of 375 kHz (0.06 km/s), more than sufficiently fine to resolve kinematic structure in the regions studied. In addition to the region from 1.9 to 2.1 THz covered in its initial configuration, SHASTA is designed to readily allow upgrades to shorter wavelengths.

9914-60, Session 12

MgB2 hot electron bolometer mixers for THz heterodyne instruments

Sergey Cherednichenko, Stella Bevilacqua, Evgenii Novoselov, Chalmers Univ. of Technology (Sweden)

NbN Hot Electron Bolometer (HEB) mixers have been used for many ground, airborne, and space borne high spectral resolution instruments from below 1THz up to 5THz. With a noise temperature of below 1000K and a very low Local Oscillator (LO) power requirements (<1μW), those devices have been the best choice available. Due to bolometric nature of

HEB mixers, their gain bandwidth (as much as the noise bandwidth) is limited, and in the best case it ranges to maximum 3GHz (or 5GHz of the noise bandwidth). Such a limitation becomes very critical when either a broadband line survey is performed, or Doppler broadened lines are observed from extra galactic sources. Another limiting factor for NbN HEBs (as much as for e.g. SIS mixers) is the requirement of 4K cooling, which is mostly accomplished with LHe or with rather bulky and power consuming cryo-coolers.

Both the problem of the limited gain bandwidth and the necessity of 4K cooling can be resolved with HEB mixers made from MgB2 films where a superconducting critical temperature up to 39K is feasible. Recently, we have shown that a gain bandwidth of up to 10GHz can be reached with thin MgB2 films. Furthermore, a noise temperature of <1000K can be obtained at a 1.6 THz LO frequency. Furthermore, we demonstrated that at 14K the mixer noise temperature is <2000K which can be further improved with the proper optimization of MgB2 films.

In our presentation we will also discuss the latest results of the MgB2 HEB mixer technology, as well as on the mixer sensitivity at temperatures from 10K to 25K.

9914-61, Session 12

A 2 THz Schottky solid-state heterodyne receiver for atmospheric studies

Jeanne Treuttel, Jet Propulsion Lab. (United States) and Observatoire de Paris (France); Erich T. Schlecht, Jose Siles, Robert H. Lin, Jet Propulsion Lab. (United States); Bertrand Thomas, Radiometer Physics GmbH (Germany); Jeng-Hwa Yee, Johns Hopkins Univ. Applied Physics Lab., LLC (United States); Imran Mehdi, Jet Propulsion Lab. (United States)

Both interstellar medium and planetary atmosphere are incredibly rich in molecular species with spectral rotational and vibrational signatures that lie in the 1-10 THz frequency range. The neutral atomic oxygen (OI) emissions at 2.06 THz (145.525 um) and 4.7 THz (63.184 um) are the two brightest (in terms of photon flux) emission lines in the terrestrial thermosphere and have been observed from balloon, sounding rocket and orbital platforms [1].

We will present laboratory demonstration of a heterodyne receiver for the 2.06 THz OI line, similar to our previous 1.2 THz receiver [2]. This measurement takes advantage of a Schottky diode based all solid state receiver front-end that can be deployed on a CubeSat or similar miniature platform, and will be the first 2THz all solid-state heterodyne receiver measurement at 150 K ambient temperature.

The receiver consists of a mixer pumped by a local oscillator (LO) source whose fundamental source is a fixed-frequency DRO at 38 GHz. Its output is split and amplified in two separate amplifiers, each giving over a watt of power to pump four 114 GHz triplers through two waveguide power dividers. These in turn pump four 343 GHz triplers whose output is combined into a single 40 mW signal to pump the final 1.03 THz tripler. This provides the LO signal for the subharmonically-pumped 2.06 THz mixer. The mixer used in the experiment was originally designed for the 1.8 to 2.0 THz band [3].

The design was modified to extend the frequency coverage to 2.06 THz, minimizing noise and conversion loss over a reduced 20 GHz band since the system is required to cover only the narrow OI line but with the best performance achievable. The predicted output power of the LO chain is between 1 and 3 mW at 1.03 THz at 150 K, depending strongly on the power available from the combined 343 GHz pump chains. Harmonic balance and mixer temperature simulations indicate the mixer effective DSB temperature should be about 10,000 K.

9914-62, Session 13

CryoPAF4: a cryogenic phased array feed

Lisa S. Locke, Doug W. Henke, Frank Nianhua Jiang, Gordon Lacy, Ramunas Wierzbicki, Gary J. Hovey, NRC - Herzberg Astronomy & Astrophysics (Canada)

For earth- and space-based astronomical telescopes, the microwave (1-10 GHz) and millimeter-wave (10-300 GHz) frequency ranges contribute a wealth of information inaccessible at optical frequencies. There is a drive for wider bandwidths and larger fields of view without compromising the stringent sensitivity required to detect farther and fainter sources, pushing antenna and receiver technology to extreme limits.

Currently microwave/millimeter telescopes with mature cryogenic single pixel receivers have been upgraded to multi-pixel receivers and phased array feeds (PAFs) to increase effective field of view and in turn, imaging speeds. The Square Kilometer Array (SKA) has fostered early research and development of room temperature L-band (1-2 GHz) PAFs at DRAO (Canada), ASKAP (Australia) and at ASTRON (Netherlands) with system temperatures in the 40-70K range. However to attain superlative performance as compared to a single pixel feed, cryogenically cooling part or all of the front end is essential to match the high level of sensitivity possible with large reflector diameters and very low system temperatures. Cryogenic PAF research at L-band with AOPAF (Cornell U.-Arecibo) and NRAO/BYU's warm dipole and cooled LNA system have achieved 36K and 45K system temperatures respectively.

We propose a 2.8 – 5.18 GHz dual polarization coherent PAF receiver with cryogenically cooled antennas and amplifiers, to demonstrate the feasibility of sub-20K system temperatures to compete similar noise levels of single pixel receivers but at a higher frequency than current cryogenic PAFs. The resulting increase in field of view and survey speed is a factor of ~5 compared to a single pixel receiver through the production of multiple farfield beams in the beamformer.

The PAF receiver architecture is composed of a cryostat with a 50 cm diameter composite laminate radome window/aperture. Internal to the cryostat are layers of RF transparent heat shields reflecting the infrared radiation through the radome, attenuating the thermal transfer from ambient onto the large metal antenna array elements. This antenna array is composed of 140 dual-linear Vivaldi blades configured on a square grid. The 3.5K noise temperature amplifiers and the Vivaldi blades and feeds are all cooled to 16K. Concentric thin metal cylinders at 16K, 70K and 300K provide necessary thermal insulation to the low noise amplifiers and coaxial cables leading out of the dewar. External to the cryostat for each of the 96 active receiver chains is a bandpass filter followed by a 35 dB amplifier and a digital beamformer performing direct digital 8-bit sampling, 500 MHz instantaneous frequency band selection, time-domain beamforming and array covariance matrix calculation. The 96 input RF signals form 18 dual-polarization beams; 36 in total. The expected total system temperature is 18.5K.

Planned tests on DVA-1, an offset Gregorian 15 m dual-reflector telescope located at DRAO Penticton. The half opening angle at the focus to secondary is 55 degrees with a -16 dB feed edge taper. Physical and geometrical optics modelling analysis of the focal plane array will be shown including focal plane beam placement and resulting farfield beams, overlap, and aberrations off axis.

9914-63, Session 13

Progress on SuperSpec: a broadband on-chip millimeter-wave spectrometer

Steven Hailey-Dunsheath, California Institute of Technology (United States); Erik D. Shirokoff, The Univ. of Chicago (United States); Peter S. Barry, Cardiff Univ. (United Kingdom); C. Matt Bradford, Jet Propulsion Lab. (United States); Scott C. Chapman, Dalhousie Univ. (Canada); George Che, Arizona State Univ. (United States); Jason Glenn, Univ. of Colorado Boulder (United States); Matthew I. Hollister, California Institute of Technology (United States); Attila Kovacs, California Institute of Technology (United States) and Univ. of Minnesota (United States); Henry G. Leduc, Jet Propulsion Lab. (United States); Philip D. Mauskopf, Arizona State Univ. (United States); Christopher M. McKenney, California Institute of Technology (United States); Roger C. O'Brient, Jet Propulsion Lab. (United States); Stephen Padin, The Univ. of Chicago (United States); Theodore J. Reck, Jet Propulsion Lab. (United States); Corwin Shiu, California Institute of Technology (United States); Carole E. Tucker, Cardiff Univ. (United Kingdom); Jordan D. Wheeler, Univ. of Colorado Boulder (United States); Ross Williamson, Jet Propulsion Lab. (United States); Jonas Zmuidzinas, California Institute of Technology (United States)

SuperSpec is a novel on-chip spectrometer we are developing for moderate resolution (R ~ 100 - 500), large bandwidth (~1.65:1) submillimeter and millimeter wavelength astronomy. Its very small size, wide spectral bandwidth, and highly multiplexed detector readout will enable construction of powerful multi-beam spectrometers for observations of high-redshift galaxies. SuperSpec will be used to search for redshifted atomic and molecular line emission, particularly that in the [CII] 158 micron fine-structure transition, which is observable from z = 5 - 9 in the 250 GHz telluric window. SuperSpec will be a pathfinder instrument for future multi-object spectrometers, which will use the [CII] and other atomic lines to rapidly measure the redshifts and ISM properties of large samples of distant galaxies.

SuperSpec employs a filterbank architecture, constructed by lithographically patterning superconducting transmission line resonators. Incoming radiation propagates down a feedline past a series of tuned half-wave resonators, which are coupled to the feedline and to power detectors with adjustable coupling strengths that determine the net filter quality factor Q, which is equal to the spectrometer resolving power R. The transmission line for both the feedline and the resonator are microstrip, consisting of superconducting Nb traces on Si substrate beneath an amorphous silicon-nitride dielectric and Nb ground plane. The signal power admitted by each resonator is dissipated in a segment of lossy meander formed from titanium nitride (TiN), breaking Cooper pairs for radiation at frequencies above the superconducting gap in the TiN film. The TiN meander is connected in parallel to an interdigitated capacitor (IDC) made from the same TiN material to form a lumped element kinetic inductance detector (KID). The KIDs operate with resonant frequencies in the 100 - 200 MHz range, and are each coupled to a coplanar waveguide readout feedline (CPW) by a small coupling capacitor.

We will present the full characterization of prototype devices operating at 180 - 280 GHz. These devices couple to free space radiation with a double-slot antenna and a hyperhemispherical lens. We use a swept coherent source along with total power detectors to measure the intrinsic spectral response and on-chip efficiency of our spectral channels. Our most recent devices include low volume KIDs with an improved responsivity, and are photon-noise limited at low optical loading. The detector NEPs are better than 10^-17 W/root(Hz), sufficient for background limited performance at R = 100 on a ground-based telescope. We employ a new method for measuring photon noise using both coherent and thermal sources of radiation to cleanly separate the contributions of shot and wave noise. This allows an estimate of the detector responsivity and the end-to-end system optical efficiency. We will detail our on-going efforts to maximize the system efficiency, and develop an on-sky demonstrator.

9914-64, Session 13

Proof of concept demonstration for coherent beam pattern measurements of KID detectors

Kristina Davis, Arizona State Univ. (United States); Andrey M. Baryshev, Willem Jellema, Stephen J. C. Yates, SRON Netherlands Institute for Space Research (Netherlands)

We present the preliminary results from the first coherent beam pattern measurement of Kinetic Inductance Detectors (KIDs). KIDs are inherently direct detectors and cannot record phase information which has previously made coherent measurements with these detectors impossible. Our testing strategy utilizes a heterodyne technique where the source signal to the LO and RF sources are split and one channel from each source is combined to create a reference signal for a data acquisition system. The reference signal triggers the start of a time series measurement of the beat frequency signal as measured by the detector. The key requirement is that the time-series record always begins at a positive zero crossing of the reference signal. Any phase offset must therefore come from the location of the scanned source within the beam of the receiver. We have tested this technique on a single pixel of an Apex Microwave KID (AMKID) test array operating at 340 GHz. The results demonstrate that the technique described here accurately measures phase and amplitude of a KID pixel. This technique will allow near-field coherent beam pattern measurements to be performed on KID detectors, which has advantages in standing wave reduction, spatial filtering, and side lobe characterization. Importantly, coherent measurements allow full characterization of astronomical instruments including their optical systems, for which a far-field measurement may be inconveniently far from the receiver to be tested in-situ.

9914-65, Session 13

A far-infrared spatial/spectral Fourier interferometry laboratory-based test bed instrument

Locke D. Spencer, David A. Naylor, Jeremy P. Scott, Vince Weiler, Rodderick MacCrimmon, Univ. of Lethbridge (Canada); Peter A. R. Ade, Cardiff Univ. (United Kingdom)

With the recent completion of the European Space Agency Herschel and Planck missions, as demonstrated by main post-operations support ending in 2016, there is anticipation of the next Far-Infrared space missions in both Europe, North America, Japan, and throughout the world. While FIR astrophysics was significantly advanced through the observations of Herschel and Planck, with more advances coming as the data is further analyzed, there exist two fundamental limitations in the related FIR observing technology available to present-generation FIR astrophysical instruments: observation sensitivity and spatial resolution.

Observation sensitivity is advanced through improvements in FIR detector technology as well as cooled instrument and telescope optics to reduce the deleterious effects of thermal noise on the recorded data. Although Herschel housed the largest single-dish primary mirror available given the design constraints, it's spatial resolution is similar to that of Galileo's telescope 400 years ago, albeit at much longer wavelengths.

Improvements in the spatial resolution available to astrophysical observations must come from either significantly larger telescope optics, or through the use of interferometric techniques simulating large apertures. Both of these techniques are difficult and costly on a space-based platform, and are not presently found within the next-generation of FIR instruments and observatories on the funded horizon.

We describe the current status, including preliminary design, characterization efforts, and recent progress, in the development of a spatial/spectral double Fourier laboratory-based interferometer testbed instrument within the Astronomical Instrumentation Group (AIG) laboratories at the University of Lethbridge, Canada (UL). This development is supported by Canada Research Chairs (CRC), Canada Foundation for Innovation (CFI), and the National Science and Engineering Research Council of Canada (NSERC) grants. With motivation to further progress in areas including the development of spatial/spectral interferometry observation, data processing, characterization, and analysis techniques in the Far-Infrared (FIR) region of the electromagnetic spectrum, this instrument will provide laboratory demonstration of spatial-spectral interferometry.

Component characterization efforts include the validation of the testbed instrument subsystems such as the translation stage metrology calibration, optical component performance, and detector system characteristics. Theoretical design simulation results are compared against laboratory measurements. Expected system performance characteristics are provided from both a theoretical/simulation, and experimental perspective. The astronomy long range plans of several astronomy communities have identified both cooled apertures and interferometry as two FIR roadmap priorities. This instrumentation development program is in support of these international FIR priorities.

9914-66, Session 13

Laboratory demonstration of first-generation μ-Spec: a superconducting photonic spectrometer for far-infrared astrophysics

Omid Noroozian, NASA Goddard Space Flight Ctr. (United States) and Univ. of Maryland (United States); Emilly M. Barrentine, Ari Brown, Giuseppe Cataldo, Negar Ehsan, Wen-Ting Hsieh, Thomas R. Stevenson, Edward J. Wollack, Kongpop U-Yen, Samuel H. Moseley, NASA Goddard Space Flight Ctr. (United States)

We are developing a highly integrated photonic spectrometer-on-chip called μ-Spec for application on space or balloon telescopes for submillimeter/THz astrophysics. All components including the detectors and optical dispersion elements are integrated into a single photonic chip that can be mass produced, and utilize a highly confined microstrip architecture that provides excellent immunity to stray radiation. We use low-loss superconducting niobium transmission lines with a 0.45 ?m single-crystal silicon dielectric to produce a synthetic grating with spectral resolution and efficiency ultimately only limited by the intrinsic loss of crystalline Si at cryogenic temperatures. The photon detectors are half-wave resonator microstrip-line KIDs with aluminum top and Nb ground plane on 0.45 μm Si. We have built laboratory demonstration versions of μ-Spec in the 400—600 GHz band with 48 optical channels that operate with resolution R=64.

We report on the optical measurements of the spectrometer channels, and on characterization of the KIDs. We successfully demonstrate end-to-end optical performance that matches the expected resolution of 64, achieve channel yield of 47 out of 48, and obtain uniform channel response. Our new devices demonstrate high contrast in overlapping adjacent channels with zero out-of-band response in the 100-800 GHz range. On the materials front for our 100 nm aluminum detectors fabricated on separate test structures we obtain high quality factor resonators with Qi ~ 0.5x10^6 (at single photon readout powers) and Qi > 2x10^6 (for medium level powers), and measure quasi-particle lifetime of order 1.0 ms. We describe measurement results and challenges to integrate these high-quality films into the full μ-Spec fabrication process, which is necessary for producing ultra-sensitive MKIDs for a space or balloon instrument.

9914-111, Session 13

Multichroic seashell and cross-slot antennas with cold electron bolometers for future CMB polarization missions

Leonid S. Kuzmin, Chalmers Univ. of Technology (Sweden); Alexander Chiginev, Nizhny Novgorod State Technical Univ. (Russian Federation) and Institute of Applied Physics (Russian Federation); Anna Gordeeva, Nizhny Novgorod State Technical Univ. (Russian Federation); Alexander Sobolev, Institute of Radio Engineering and Electronics (Russian Federation); Andrey Pankratov, Nizhny Novgorod State Technical Univ. (Russian Federation) and Institute of Applied Physics (Russian Federation)

A novel type of the “seashell” multichroic antenna is proposed for cosmology space missions [1]. This polarized slot antenna is arranged in the form of a seashell with individual slots for each frequency and each polarization. Such an arrangement gives unique opportunity for independent adjusting parameters of antenna. For each frequency band the seashell antenna contains two pairs of orthogonal slots for each polarization connected by microstrip lines (MSLs) with a bolometer in the middle for in-phase operation.

The seashell antenna gives a unique opportunity to select needed bandwidth using two options. The first option is frequency selection by Resonant Cold-Electron Bolometer (RCEB) [2] with an internal nanofilter organized by a kinetic inductance of the NbN superconducting nanostrip and a capacitance of the nanoscale SIN (Superconductor-Insulator-Normal) tunnel junction. The second option is frequency selection by resonance properties of slots with MSLs and resistive Cold-Electron Bolometer (CEB) [3]. These resonance properties were properly developed when we squeezed Lambda/2-slots to smaller size by lumped capacitances for better beam shape. Matching with MSL and bolometer is organized by choosing proper position of a feeding stub relatively to the end of the slot. One of these options of frequency selection or combination of two of them can be chosen in dependence on tasks and requirements on bandwidth selection.

A Cross-Slot Antennas with RCEBs for two frequencies in one pixel is another candidate for multichroic systems. We selected a single cross-slot antenna with two RCEBs in each slot for dual frequencies of 75 and 105 GHz. The antennais designed for coupling with a Si lens in one pixel with two orthogonal polarisations. CEBs with resonance circuits are placed in the center of slots. Preliminary frequency selection in each pixel is done by antenna and final selection is realized by RCEB.

The RCEB can be effectively used to create multiband elements that is an actual task in radioastronomy due to benefits that come from their ability to use co-located data, and problems with the dramatic increase of size of the focal plane.

Development of this system is done in scope of the ESA project on creating new concepts of multifrequency pixels for a COrE space mission [3]. These multifrequency systems could be also effectively used in new projects for detecting the primordial gravitational wave background. In particular, some uncertainty in interpretation of BICEP2 results on observation of gravitational waves [4] has been just due to absence of measurements at two frequencies, 150 GHz and 95 GHz, planned originally for this experiment.

Conference 9915: High Energy, Optical, and Infrared Detectors for Astronomy VII

Sunday - Wednesday 26–29 June 2016

Part of Proceedings of SPIE Vol. 9915 High Energy, Optical, and Infrared Detectors for Astronomy VII

9915-1, Session 1

The status of European Space Agency supported detector developments

Nick Nelms, Kyriaki Minoglou, Alessandra Ciapponi, Thibaut Prod'homme, Roland Meynart, Yves Levillain, Ludovic Duvet, Pierre-Elie Crouzet, European Space Research and Technology Ctr. (Netherlands)

The European Space Agency has a very strong interest in the performance enhancement of detector arrays for future scientific and astronomy missions. Improvements in Visible and Infrared wavelengths are of particular interest and the Agency undertakes a programme of continuous development aimed at enhancing the capability of detectors in these wavebands. This paper presents the status of these detector technology development activities.

Selex infrared sensors for scientific applications: present and future

Ian M. Baker, Chris D. Maxey, Les G. Hipwood, Ray P. Davis, Keith Barnes, Selex-ES Ltd. (United Kingdom)

Many branches of science require infrared detectors sensitive to individual photons. Applications range from low background astronomy to high speed imaging. Selex-ES Ltd in Southampton, UK, has been developing HgCdTe avalanche photodiode (APD) sensors for astronomy in collaboration with ESO since 2008 and more recently the University of Hawaii. The devices utilise MOVPE grown on low-cost GaAs substrates and in combination with a mesa device structure achieve very low dark current and near-ideal MTF. MOVPE provides the ability to grow complex HgCdTe heterostructures which have proved crucial to suppress breakdown currents and allow high avalanche gain in low background situations. A custom device called Saphira (320x256/24µm) has been developed for wavefront sensors, interferometry and transient event imaging. This device has achieved read noise as low as 0.26 electrons rms and single photon imaging with avalanche gains up to x100. It is used in the ESO Gravity program for adaptive optics and fringe tracking and has been successfully trialled on the 3m NASA IRTF, 8.2m Subaru and 60 inch Mt Palomar for lucky imaging and wavefront sensing. In future the technology offers much shorter observation times for read-noise limited instruments, particularly spectroscopy. The paper will describe the MOVPE APD technology and current performance achievements. It will also summarise the telescope deployments and laboratory measurements in the astronomy community. Plans for a larger format version of Saphira for 30m class telescope era will be outlined.

9915-5, Session 2

Technological improvements on the OGRE x-ray camera system

Matthew Lewis, Neil J. Murray, Andrew D. Holland, Daniel P. Weatherill, The Open Univ. (United Kingdom); James H. Tutt, Randall L. McEntaffer, Casey T. DeRoo, Ted B. Schultz, The Univ. of Iowa (United States); Karen Holland, XCAM Ltd. (United Kingdom)

At present half of the universes baryonic matter is missing. Some theories believe that this could be residing in intergalactic filaments which emit strongly in the X-ray regime. Present space based technology is limited when it comes to imaging at these wavelengths and so new techniques are required. The Off-Plane Grating Rocket Experiment (OGRE) aims to improve the technology readiness levels of three components by using them in a sounding rocket, hopefully encouraging their use in future missions and allowing such theories to be tested. These three components consist of a newly manufactured off-plane X-ray diffraction grating, a Wolter Type 1 mirror made using single crystal silicon, and the use of EM-CCDs to capture soft X-rays. Each of these components have been previously reviewed with OGRE being the first project to utilise them in a space mission by collecting data from the binary star system Capella, a well-known X-ray source. This paper focuses on the EM-CCDs that will be used and their optimisation with a camera purposely designed for OGRE. Tests were carried out on a prototype to determine the optimal operating voltages and clock sequences for the desired operating environment allowing efficient detections of X-rays when operated at low temperatures in a vacuum. Further tests which will need to be carried out are discussed with an emphasis on differences in the operating conditions due to the camera being mounted into a sub-orbital rocket.

9915-6, Session 2

The faint intergalactic-medium red-shifted emission balloon: future UV observations with EMCCDs

Gillian Kyne, Erika T. Hamden, Nicole R. Lingner, Patrick Morrissey, D. Christopher Martin, California Institute of Technology (United States)

We present the latest developments in our joint NASA/CNEThis project is a balloon-borne UV multi-object spectrograph, which has been designed to detect faint emission from the circumgalactic medium (CGM) around low redshift galaxies. One major change from FIREBall-1 has been the use of a delta-doped Electron Multiplying CCD (EMCCD). EMCCDs can be used in photon-counting (PC) mode to achieve extremely low readout

noise (< 1e^{-}). Our testing initially focused on reducing clock induced charge (CIC) through wave shaping and well depth optimisation with the CCD Controller for Counting Photons (CCCP). This optimisation also includes methods for reducing dark current, via cooling and substrate voltage adjustment. We will present some of our dark current results from laboratory testing. Furthermore, we will briefly present some initial results from our first set of on-sky observations using our EMCCD on the 200 inch telescope at Palomar, using the Palomar Cosmic Web Imager (PCWI) with a delta-doped EMCCD.

9915-7, Session 2

The effect of proton radiation on the EMCCD for a low Earth orbit satellite mission

Kenneth W. Smith, COM DEV Canada (Canada); Olivier Daigle, Nüvü Caméras Inc. (Canada); Alan D. Scott, Louis Piche, Danya Hudson, COM DEV Canada (Canada)

We report on the proton radiation effects on a 1k x 1k ev2 EMCCD utilized in the Nüvü EM N2 1024 camera. Radiation testing was performed at the TRIUMF Proton Irradiation Facility in Canada, where the e2v CCD201-20 EMCCD received a 105 MeV proton fluence up to 5.16E+09 protons/cm2, emulating a 10 year maximum mission in low earth orbit with nominal shielding that would be expected from a small or microsatellite. The primary space-based application is for space situational awareness (SSA), where a small telescope images faint orbiting RSOs (resident space objects) on the EMCCD, resulting in faint streaks at the photon level of signal in the images. Of particular concern is the effect of proton radiation on low level CTE, where very low level signals could be severely impaired if not lost. Although other groups have reported on the characteristics of irradiated EMCCDs, their CTE results are not portable to this application. To understand the real impact of proton irradiation the device must be tested under realistic operating conditions with representative backgrounds, clock periods, and signal levels. Testing was performed both in the laboratory and under a night sky on the ground in order to emulate a complex star background environment containing RSOs. The degradation is presented and mitigation techniques are proposed. As compared to conventional CCDs, the EMCCD with high gain allows faint and moving RSOs to be detected with a relatively small telescope aperture, at improved signal to noise ratio at high frame rates. This allows the satellite platform to take sharp images immediately upon slewing to the target without the need for complex and relatively slow attitude stabilization systems.

9915-8, Session 2

Mitigating radiation damage in EMCCDs for the WFIRST coronagraph instrument: improving charge transfer efficiency

Leon K. Harding, Richard T. Demers, Bijan Nemati, Michael E. Hoenk, Max Bryk, Michael Cherng, Pavani Peddada, Jet Propulsion Lab. (United States); Nathan L. Bush, David J. Hall, Neil J. Murray, Jason P. D. Gow, Ross Burgon, Andrew D. Holland, The Open Univ. (United Kingdom)

We have established a test laboratory at JPL where we have fully characterized the CCD201-20 EMCCD sensor, which has been base-lined for both of the WFIRST coronagraph instrument's (CGI) integral field spectrograph, and imaging sensors. We can report that it meets CGI performance requirements at beginning of life. However, the difficult challenges of the WFIRST L2 space environment must also be considered, specifically its effect on the charge transfer efficiency (CTE) of the EMCCD due to radiation damage. In order to investigate these affects, we designed and completed a two-phase radiation study of a number of CCD201-20 sensors, which were irradiated at CGI-specific cryogenic temperatures. Read noise, multiplication gain, dark current, clock induced charge and CTE were assessed, pre- and post-irradiation. Since particles such as protons, electrons and cosmic rays can cause severe degradation of such performance, techniques designed to identify and mitigate this damage must therefore be developed.

Here we present the latest results designed to improve the CTE of radiation-damaged CCD201-20 sensors from the above radiation study – specifically, displacement damage from protons and the effects of electron trapping. Since the CCD201-20 is a 2-phase device, some challenges exist when attempting to probe a full pixel within the device for the purposes of assessing damage. We outline the strategies that were used and the difficulties that were encountered. Finally, we will discuss the relevant trap species and their properties that are predicted to be present for the WFIRST-CGI devices, based on the clocking rates and timings that are being used. This discussion will include predictions from a detector performance model developed at JPL, where we have assessed how WFIRST-CGI planetary yield predictions are affected by a reduction in CTE.

9915-9, Session 3

MCT APD focal plane arrays for astronomy at CEA-LETI

Johan Rothman, Eric D. de Borniol, CEA-LETI (France); Olivier Gravrand, CEA-LETI (France) and MINATEC (France); Pierre Kern, Philippe Feautrier, Institut de Planétologie et d'Astrophysique de Grenoble (France); Olivier Boulade, CEA-IRFU (France); Jean-Baptiste Le Bouquin, Institut de Planétologie et d'Astrophysique de Grenoble (France)

HgCdTe avalanche photodiodes (MCT APDs) are of first interest for tomorrow astronomy sensing. Indeed, cooled MCT APD focal plane arrays allow for wideband (from IR to visible range) high quantum efficiencies (QE) with high APD gain (larger than 10) at reasonable reverse biases (typically below 10V, depending on cutoff wavelength). Moreover, these features are associated with low excess noise factors (around 1.2) ensuring a low degradation of the information carried out by the incoming photons. The high sensitivity and low noise associated with the APD arrays enables very high frame rates (larger than 1000 frames per second) even for low flux applications which is why they are a strong candidate for the next generation of sensors for adaptive optics (AO) and fringe tracking, in which a small number of photons is detected during short integration times. During the past few years, LETI and Sofradir have been working on such an APD focal plane array in close collaboration with astronomers from IPAG. This work led to the development of the so called RAPID detector which has been used to demonstrate 2kHz frame rates IR imaging with a close to single electron read noise using APD arrays with a cut-off wavelength around 3 μm. In the present communication we will present APD gain and dark current noise characteristics obtained on detector arrays with shorter (2.5 μm) and longer (3.7 μm) cut-off wavelengths, hybridized with the RAPID ROIC and with low noise source follower (SFD) ROIC. The results will be discussed with the perspective of using these detectors in other applications such as very low flux (2.5 μm arrays) and mid IR spectroscopy (3.7 μm arrays).

9915-10, Session 3

Development activities on NIR large format MCT detectors for astrophysics and space science at CEA/SOFRADIR

Olivier Boulade, Vincent Moreau, Patrick Mulet, Pierre

Castelein, Cyril Cervera, Olivier Gravrand, Jean-Paul Zanatta, Commissariat à l'Énergie Atomique (France); Philippe Chorier, Bruno Fièque, SOFRADIR (France)

CEA and SOFRADIR have been manufacturing and characterizing near infrared detectors in the frame of ESA's Near Infrared Large Format Sensor Array roadmap to develop a 2Kx2K large format low flux low noise device for space applications such as astrophysics. These detectors use HgCdTe as the absorbing material and p/n diode technology. The technological developments (photovoltaic technology, readout circuit, ...) are shared between CEA/LETI and SOFRADIR, both in Grenoble, while most of the performances are evaluated at CEA/IRFU in Saclay where a dedicated test facility has been developed, in particular to measure very low dark currents. The paper will present the current status of these developments at the end of ESA's NIRLFSA phase 2. The performances of the latest batch of devices meet or are very close to all the requirements (quantum efficiency, dark current, cross talk, readout noise, ...) even though a glow induced by the ROIC prevents the accurate measurement of the dark current. The current devices are fairly small, 640x512 15µm pixels, and the next phase of activity will target the development of a full size 2Kx2K detector. From the design and development, to the manufacturing and finally the testing, that type of detector requests a high level of mastering. An appropriate manufacturing and process chain compatible with such a size is needed at industrial level and results obtained with CEA technology coupled with Sofradir industrial experience and work on large dimension detector allow French actors to be confident to address this type of future missions.

9915-11, Session 3

Candidate 10 micron HgCdTe arrays for the NEOCam space mission

Craig W. McMurtry, William J. Forrest, Judith L. Pipher, Meghan L. Dorn, Mario S. Cabrera, Univ. of Rochester (United States); Donald L. Lee, James W. Beletic, Chi-Yi A. Chen, Dennis D. Edwall, Teledyne Imaging Sensors (United States); Amanda K. Mainzer, Jet Propulsion Lab. (United States)

The Near Earth Object Camera (NEOCam, Mainzer et al. 2015 is one of five NASA Discovery Class mission experiments selected for Phase A: down-select to one or two experiments will take place late in 2016. NEOCam will survey the sky in search of asteroids and comets, particularly those close to the Earth's orbit. The NEOCam infrared telescope will have two infrared (IR) cameras; one covering 3 to 5 microns, and one covering 6-10 microns. Both IR cameras will use multiple 2Kx2K pixel format HAWAII-2RG arrays with different cutoff wavelength HgCdTe detectors from Teledyne Imaging Sensors. Past development work by the University of Rochester with Teledyne Imaging Sensors and JPL (McMurtry et al. 2013, Dorn et al. 2016) focused upon bringing the 10 micron HgCdTe detector technology up to NASA TRL 6+ while simultaneously meeting the requirements of NEOCam. This work extends that development program to push the format from 1Kx1K to the larger 2Kx2K pixel array. We present results on the first candidate 10 micron cutoff HgCdTe arrays, where we measured the dark current, read noise, total noise, and quantum efficiency.

9915-12, Session 3

13 micron cutoff HgCdTe detector arrays for space- and ground-based astronomy

William J. Forrest, Craig W. McMurtry, Univ. of Rochester (United States); Donald L. Lee, James W. Beletic, Teledyne Imaging Sensors (United States); Mario S. Cabrera, Univ. of Rochester (United States); Chi-Yi A. Chen, Teledyne Imaging Sensors (United States); Meghan L. Dorn, Univ. of Rochester (United States); Dennis D. Edwall, Teledyne Imaging Sensors (United States); Amanda K. Mainzer, Jet Propulsion Lab. (United States); Judith L. Pipher, Univ. of Rochester (United States)

With the recent success of our development of 10 micron HgCdTe infrared (IR) detector arrays (McMurtry et al. 2013, Girard et al. 2014, Dorn et al. 2016), we have used what we learned and extended the cutoff wavelength to 13 microns. These 13 micron HgCdTe detector arrays can operate at higher temperatures than Si:As, e.g. in a properly designed spacecraft with passive cooling, the 13 micron IR array will work well at temperatures around 30K. We present the initial measurements of dark current, noise and quantum efficiency for the first deliveries of 13 micron HgCdTe detector arrays from Teledyne Imaging Sensors. We also discuss our plans to develop 15 micron cutoff HgCdTe detector arrays which would facilitate the detection of the broad CO2 absorption feature in the atmospheres of exoplanets, particularly those in the habitable zone of their host star.

9915-13, Session 3

Performance of science-grade HgCdTe H4RG-15 image sensors

Majid Zandian, Teledyne Imaging Sensors (United States)

We present the test results of science grade substrate-removed 4K?4K HgCdTe H4RG-15 NIR 1.7 micron and SWIR 2.5 microns sensor chip assemblies (SCAs). Teledyne's 4K?4K, 15 ?m pixel infrared array, which was developed for the era of Extremely Large Telescopes, is first being used in new instrumentation on existing telescopes. We report the data on H4RG-15 arrays that have achieved science grade performance: very low dark current (<0.01 e-/pixel/sec), high quantum efficiency (70-80%), single CDS readout noise <18 e-, operability >99%, total crosstalk <2%, well capacity >75 ke-, and power dissipation less than 4 mW. These SCAs are substrate-removed HgCdTe which simultaneously detects visible and infrared light, enabling spectrographs to use a single SCA for Visible-IR sensitivity. Larger focal plane arrays can be constructed by assembling mosaics of individual arrays.

SCA 18315

Array format 4098 x 4096

Read-out integrated circuit (ROIC) H4RG-15

Power Dissipation: 3.05 mW

Cutoff wavelength (50% of peak QE): 1.79 micron

Mean Quantum Efficiency (QE) at 1,500 nm @ 110 K: 76.7 %

Median Dark current @ 0.3 V bias and 110 K: 0.0056 e-/s/pixel

Median Readout Noise, (CDS) at 100 kHz pixel readout rate: 17.8 e-

Well Capacity at 0.3 V bias: 79400 e-

Crosstalk including optical and electrical components: 1.1 %

Operability: 99.1 %

Cluster: 50 or more contiguous inoperable pixels: 0.11%

9915-14, Session 3

Mitigation of image persistence in a HAWAII2-RG by illumination

Brian McLeod, Harvard-Smithsonian Ctr. for Astrophysics (United States); Roger M. Smith, California Institute of Technology (United States)

Residual charge generation, or image persistence, in infrared detectors is a problem that affects many low-light astronomical instruments. The HAWAII-2RG in the MMT & Magellan Infrared Spectrograph shows significant persistence when first powered up. We describe here how we reduce the persistence sensitivity of this detector by exposure to light.

9915-20, Session 3

Random telegraph signal (RTS) and other anomalies in the near-infrared detector systems for the Euclid mission

Ralf Kohley, European Space Astronomy Ctr. (Spain); Rémi Barbier, Bogna Kubik, Institut de Physique Nucléaire de Lyon (France); Jean Claude Clemens, Anne Ealet, Aurélia Secroun, Ctr. de Physique des Particules de Marseille (France); Luca Conversi, European Space Astronomy Ctr. (Spain)

Euclid is an ESA mission to map the geometry of the dark Universe with a planned launch date in 2020. Euclid is optimised for two primary cosmological probes, weak gravitational lensing and baryonic acoustic oscillations. They are implemented through two science instruments on-board Euclid, a visible imager (VIS) and a near-infrared photometer and spectrometer (NISP), which are being developed and build by the Euclid Consortium instrument development teams. The NISP instrument contains a large focal plane assembly of 16 Teledyne HgCdTe H2RG detectors with 2.3 μm cut-off wavelength and SIDECAR readout electronics. The performance of the detector systems is critical to the science return of the mission and extended on-ground tests are being performed for characterisation and calibration purposes. Special attention is given also to effects even on the scale of individual pixels, which are difficult to model and calibrate, together with the identification of any possible impact on science performance.

Based on initial on-ground test results from demonstrator model detector systems, this paper discusses a variety of undesired pixel behaviour including the known effect of random telegraph signal (RTS). Stability aspects of pixel populations under changing operating conditions are addressed as well.

9915-15, Session 4

A study of the silicon divacancy in n n-channel CCDs

Daniel Wood, David J. Hall, Jason P. D. Gow, Neil J. Murray, The Open Univ. (United Kingdom); Peter Turner, e2v technologies plc (United Kingdom); Andrew D. Holland, The Open Univ. (United Kingdom)

The increasingly demanding science goals of off-ground imaging systems require exceptional charge transfer performance from the responsible image sensor, often a charge coupled device (CCD). This places importance on detailed knowledge of radiation induced charge-trapping defects within the silicon lattice of a CCD, which can degrade performance and reduce the useful lifetime of a detector. For a large range of operational temperatures and conditions, the silicon divacancy is expected to be a dominant charge-trapping defect in n-channel CCDs. This paper describes a study of the silicon divacancy in an n-channel e2v CCD 47-10 after proton irradiation to a 10 MeV equivalent fluence of 2.5?10^9 protons.cm-2. The method of trap pumping is used to analyse the defect time constants and trapping efficiencies across a broad temperature range, which are studied in the context of charge-transfer performance measurements.

9915-16, Session 4

Mapping radiation-induced defects in CCDs through space and time

David J. Hall, Nathan L. Bush, Daniel Wood, Neil J. Murray, Jason P. D. Gow, The Open Univ. (United Kingdom); Andrew D. Holland, e2v Ctr. for Electronic Imaging (United Kingdom) and The Open Univ. (United Kingdom)

The Charge Coupled Device (CCD) has long been the detector of choice for many space-based applications. The CCD converts the signal X-rays or visible light into electrons (n-channel devices) or holes (p-channel devices) which are stored in the pixel structure during integration until the subsequent transfer of the charge packets through the device to be read out. The transfer of this signal charge is, however, not a perfect process.

Throughout the lifetime of a space-based mission the detector will be bombarded by high-energy particles and gamma rays. As time progresses, the radiation will damage the detectors, causing the Charge Transfer Efficiency (CTE) to decrease due to the creation of defects or “traps” in the silicon lattice of the detector. The defects create additional energy levels between the valence and conduction band in the silicon of the detector and electrons or holes (for n-channel or p-channel devices respectively) that pass over the defect sites may be trapped. The trapped electrons or holes will later be emitted from the traps, subject to an emission-time constant related to the energy level of the associated defect. The capture and emission of charge from the signal leads a characteristic trailing or “smearing” of images that must be corrected to enable the science goals of a mission to be met.

Over the past few years, great strides have been taken in the development of the pocket-pumping (or strictly-speaking “trap-pumping”) technique. This technique not only allows individual defects (or traps) within the device to be located to the sub-pixel level, but it enables the investigation of the trap parameters such as the emission time constant to new levels of accuracy. Recent publications have shown the power of this technique in characterizing a variety of different defects in both n- and p-channel devices and the potential for use in correction techniques, however, we are now exploring not only the trap locations and properties but the life cycle of these traps through time after irradiation. In orbit, most devices will be operating cold to suppress dark current and the devices are therefore cold whilst undergoing damage from the radiation environment. The mobility of defects varies as a function of temperature such that the mix of defects present following a cryogenic irradiation may vary significantly from that found following a room temperature irradiation or after annealing. It is therefore essential to study the trap formation and migration in orbit-like conditions and over longer timescales.

In this paper we present a selection of the latest methods and results in the trap pumping of n- and p-channel devices and demonstrate how this technique now allows us to map the radiation-induced defects in CCDs through both space and time.

9915-17, Session 4

Radiation effects on Gaia CCDs after 30 months at L2

Cian M. Crowley, European Space Astronomy Ctr. (Spain) and HE Space Operations BV (Netherlands); Ralf Kohley, European Space Astronomy Ctr. (Spain); Asier Abreu Aramburu, European Space Astronomy Ctr. (Spain) and Elecnor Deimos Space S.L.U. (Spain); Thibaut Prod’homme, European Space Research and Technology Ctr. (Netherlands)

Since the launch of ESA’s Gaia satellite in December 2013 the 106 large-format scientific CCDs onboard have been exposed to the

radiation environment at L2. Due to a combination of the high-precision measurement requirements of the mission and the predicted proton fluxes, the effect of non-ionising radiation damage on the detectors was early identified pre-launch as potentially being a limiting factor for end-of-life scientific performance.

A number of Charge Transfer Inefficiency (CTI)-mitigation techniques have been implemented at the hardware level. These include, for example, the periodic injection of lines of charge in order to fill traps and reset the illumination history. Additionally, a supplementary buried channel was included in the pixel architecture in order to funnel small charge packets into a smaller silicon volume to reduce the number of radiation-induced traps encountered at low signal levels. An analysis of the temporal behaviour of the periodic charge injection features (both First Pixel Response and charge trails), in particular, provides a useful means of tracking the evolution of the CTI. As well as mitigation and diagnostic functionality, it also provides a platform for the comparison with similar diagnostics obtained from onground data on irradiated devices.

There is an extensive onground dataset consisting of data obtained from Gaia flight-model and engineering-model CCDs which were irradiated to known proton fluences. These datasets are used to compare the pre-flight CTI predictions to results from in-flight measurements. We also take advantage of the occasional controlled payload heating events (performed for decontamination purposes) to examine the temperature effect on the diagnostics and compare these to model predictions as well as to similarly-obtained onground results.

Despite the fact that earth-directed solar activity has been relatively low since launch, and radiation damage (so far) is less than originally feared, there are clear cases of correlation between earth-directed solar coronal mass ejection events and changes in CTI. We pay particular attention to these events and use onboard cosmic ray detection counters, solar proton data from other satellites and spacecraft spin-phase information to help examine their effects on CTI and disentangle the effects of incident proton energies and differential spacecraft shielding. A comparison of the effects on the two main types of CCD (16 micron thick standard silicon devices and 40 micron thick, high-resistivity red-enhanced devices) on the focal plane is also performed. Radiation-induced CTI in the CCD serial registers and effects of ionising radiation on the operating points of the devices are also addressed.

9915-18, Session 4

Charge transfer efficiency in a p-channel CCD irradiated cryogenically and the impact of room temperature annealing

Jason P. D. Gow, Neil J. Murray, Daniel Wood, The Open Univ. (United Kingdom); David J. Burt, e2v technologies plc (United Kingdom); David J. Hall, Andrew D. Holland, The Open Univ. (United Kingdom)

It is important to understand the impact of the space radiation environment on detector performance, thereby ensuring that the optimal operating conditions are selected for use in flight. The best way to achieve this is by irradiating the device using appropriate mission operating conditions, i.e. holding the device at mission operating temperature with the device powered and clocking. This paper describes the Charge Transfer Efficiency (CTE) measurements made using an e2v technologies p-channel CCD204 irradiated using protons to the 10 MeV equivalent fluence of 1.24?109 protons.cm-2 at 153 K. The device was held at 153 K for a period of 7 days after the irradiation before being allowed up to room temperature where it was held at rest, i.e. unbiased, for twenty six hours to anneal before being cooled back to 153 K for further testing, this was followed by a further one week and three weeks of room temperature annealing each separated by further testing. A comparison to results from a previous room temperature irradiation of an n-channel CCD204 is made using assumptions of a factor of two worse CTE when irradiated under cryogenic conditions which indicate that p-channel CCDs offer improved tolerance to radiation damage when irradiated under cryogenic conditions.

9915-19, Session 4

The effect of radiation-induced traps on the WFIRST coronagraph detectors

Bijan Nemati, Jet Propulsion Lab. (United States); David J. Hall, e2v Ctr. for Electronic Imaging (United Kingdom); Leon K. Harding, Michael E. Hoenk, Richard T. Demers, Jet Propulsion Lab. (United States); Nathan L. Bush, Jesper Skottfelt, e2v Ctr. for Electronic Imaging (United Kingdom)

The WFIRST Coronagraph will the most sensitive instrument ever built for direct imaging and characterization of extra-solar planets. With a design contrast expected to be better than 1e-9 after post processing, this instrument will directly image gas giants as far in as Jupiter's orbit. Direct imaging places high demand on optical detectors, not only in noise performance, but also in the need to be resistant to traps. Since the typical scene flux is measured in milli-electrons per second, the signal collected in each practicable frame will be at most a few electrons. At such extremely small signal levels, traps and their effects on the image become extremely important. To investigate their impact on the WFIRST coronagraph mission science yield, we have constructed a detailed model of the coronagraph sensor performance in the presence of traps. Built in Matlab, this model incorporates the expected and measured trap capture and emission times and cross-sections, as well as occurrence densities after exposure to irradiation in the WFIRST space environment. The model also includes the detector architecture and operation as applicable to trapping phenomena. In this presentation we describe the model, the results, and implications on sensing performance. We conclude with a discussion of mitigation strategies.

9915-37, Session PSun

Electron multiplying CMOS imaging sensor

Clément Buton, Rémi Barbier, Institut de Physique Nucléaire de Lyon (France); Mathieu Fournier, Frédéric Mayer, Pierre Fereyre, e2v (France)

The electron multiplying CCD (emCCD) imaging sensors have improved drastically the Signal over Noise Ratio (SNR) in astrophysical measurements (typically for the faintest sources or the shortest integration times). With the obvious progresses in image quality and functionalities (low noise, small pixels, high quantum efficiency, backside Illumination, through silicon via for 3D stacks, low power consumption, large scale, fast frame rate) of the CMOS Imaging Sensors (CIS), it is appealing to combine the benefit of the electron multiplication in the charge domain before charge-to-voltage conversion to the CMOS 5T or 6T current pixel architecture with pinned photodiode as sensitive volume.

The introduction of high voltage gates inside the pixel has been proposed with a non-conventional CIS technology for the first time by the Sanyo Electric Company (Shimizu et al. 2009). Recently, different emCMOS pixel structures (Fereyre et al., 2015) made in a 180nm standard CIS technology have proved their ability to multiply signal significantly during integration of photo-generated carriers with an impact ionizing coefficient of the order of 1%. A significant gain in SNR has been obtained. This proof of concept open the way for CIS towards fast and single-photon imagers similar to the emCCD, but including all the benefits from CIS such as the large scale and the windowing per multiplication gain (in order to increase the dynamic range over the full image: faintest and brightest sources at the same time). However, with this reciprocation of electron packets inside the pixel during the integration phase, a new model of the gain and Excess Noise Factor (ENF) has to be developed since the emCCD Excess Noise Factor model cannot be applied to this readout architecture.

This contribution will present first a summary of the tested pixel structures, together with the modeling of the multiplication gain and Excess Noise Factor formulation introduced in Brugière et al., 2014. We will show next how the theory of the Excess Noise Factor through a generalized Burgess variance formula can be used to measure precisely the impact ionization coefficient. Among the structures tested, we will display the results obtained with the best candidates for further developments of a full size emCMOS imaging sensor. A careful study of the different sources of charge carriers during the integration, multiplication and readout phases has been conducted and the main results will be discussed to understand the contribution of the electron multiplication to the ENF and to the SNR. To conclude this paper will discuss the potential of this low light imaging technology applied to the astrophysics field.

Shutter heater system for Antarctic Bright Star Survey Telescope

Jie Chen, Hong-fei Zhang, Shu-cheng Dong, Feng-xin Jiang, Jian Wang, Univ. of Science and Technology of China (China)

BSST is a small telescope with 30cm aperture, which is used to study extrasolar planet and will be located at Antarctic. Its field of view is wide, so it can observe many targets simultaneously, which has advantage of bright star survey. After its construction, BSST will take advantage of polar night to make observation on wide scope sky area.

The camera system in BSST is composed of two parts: a camera and a shutter system. The type of camera is Andor iKon-XL CCD camera, a custom designed model for BSST. The type of CCD sensor is CCD203-82 from E2V Technologies, which is a back-illuminated, full frame transfer sensor. The pixel size of CCD sensor is 12 μm?12 μm and the sensor is arranged as a nominally resolution of 4096?4096 array. The shutter is a mechanical one, which will run normally with the ambient temperature above 0 °C while the average temperature in Dome A is about -60°C when the polar night is coming. Therefore, a heater system is designed for the shutter including a heat-hold shutter housing, temperature sensors, heater plates, an electronic board for heater driver and temperature sensor sampling and a control software in the computer.

The titanium alloy with low thermal conductivity is used on the heat-insulation cavity which is also wrapped with insulation material to hold the heat. There are two circular heater plates are mounted on upside and downside of the cavity to heat the shutter. Two temperature sensors are installed on the cavity and the upper heater plates to measure the corresponding temperatures, respectively. A thermal drive circuit board and control software are designed to control and monitor the temperature of shutter housing. The insulation cavity can insure that the ambient temperature of the shutter is above 0 °C. The Shutter System provides power input to ensure a relatively stable temperature distribution of shutter house. A closed loop feedback control—fuzzy PID control is formed with sampling temperature of inside the insulation cavity and the surface of heating plate, driving the heater to work, which can ensure that temperature inside shutter house is within the safe work range of the shutter. A simple fuzzy control algorithm is designed to improve the control precision. The temperature accuracy is measured as ±0.1°C.

Also an operation software is designed for configuration and control shutter system which is based on the EPICS(Experimental Physics and Industrial Control System) and easy to integrated into whole control system of BSST

The shutter system is tested in a deep-cooled refrigerator whose minimum chilling temperature could be -85 °C which is near the minimum temperature in Antarctic Dome Argus. The test result shows the design can meet the requirements of BSST camera system.

Scientific CCD controller for the extreme environment at Antarctic

Hong-fei Zhang, Jian-min Wang, Yi Feng, Dong-xu Yang, Jie Chen, Sheng-zhao Lin, Jian Wang, Univ. of Science and Technology of China (China)

Scientific CCD detectors are important instruments in the field of astronomical observation for its ultrahigh quantum efficiency and ultralow readout noise. Moreover the unique geographical environment, making the Antarctica the most superior astronomical observation site. So many countries have carried out the telescope projects in Antarctica. However, all the scientific CCD cameras in the commercial area basically are based on normal temperature operating condition which have not passed the reliability tests under low temperature environment as in Antarctica. And in electronic systems, the nominal normal operating temperature ranges of commercial chips are mostly above 233K, which are not reliable under condition of Antarctica.

In this paper, we report a prototype of scientific CCD controller with low noise and low temperature design. The CCD chip we used is CCD47-20 with 1k*1k pixels.

The CCD controller includes three main part, which are low noise power board (PB), the front-end electronics (FEE) and the mother board (MB). A TEC is used to cool down the CCD chip. The TEC and CCD are installed in a vacuum chamber which connect with MB through vacuum connectors. The PB and FEE also connect with MB through proper connectors, and supply low noise biases and clocks to drive the CCD. Two pre-amplifiers are set on the MB to amplify the CCD output video signals. Then the amplified video signals are transmitted to FEE for correlated double sampling (CDS) and ADC sampling. Meanwhile, the FEE monitors the temperature of CCD and TEC for CCD cooling. The FEE also controls the shutter and monitors the temperature of the shutter for shutter temperature holding. For using in the low temperature environment, most of the chips used in the controller are industrial grade products. The chip workmanship are mainly MOS process, and chips of bipolar process are usually avoided.

The controller is small in size and easy to use. A 24V power is supplied to the PB and usb3.0 is used for transmitting data and command between the system and PC. The readout noise of system could be as low as 5e^- when the CCD is cooled down to 213K and the CCD readout speed is 100kpixs/s. We simulated the extreme low temperature environment of Antarctic to test the system, and verified that the system has the ability of long time working in the extreme low temperature environment of 213K to 193K. Moreover a shutter temperature hold system which keeps the temperature of shutter above 273K is achieved for the shutter could only work steady in temperature above 273k. The whole system has been tested in low temperature environment for long time and keeps working steadily.

Back-illuminated large area frame transfer CCDs for space-based hyper-spectral imaging applications

Robert H. Philbrick, Angelo S. Gilmore, Ronald J. Schrein, Ball Aerospace & Technologies Corp. (United States)

Standard offerings of large area, back-illuminated full frame CCD sensors are available from multiple suppliers and they continue to be commonly deployed in ground- and space-based applications. By comparison the availability of large area frame transfers CCDs is sparse, with the accompanying ~2x increase in die area no doubt being a contributing factor. Modern back-illuminated CCDs yield very high quantum efficiency in the 290 to 400 nm band, a wavelength region of great interest in space-based instruments studying atmospheric phenomenon. In fast framing (e.g. 10 – 20 Hz), space-based applications such as hyper-spectral imaging, the

use of a mechanical shutter to block incident photons during readout can prove costly and lower instrument reliability. The emergence of large area, all-digital visible CMOS sensors, with integrate while read functionality, are an alternative solution to CCDs; but, even after factoring in reduced complexity and cost of support electronics, the present cost to implement such novel sensors is prohibitive to cost constrained missions. Hence, there continues to be a niche set of applications where large area, back-illuminated frame transfer CCDs with high UV quantum efficiency, high frame rate and full well, and low noise provide an advantageous solution. To address this need a family of large area frame transfer CCDs has been developed that includes 2048 (columns) x 256 (rows) (FT4), 2048 x 512 (FT5), and 2048 x 1024 (FT6) full frame transfer CCDs; and a 2048 x 1024 (FT7) split-frame transfer CCD. Each wafer contains 4 FT4, 2 FT5, 2 FT6, and 2 FT7 die. The designs have undergone radiation and accelerated life qualification and the electro-optical performance of these CCDs over the wavelength range of 290 to 900 nm is discussed.

LFA controller tests and characterisation at ESA

Frederic Lemmel, Jörg Ter Haar, John van der Biezen, Ludovic Duvet, Sander Blommaert, Bart Butler, Cornelis van der Luijt, Jerko Heijnen, Hans Smit, Ivo Visser, European Space Research and Technology Ctr. (Netherlands)

ESA is developing a photon to SpaceWire system for future missions in particular M4 and on a longer term M5 missions. For this purpose, ESA has initiated the development of NIR detectors activity (the Large Format Array (L.F.A) activity) and a versatile cryogenic detector controller (the L.F.A controller activity), in Europe in preparation of future Astronomy missions. The L.F.A controller activity is a parallel contracts between Caeleste (Belgium) and IDEAS (Norway). In order to validate the performances of the LFA controller developed by Caeleste a dedicated test bench has been designed and developed at ESTEC. This publication presents the test set up and the performances validation of the first prototype of the Caeleste controller at room temperature and at cryogenic temperature. The test set up and software needed to test the HAWAII-2RG and L.F.A detectors with the L.F.A controller at cryogenic temperature will be as well presented.

9915-60, Session PSun

Low temperature performance of a commercially available InGaAs image sensor

Hidehiko Nakaya, Yutaka Komiyama, Nobunari Kashikawa, National Astronomical Observatory of Japan (Japan); Tomohisa Uchida, High Energy Accelerator Research Organization, KEK (Japan); Takahiro Nagayama, Kagoshima Univ. (Japan); Michitoshi Yoshida, Hiroshima Univ. (Japan)

We report evaluation results of a commercially available InGaAs image sensor G12242-0707W manufactured by Hamamatsu Photonics K. K. The InGaAs photo diode array of the sensor sensitive between 1 ?m and 1.7 ?m wavelengths at the room temperature is hybridized on a Si CMOS circuit. Although the sensor format reported in this conference is 128 ? 128 with the 20 ?m pixel pitch, the 640 ? 512 format is also available with the same pixel circuit. Because the sensor is designed for industrial purposes used with a thermoelectric cooler, using the sensor at the low temperature to minimize the dark current is not considered. Information about the characteristics of the sensor such at the low temperature is not provided from the manufacturer. Although the sensitive wavelength of an InGaAs sensor is narrow, the availability at a lower cost compared with commonly used HgCdTe sensors for astronomy is attractive for astronomical applications such as a wide field camera which uses a lot of sensors, an instrument for a small telescope, and so on.

We tested a sample of the image sensor with our original readout electronics system with a precise 16 bit ADC. The sensor was placed on a temperature controlled stage in a vacuumed cryostat with a mechanical cooler. The sensor performance was measured at a low temperature enough to minimize the dark current. The readout noise, conversion gain, linearity, and intra-pixel response were measured at 140 K. The temperature dependence of the relative wavelength response was measured between 140 K and 300 K, and the one of the dark current was measured between 80 K and 293K.

The conversion gain obtained from photon transfer curves was 1.0 ?V/e-. The full-well was larger than 1.3E6 e- within ±1.5% linearity error. The readout noise was 60 e- calculated from pixels in a line of a frame, whereas the noise calculated from pixels over lines was 200 e-. There was a bias level variation line by line and frame by frame, which we were not able to eliminate by adjusting the clock timing and coupling capacitors. The dark current decreased to the minimum value of ~20 e-/sec at 170 K. It did not become lower at the lower temperature. The sensor had a light sensitivity between 0.90 ?m and 1.57 ?m at the temperature of 140 K. We also measured the intra-pixel response. It showed a sensitivity variation within ±3 % across several pixels, and no blind area.

We found the performance of the sensor had no serious problems except for the readout noise and the dark current. This sensor would not be suitable for the astronomical observation which requires low readout noise and dark current. It, however, becomes a choice for near infrared astronomical applications such as broadband imaging observations for which the readout noise and dark current are acceptable.

Noise optimization of the source follower of a CMOS pixel using BSIM3 noise model

Swaraj Bandhu Mahato, KU Leuven (Belgium); Guy Meynants, CMOSIS International NV (Belgium); Gert Raskin, Joris De Ridder, Hans Van Winckel, KU Leuven (Belgium)

CMOS imagers are becoming increasingly popular in astronomy. A very low noise level is required to observe extremely faint targets and to get high-precision flux measurements. Although CMOS technology offers many advantages over CCDs, a major bottleneck is still the read noise. To move from a CMOS sensor designed for industrial applications to one suitable for scientific applications, an improved design that optimizes the noise level is essential. Here, we study the 1/f and thermal noise performance of the source follower of a CMOS pixel in detail. We identify the relevant design parameters, and analytically study their impact on the noise level using the BSIM3v3 noise model with an enhanced model of gate capacitance of the source follower in operation region. Our detailed analysis shows the dependence of the 1/f noise on the geometrical size of the source follower is not limited to minimum channel length, compared to the classical approach to achieve the minimum 1/f noise. We derive the optimal gate dimensions (the width and the length) of the source follower that minimize the 1/f noise, and validate our results using numerical simulations. By considering the thermal noise or white noise along with 1/f noise, the total input noise of the source follower depends on the capacitor ratio CG/CFD and the drain current (Id). Here, CG is the total gate capacitance of the source follower and CFD is the total floating diffusion capacitor at the input of the source follower. We demonstrate that the optimum gate capacitance (CG) depends on the chosen bias current but ranges from CFD/3 to CFD to achieve the minimum total noise of the source follower. Numerical calculation and circuit simulation with 180nm CMOS technology are performed to validate our results.

A thermal blocking filter reveals the extended red sensitivity of a 1.7 micron cutoff H2RG detector

Ryan C. Terrien, Suvrath Mahadevan, Lawrence W. Ramsey, Samuel P. Halverson, Chad F. Bender, Andrew Monson, The Pennsylvania State Univ. (United States)

Infrared detectors with cutoff wavelengths of ~1.7 microns have much lower sensitivity to thermal background contamination than those with longer cutoff wavelengths. This low sensitivity reduces the need for fully cryogenic systems for YJH-band work, offering the potential for “warm-pupil” instrumentation that nonetheless reduces detected thermal background to the level of dark current. However, residual sensitivity beyond the cutoff wavelength is not well characterized, and may preclude the implementation of such warm-pupil instruments. Using a custom thermal blocking filter, we characterize the long-wavelength sensitivity tail of a 1.7 micron-cutoff H2RG array, and find evidence for sensitivity beyond the cutoff. We demonstrate the performance of our custom filter, which enables warm-pupil operation at a level previously achievable only with a combination of interference filters and specialized blocking glass. This filter enables warm-pupil NIR instrument operation, which is particularly valuable for cost-effective and efficient testing systems: it has facilitated NIR detector characterization and will enable crucial laboratory tests of laser frequency comb calibration systems and other NIR calibration sources.

9915-63, Session PSun

Caliste-SO spectral response to high x-ray photon count rate produced during bright solar flares

Aline Meuris, Olivier Limousin, Olivier Gevin, Claire Blondel, CEA-IRFU (France); Oliver Grimm, ETH Zürich (Switzerland) and Fachhochschule NordWestschweiz (Switzerland)

On board the Solar Orbiter mission to be flown in 2018, the Spectrometer Telescope Imaging X-rays (STIX) will perform time-resolved imaging spectroscopy of solar flares in the hard X-ray range (4-150 keV) to give information about the intensity, the location and the energy of electrons accelerated in the heliosphere. The imaging technique consists in a Fourier transform based on 32 X-ray collimators, each of them with a pair of grids and a spectrometer. Caliste-SO is a hybrid CdTe detector specially designed to meet the science requirements (pixel size, spectral performance) and the technical requirements (small power and volume) of STIX. A hundred of Caliste-SO devices were produced for the STIX validation models including 32 units for the flight model. Typical energy resolution of the pixels is between 0.9 keV FWHM at 14 keV when the detector is cooled down at -20°C and biased at -300V, for a peaking time of 2 μs. The low-level threshold can be set as low as 3 keV for all the pixels.

Solar flares detection is done automatically on-board Solar Orbiter and STIX trigger could be used by other instruments. Besides the datalink on this orbit has a too low rate to be shared between the 10 instruments to get from STIX photon-photon information on-ground (time, address, amplitude of each event). As a result, amplitudes from Caliste spectrometers shall be on-board converted in energy to build histograms in energy channels. For this reason, we need to study all factors contributing to variations and evolutions of the pixel transfer function on-board the spacecraft. Several weak 133Ba calibration sources will be used to correct for long-term variations due to proton irradiation in particular. Other short-term variations cannot be recovered by on-board calibration sources and are studied before the mission launch, such as the influence of the temperature and the influence of the photon count rate. Simulations performed with an event generator and the Caliste-SO geometry predicts a pile-up fraction inferior to 1 % for 2 μs peaking time setting for the maximal count rate of 100.000 counts/s/cm2. This behavioral model was completed by experimental studies that are reported here.

The first measurement campaign consisted in placing a strong 57Co source at various distances of a Caliste-SO device to access photon rates from 300 to 15000 counts/s/pixel (photon energies from 6 to 136 keV). Effects were mainly observed on the offset values and have been explained by the ASIC design. The next measurement campaign set will consist in using an X-ray generator (photon energies below 30 keV) to see if both rate and energy deposit play a role in the evolution of the spectral transfer function. The paper will present timing and spectral analysis performed with these data sets.

DCDS weighted averaging theory and development for improved noise filtering in scientific CCD applications

Matthew J. Clapp, Ionut Mihalcea, Nick R. Waltham, Tom E. Morse, STFC Rutherford Appleton Lab. (United Kingdom)

Readout noise is a key factor in the performance of optical systems based on charge coupled devices (CCDs). Recent developments have shown that digital correlated double sampling (DCDS) using weighted averaging may provide a further reduction in the system readout noise. This paper describes recent advances in noise filtering using DCDS. Particular emphasis is placed on optimising weighted averaging filters to reduce 1/f noise and the characterisation of system performance when using the unsettled samples within the pixel period. Experimental results are presented and compared with theoretical predictions based on the extracted noise spectrum. The analysis provides a detailed study of the relationship between the 1/f corner frequency, the pixel frequency and weighted averaging technique in comparison with the theory of matched filters. Furthermore, the results include a comparison of the noise profile with measured and simulated noise patterns. Key system metrics, including linearity and gain stability, have been characterised and are presented to confirm the suitability of this technique for high-performance scientific applications.

9915-66, Session PSun

NUV performance of e2v large BICMOS array for CASTOR

Alan D. Scott, Alexander Beaton, Niladri Roy, COM DEV International Ltd. (Canada); Patrick Côté, John B. Hutchings, National Research Council Canada (Canada); Oleg Djazovski, Denis Laurin, Canadian Space Agency (Canada)

We have characterized the e2v CIS113 16 micron pitch 4608 x 1920 back-illuminated CMOS (BICMOS) array with near Ultraviolet (NUV) sensitization surface processing and measured its quantum efficiency over the wavelength range from 150 to 350 nm.

The Cosmological Advanced Survey Telescope for Optical and UV Research (CASTOR) is a proposed Canadian Space Agency (CSA) mission that would provide panoramic, high-resolution imaging of 1/8th of the sky in the UV/optical (150-550 nm) spectral region. This small-satellite class mission would provide high angular resolution ultra-deep imaging in three broad filters to supplement data from planned international dark energy missions (Euclid, WFIRST) as well as from the Large Synoptic Survey Telescope

(LSST). One of the leading technical risks on this mission is the UV sensitivity required to approach 26th magnitude in the near UV band.

In this paper we briefly describe the architecture of this new high speed, high sensitivity CMOS detector and report on the results of our characterization and the implications for the proposed CASTOR survey mission.

9915-67, Session PSun

Characterization of infrared APD arrays

Tim Hardy, NRC - Herzberg Institute of Astrophysics (Canada)

We present results from our testing of near infrared APD arrays from SELEX ES. We discuss the non-linear behaviour of these devices and compare to mathematical models which show good agreement with our experimental data. We also discuss some other non-ideal characteristics we have encountered. Finally, we describe a compact detector system designed as an easily deployable demonstrator for on-sky testing.

9915-68, Session PSun

The test results of signal processing ASIC for astronomical CCD system

Mingzhi Wei, Qian Song, Yuheng Zhang, National Astronomical Observatories (China)

An astronomical CCD system ASIC (Application-Specific Integrated Circuit) development plan has started in the National Astronomical Observatories of China(NAOC). The plan is to develop universal ASICs for astronomical CCD systems, which are used for ground-based or space-based Astronomical equipment. One of projects is to develop an eight channel universal signal processing ASIC. Signal processing chain is a very important part of the CCD electronics. It is a decisive factor for the final performances of the CCD system, such as readout noise, linearity, etc.. There is a big amount of signal channels in a multi CCD system. In this case, using the signal processing ASICs will greatly reduce the size and power consumption of the system. The first prototype chips with two channel signal processing circuits have been designed and fabricated in the NAOC. The function tests and performance measurements with an e2v astronomical CCD in LN dewar have been done in the CCD lab of the NAOC. This presentation will describe the function and the performance of this ASIC chip and will report the test results.

9915-69, Session PSun

NIR camera and spectrograph SWIMS for TAO 6.5m telescope: array control system and its performance

Yasunori Terao, Kentaro Motohara, Masahiro Konishi, Hidenori Takahashi, Natsuko M. Kato, Yutaro Kitagawa, Yutaka Kobayakawa, Hirofumi Ohashi, The Univ. of Tokyo (Japan); Ken Tateuchi, East Japan Railway Co. (Japan); Soya Todo, Canon Inc. (Japan)

SWIMS (Simultaneous-color Wide-field Infrared Multi-object Spectrograph) is a near infrared imager and multi-object spectrograph as one of the first generation instruments for the University of Tokyo Atacama Observatory (TAO) 6.5m telescope. One of the advantages of SWIMS is simultaneous imaging or spectroscopy at short (0.9?1.4um) and long (1.4?2.5um) wavelength ranges in the near infrared. Incident light is split into blue and red arms by a dichroic mirror and focused onto two focal plane arrays (2k ? 2k HAWAII-2RGs) on each arm.

In this presentation, we will show a software system of SWIMS for simultaneous driving of HAWAII-2RGs and results of its performance evaluation.

HAWAII-2RG is an infrared detector developed by Teledyne Imaging Sensor (TIS). It is controlled and read out by two circuits, SIDECAR ASIC and JADE2 card. SIDECAR ASIC controls HAWAII-2RG by generating clocks to drive it, amplifying output signals and performing AD conversion. It is located near the detector and driven under cryogenic temperature with vacuum condition. JADE2 card provides power supply for SIDECAR ASIC and works as an interface board between a PC and the ASIC. It is driven under room temperature with vacuum condition and controlled by the PC via a USB 2.0 interface. In the case of SWIMS, we have fabricated special flat cables to connect SIDECAR ASICs and JADE2 cards instead of what provided by TIS as the distance between them is long (~1.7m).

We use two Linux PCs to control the detector systems on blue and red arms for simultaneous driving of the four HAWAII-2RGs. Each PC runs two virtual Windows machines on which GUI-based software runs to control JADE2 card and socket communication is performed to control them from the Linux PC. Two HAWAII-2RGs on the same arm are controlled simultaneously by a software with multi-thread process. Linux PCs are controlled by a superordinate PC which controls all systems of SWIMS through asynchronous TCP/IP communication. In this way, finally we can drive all four HAWAII-2RGs simultaneously. Whole the Linux software system is scripted by Python.

The requirement for readout noise of SWIMS is less than 14e- for background limit observations. We confirmed the readout noise to be 4.3e- r.m.s. by 32 times multisampling when we operate only single HAWAII-2RG. In the case of simultaneous driving of two HAWAII-2RGs, we got sufficiently low readout noise of 10e- r.m.s. using shielded flat cables between the SIDECAR ASIC and the JADE2 card.

9915-70, Session PSun

EMCCD camera characterization for optimal use in astronomical applications

José Leonardo Garcés Medina, Valeri G. Orlov, Univ. Nacional Autónoma de México (Mexico)

Electron-Multiplying Charge-Coupled Device (EMCCD) are a high favorable technology for faint photon flux sources photometry encountered in astronomy and high frame rate imaging for high spatial resolution techniques. It operates by passing the photoelectron pixel charge through a multiplication gain register before the readout process improving the signal-to-noise ratio of the image. However, some unwanted characteristics not found in conventional CCDs arise and need to be considering for optimal observations. Accordingly, in addition of the conventional methods used for CCDs like dark current analysis and Photon Transfer Curve different methods for the characterization of the EMCCD have to be performed. We present the results of the characterization of a 1004x1002 pixels EMCCD for optical wavelengths housed and controlled by the Andor iXon 885 camera for use in astronomical applications. The results provide the optimal parameters for conventional mode, analog mode and photon counting mode EMCCD operation.

9915-71, Session PSun

Characterization of H2RG IR detectors for the Euclid NISP instrument

Aurélia Secroun, Benoit Serra, Jean Claude Clémens, Romain Legras, Philippe Lagier, Mathieu Niclas, Laurence Caillat, William Gillard, André Tilquin, Anne Ealet, Ctr. de Physique des Particules de Marseille (France); Rémi

Barbier, Sylvain Ferriol, Bogna Kubik, Gérard Smadja, Institut de Physique Nucléaire de Lyon (France); Eric Prieto, Thierry Maciaszek, Lab. d'Astrophysique de Marseille (France); Anton Norup Sorensen, Niels Bohr Institute (Denmark)

Euclid is a major ESA mission for the study of dark energy planned to launch in 2020. Euclid will probe the expansion history of the Universe using weak lensing and BAO probes. A survey of 15,000 deg2 of the darkest sky with NISP (Near-Infrared Spectro-Photometer), in the 900 – 2100 nm band, will give redshifts of tens of millions of galaxies. NISP's FPA will be filled with 16 of Teledyne's 2.3 μm cutoff 2048x2048 pixels H2RG infrared detectors, for which strong requirements have been derived from scientific goals. These IR HgCdTe detectors are a key element of the instrument. They must show very high performances over more than 95% of pixels, in terms of median dark current (<0.07 e-/s), total noise (<13 e-), a budget error on non-linearity after correction (<1%), residual dark due to latency effects (<0.5 e-/s after 5 hours) and quantum efficiency (>75% over the wavelength range). While NASA, who will select flight detectors under Euclid specification, will do the acceptance tests, CPPM is responsible for the characterization of the detectors performances, namely the production of the pixel map calibration database of the Focal plan for the Euclid mission.

Characterization is challenging in many ways: each detector will have to be fully and accurately characterized in 21 days. Some of the tight characterization requirements are: dark levels as low as 10^{-3} e-/s with an accuracy of 10% (Goal 5%), a relative Pixel Response map better than 1%, obtained with an illumination flatness better than 1%, measurements alternating dark and high level illumination should be implemented taking care of latency impacts on successive parameter measurements. Due to statistics needs, very long runs (24h to 48h without interrupts, ~99% of duty cycle) of scripted measurements would be executed. Systematics of the test bench should be at the end the limiting factor of the parameter measurement accuracy. Facilities with functionalities developed for those specific purposes and associated performances will be described. A pilot run with high performances detectors will verify the characterization chain from the hardware acquisitions to the analysis methods and software tools, and will validate the characterization flow down to reach the desired accuracy. First results of this pilot run will be presented that show the quality of the characterization chain, including measurements of dark/ noise, conversion gain with PTC method and non-linearity measurements. Next step will be the characterization of flight detectors expected to start in Summer 2016.

9915-72, Session PSun

Using an OLED smartphone display for in-lab microwave kinetic inductance detector illumination tests

Seth R. Meeker, Benjamin A. Mazin, Univ. of California, Santa Barbara (United States)

We present our efforts to develop a flexible smartphone based platform for in-lab optical testing of optical/near-IR detectors, namely Microwave Kinetic Inductance Detectors (MKIDs). MKIDs are a rapidly developing technology; the first 1,000-pixel UV, optical, near-IR (UVOIR) MKID array was fielded on sky in 2011, and the next generation of near-IR MKID instruments scheduled for deployment in 2016 will house 10- to 20-kilopixel arrays. As with any detector development, we require the ability to verify our MKIDs in the laboratory with various patterns and intensities of illumination across multiple wavelengths. However, previous schemes employing fiber-fed lithographic masks mounted on precision translation stages were limited by the reliability and price of these components, and did not easily scale up to accommodate testing of larger arrays. A smartphone with organic LED (OLED) displays presents a cost-effective alternative because it allows us to change projected images without needing to handle delicate glass masks, and test patterns can be moved across the detector without the need for expensive translation stages. The use of an OLED display, rather than a backlit LCD, is especially attractive as it lets us achieve true-black in images and control individual pixel brightness absolutely when generating illumination patterns. Additionally, the open-source nature of the Android operating system ensures ease of programming and readily shareable code. Here we present the opto-mechanical design of the lab setup and lessons learned while applying it to the characterization of DARKNESS, a 10-kilopixel MKID integral field spectrograph deploying to Palomar's Hale Telescope in July 2016.

Evaluating noise performance of the IUCAA SIDECAR drive electronics controller (ISDEC) based system for TMT on instrument wavefront sensing (OIWFS) application

Mahesh P. Burse, Anamparambu N. Ramaprakash, Swapnil M. Prabhudesai, Sujit P. Punnadi, Sabyasachi Chattopadhyay, Pravinkumar A. Chordia, Abhay Kohok, Sakya Sinha, Inter-Univ. Ctr. for Astronomy and Astrophysics (India)

As a part of the design study of the On-Instrument Low Order Wave-front Sensor (OIWFS) for the TMT Infra-Red Imaging Spectrograph (IRIS), we recently evaluated the noise performance of a detector control system consisting of IUCAA SIDECAR DRIVE ELECRONICS CONTROLLER (ISDEC), SIDECAR ASIC and HAWAII-2RG (H2RG) MUX. To understand and improve the performance of this system to serve as a near infrared tip tilt sensor, we implemented new read out modes like multiple region of interest with differential multi-accumulate readout schemes for the HAWAII-2RG (H2RG) detector. In this system, firmware running in SIDECAR ASIC programs the detector for ROI readout, reads the detector, processes the detector output and writes the digitized data into its internal memory. ISDEC reads the digitized data from ASIC, performs the differential multi-accumulate operations and then sends the processed data to PC over a USB interface. A special loopback board was designed and used to measure and reduce the noise from ASIC. This paper describes the methods and techniques used to measure and reduce readout noise of the system. With bias and reference filtering and co-adding, we were able to reduce the mean r.m.s. read noise of this system down to 1-2 e. for any arbitrary window frame of 4x4 size at frame rates below about 200 Hz.

ESA's CCD test bench for the PLATO mission

Thierry Beaufort, Thibaut Prod'homme, European Space Research and Technology Ctr. (Netherlands); Sander Blommaert, ATG Europe (Netherlands); Peter Verhoeve, European Space Research and Technology Ctr. (Netherlands) and European Space Agency (Netherlands); Frederic Lemmel, Hans Smit, European Space Agency (Netherlands); Ludovic Duvet, European Space Research and Technology Ctr. (Netherlands); Ivo Visser, Klok Vacuum Service (Netherlands); Bart Butler, Cornelis van der Luijt, Jerko Heijnen, European Space Research and Technology Ctr. (Netherlands)

PLATO is a mission proposed in 2007 to the European Space Agency (ESA) in response to the call for ESA Cosmic Vision 2015–2025. The main mission goal is to find planets like Earth around solar-type stars by the transit method..The payload will consist of 34 separate small telescopes, with 4 CCDs of 4510 x 4510 pixels, at the focal plane of each of them. In support of the CCD development and characterization (the procurement of which is ESA's responsibility), the Payload Technology Validation team has built a dedicated test bench. This bench allows for a flexible operation and readout of the CCDs. It provides the basic tools for noise and gain calibration, and CTI, QE and PRNU measurements.

The bench hosts an in-house manufactured cryostat, where the CCDs can be placed in a vacuum environment and actively cooled using a Cryo-tiger. The cryostat was designed to host the PLATO CCD in its own package and handling jig to minimize handling, and is fitted with a large window for full illumination of the CCD. A python based software was developed in-house to support the bench two main functionalities the control and readout of the CCD under test, and the control, monitoring as well as safety of the CCD in its cryostat environment.

The CCD controller and readout is performed by an Archon controller (provided by Semiconductor Technology Associates). It is able to operate up to (and beyond) the PLATO CCD nominal pixel rate of 4 MHz. Among the many features of this controller one can note the use of digital correlated double sampling to measure pixel values and the possibility of defining clock slew rates. The bench software controls, on top of the CCD controller, all the elements necessary for the tests to be performed, light sources, translation stages for spot scanning etc.

The CCD operating environment must be closely controlled and monitored, in particular the temperature range and stability of the CCD under test, as this information is critical to data analysis. The temperature setting and control elements consist of a cold finger, a copper block on which the CCD within its transport jig is mounted and between these two elements, a set of straps – of which the thermal conductivity sets the temperature range at the CCD. To achieve the thermal stability of the CCD package, the thermal control loop consists of a Lakeshore controller with two heaters glued on the copper block. The PID loop temperature set-point is given by a temperature sensor placed on the copper block which gives a stable control loop, the challenge is to reach the required stability and readout accuracy at the CCD package level.

The paper will focus on the solutions implemented and the performance achieved on the thermal stability of the CCDs tested in the bench.

Experiments with synchronized sCMOS cameras

Iain A. Steele, Helen E. Jermak, Chris M. Copperwheat, Robert M. Barnsley, Robert J. Smith, Liverpool John Moores Univ. (United Kingdom)

Scientific-CMOS (sCMOS) cameras can combine low noise with high readout speeds and do not suffer the charge multiplication noise that effectively reduces the quantum efficiency of electron multiplying CCDs by a factor 2. As such they have strong potential in fast photometry and polarimetry instrumentation. In this paper we describe the results of laboratory experiments using a pair of commercial sCMOS cameras based around a 4 transistor per pixel architecture. In particular we evaluate the timing precision that may be obtained in rolling and pseudo-global shutter modes both individually and when the cameras readouts are synchronized either in software or electronically. This precision is important for potential applications of these detectors to high-speed simultaneous multi-band photometry and polarimetry.

A project plans to develop two ASICs for CCD control

Qian Song, Quan Sun, National Astronomical Observatories (China)

Astronomical instrumentation, in more and more cases, especially in the large field of view application while the huge mosaic of CCD or CMOS is needed, requires the controlling electronics of the camera to be much more compact and of much smaller a size than the discrete-part controller used to be. Making the major parts of CCD driving circuits into an ASIC or ASICs can greatly bring down the controller's volume, weight and power consumption and make it easier to control the crosstalk brought up by the long length of the cables connecting the controller's front end and back end, and, therefore, it's the most desirable way to build the large mosaic CCD camera. In our presentation, we will introduce our ASIC develop project that is engaged to develop two ASICs to handle with CCD signal readout and clock driver generating.

IDSAC-IUCAA digital sampler array controller

Sabyasachi Chattopadhyay, Pravinkumar A. Chordia, Anamparambu N. Ramaprakash, Mahesh P. Burse, Bhushan Joshi, Kalpesh Chillal, Inter-Univ. Ctr. for Astronomy and Astrophysics (India)

In order to run the large format detector arrays and mosaics that are required by most astronomical instruments, high speed readout electronic controllers are required which can process multiple CCD outputs simultaneously at high speed and low noise. These CCD controllers needs to be modular and configurable, should be able to run multiple CCDs. IDSAC, a generic CCD Controller has been developed which is adequately flexible and powerful enough to control wide variety of CCDs used in ground based astronomy. It has a fully scalable architecture, which can control multiple CCDs and can be easily expanded. The controller has a modular backplane architecture consists of Single Board Controller Cards (SBCs) and can control a mosaic or independent of 5 CCDs. Each Single Board Controller (SBC) has all the resources to a run Single large format CCD having up to four outputs. All SBCs are identical and are easily interchangeable without any reconfiguration. A four channel video processor can process up to four output CCDs with or without dummy output at 1Mpixels/Sec/Channel with 16 bit resolution. Each SBC will have USB 2.0 interface which will be connected to a separate computer via USB to Fiber converters. The SBC uses a reconfigurable hardware (FPGA) as a Master Controller. The best feature of IDSAC is it uses the technique of Digital Correlated Double Sampling(DCDS). It is known that CCD video output is dominated by thermal KTC noise contributed from the summing well capacitor of the CCD output circuitry. To eliminate thermal KTC noise Correlated Double Sampling (CDS) is a very standard technique. CDS performed in Digital domain (DCDS) has several advantages over its analog counterpart, such as - less electronics, faster readout and easier post processing. It is also flexible with sampling rate and pixel throughput while maintaining the core circuit topology intact. The noise characterization of the IDSAC CDS signal chain has been performed by analytical modelling, software simulation and practical measurements. Various types of noise such as white, pink, power supply, bias etc. has been considered while creating a analytical noise model tool to predict noise of a controller system like IDSAC. Standard test bench softwares like Pspice and Multisim are used to simulate the noise performance while several tests are performed to measure the actual noise of IDSAC.The theoretical calculation matches very well with component level simulation as well as practical measurements within 10% accuracy.

9915-79, Session PSun

An optical test bench to measure the effective pixels positions for the HARPS3 CCD

Richard Hall, Samantha J. Thompson, Didier Queloz, Univ. of Cambridge (United Kingdom)

We present our work on an optical test bench to measure the effective pixel positions on a CCD for the high resolution (R~115,000) spectrograph HARPS3, which is a new instrument planned for the Isaac Newton Telescope (INT).

In the radial velocity (RV) technique of exoplanet detection, an Earth-mass planet produces a radial velocity signal of amplitude 0.1ms-1. On the HARPS3 4k x 4k CCD, this RV measurement corresponds to a Doppler shift in single spectral line of ~1x10-4pixel. One of the sources of systematic error in the system is in the calculation of the wavelength solution. Improvements in this wavelength calibration require a better understanding of the effective pixel positions.

In this paper we present our initial experiment design, a description of our CCD test bench, the measures we take to minimize environmental noise, and the principle and techniques used to determine the effect pixel sizes and locations to the 1x10-4px limit. We also present results from our preliminary feasibility experiments.

9915-80, Session PSun

ISDEC-2 and ISDEC-3 controllers for HAWAII detectors

Mahesh P. Burse, Anamparambu N. Ramaprakash, Pravinkumar A. Chordia, Sujit P. Punnadi, Kalpesh Chillal, Vilas Mestri, Sakya Sinha, Rupali Bharti, Abhay Kohok, Inter-Univ. Ctr. for Astronomy and Astrophysics (India)

ISDEC-2 - IUCAA SIDECAR drive electronics controller is an alternative for Teledyne make JADE2 based controller. It is a ready to use complete package and has been developed keeping in mind general astronomical requirements and widely used observatory set-ups like preferred OS-Linux , multi-extensions fits output with fully populated headers (with detector as well as telescope and observation specific information), etc. Actual exposure times are measured for each frame to a few tens of microsecond accuracy and put in the fits header. It also caters to the application specific requirements like fast resets, strip mode, multiple region readout with on board co-adding, etc. ISDEC-2 is designed to work at -40 deg. and already in use at many places worldwide.

ISDEC-3 - is a Artix-7 FPGA based SIDECAR drive electronics controller currently being developed at IUCAA. It would retain all the functionality supported by ISDEC-2 and would also support the operation of H2RG in fast (32 output, 5 MSPS, 12 bit) mode. It will have 5 Gbps USB 3.0 PC interface and 1 Gbps Ethernet interface for image data transfer from SIDECAR to host PC. Additionally, the board will have DDR-3 memory for on-board storage and processing. ISDEC-3 shall be capable of handling two nos. of SIDECAR simultaneously (in sync) for H2RG slow modes.

9915-81, Session PSun

Array controller system with cryogenic pre-amplifiers for MIMIZUKU

Kazushi Okada, Shigeyuki Sako, Takashi Miyata, Takafumi Kamizuka, Ryou Ohsawa, Masahito S. Uchiyama, Kiyoshi Mori, Jumpei Yamaguchi, The Univ. of Tokyo (Japan); Kentaro Asano, Japan Aerospace Exploration Agency (Japan); Mizuho Uchiyama, National Astronomical Observatory of Japan (Japan)

MIMIZUKU is a mid-IR imager and spectrograph being developed for the University of Tokyo Atacama Observatory (TAO) 6.5-m telescope (Yoshii et al. 2014). To fully utilize high atmospheric transmission of the Co. Chajnantor site, MIMIZUKU covers a wide wavelength range from 2 to 38 microns with three arrays: a HAWAII-1RG 1024x1024 detector manufactured by Teledyne (for 2-5.3 microns), an AQUARIUS 1024x1024 detector by Raytheon (for 6.8-26 microns), and a MF-128 Si:Sb 128x128 detector by DRS (for 24-38 microns). To operate and read out these various arrays, an array controller system has been developed.

The array controller system was originally developed for MF-128 Si:Sb array equipped in our previous camera MAX38 (Miyata et al. 2008; Sako et al. 2008). Some modifications have been adopted for adding the operationability of the H1RG and the AQUARIUS arrays. Three array controllers are used for MIMIZUKU in parallel, and they operate independently. This is effective to simplify the system and make debugging easy. Because thermal background is very high in the mid-infrared wavelength range, a sampling rate is needed to be higher than 0.5 MHz. Such a high speed signal is dulled while passing through a signal line from the array to the pre-amplifiers. This is very serious in the case of MIMIZUKU, because MIMIZUKU is a large-scaled complicated instrument. To overcome this problem, a high-speed pre-amplifier system operating at a cryogenic temperature has been developed. This employs GaAs-MESFETs, instead of Si-JFETs. Their cryogenic noise performances were confirmed to satisfy our requirement. This system is installed at the outer side of the optical bench in the MIMIZUKU cryostat, and cooled to 20 K.

In this paper we describe the details of the array controller system and present the current status of the development. We also report preliminary results of operation tests of the AQUARIUS array with our system.

Silicon photomultipliers as readout elements for a Compton Effect polarimeter: the COMPASS project

Ettore Del Monte, Alda Rubini, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Armando Brandonisio, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy) and Sapienza Univ. di Roma (Italy); Fabio Muleri, Paolo Soffitta, Enrico Costa, Giuseppe Di Persio, Sergio Di Cosimo, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Enrico Massaro, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy) and Sapienza Univ. di Roma (Italy); Alfredo Morbidini, Ennio Morelli, Luigi Pacciani, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Sergio Fabiani, Istituto Nazionale di Fisica Nucleare (Italy); Daniele Michilli, Astronomical Institute Anton Pannekoek (Netherlands) and ASTRON (Netherlands); Salvatore Giarrusso, Osvaldo Catalano, Domenico Impiombato, Teresa Mineo, Giuseppe Sottile, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy); Sergio Billotta, INAF - Osservatorio Astrofisico di Catania (Italy)

The measurement of the polarisation of hard X-rays by means of the Compton Effect is the scientific objective of a research and development project named COMpton Polarimeter with Avalanche Silicon readout (COMPASS). The measurement is obtained by using a set of small rods of fast scintillators of both low-Z (as active scatterer) and high-Z (as absorber), all read-out with Silicon Photomultipliers (SiPMs). By this

method we can operate scattering and absorbing elements in coincidence, in order to reduce the background.

In the laboratory we are characterising the SiPMs using different types of scintillators and we are optimising the performances in terms of energy resolution, energy threshold and photon tagging efficiency.

We aim to study the design of two types of satellite-borne instruments: a focal plane polarimeter to be coupled with multilayer optics for hard X-rays and a large area and wide field of view polarimeter for transients and Gamma Ray Bursts.

In this paper we describe the status of the COMPASS project, we report about the laboratory measurements and we describe our future perspectives.

Comparing simulations and test data of a radiation damaged CCD for the Euclid mission

Jesper Skottfelt, David J. Hall, Jason P. D. Gow, Neil J. Murray, Andrew D. Holland, e2v Ctr. for Electronic Imaging (United Kingdom)

The radiation damage effects from the harsh radiative environment outside the Earth's atmosphere can be a cause for concern for most space missions. With the science goals becoming ever more demanding, the requirements on the precision of the instruments on board these missions also increases, and it is therefore important to investigate how the radiation induced damage affects the Charge-Couple Devices (CCDs) that most of these instruments rely on.

In a radiative environment traps can be induces in the silicon lattice of a CCD. These traps are able to capture electrons from one charge package and release them into another charge package at a later time, thus deteriorating the charge transfer efficiency. This leads to a smearing of the image which can have a large impact on the precision of the data.

The primary goal of the Euclid mission is to study the dark universe using weak lensing and baryonic acoustic oscillation techniques. The weak lensing technique depends on very precise shape measurements of distant galaxies obtained by a large CCD array. Over the 5 year nominal lifetime of mission, the CCDs will be degraded to an extent that these measurements will not be possible unless the radiation damage effect are corrected.

In order to further our understanding of the positions and properties of the individual traps, we have created a Monte Carlo model that simulates the physical processes taking place in a radiation damaged CCD. The software is based on Shockley-Read-Hall theory, and are made to mimic the physical properties in the CCD as close as possible. The code runs on a single electrode level and takes charge cloud size and density, three dimensional trap position, and multi-level clocking into account.

This paper will present a comparison between simulations and test data obtained with the CCD273 for the Euclid mission.

9915-84, Session PSun

Simplified charge transfer inefficiency mitigation by trap pumping

Jason P. D. Gow, Neil J. Murray, The Open Univ. (United Kingdom)

The issue of radiation induced Charge Transfer Inefficiency (CTI) is the main disadvantage of using a Charge Coupled Device (CCD) in hostile radiation environments. The CTI increases as a result of defects created within the silicon lattice arising from displacement damage from radiation incident on the detector, these defects can capture and hold charge for a period of time dependant on the operating temperature and the type of defect. The location and type of defect can be determined using trap pumping, where charge is shuffled forwards and backwards between pixels using different transfer times to determine the defects emission time constant. It is also possible to move the charge forwards and backwards using the clocking scheme used to perform normal CCD readout, in this case producing a trap map of the defects which will likely impact charge loss when the device is readout. This paper describes an analytical algorithm created to investigate the ability to recover lost charge in X-ray images from a p channel CCD204, irradiated at 153 K, and assess the ability to add charge back into the X-ray event from which it was lost and report the subsequent improvement in the effective CTI.

9915-85, Session PSun

MeV-level electron and gamma ray sensitivity of modern far ultraviolet sensitive microchannel plate detectors

Michael W. Davis, Thomas K. Greathouse, Southwest Research Institute (United States); Chathan M. Cooke, Massachusetts Institute of Technology (United States); Ryan C. Blase, G. Randall Gladstone, Kurt D. Retherford, Southwest Research Institute (United States)

The Jovian system is the focus of multiple current and future NASA and ESA missions, but dangerously high radiation levels surrounding the planet make operations of instruments sensitive to high energy electrons or gamma rays problematic. Microchannel plate (MCP) detectors have been the detectors of choice in planetary ultraviolet spectrographs for decades. However, the same properties that give these detectors high response to vacuum ultraviolet photons also make them sensitive to high energy electrons and gamma rays. The success of ultraviolet investigations in the Jovian system depends on effectively shielding these MCP detectors protecting them as much as possible from the withering radiation environment. The design of such shielding hinges on our understanding of the response of MCP detectors to the high energy electrons and gamma rays found there. To this end, Southwest Research Institute and Massachusetts Institute of Technology collaborated in 2012-13 to measure the response of a flight-spare microchannel plate detector to a beam of high energy electrons. The detector response was measured at multiple beam energies ranging from 0.5-2.5 MeV and multiple currents. This response was then checked with MCNP6, a radiation transport simulation tool, to determine the secondary gamma rays produced by the primary electrons striking the detector window. We report on the measurement approach and the inferred electron and gamma sensitivities.

9915-86, Session PSun

Further performance evaluation of 2.5 and 5 μm cut-off Hawaii-2RG detectors

Derek J. Ives, Gert Finger, Leander H. Mehrgan, Domingo Alvarez, Christoph Geimer, European Southern Observatory (Germany)

ESO has now delivered or tested in-house, new 5 μm cut-off H2RG detectors, for various projects, such as MATISSE for the VLTI and the upgrade project for CRIRES, the cryogenic high-resolution infrared echelle spectrograph for the VLT. These instruments have required the implementation of some of the more unusual read out options for these detectors, which are may have already been used by other groups, for example, the line-reset-read and line-read-reset modes compared to the standard global reset mode. The detectors are also offered with both output speed options, that is, the standard slow, low noise readout and the faster, higher noise readout, where > 10 frames/s are possible. In the

process of building these detector systems and implementing these new options we have delved deeper into some of the lesser known features of these detectors and tried to characterize them more fully. It is important that these characteristics are well understood before delivery of the next generation of detectors for the ELTs. We obtain very good performance at 2 Mpixel/s speeds with less than 40 e- rms read noise, in all other aspects such as linearity, noise versus number of non-destructive reads and cross talk then their performance of the outputs is the same as slow speed operation. However, the high speed output stages are quite complex to operate, they need to be very well tuned and are prone to oscillation, if not set correctly. We will report on the best bias options to optimize their performance. Likewise we have observed differences between global reset and line reset for the detectors, manifested in a significant increase in detector full well for the line reset option, this also will be reported on. We have also determined that there may signal induced by the detector readout for certain detector material or ROIC revision, at a significant level such that this might be the probable limiting factor of why Fowler sampling reaches a minimum noise value of approximately 3 e- rms for 64 reads and then increases with further non-destructive reads. Finally we also report on some of the other features of the devices where we are still trying to determine if these aspects of performance are a function of the detectors themselves or our controller electronics.

9915-87, Session PSun

A novel reflectometer for relative reflectance measurements of CCDs

Murdock Hart, Robert H. Barkhouser, Stephen A. Smee, Johns Hopkins Univ. (United States); James E. Gunn Sr., Princeton Univ. (United States)

The high quantum efficiencies (QE) of backside illuminated charge coupled devices (CCD) has ushered in the age of the large-scale astronomical survey. The QE of these devices can be greater than 90%, and is dependent upon temperature, the device thickness, backside charging mechanisms, and anti-reflection (AR) coatings. At optical wavelengths the QE can be well approximated as one minus the reflectance, thus the measurement of the backside reflectivity of these devices provides a second independent measure of QE. We have designed and constructed a novel instrument to measure the relative specular reflectance of CCD detectors, with a significant portion of this device being constructed using a 3D fused deposition model (FDM) printer. This device implements both a monitor and measurement photodiode to simultaneously collect input and reflected measurements reducing errors introduced by the relative reflectance calibration process. While most relative reflectometers are highly dependent upon a precisely repeatable target distance for accurate measurements, we have implemented a method of measurement, which virtually eliminates these errors. Using this device we have measured the reflectance of two types of Hamamatsu CCD detectors. The first detector being a 2k x 4k backside illuminated high resistivity silicon detector optimized for use in the 7000 Ang. - 10000 Ang. wavelength range. The second device is similarly a 2k x 4k backside illuminated high resistivity silicon detector, which due to thinning and a different AR coating has been optimized to operate in the 4000 Ang. - 7000 Ang. range. We have not only been able to measure the reflectance of these devices as a function of wavelength, we have also measured the reflectance as a function of position on the device, and found a reflection gradient on these devices.

9915-88, Session PSun

Detector characterization for the Subaru prime focus spectrograph (PFS)

Murdock Hart, Robert H. Barkhouser, Stephen A. Smee, Johns Hopkins Univ. (United States); James E. Gunn Sr., Craig P. Loomis, Princeton Univ. (United States)

The first science grade focal plane array (FPA) for the Subaru Prime Focus Spectrograph (PFS) has been assembled and characterized. PFS will use pairs of Hamamatsu 2k x 4k deep-depletion charge coupled devices (CCDs). We were able to achieve an FPA flatness of less than 2 micron RMS, using a white light confocal microscope for measurement, and selective shims for adjustment. The characterization process for these devices optimized the bias voltages, and measured the quantum efficiency (QE), charge transfer efficiency CTE, gain, and read noise. The reflectance of these devices was also measured as an independent verification of the QE.

9915-89, Session PSun

The ESO 4-Kelvin mid-IR detector test facility

Gerd H. Jakob, Derek J. Ives, European Southern Observatory (Germany)

A crucial requirement for the success of ESO's mid-infrared instruments VISIR and MATISSE is the possibility for extensive laboratory characterization of performance and properties of the 1k x 1k Si:As AQUARIUS detector array. In this context the Thermal Infrared Multi-Mode Instrument TIMMI-2, which was formerly installed at ESO's La Silla 3.6-m telescope, was re-commissioned at ESO headquarters in Germany serving as detector test facility. This instrument provides a 150-liter volume vacuum vessel with integrated cryogenic optics system optimized for the 10-μm and 20-μm-bands, five cryo-mechanisms for apertures, filters, objectives and polarimetric mode selection, a 4-Kelvin cryo-cooler and an IR-window. During the last years it was successively upgraded to a multi-purpose (mid-) infrared detector test facility including external calibration optics for signal chopping, star simulation and drift scan simulation over homogenous background. Emphasis was put on complying with specific electrical, optical, mechanical, thermal and low background requirements of the new detector device. A new AQUARIUS detector mount was developed which allows detector operational temperatures down to 4 Kelvin, whilst at the same time ensuring good shielding characteristics, electrical isolation of the detector system and operating the cryogenic pre-amplifier at 70 Kelvin. We present an overview of the mid-IR test facility capabilities. This will include some latest results on measurements of the test facility optical throughput and the quantum efficiency of the detector device. Another major facility upgrade is planned for 2016 providing significant reduction of thermal background.

9915-91, Session PSun

Second generation large area microchannel plate flat panel phototubes

Camden D. Ertley, Oswald H. W. Siegmund, Sharon R. Jelinsky, Joe Tedesco, Space Sciences Lab. (United States); Michael J. Minot, Aileen O'Mahony, Christopher A. Craven, Incom Inc. (United States)

Very large (20 cm ? 20 cm) flat panel phototubes are being developed using novel microchannel plates (MCPs). Commercial devices (currently limited to a ~5 cm format) use either conventional MCPs or dynode multipliers for amplification and are readout by a pad array. A program is underway for developing MCPs made by atomic layer deposition (ALD) on a borosilicate microcapillary array which has the potential to advance detector performance beyond that available with conventional MCPs. The borosilicate substrates are robust, including the ability to be produced in large formats (20 cm square) and withstanding high processing temperatures (>700˚C), low intrinsic background (<0.06 events cm-2 sec-1), and high open area ratios (up to 85%). The substrates are functionalized

by the application of resistive and secondary emissive layers using ALD. This allows the operational parameters to be set by tailoring sequential ALD deposition processes. ALD MCPs have performance characteristics (gain, pulse amplitude distributions, and imaging) that are equivalent or better than conventional MCPs. Life testing has shown stable gains during >7 C cm-2 charge extraction after preconditioning (vacuum bake and burn-in). Sealed tube assemblies using a pair of 20 cm ? 20 cm ALD MCPs comprise of a borosilicate entrance window, a proximity focused bialkali photocathode, and a strip-line readout anode. The second generation design employs an all glass body with a hot indium seal and a transfer photocathode. We have achieved >20% quantum efficiency and good gain uniformity over the 400 cm2 field of view, spatial resolution of <1 cm and obtained event timing accuracy of close to 100 ps FWHM.

9915-92, Session PSun

Positional calibrations of the high-purity germanium double-sided strip detectors for the Compton spectrometer and imager

Alexander W. Lowell, Steven E. Boggs, Andreas Zoglauer, Carolyn A. Kierans, Univ. of California, Berkeley (United States); Chao-Hsiung Tseng, Chien-Ying Yang, National Tsing Hua Univ. (Taiwan); Clio Sleator, Jeng-Lun Chiu, John A. Tomsick, Univ. of California, Berkeley (United States); Pierre Jean, Institut de Recherche en Astrophysique et Planétologie (France)

The Compton Spectrometer and Imager is a medium energy gamma ray (200 keV - 10 MeV) imager designed to observe high-energy processes in the universe from a high altitude balloon platform. At its core, COSI is comprised of twelve high purity germanium double sided strip detectors which measure particle interaction energies and locations with high precision. This manuscript focuses on the positional calibrations of the COSI detectors. The interaction depth in a detector is inferred from the collection time difference (CTD) between the anode and cathode signals. In order to map the CTD measurements back to interaction depths, we modelled the charge transport in the germanium detectors along with the read out electronics and produced simulated anode and cathode signals which yielded the simulated CTD at a given interaction depth. These simulated CTDs were adjusted on a per pixel basis for timing offsets in the read-out electronics and electric field differences across a detector. The X and Y position of an interaction are simply determined by the location of the triggered strips on each side of the detector. However, We investigated the possibility of refining the X and Y positions by using timing information from neighboring "spectator" strips. With the current positional calibrations, COSI achieves an angular resolution of 6.4 degrees FWHM at 662 keV. The theoretical minimum, ignoring detector effects, is approximately 5 degrees at 662 keV. We discuss future work aimed at reducing this margin.

9915-93, Session PSun

Signal dependence of inter-pixel capacitance in hybridized HgCdTe H2RG arrays for use in James Webb Space Telescope's NIRcam

Kevan Donlon, Zoran Ninkov, Rochester Institute of Technology (United States); Stefi A. Baum, Univ. of Manitoba (Canada)

Inter-pixel capacitance (IPC) is a deterministic electronic coupling by which signal generated in one pixel is measured in a neighboring pixel. Examination of both dark and proton irradiated frames from test NIRcam arrays corroborates earlier results and simulations illustrating a signal dependent coupling. When the signal on an individual pixel is larger, the fractional coupling to nearest neighbors is lesser than when the signal is lower. Frames from test arrays indicate a drop in average coupling from approximately 1.0% at low signals down to approximately 0.7% at high signals.

The photometric ramifications of this non-uniformity are not completely understood. This non-uniformity introduces a non-linearity in the current mathematical model for IPC coupling. IPC coupling has been mathematically formalized as convolution by a blur kernel. Signal dependence requires that the blur kernel be locally defined as a function of signal intensity. Through application of a signal dependent coupling kernel the IPC coupling can be modeled computationally. This method allows for simultaneous knowledge of the intrinsic parameters of the image scene, the impact of a normal imaging system on that scene if IPC were not present, the result of applying a constant IPC, and the result of a signal dependent IPC. Comparison between these results is quantified by changes in SNR, perceived brightness, and centroiding of objects. In the age of sub-pixel precision in astronomy these effects must be properly understood and accounted for in order for the data to accurately represent the object of observation. In addition, this method allows for the validity of corrective filtering techniques to be assessed. The result of using a linear correction on a non-linear data set is explored. By using simulated scenes, which allows access to the intrinsic properties of the scene, the magnitude of error introduced through such techniques is quantified.

Implementation of this method is done through python scripted modeling of image fields including application of established James Webb Space Telescope's NIRcam point spread functions and verified noise simulation and propagation techniques. The introduction of IPC is accomplished through convolution of the image with a blur kernel whose parameters are themselves locally defined functions of the image. These techniques can be used to enhance the data processing pipeline for NIRcam.

Design and development of hard x-ray imaging detector using scintillator and SiPhotomultiplier

Shiv Kumar Goyal, Nirma Univ. (India) and Physical Research Laboratory (India); Santosh V. Vadawale, Physical Research Lab. (India); Amisha P. Naik, Nirma Univ. (India); Yashwant B. Acharya, Arpit R. Patel, Physical Research Lab. (India); N. P. S. Mihtun, Physical Research Laboratory (India); Tinkal Ladiya, Physical Research Lab. (India); Niranjan M. Devashrayee, Nirma Univ. (India)

Silicon Photomultiplier (SiPM) is a new development in the field of photon detection and can be described as 2D array of small (hundreds of μm2) Avalanche Photodiodes. The Avalanche Photo Diode (APD) operate in Geiger mode, where the output is independent of the number of incoming photons. The gain of each APD is ~ 1e5 - 1e6 electrons. When a photon creates a photoelectron through the photoelectric effect in one of such APD microcells, a large breakdown current is produced. This current through APD is controlled using in-built quenching resistor. The current flow through the parallel combination of APDs is linearly proportional to the number of incoming photons. Hence the SiPM is a linear amplifier device, where the amount of output charge is linearly proportional to the number of incoming photons, as long as these numbers of incoming photons does not exceed the total number of APDs in detection area. SiPM is an alternate option of using conventional PMTs (Photo Multiplier Tubes), as this offers comparable photon detection efficiency, small size, feasibility of compact array, low cost, low operating voltage and insensitivity to the external magnetic field.

Here, we are developing a hard X - ray imaging detector using Scintillator and SiPM devices. In our experiment, we are using CeBr3 Scintillator crystals of size 25 mm x 25 mm x 5 mm, which is optically coupled to SiPM array of size 6 x 6. These SiPMs are sensL make, surface mount device of total size 4 mm x 4 mm with an active area of 3 mm x 3 mm. We are using this setup in two different modes; 1) Total charge output of all SiPMs added together to get the energy information. 2) In the imaging mode to get the X - Y position of the incoming X - ray. We have also carried out this experiment with CsI Scintillator detector of size 15 mm x 15 mm x 3 mm optically coupled with 4 x 4 array of SiPM (SensL make SiPM) for comparison.

We are comparing the photon distribution profile in the Scintillator detector using GEANT4 simulation for different types of Scintillator detectors NaI, CsI, LaBr3, CeBr3, and BGO. This simulation also gives the idea of minimum position accuracy which can be achieved using a particular type of Scintillator.

We will present the preliminary results from the experiment for low energy threshold and the achieved position accuracy and will also provide comparative study of the sizes, thicknesses and type of Scintillator detectors from GEANT4 simulation.

A generic FPGA-based detector readout and real-time image processing board

Mayuresh N. Sarpotdar, Joice Mathew, Margarita Safonova, Jayant Murthy, Indian Institute of Astrophysics (India)

For space based astronomical observations we don’t have the luxury to use detectors with large readout electronic systems as on ground based telescopes. Moreover the data generated by the image sensor being very large in size cannot be sent completely from the spacecraft to a ground station. Hence a certain amount of real-time image processing is indispensable. An FPGA solution is suitable to develop a generic approach, with respect to various types of detectors, for this task because of the main advantage of easy reconfiguration of the FPGA.

We explored the basic requirements of a generic Real-Time Image processing board. This includes the readout clocks, synchronizing line drivers, RAM requirement for temporary storage and the FPGA implementation of the complete digital logic. We have developed an FPGA board to readout the digital output from the standard semiconductor detectors such as CMOS and CCD. A microcontroller LEON SPARC v8, which is Fault Tolerant to SEU, is implemented on the FPGA to process the images. Various architectures for sharing RAM between the digital logic and the microcontroller were considered.

As an application we have used this board for the readout of a UV CCD. The CCD came with an FPGA board to readout the image data and send in a video format to the computer over USB port. This was replaced by our board which could now readout and process the images in real-time. Image calibrations such as bias, dark and flat field corrections and low level image processing like centroiding and distortion correction is implemented on this board for the UV CCD. The data size reduces from the complete image to a mere list of centroids and their coordinates on the detector.

Characterization of an ultraviolet imaging detector with high event rate ROICs (HEROICs) readout

Nicholas Nell, Kevin C. France, Univ. of Colorado Boulder (United States); Alex Harwit, M. Scott Bradley, Steven Franka, Edward D. Freymiller, Dennis D. Ebbets, Ball Aerospace & Technologies Corp. (United States)

We present characterization results from a photon counting imaging detector consisting of one microchannel plate (MCP) and an array of two readout integrated circuits (ROIC) that record photon position. The ROICs used in the position readout are the high event rate ROIC (HEROIC) devices designed to handle event rates up to 1 MHz per pixel recently developed by the Ball Aerospace and Technologies Corporation in collaboration with the University of Colorado. An opaque photocathode sensitive in the far-ultraviolet (FUV) is deposited on the upper surface of the MCP. The detector is characterized in a chamber developed by CU Boulder capable of illumination with vacuum-ultraviolet (VUV) monochromatic light and measurement of absolute flux with a calibrated photodiode. Testing includes investigation of the effects of adjustment of internal settings of the HEROIC devices including charge threshold, gain, and amplifier bias. The detector response to high local and global count rates is tested. We report initial results including background, uniformity, resolution, and quantum efficiency (QE) as a function of wavelength.

Radiation testing of CID arrays

Zoran Ninkov, Rochester Institute of Technology (United States); Suraj K. Bhaskaran, Carey Beam, Thermo Fisher Scientific Inc. (United States); Bryan C. Fodness, Rochester Institute of Technology (United States)

A Charge Injection Device (CID) is a broadband (200 to 1100 nm) charge-transfer-device image sensor with a range of innovative capabilities, such as non-destructive readout and random addressability, not normally found in charge-coupled devices (CCDs), CMOS or active pixel sensors. CID imagers with formats up to 4 million pixels are available. Significant improvements in the performance of CID arrays have been achieved in recent years due to the accessibility of smaller feature design rules at commercial silicon foundries. In most imaging devices, radiation normally affects certain key parameters (e.g. gate threshold voltage, field/channel stop threshold voltage, charge transfer efficiency, dark current and noise). The CID technology is inherently “hard” to radiation effects due to the high resistivity of the P-channel process and the individually addressed pixels during readout.

As with any solid-state device, CIDs are susceptible to degraded performance from ionizing and non-ionizing radiation. While CID arrays have been tested for susceptibility to both gamma radiation and neutron fluxes in the past there has been no comprehensive testing of the durability of these devices to proton irradiation. This paper reports on a study conducted at the Lawrence Berkeley National Laboratory 88” Cyclotron using a Thermo Scientific™ CID8825D (18.0 x 16.4 micron pixels, 710 x 484 format) radiation-hardened color camera, which features a new Low-Noise, Preamplifier Per Pixel Radiation Hardened CID imager technology specially designed for use in radiation environments. The resultant CID imager performance tests indicate that the device would perform well in extremely harsh radiation environments.

9915-98, Session PSun

Characterizing persistence in JWST NIRCam flight detectors

Jarron M. Leisenring, Marcia Rieke, Karl Misselt, The Univ. of Arizona (United States); Massimo Robberto, Space Telescope Science Institute (United States)

Near-IR detectors are commonly reported to display latent images persisting between integration ramps. After array reset, pixels previously subjected to illumination show an anomalous charge accumulation rate that is initially high but decreases to negligible levels after several hundred

seconds. Depending on the characteristic intensity and timescale, this persistence can dramatically affect science observations if not properly understood. We characterize the persistent behavior of JWST/NIRCam's flight detectors with respect to source intensity, pixel dwell time, and well fill level in order to better understand the underlying physical processes contributing to this phenomenon. Results show that the coefficients of functional fits to the latent signal directly correlate with the stimulating flux as well as the pixel dwell time, enabling predictions of the latent emission. Such relationships provide the potential to model and remove the majority of the persistent flux in NIRCam detectors. Because NIRCam lacks internal calibration lamps, we explore other alternatives to characterize persistence during flight operations.

CCD emulator design for LSST camera

Wei Lu, Paul O'Connor, Jack Fried, Brookhaven National Lab. (United States); John Kuczewski, Brookhaven National Lab, (United States)

A 3.2G pixel wide-field camera constituting of 189 4K x 4K CCDs is under construction at the LSST project. With each CCD having 16 output channel, a total of 3024 channels are implemented in the camera to enable to read out the full picture in 2 second. As part of the LSST project, a comprehensive CCD emulator corresponding to 3 CCDs have been developed for testing multichannel readout electronics.

Based on an Altera Cyclone V FPGA for timing and control, the emulator generates 48 channels of simulated video waveform in response to appropriate sequence of parallel and serial clocks, which has a speed of 550KSPS. Two 256Mb serial memory is adopted for storage of arbitrary grayscale bitmaps. The bitmap or any test pattern can be generated from the emulator in triple as 3 real CCDs do, verifying and testing the LSST 3-stripe REB(science Raft Electronics Board) simultaneously. Using the method of comparator threshold scanning, all 24 parallel clocks and 24 serial clocks from REB are qualified for sequences, levels and periods, before video signal generation. In addition, 66 channels of input bias and voltages are sampled through multi-channel ADC to verify the correctness of the supply provided to the CCD. In spite of this complexity, a emulator board with medium size and less than 8W power consumption can meet all these requirements.

In addition, either Gigabit Ethernet connector or USB bus can be used for controlling and read back from the emulator board. A user friendly Python software is developed for implementing the automatic REB testing process.

9915-101, Session PSun

Commissioning a MKID for the seeing limited focal plane of the DAG Telescope

Tolga Guver, Istanbul Univ. (Turkey); Benjamin A. Mazin, Univ. of California, Santa Barbara (United States); Kieran O'Brien, Univ. of Oxford (United Kingdom); Cahity Ye?ilyaprak, Atatürk Üniv. (Turkey); Sinan K. Yerli, Middle East Technical Univ. (Turkey); Onur Keskin, Isik Üniv. (Turkey)

Eastern Anatolia Observatory (DAG) is a 4m class telescope project aimed to build an observatory in Erzurum Turkey to an altitude of 3170m. One of the instruments on the seeing limited Naysmth focus of the telescope starting from 2019 will be a microwave kinetic inductance detector (MKID). DAG-MKID will house and MKID array of 10,000 pixels. Functioning at around 100mK hundred mK temperatures, MKID based instruments allow for the detection of individual photons tagging their wavelength (R-20 at 1 micron) and time of arrival (micro seconds precision) simultaneously. In this poster we provide some information on the technical capabilities of this proposed instrument and the science it will allow.

Single event effects in 0.18um CMOS image sensors

Joseph E. Rushton, Konstantin D. Stefanov, Andrew D. Holland, The Open Univ. (United Kingdom); Henri Bugnet, Matthew Cordrey-Gale, e2v (France); James Endicott, e2v technologies plc (United Kingdom)

Single Event Effects (SEE) in the on-chip circuitry of CMOS image sensors are discussed. SEE results from heavy ion irradiation are presented. Various design techniques to mitigate against latchup are compared. Latchup and single event upset cross sections are presented at a range of LET up to 109 MeV.cm?/mg.

9915-103, Session PSun

Characterization results of a large format 4k x 4k EMCCD

Olivier Daigle, Nüvü Caméras Inc. (Canada); Oleg Djazovski, Canadian Space Agency (Canada); Étienne Artigau, René Doyon, Univ. de Montréal (Canada)

Since the advent of the first commercial EMCCD in early 2000, users have been requesting a large format EMCCD that would enable sub-electron read-out noise as well as photon counting. Very high resolution spectroscopy (R>30000) can't be efficiently accomplished on a 1k x 1k device. Wide field surveys looking for transient phenomenon require large format detectors. The 4k x 4k device being developed over the last few years will open-up new possibilities in astronomical instrumentation. Providing the community with rigorous characterization data of this device will allow realistic simulations to be developed to better understand the its potential for foreseen applications.

9915-104, Session PSun

The PizzaBox-1 array controller: a high speed low noise array controller for Teledyne H2RG, H4RG, and Selex SAPHIRA devices

Charles Lockhart, Eric A. Warmbier, Donald N. B. Hall, Shane M. Jacobson, Dani E. Atkinson, Sean B. Goebel, Univ. of Hawai'i (United States)

The PizzaBox-1 (PB-1) array controller provides out of the box functionality for controlling and reading out Teledyne H2RG, H4RG, and Selex SAPHIRA arrays at up to a 3 MHz pixel rate. The PB1 provides 34 readout channels with a single board solution for H2RG and SAPHIRA devices, and provides 68 readout channels with the dual board configuration for supporting the H4RG devices.

The overall operation of the controller is managed through an embedded Linux device integrated into the board design. This embedded device provides a variety of industrial interfaces, such as I2C and SPI, allowing for easy configuration, control, and access to the components that provide much of the functionality designed into the system. The embedded Linux device also provides a set of general purpose I/O (GPIO) lines that are used to interface with the multiple FPGAs used.

Deterministic control and operation of the arrays is accomplished using FPGAs designed for the specific device type being used. FPGAs are also used to move digital pixel data from the ADCs to the data transfer pipe for uploading data to the host PC.

USB 3.0 is used for transferring data to the host PC, and using the integrated USB 3.0 module the PB-1 is capable of providing a 3Mpixel/sec sampling rate per channel, allowing for a 20Hz full frame rate with H2RG devices in high speed mode, and a 1Khz full frame rate with the 320x256 SAPHIRA devices - 4 kHz for a 128x128 sub-array.

The PB-1 accepts an external input trigger for coordinated readouts, and provides two optical outputs, one that can be used for accurate timestamping, and another that allows for controlling and synchronizing other PB-1 controllers for multi-array control.

The embedded Linux device's industry standard serial interfaces allow for on-board sensing of system status. Through functionality integrated into the board accurate real-time telemetry for bias voltages, supply power, array temperatures, and board temperatures, can be collected which provides a high level of insight into system status.

The PB-1 array controller is used for evaluating and characterizing H2RG, H4RG, and SAPHIRA devices, as well as being used to control a H2RG device at high speed in the Daniel K. Inouye Solar Telescope's Cryogenic Near-Infrared Spectro-Polarimeter (CryoNIRSP). Integration into an instrument is straightforward, requiring minimal NRE due to the PB-1's modularity and device specific design. The presentation will provide a review of the measured PB-1 performance, guidelines for evaluating its application for meeting instrument requirements, and outlines a path for integrating the PB-1 into an instrument's overall design.

9915-105, Session PSun

Front-end and slow control electronics for large area SiPMs used for the single mirror Small Size Telescope (SST-1M) of the Cherenkov Telescope Array (CTA)

Matthieu Heller, Univ. de Genève (Switzerland); Enrico Junior Schioppa, CERN (Switzerland)

A new large area (94 mm2) hexagonal silicon photomultiplier has been developed in collaboration with Hamamatsu for applications in gamma ray astronomy with Imaging Atmospheric Cherenkov Telescopes. A sensor with such a large area poses several challenges in the design of a readout electronics. In this contribution, we review the steps that led to the design of a preamplication stage that allows to reach performances that, scaled by its surface, are comparable to those of conventional SiPMs.

We also describe the slow control electronics that has been designed to stabilize the working point of each of the 1296 sensors employed in the camera prototype of one of the proposed Small Size Telescopes (SSTs) of the Cherenkov Telescope Array (CTA), the single mirror SST (SST-1M). This system exploits the temperature probes implemented within the package of each SiPM to ne-tune the bias voltage (of order 50-60 V) of individual sensors as a function of the instantaneous temperature, with a precision of a few millivolts.

9915-106, Session PSun

Persistence characterization and data calibration scheme for the RSS-NIR H2RG detector on SALT

Gregory Mosby Jr., Nathan Eggen, Marsha J. Wolf, Kurt P. Jaehnig, Ralf Kotulla, Univ. of Wisconsin-Madison (United States)

To enhance the science capability of the Southern African Large Telescope (SALT), the University of Wisconsin – Madison is building a NIR spectrograph (RSS-NIR). RSS-NIR will complement the visible imaging spectrograph (RSS-VIS) currently available on the telescope. RSS-NIR will deliver medium spectral resolution spectroscopy from 0.9 – 1.7 µm using VPH gratings and a 6 element camera. The detector system uses a H2RG HdCdTe 1.7 µm cutoff array that has been optimized to have low CDS read noise (~20 e-) and fast readout with a pixel sampling speed of 200 kHz. To develop strategies to mitigate persistence, the releasing of trapped charges in subsequent frames, we performed tests to measure and characterize the persistence in the detector. We also performed tests to measure the suppression of the persistence as a function of the relative signal strength between two consecutive frames. These tests use up-the-ramp group samples to get finer time resolution of the release of persistence. The final tests characterizing the persistence of the detector have been completed, and we share these results. We also present preliminary results of the dependence of persistence on detector temperature. We conclude with an outline of a persistence calibration scheme and assess the performance of this routine using the test data.

9915-107, Session PSun

Detector control and data acquisition for the Wide-Field Infrared Survey Telescope (WFIRST) with a custom ASIC

Brian Smith, Stargazer Systems (United States); Markus Loose, Markury Scientific, Inc. (United States); Greg T. Alkire, Stargazer Systems (United States); Atul B. Joshi, SAAZ Technologies LLC (United States); Daniel P. Kelly, NASA Goddard Space Flight Ctr. (United States); Eric J. Siskind, NYCB Real-Time Computing, Inc. (United States); Dino J. Rossetti, Jonathan S. Mah, Conceptual Analytics, LLC (United States); Edward S. Cheng, Conceptual Analytics, LLC (United States); Harry L. Culver, NASA Goddard Space Flight Ctr. (United States); David A. Content, NASA Goddard Space Flight Ctr. (United States)

Modern generation large astronomy focal plane arrays (FPAs) place stringent demands on the control and data acquisition electronic support systems. Most of the detectors used in these FPAs require cryogenic operation, and present interesting signal integrity and thermal isolation trades and challenges. At one extreme, a solution for hybrid detectors is to incorporate ever-increasing function into the Read-Out Integrated Circuit (ROIC). Using modern CMOS designs, these ROICs can be made to include all control and even data acquisition (analog-to-digital conversion, ADC) functions. However, the additional power dissipation at the cold detector may present an undesirable system-level thermal trade. At the other extreme, for small numbers of detectors, it is possible to use only electronics at the warm ambient temperature of the instrument with a relatively simple ROIC. However, this approach requires extreme care in interconnect design since the main thermal break also needs to ensure signal integrity for very small analog signals over potentially large distances.

For NASA's Wide-Field Infrared Survey Telescope (WFIRST) mission, we have a adopted a system-level approach where 1) control and processing intelligence is pushed into components closer to the detector to minimize signal integrity challenges, and 2) functions are performed at the highest allowable temperatures, simplifying the system-level thermal design by not cooling components that do not require such cooling to function. For our design space, the detectors operate at 90K to 100K, the detector control and ADC functions are performed by a custom ASIC at 150K to 180K, and the data processing electronics are at the ambient temperature of the spacecraft, notionally ~300K.

The new ASIC is the main interface between the cryogenic detectors and the warm instrument electronics (an on-board FPGA or computer). This

single-chip design provides basic clocking for most types of hybrid detectors with CMOS ROICs. It includes a flexible but simple to program sequencer, with the option of microprocessor control for more elaborate readout schemes that may be data-dependent. All analog biases, digital clocks, and ADC functions are incorporated and are connected to the nearby detectors with a short cable that also provides some thermal isolation. The interface to the warm electronics is simple and robust through multiple LVDS channels. It also includes design features that support parallel operation of multiple ASICs to control detectors that may have more capability or requirements than can be supported by a single chip.

We report on the design of the new ASIC, current status, and future plans.

9915-108, Session PSun

Design and development of the full scale polar coordinate detector

Sean M Adkins, W M Keck Observatory (United States); Bradley J Felton, Kevin K Ryu, Michael A Brattain, Daniel M O'Mara, Lincoln Laboratory, Massachusetts Institute of Technology (United States); Corinne Boyer, Brent L Ellerbroek, TMT Observatory Corporation (United States)

The Thirty Meter Telescope project, in collaboration with the Lincoln Laboratory of the Massachusetts Institute of Technology is developing a full scale, 60 x 60 subaperture version of the Polar Coordinate Detector first demonstrated in 2012. The Polar Coordinate Detector is designed to address the problem of adaptive optics (AO) laser guide star (LGS) spot image elongation in Shack Hartmann wavefront sensors for extremely large telescopes. The prototype detector, designated the CCID61, was developed in collaboration with Lincoln Laboratory. The new device is designated the CCID87 and will be used as the LGS wavefront sensor detector in the TMT's first light AO system NFIRAOS. This paper will report on the design and initial test results from the fabrication of the first device lot through front illumination processing.

9915-109, Session PSun

RVS large format arrays for astronomy

Barry M. Starr, Raytheon Co. (United States)

Raytheon Vision Systems (RVS) has a long history of providing state of the art infrared focal planes for the astronomical community. This paper will provide an update of RVS capabilities and products for the community not only for the infrared wavelengths but also in the visible wavelengths as well. Large format infrared detector arrays are now available that meet the demanding requirements of the low background scientific community across the wavelength spectrum. These detector arrays have formats from 1K x 1K to as large as 8K x 8K with pixel sizes ranging from 8 to 27 ?m. Focal plane arrays have been demonstrated with a variety of detector materials: SiPiN, HgCdTe, InSb, and Si:As IBC. All of these detector materials have demonstrated low noise and dark current, high quantum efficiency, and excellent uniformity. All can meet the high performance requirements for low-background within the limits of their respective spectral and operating temperature ranges

9915-110, Session PSun

Prototype near-infrared detectors for WFIRST

Robert J. Hill, Conceptual Analytics, LLC (United States); Roger D. Foltz, Emily Kan, Yiting Wen, Analia Cillis, NASA Goddard Space Flight Ctr. (United States); Nicholas Boehm, Global Science & Technology, Inc. (United States); Augustyn Waczynski, NASA Goddard Space Flight Ctr. (United States); Edward S. Cheng, Conceptual Analytics, LLC (United States); David A. Content, NASA Goddard Space Flight Ctr. (United States)

NASA has initiated a technology development effort to produce prototype near-infrared detectors for the WFIRST (Wide Field Infrared Survey Telescope) Project. WFIRST envisions a focal plane array comprised of 18 4K x 4K Sensor Chip Assemblies (SCAs) arranged in a 6 x 3 mosaic. The prototype SCAs have been fabricated by Teledyne Imaging Systems and have a 10um pixel pitch with a 2.5um long wavelength cut-off. Early efforts have focused on variations in the pixel design aimed at optimizing aspects of performance such as image persistence and read noise, which are expected to be key factors in driving the scientific capability of the Wide Field Imaging instrument. We report here on the testing of the prototype detectors at the Goddard Space Flight Center Detector Characterization Lab.

9915-111, Session PSun

Low voltage electron multiplying CCD in a CMOS process

Alice Dunford, Konstantin D. Stefanov, Andrew D. Holland, The Open Univ. (United Kingdom)

Low light level and high speed image sensors as required for space applications can suffer from a decrease in the signal to noise ratio (SNR) due to the photon-starved environment and limitations of the sensor's readout noise. The SNR can be increased by the implementation of Time Delay Integration (TDI) as it allows photoelectrons from multiple exposures to be summed in the charge domain with no added noise. Electron Multiplication (EM) can further improve the signal to noise ratio and lead to an increase in device performance. However, both techniques have traditionally been confined to Charge Coupled Devices (CCD) due to the efficient charge transfer required. With the increase in demand for CMOS sensors with equivalent or superior functionality and performance, this paper presents findings from the analysis of a low voltage EMCCD in a CMOS process using advanced design features to improve gate design and increase the electron multiplying gain. By using CMOS process it is possible to increase chip integration and functionality and achieve higher readout speeds and reduced pixel size. Characterisation tests have been completed including analysis of the dark current, charge transfer efficiency, readout noise, the electron multiplying gain and analysis of the parameters' dependence on temperature and voltage.

9915-112, Session PSun

A temperature controller board for the ARC controller

Simon M. Tulloch, European Southern Observatory (Germany)

A high-performance temperature controller board has been produced for the ARC generation-3 CCD controller. It contains two 9W temperature servo loops and four temperature input channels and is fully programmable via the ARC API and OWL data acquisition program. PI-loop control is implemented in an on-board micro. Both diode and RTD sensors can be used. Control and telemetry data is sent via the ARC backplane although a USB-2 interface is also available. Further functionality includes hardware timers and high current drivers for external shutters and calibration LEDs, an LCD display interface, a parallel i/o port, a pressure sensor interface and an uncommitted analogue telemetry input.

9915-113, Session PSun

Implementation of an FPGA-based DCDS video processor for CCD imaging

Simon M. Tulloch, European Southern Observatory (Germany)

Noise modelling of an E2V CCD231 suggested that a weighted double correlated sampler (DCDS) processor could offer small noise improvements at low pixel rates. The model was used to produce synthetic video waveforms that were then processed at various ADC frequencies and analogue bandwidths to identify the best weighting strategy and preamplifier design. An FPGA-based DCDS controller was then built, first to measure the actual CCD noise spectrum and then to verify the earlier theoretical results.

9915-114, Session PSun

Performance of the Euclid Mission infrared focal plane detector subsystem

Seiffert, Jet Propulsion Lab. (United States); Paolo Strada, European Space Research and Technology Ctr. (Netherlands); Corey Tucker, Arctic Slope Regional Corp. (United States); Kyle Turck, Global Science & Technology, Inc. (United States); Frederick Wang, Arctic Slope Regional Corp. (United States); Carissa T. Weber, Jet Propulsion Lab. (United States); James W. Williams, Global Science & Technology, Inc. (United States)

In support of the European Space Agency's (ESA) Euclid mission, NASA's Detector Characterization Laboratory (DCL) is responsible for the evaluation of the H2RG mercury cadmium telluride (MCT) detectors and electronics assemblies fabricated by Teledyne Imaging Sensors. The detector evaluation is performed in the DCL at the NASA Goddard Space Flight Center (GSFC) in close collaboration with engineers and scientists from the Jet Propulsion Laboratory (JPL) and the Euclid project. The Euclid Near-Infrared Spectrometer and Photometer (NISP) will perform large-area optical and spectroscopic sky surveys in the 0.9 2.02 μm infrared (IR) region. The NISP instrument will contain sixteen 4-megapixel detector arrays each coupled to a Teledyne SIDECAR application specific integrated circuit (ASIC). The focal plane will operate at 100K and the SIDECAR ASIC will be in close proximity operating at a slightly higher temperature of 125K. This paper will describe the test configuration, performance tests, and results of the latest engineering run, also known as Pilot Run. This Pilot Run consisted of four H2RG detectors operating simultaneously. Performance data will be presented on the noise, spectral quantum efficiency, dark current, persistence/latency, pixel yield, pixel-to-pixel uniformity, linearity, inter-pixel crosstalk, full well, dynamic range, power dissipation, thermal response and unit cell input sensitivity.

9915-21, Session 5

Towards the next generation of L-APD MOVPE HgCdTe arrays: beyond the SAPHIRA 320 x 256

Donald N. B. Hall, Univ. of Hawai'i (United States); Ian M. Baker, SELEX ES Ltd. (United Kingdom); Gert Finger, European Southern Observatory (Germany)

The basic Selex SAPHIRA 320 X 256 @24um pitch L-APD MOVPE HgCdTe array is now generally accepted as the sensor of choice for near infrared (NIR – 0.8 to 2.5um) adaptive optics (AO) wavefront(WF) sensing using natural guide stars. With larger formats and improved readout integrated circuits (ROICs), this technology shows great potential for both more sophisticated wavefront correction and also broader, lower background astronomy applications. This opens the path to larger format arrays for optimized for either AO WF sensing or low background applications. We present Selex-UH initiatives in both areas.

The current SAPHIRA arrays are already ideally suited to NIR AO WF tip-tilt sensing using natural guide stars. However applications involving WF sensing for higher order WF correction and correction for aplanatism over the field require larger formats, in the 512 x 512 to 2048 x 2048 range, at maximum pixel read rates. Broader applications involving much lower background astronomical observations require these same larger formats with relaxed requirements on pixel read rate but with reference pixels to track long term drifts. Considerations of cost of the arrays and the instruments utilizing them also drive toward smaller pixels. In the 6 months between submission of abstracts and the SPIE meeting, Selex and UH will replicate planned 320 x 256 @24um pitch developments as 640 x 512 @12um pitch detector arrays and hybridize every alternate row and column of these detector arrays to the ME1001 ROIC to evaluate their performance and develop this technology. Results will be presented as part of this presentation.

For AO WF sensing applications, Selex and UH are pursuing a 1024 x 1024 @12um pitch readout that can be hybridized utilizing every alternate row and column to a 512 x 512 @24um pitch L-APD detector array or to a 1024 x 1024 @12um pitch detector array. The incorporation of 64 outputs with these ROICs will likely require an oversize package – one attractive option is a two-side close-buttable package compatible with the low background 2048 x 2048 @15um pitch, three side close-buttable array summarized below.

UH has already confirmed that the standard MOVPE L-APD design at an avalanche gain of X5 (8 volts avalanche bias) can have gain normalized dark currents as low as 0.01 e-/sec in regions of low glow. This potentially opens the technology to a broad range of lower background astronomical applications. These place a premium on low background and cosmetic quality but are compatible with a lower number of outputs (8, 16 or 32), thus allowing a three-side close-buttable package with all outputs on one side. These applications also require reference outputs and reference pixels

to track and correct long term drifts. Selex and UH are pursuing a 2048 x 2048 @12um pitch, three-side close-buttable array, responsive to these requirements. It would be 2/3 the dimensions of the Teledyne H2RG and mounted on a similar package.

9915-22, Session 5

Next-generation performance of SAPHIRA HgCdTe APDs

Dani E. Atkinson, Donald N. B. Hall, Univ. of Hawai'i (United States); Ian M. Baker, SELEX ES Ltd. (United Kingdom); Sean B. Goebel, Shane M. Jacobson, Univ. of Hawai'i (United States)

We present characterization and deployment performance of the Mark 13/14 and the next generation of Selex SAPHIRA HgCdTe APDs. Iterations on the SAPHIRA hardware, bandgap design, and production methodology have improved the performance and characteristics of the device substantially over the last two years of collaboration between UH and Selex. The Mark 13/14 devices received in Fall 2015 feature a new bandgap design that extends the short-wave response down to 0.8μm. They also marked the introduction of a high-temperature anneal stage during manufacture to bake out surface-level As traps in the HgCdTe. This resulted in a remarkable improvement in cosmetic performance and pixel operability, particularly at high bias voltages where the number of hot/inoperative pixels is greatly suppressed relative to previous SAPHIRA generations. The next generation builds on these successes and specifically targets photon counting.

Our efforts in the reduction of glow generated by the SAPHIRA readout have also greatly reduced measured dark current, and we present new upper limits on dark current in both the Mark 13/14 and next generation SAPHIRA arrays. Using a physical mask we located and identified the primary glow source on the device. The suppression of this source was included in the following round of ROIC redesign. We also present the most recent measurements of other relevant detector characteristics, including avalanche gains of >100 and resulting read noise. Of particular interest for photon counting is the pulse height distribution of avalanche events, for which we also present Monte Carlo modeling of HgCdTe avalanches and discuss agreement with measured data.

9915-23, Session 5

New progress in electron-injection detectors for NIR imagers with low noise and high frame rates

Mohsen Rezaei, Skylar Wheaton, Chee Leong Tan, Vala Fathipour, Melville P. Ulmer, Northwestern Univ. (United States); Olivier Guyon, The Univ. of Arizona (United States); Hooman Mohseni, Northwestern Univ. (United States)

We present our latest simulation and experimental results for a new generation of Electron Injection detectors with a cutoff wavelength of 1.7 um. Electron Injection detectors have an internal linear gain that effectively reduces the noise of the readout electronics. The device is made of the well-developed indium phosphide material system and can be easily made into large imaging arrays with high fill-factor, and it only requires about 1 volt to operate.

Another important property of the device is that it can potentially achieve single-photon detection at about 200 K, and at frame rates of over 1kHz. These properties of a fully developed camera will allow the low-order wavefront sensor in the SCExAO to perform near the photon-noise limit.

We have already fabricated Electron Injection detector arrays with 320x256 pixels at 30 um pitch, and hybridized them with FLIR's ISC9705 readout integrated circuit. We will report the detailed performance of the focal plane array when integrated into a temperature-controlled camera. In particular, we will report the imager overall pixel noise and dynamic range at frame rates up to ~4000 fps, and at different operating temperatures. We also plan to evaluate and report on the performance of the camera in the SCExAO Hilo test facility.

The injector size in these arrays is about 10 um. Our theoretical and experimental results show that smaller injector diameters produce a much lower dark current and higher gain. We plan to make imagers with smaller injector diameter in the future.

This work is supported by a grant from the Keck Foundation.

9915-24, Session 5

RVS WFIRST sensor chip assembly development results

Barry M. Starr, Raytheon Co. (United States)

Raytheon Vision Systems (RVS) has been developing high performance low background VisSWIR focal plane arrays suitable for the NASA WFIRST mission. These near infrared sensor chip assemblies (SCAs) are manufactured using substrate removed HgCdTe on CZT substrates with a 10 micron pixel pitch. WFIRST requirements are for a 4K x 4K format 4-side buttable package to populate a large scale 6 x 3 mosaic focal plane array of 18 SCAs. RVS devices will be compatible with the NASA developed FPA 4-side buttable package, and flight interface electronics. Initial development efforts at RVS have focused on a 2K x 2K format 10 micron pixel design based on an existing readout integrated circuit (ROIC) to demonstrate desired detector material performance at a relevant scale. This paper will provide performance results on the RVS efforts. RVS has successfully developed multiple 4K x 4K 10 micron pixel ROICs and we demonstrate readiness to scale our design efforts to the desired 4K x 4K format for WFIRST in 2016.

9915-25, Session 5

Progress on the characterization activities of new infrared detectors from Selex-ES Ltd. at the UKATC

Naidu N. Bezawada, David C. Atkinson, Chris Miller, Ian Bryson, UK Astronomy Technology Ctr. (United Kingdom); Les G. Hipwood, Nick Shorrocks, Harald J. Weller, Malcolm Jackson, Ray P. Davis, Keith Barnes, Ian M. Baker, SELEX ES Ltd. (United Kingdom)

ESA is funding the industry in Europe to bring the technologies together to manufacture high performance infrared detectors from near infrared (NIR) to very long wavelength infrared (VLWIR) detectors. The UKATC has undertaken the tasks of test and characterising the new detectors being manufactured by Selex ES Ltd in the UK. Initial test results from these programs were presented at previous meetings in 2012 and 2014. The work since has much progressed to test and characterise the Large Format NIR, SWIR and LW and VLWIR detectors. This paper will present the custom built test facilities for evaluation of large format (currently 1280x1032, 15um pixel format) near-infrared detectors for astronomy applications, the characterisation of 1Kx1K shortwave infrared detectors (cut-off at 2.5μm on a 2Kx2K ROIC) for satellite-based earth observation programs, long wavelength (8 to 11μm) and very long wavelength (10 to 14.5μm) 256x320 infrared arrays for cosmos applications. Also being evaluated in our laboratory is a SAPHIRA APD array (mark-5) for photon sensing and high speed AO applications. Custom test facilities have been setup at the UKATC and are being routinely used to test and characterise these detectors under conditions representative of the applications. The paper

will discuss the requirements placed on testing in each of these programs along with the associated challenges to evaluate the performance of these detectors. The paper will also include an overview of Selex detectors and the MOVPE process along with some of the latest test results from the characterisation programs, where appropriate.

9915-27, Session 6

A status report on STA detectors and electronics for 2016

Gregory R. Bredthauer, Kasey L. Boggs, Richard A. Bredthauer, Semiconductor Technology Associates Inc. (United States)

We report on ongoing scientific CCD detector and control electronic developments at STA. Recent astrometric and spectroscopic instruments are pushing for highly uniform pixel arrays. We present results from sensors fabricated with high resolution 1X masks aimed at minimizing the random and periodic pixel nonuniformities introduced during manufacture. Instrument requirements for large next generation telescopes tend to target larger arrays with larger pixels. We introduce the STA4500, a four output 6120 x 6120 15um CCD intended for these applications. The device includes dual transfer gates before the serial register to allow slow, high CTE vertical transfers to occur simultaneous with serial readout. We also present results from our next experimental high dynamic range CCD. This sensor uses dual outputs operating in parallel with different sensitivities to greatly expand the linear dynamic range achievable with large pixel scientific sensors without impairing noise or readout rate. Finally, we describe updates to our Archon astronomical CCD controller. Improvements include daisy chained multi-controller synchronization for mosaic readout, high resolution thermal control for sub-milliKelvin temperature stability, and high voltage biases up to +/-100V for operating deep depletion CCDs.

9915-28, Session 6

Deep depletion CCD detectors for the Transiting Exoplanet Survey Satellite

Vyshnavi Suntharalingam, Ilya Prigozhin, Douglas J. Young, Keith Warner, Barry E. Burke, Joseph S. Ciampi, Michael J. Cooper, Renee D. Lambert, Daniel M. O'Mara, Deborah F. Woods, MIT Lincoln Lab. (United States); Steven E. Kissel, Kavli Institute for Astrophysics and Space Research (United States); Gregory Y. Prigozhin, Timothy A. Sauerwein, Carolyn Thayer, Joel S. Villasenor, MIT Kavli Institute for Astrophysics and Space Research (United States)

We describe the development of the fully depleted, back-illuminated, charge coupled devices for the Transiting Exoplanet Survey Satellite (TESS). The TESS payload consists of four identical wide-angle cameras, each having a 2x2 mosaic array of CCDs in its focal plane. The devices are fabricated from start to finish on the newly upgraded 200-mm wafer line at Lincoln Laboratory. The specifications for TESS required thick (100μm) fully depleted CCDs with 2048x2048 imaging array and 2048x2048 frame store regions, 15x15μm pixels, and 4 output ports. Rapid (~4msec) frame transfer and high (>200,000 electrons) well capacity are required, as well as charge injection and binning.

We discuss techniques used to produce the devices on high resistivity substrates, including techniques to stitch, or photocompose, the 32mm x 64mm die with stepper lithography. We describe the packaging methods for 3-side abuttable arrays with 10-micron peak-to-valley flatness. Finally, we present both wafer-level and packaged device performance results, with specific discussion of the accomplishments with low dark current (<2e-/pix/sec at -30°C wafer probe), high QE (>60% at 950nm), low noise (<10e- at 625kHz), high full well (>200ke), and detector-bias controlled PSF.

9915-29, Session 6

Technology validation of the PLATO CCD at ESA

Thibaut Prod'homme, Peter Verhoeve, Thierry Beaufort, Ludovic Duvet, Frederic Lemmel, Hans Smit, Sander Blommaert, Cornelis van der Luijt, European Space Research and Technology Ctr. (Netherlands); Ivo Visser, Klok Vacuum Service (Netherlands); Jerko Heijnen, Bart Butler, European Space Research and Technology Ctr. (Netherlands)

PLATO – PLAnetary Transits and Oscillations of stars – is the third medium-class mission (M3) to be selected in the European Space Agency (ESA) Science and Robotic Exploration Cosmic Vision programme. It is due for launch in 2024 with the main objective to find and study terrestrial planets in the habitable zone around solar-like stars. The payload consists in 34 cameras; with each camera comprising 4 Charge-Coupled Devices (CCDs), a total of 136 flight model devices procured by ESA shall ultimately be integrated on the spacecraft. The CCD270 – specially designed and manufactured by e2v for the PLATO mission – is a large format (8 cm x 8 cm) back-illuminated device operating at 4 MHz pixel rate and coming in two variants: full frame and frame transfer. Due to the large number of devices and its demanding specifications, the manufacturing of the PLATO CCDs is an unprecedented industrial effort in many aspects.

In order to de-risk the PLATO CCD procurement and aid the mission definition process, ESA's Payload Technology Validation team is currently validating the PLATO CCD270. This validation consists in demonstrating that the device achieves its specified electro-optical performance in the relevant environment: operated at 4 MHz, at cold and before and after proton irradiation. It also includes investigating if the CCD280 – a smaller device produced on the same wafer as the CCD270 – can be used instead of the CCD270 for radiation testing during qualification.

In the context of this validation, two CCD270 and two CCD280 devices have been fully characterized before and after proton irradiation. This paper details the test results with respect to dark current, hot pixels, random telegraph signals and charge transfer inefficiency. It shall focus in particular on the latter, discussing our findings related to the use of a variety of measurement methods (x-ray, flat-field extended pixel edge response, first pixel response, trap pumping) characterizing radiation-induced, charge trapping defects at high readout frequency – a rather unexplored region for Astronomy applications. The outcome of this test campaign shall serve as a direct input to the PLATO consortium of scientists to study the mission end-of-life performance and as a basis for further optimization of the CCD operation.

9915-30, Session 6

Characterization and acceptance testing of fully depleted thick CCDs for the Large Synoptic Survey Telescope

Ivan V. Kotov, Paul O'Connor, Justine Haupt, Brookhaven National Lab. (United States); Homer Niel, SLAC National Accelerator Lab. (United States)

The LSST came will be made as a mosaic assembled of 189 large format Charge Coupled Devises (CCD). These are n-channel, 100 micron thick devices operated in over depleted regime. There are 16 segments, 1 million

pixels each, read out through separate amplifiers. The image quality and readout speed expected from LSST camera translates into strict acceptance requirements for individual sensors.

Prototype sensors and preproduction CCDs were delivered by vendors and been used for developing test procedures and protocols. Building upon this experience 2 test stands were designed and commissioned at Brookhaven National Laboratory for production electro-optical testing.

Sensor acceptance criteria are outlined and discussed. The test stand design and equipment used in its design is present. The results of commissioning sensor runs are present.

9915-31, Session 7

Performance of ?c=2.5µm HAWAII 4RG-15 (H4RG-15) arrays in the laboratory and at the telescope

Donald N. B. Hall, Dani E. Atkinson, Univ. of Hawai'i (United States); Richard Blank, AstroBlank Scientific LLC (United States); Mark Farris, Teledyne Imaging Sensors (United States); Sean B. Goebel, Klaus W. Hodapp, Shane M. Jacobson, Univ. of Hawai'i (United States); Markus Loose, Markury Scientific, Inc. (United States); Majid Zandian, Teledyne Imaging Sensors (United States)

The NSF supported development of the HAWAII 4RG-15 (H4RG-15) aims to provide a 16 MPxl 4096x4096@15?m pitch format array at significantly reduced price per pixel while maintaining the superb low background performance of the H2RG. The design also incorporates new features, notably clocked reference output and interleaved reference pixel readout, that promise to significantly improve noise performance; the reduction in pixel pitch from 18 to 15 microns may slightly improve transimpedance gain with modest potential impact on full well and crosstalk.

The program is segmented into 1) technology development and, 2) production demonstration phases. Phase 1, completed in June of 2012, developed and demonstrated all key technologies in four engineering grade H4RG-15 arrays. The measured performance of these arrays resulted in the selection of the ON Semiconductor ROIC for Phase 2. Initiation of the Phase 2 program to attempt six hybridizations with a goal of two science grade H4RG-15 arrays was delayed due to challenges in growing high quality MBE layers on the 7 x 7.5cm substrates required for the H4RG-15. These were surmounted in July of 2015 and, at the time this abstract is being submitted, seven excellent MBE layers are in the final stages of detector processing with hybridization scheduled early in 2016. These H4RG-15 arrays will be available to UH in March, 2016 for characterization both in the laboratory and at the UH 88-inch telescope on Mauna Kea.

We will report the performance of these Phase-2 H4RG-15s within the context of established H2RG performance for key parameters (read noise, dark current, transimpedance gain, and cross-talk), highlighting the improvements from the new readout modes.

9915-32, Session 7

Integrated system tests of the LSST raft tower modules

Paul O'Connor, Brookhaven National Lab. (United States); Pierre E. Antilogus, Institut National de Physique Nucléaire et de Physique des Particules (France); Peter E. Doherty, Harvard Univ. (United States); Justine Haupt, Brookhaven National Lab. (United States); Sven C. Herrmann, Michael Huffer, SLAC National Accelerator Lab. (United States); Claire Juramy, Institut National de Physique Nucléaire et de Physique des Particules (France); John Kuczewski, Brookhaven National Lab. (United States); Stefano Russo, Institut National de Physique Nucléaire et de Physique des Particules (France); Christopher W. Stubbs, Harvard Univ. (United States); Richard Van Berg, Univ. of Pennsylvania (United States)

The science focal plane of the LSST camera is made up of 21 fully autonomous 144 Mpixel imager units designated "raft tower modules" (RTM). These imagers incorporate nine 4K x 4K fully-depleted CCDs and 48 channels of readout electronics, including a dedicated CMOS video processing ASIC and components that provide CCD biasing and clocking, video digitization, thermal stabilization, and a high degree of monitoring and telemetry. The RTM achieves its performance goals for readout speed, read noise, linearity, and crosstalk with a power budget of less than 400mW/channel. Series production is underway on the first units and will run until 2018.

We will present the RTM final design, tests of the integrated signal chain, and performance results for the fully-integrated module with pre-production CCDs.

9915-33, Session 7

Development of low-noise CCD drive electronics for the World Space Observatory ultra-violet spectrograph subsystem

Mike A. Salter, Matthew J. Clapp, Nick R. Waltham, Science and Technology Facilities Council (United Kingdom)

World Space Observatory Ultra-Violet (WSO-UV) is a major Russian-led international collaboration to develop a large space-borne 1.7 m Ritchey-Chrétien telescope and instrumentation to study the universe at ultra-violet wavelengths between 115 nm and 310 nm, exceeding the current capabilities of ground-based instruments. The WSO Ultra-Violet Spectrograph subsystem (WUVS) is led by the Institute of Astronomy of the Russian Academy of Sciences and consists of two high resolution spectrographs covering the Far-UV range of 115-176 nm and the Near-UV range of 174-310 nm, and a long-slit spectrograph covering the wavelength range of 115-305 nm. The custom-designed CCD sensors and cryostat assemblies are being provided by e2v technologies (UK). STFC RAL Space is providing the Camera Electronics Boxes (CEBs) which house the CCD drive electronics for each of the three WUVS channels.

This paper presents the results of the detailed characterisation of the WUVS CCD drive electronics. The electronics include a novel high-performance video channel design that utilises Digital Correlated Double Sampling (DCDS) to enable low-noise readout of the CCD at a range of pixel frequencies, including a baseline requirement of less than 3 electrons rms readout noise for the combined CCD and electronics system at a readout rate of 50 kpixels/s. These results illustrate the performance of this new video architecture as part of a wider electronics sub-system that is designed for use in the space environment. In addition to the DCDS video channels, the CEB provides all the bias voltages and clocking waveforms required to operate the CCD and the system is fully programmable via a primary and redundant SpaceWire interface. The development of the CEB electronics design has undergone critical design review and the results presented were obtained using the engineering-level electronics box. A variety of parameters and tests are included ranging from general system metrics, such as the power and mass, to more detailed analysis of the video performance including noise, linearity, crosstalk, gain stability and transient response.

9915-34, Session 7

Optical characterization of the PLATO CCD at ESA

Peter Verhoeve, Thibaut Prod'homme, Tim Oosterbroek, Ludovic Duvet, Thierry Beaufort, Sander Blommaert, Bart Butler, Jerko Heijnen, Frederic Lemmel, Cornelis van der Luijt, Hans Smit, Ivo Visser, European Space Research and Technology Ctr. (Netherlands)

PLATO – PLAnetary Transits and Oscillations of stars – is the third medium-class mission (M3) to be selected in the European Space Agency (ESA) Science and Robotic Exploration Cosmic Vision programme. It is due for launch in 2024 with the main objective to find and study terrestrial planets in the habitable zone around solar-like stars. The payload consists of 34 cameras; with each camera comprising 4 Charge-Coupled Devices (CCDs), a total of 136 flight model devices procured by ESA shall ultimately be integrated on the spacecraft. The CCD270 – specially designed and manufactured by e2v for the PLATO mission – is a large format (8 cm x 8 cm) back-illuminated device operating at 4 MHz pixel rate and coming in two variants: full frame and frame transfer. Due to the large number of devices and its demanding specifications, the manufacturing of the PLATO CCDs is an unprecedented industrial effort in many aspects.

In order to de-risk the PLATO CCD procurement and aid the mission definition process, ESA's Payload Technology Validation section is currently validating the PLATO CCD270. This validation consists in demonstrating that the device achieves its specified electro-optical performance in the relevant environment: operated at 4 MHz, at cold and before and after proton irradiation.

In the context of this validation, CCD270 devices have been characterized optically with respect to performance parameters directly relevant for the photometric application of the CCDs. This paper details the results of measurements of Quantum Efficiency for a range of angles of incidence, Pixel Response Non Uniformity, intra–pixel response (non-)uniformity, and response to spot illumination, before and after proton irradiation. In particular, the effect of radiation induced degradation of the charge transfer efficiency on the measured charge in a star-like spot has been studied as a function of signal level and of position on the pixel grid. Also, the effect of various levels of background light on the amount of charge lost from a star image will be described. The outcome of this test campaign shall serve as a direct input to the PLATO consortium of scientists to study the mission performance and as a basis for further optimization of the CCD operation.

9915-35, Session 7

On-ground characterization of the Euclid's CCD273-based readout chain

Magdalena B. Szafraniec, Ruyman Azzollini, Mark R. Hailey, Dahoa Hu, Univ. College London (United Kingdom); Ralf Kohley, European Space Astronomy Ctr. (Spain); Neil J. Murray, The Open Univ. (United Kingdom); Ashley Cutts, Abdullah Khalil, Christian Plana, David M. Walton, Mark S. Cropper, Univ. College London (United Kingdom)

Euclid is a medium class European Space Agency mission scheduled for launch in 2020. The main goal of the survey is to study the dark matter and energy content of the Universe. One of the cosmological probes used, the Weak Lensing technique, looks at distortions in galaxy shapes and requires very accurate knowledge of the system point spread function (PSF). To measure those shapes with maximum accuracy the camera system of the telescope's VISible Instrument (VIS) needs to provide high charge transfer efficiency and low noise operation. A single readout chain of VIS consists of 3 CCDs, readout electronics (ROE) and a power supply unit (RPSU). The entire Euclid focal plane for flight features 36 CCDs, which are read out by 12 ROEs and powered by 12 RPSUs. All three components of the readout chain have been explicitly designed for Euclid. The CCD273 device manufactured by e2v provides maximum charge transfer efficiency to reduce the charge trailing during the readout. The CCD is also fitted with a charge injection structure which is used for the calibration of the Charge Transfer Inefficiency. The readout electronics (ROE) and the ROE power supply unit (RPSU) have been designed and manufactured at the Mullard Space Science Laboratory (MSSL) and offer low noise, radiation-resistant operation.

The VIS readout chain undergoes a rigorous on-ground testing at several development stages to guarantee that strict mission requirements are met before the launch of the telescope. This paper summarizes the results of the commissioning of an advanced flight-like VIS readout chain consisting of an electro-mechanical model (EM) of the CCD273 device, EM ROE and EM RPSU. In particular, the chosen CCD operation modes, design trade-offs and performance parameters are discussed. Aspects to improve uniformity and stability of device operation are addressed as well.

9915-36, Session 8

LGSD/NGSD: high QE, 3e-RoN, fast 700fps, 1760x1680 pixels, AO LGS CMOS imager for the E-ELT

Mark Downing, European Southern Observatory (Germany); Bart M. Dierickx, Arnaud Defernez, Caeleste CVBA (Belgium); Philippe Feautrier, Institut de Planétologie et d'Astrophysique de Grenoble (France); Martin Fryer, Jamie Forrest, e2v technologies plc (United Kingdom); Jean-Luc Gach, Lab. d'Astrophysique de Marseille (France); Paul Jerram, Paul R. Jorden, e2v technologies plc (United Kingdom); Manfred Meyer, European Southern Observatory (Germany); Andrew Pike, e2v technologies plc (United Kingdom); Javier Reyes, European Southern Observatory (Germany); Robert Simpson, e2v technologies plc (United Kingdom); Eric Stadler, Institut de Planétologie et d'Astrophysique de Grenoble (France); Jeremy Stent, Nick Swift, e2v technologies plc (United Kingdom)

The success of the next generation of instruments for ELT class telescopes will depend upon improving the image quality by exploiting sophisticated Adaptive Optics (AO) systems. One of the critical components of the AO systems for the E-ELT has been identified as the optical Laser/Natural Guide Star WFS detector. The combination of large format, 1760x1680 of 24 ?m pixels to finely sample the wavefront and the spot elongation of laser guide stars, fast frame rate of 700 frames per second (fps), low read noise (< 3e-), and high QE (>90%) makes the development of this device extremely challenging. Design studies concluded that a highly integrated Backside Illuminated CMOS Imager built on High Resistivity silicon as the most likely technology to succeed.

Two generations of the CMOS Imager are being developed: a) the already designed and manufactured NGSD, a quarter sized pioneering device of 880x840 pixels capable of meeting first light needs of the E-ELT; b) the LGSD, the larger full size device. The detailed design is presented including the approach of using massive parallelism (70,400 ADCs) to achieve the low read noise at high pixel rates of 3 Gpixel/s and the 88 channel, 220 Mbps, LVDS serial interface to get the digitized data off-chip. To enable read noise closer to the goal of 1e- to be achieved, a split wafer run has allowed the NGSD to be manufactured in the more speculative, but much lower read noise, Ultra Low Threshold Transistors in the unit cell. The NGSD has come out of production, it has been thinned to 12?m, backside processed and packaged in a custom 370pin Ceramic PGA (Pin Grid Array).

Results of comprehensive tests performed both at e2v and ESO have validated the technological choice. These results along with the plan for a further tweaking of the design to solve the remaining issues of hot pixels and cross-talk are presented.

9915-38, Session 8

Fully depleted backside biased CMOS image sensor

Konstantin D. Stefanov, Andrew D. Holland, Andrew S. Clarke, The Open Univ. (United Kingdom)

We are presenting a novel concept for a fully depleted, pinned photodiode CMOS image sensor using reverse substrate bias. The principle of operation allows the manufacture of fully depleted, backside illuminated CMOS sensors with active thickness in excess of 100 μm. This helps increase the QE at near-IR and soft X-ray wavelengths, while preserving the excellent characteristics associated with the pinned photodiode sensitive elements. Such sensors are applicable to wide range of applications, including scientific imaging, astronomy, Earth observation and surveillance.

A prototype device with 10 μm and 5.4 μm pixels using this concept has been designed and manufactured on a 0.18 μm image sensor process. An additional implantation step has been introduced in order to achieve full depletion without large parasitic substrate currents. The paper discusses the design of the sensor and the challenges that had to be overcome to realise it in practice. The first characterisation data from a number of design variants is presented and discussed, as well as the plans for producing full scale devices in the near future. It is expected that this new technology can be competitive with modern backside illuminated thick CCD for use at visible to near-IR telescopes and synchrotron light sources.

9915-39, Session 8

A 9 megapixel large-area back-thinned CMOS sensor with high sensitivity and high frame-rate for the TAOS II program

Jérôme Pratlong, e2v technologies plc (United Kingdom); Shiang-Yu Wang, Matthew J. Lehner, Institute of Astronomy and Astrophysics - Academia Sinica (Taiwan); Paul R. Jorden, Paul Jerram, Steven Johnson, e2v technologies plc (United Kingdom)

The Transneptunian Automated Occultation Survey (TAOS II) is a robotic telescope system using three telescopes in San Pedro Martir Observatory in Mexico. It measures occultation of background stars by small TransNeptunian Objects in order to determine their size distribution. Each telescope focal plane uses ten buttable backthinned CMOS sensors. Key performance features of the sensors are: Large array format 4608 x 1920, Pixel size 16μm, Multi ROIs, 8 analogue video channels, Frame rate of 20-40 fps [using ROIs], Low noise <5e-, Cryogenic dark current <0.1e-/pixel/s, backthinned for >90% peak quantum efficiency.

The paper describes top level application requirements for the TAOS II detector. The sensor design including the pixel and buttable package are described together with performance at room temperature and cryogenic temperature of backthinned devices. The key performance specifications have been demonstrated and will be presented. The production set of 40 devices are due for completion within 2016.

9915-40, Session 8

Electro-optic and radiation damage performance of the CIS115: an imaging sensor for the JANUS optical camera on-board JUICE

Matthew R. Soman, Edgar A. H. Allanwood, Andrew D. Holland, Konstantin D. Stefanov, Mark Leese, Jason P. D. Gow, The Open Univ. (United Kingdom)

The Jupiter Icy Moon Explorer (JUICE) has been officially adopted as the next Large-class mission by the European Space Agency, with a launch date of 2022. The science payload includes an optical camera, JANUS, which will perform imaging and mapping observations of Jupiter, its moons and icy rings across a 1.72 ? 1.29 degree^2 field of view. A 13 slot filter wheel will be used to provide spectral information in order for the JANUS experiment to study the geology and physical properties of Ganymede, Europa and Io, and to investigate processes and structures in the atmosphere of Jupiter.

The sensor selected for JANUS is the back-thinned CIS115, a 3 MPixel CMOS Image Sensor from e2v technologies. The CIS115 has a 4-Transistor pixel design with a pinned photodiode to improve signal to noise performance by reducing dark current and allow for reset level subtraction. The JUICE mission will consist of an 8 year cruise phase followed by a 3 year science phase in the Jovian system. Models of the radiation environment throughout the JUICE mission predict that the End of Life (EOL) non-ionising damage will be equivalent to 10^10 10 MeV protons and the EOL ionising dose will be 100 krad(Si), once the shielding from the spacecraft and instrument design is taken into account. An extensive radiation campaign is therefore being carried to qualify and characterise the CIS115 for JANUS, as well as other space and terrestrial applications.

Radiation testing to take the CIS115 to twice the ionising dose and displacement damage levels was completed in 2015. Good sensor performance was observed following irradiation and a summary of the key results will be presented here, including changes to the readout noise, image lag, the dark current between -55˚C and 40˚C, and the observed flat-band voltage shift. In 2016, further radiation campaigns on flight-representative CIS115s will be undertaken and will include an electron irradiation campaign since electrons are the primary damaging particle expected in the Jovian environment. Latest results will be presented and comparisons to earlier gamma and proton campaigns will be drawn.

9915-41, Session 9

An overview of advanced development and field observations with delta-doped arrays in ground-based observatories, suborbital missions, and satellite missions

Shouleh Nikzad, Michael E. Hoenk, April D. Jewell, Alexander G. Carver, Todd J. Jones, John J. Hennessy, Timothy M. Goodsall, Jet Propulsion Lab. (United States); Erika T. Hamden, D. Christopher Martin, California Institute of Technology (United States); David Schiminovich, Columbia Univ. (United States); Kevin C. France, Univ. of Colorado Boulder (United States)

A number of exciting concepts are under development for flagship, Explorer, and suborbital missions in the ultraviolet/optical spectral range, including various concepts for a Next Generation large aperture UV/optical telescope. These missions will depend on high performance silicon detector arrays to be delivered affordably and in high numbers. In a focused effort, and through investments by NASA, industry, and JPL-

internal funds, we have advanced delta-doping technology from small-scale processing to high throughput and high yield scale, and we have demonstrated delta-doping technology with a multitude of CCD and CMOS detector formats and designs. We have embarked on a number of field observations, instrument integration, and independent evaluation of delta-doped arrays as part of this technology advancement and in preparation for upcoming missions,

Delta-doped arrays have been independently evaluated and have had their performance verified by various groups, including the group led by the Kepler PI for precision photometry. Delta-doped CCDs of various formats have successfully flown on multiple suborbital flights, including several sounding rockets with the University of Colorado, Johns Hopkins University, and Cornell/ Dartmouth/ Southwest Research Institute (SwRI). A delta-doped and atomic layer deposition (ALD) antireflection (AR)-coated electron-multiplying CCD (EMCCD -- e2v CCD201) is being delivered to Caltech for Faint Intergalactic Redshifted Emission Balloon (FIREBall), a stratospheric balloon payload. A 12-megapixel fully-depleted p-channel delta doped array designed at Lawrence Berkeley National Laboratory (LBNL), fabricated at DALSA, and post-fab processed at JPL will also fly on University of Colorado's CHESS (Colorado High-resolution Echelle Stellar Spectrograph) rocket. Recent and ongoing ground-based observations include a delta-doped, AR-coated EMCCD at Palomar's Cosmic Web Imager (CWI) and the delta doped p-channel arrays (bare and coated) at Mount Bigelow.

In this paper, we present recent developments of JPL's Advanced Detectors and Systems program, including delta-doping technology; JPL's end-to-end post fabrication of high performance delta-doped arrays; advanced coatings (for detectors and optical elements), and various instrument integrations. We present examples of past, in-progress, and planned observations and deployments of delta-doped arrays.

9915-42, Session 9

High accuracy measurements of the intrapixel sensitivity of VIS to LWIR astronomical detectors: experimental demonstration

Thibault Viale, ONERA (France); Christian C. K. Ketchazo, CEA-Ctr. de SACLAY (France); Nicolas Guerineau, ONERA (France); Olivier Boulade, CEA-Ctr. de SACLAY (France); Florence de la Barrière, ONERA (France); Vincent Moreau, CEA-Ctr. de SACLAY (France); Laurent M. Mugnier, ONERA (France); Didier Dubreuil, CEA-Ctr. de SACLAY (France); Aurélie Montmerle Bonnefois, ONERA (France); Cyrille Delisle, Patrick Mulet, CEA-Ctr. de SACLAY (France)

The reduction of systematic effects is necessary to improve the level of accuracy in imaging and astrometry. For example, in Euclid Mission which aims at carrying out accurate measurements of dark energy and quantifying precisely its role in the evolution of the Universe, the systematic effects need to be controlled to a level better than 10-7 (Euclid, Science Book). To achieve this goal, a high-level of knowledge of the system point spread function (PSF) is required. The system PSF is a combination of the performance of the optical system, space-craft pointing accuracy, pixellisation and intrapixel sensitivity. The intrapixel sensitivity, often neglected, represents in the case of under-sampled instruments a non-negligible contribution in the error budget. For this reason, the measurement of the detector intrapixel sensitivity is already required by ESA in detector technology development activities.

This paper follows the concept-paper presented at the last SPIE conference and gives the recent developments achieved in the design of the test bench for the intrapixel sensitivity measurements. The measurement technique we use is based on the projection of a high spatial resolution periodic pattern on the detector using the self-imaging property of a new class of diffractive objects named continuously self-imaging gratings (CSIG) and developed at ONERA. The principle combines the potential of global techniques, which make measurements at once on the whole FPA, and the accuracy of spot-scan-based techniques, for which high local precisions can be achieved. To reconstruct a pixel profile with a resolution of a 10th of a pixel, it is necessary to explore MTF up to high spatial frequencies, 10 times higher than the pixel Nyquist frequency. To avoid aliasing effect, the procedure consists in performing a microscan of the self-image produced by the CSIG in front of the tested detector at a step of pixel pitch/10. An appropriate deconvolution algorithm is then used to reconstruct the pixel profile at a local scale (one pixel) or a semi-global scale (NxN pixels). This algorithm has been tested and validated on simulated images.

A demonstrator test bench working in the visible spectral range has been designed and commissioned to experimentally validate the microscan-based local technique. A CSIG corresponding to the extended spatial frequency range to explore has been designed and mounted on a 2D axis translation stage in order to perform the microscan. The under-sampled images acquired are recombined in order to obtain an over-sampled interferogram corresponding to the self-image of the CSIG. This recombination is performed by an interpolation-based algorithm. The deconvolution algorithm then allows to reconstruct the estimated pixel profile. This visible demonstrator prepares the future version of a unique test bench working from visible to LWIR (7 μm to 11 μm) spectral ranges.

The paper will detail the latest improvements. It will also discuss the well-appropriated architecture solutions for the final test bench. Considering the visible demonstrator as an intermediate step, we will address how to overcome the limitations encountered in the demonstrator to design the final test bench.

9915-43, Session 9

Ultraviolet/optical detector coatings for ground-based, suborbital, and satellite astronomy and astrophysics

April D. Jewell, Jet Propulsion Lab. (United States); Erika T. Hamden, California Institute of Technology (United States); John J. Hennessy, Timothy M. Goodsall, Samuel R. Cheng, Todd J. Jones, Alexander G. Carver, Charles A. Shapiro, Michael E. Hoenk, Shouleh Nikzad, Jet Propulsion Lab. (United States)

Here we describe the development of optical coatings for silicon-based detectors for astronomy and astrophysics. JPL's delta- and superlattice-doped (2D-doped) silicon arrays exhibit 100% internal quantum efficiency (QE) spanning the UV and visible wavelength ranges. This reflection-limited response can be further improved with optical coatings. At JPL, thin-film filters and antireflection coatings are incorporated with existing detector technologies by atomic layer deposition (ALD). Using ALD we are able to achieve precision growth of nanometer-scale multilayer optical films to provide tailored, repeatable performance for targeted band passes on a variety of detector platforms, including CCD, EMCCD, CMOS, and APD. Recent examples include broadband detectors with >70% QE spanning 300-900 nm, offering unprecedented sensitivity for ground-based observations, as well as a 2D-doped detector with absolute QE >70% at 205 nm for the Faint Intergalactic Red-shifted Emission Balloon (FIREBall-2) experiment. We will review coating development and detector performance for these applications, as well as review possibilities for future satellite missions. We will also briefly describe the development of solar-blind silicon detectors with high UV performance and >103 out-of-band rejection (i.e., red rejection); this topic will be covered in greater detail in complementary paper presented at this conference.

9915-44, Session 9

Solar-blind superlattice-doped avalanche photodiodes

Michael E. Hoenk, John J. Hennessy, April D. Jewell, Jet Propulsion Lab. (United States); Mickel McClish, Radiation Monitoring Devices, Inc. (United States); David G. Hitlin, California Institute of Technology (United States)

Large area solid state detectors with sensitivity around 200 nm and nanosecond rise times have potential applications in astrophysics and high energy physics. Next generation high energy physics experiments require detectors of high energy gamma rays that can withstand unprecedented rates and radiation doses. Current experiments employ crystals such as PbWO4 or LYSO, which have scintillation decay times of ~30ns, which is too slow for the new high rate experiments being studied for the 2020s and beyond. There is a faster crystal, BaF2, with a scintillation component having a 0.9 ns decay time at 220nm that would be a good match to this task. The fast component is, however, accompanied by a larger (85% of the light) slow component (650 ns at 330nm).

We report the development of gamma ray scintillator technology with subnanosecond temporal resolution and the capability to withstand unprecedented rates and doses of high energy gamma radiation. The system consists of doped BaF2 scintillating crystals and solar-blind silicon avalanche photodiodes for detecting the fast scintillation component of BaF2. High efficiency and fast response are achieved by using molecular beam epitaxy to grow a doping superlattice on the avalanche photodiode. Integrated solar-blind antireflective coatings formed by atomic layer deposition enable efficient detection of the fast BaF2 scintillation at 220nm, with strong suppression of the slow BaF2 scintillation at 330nm.

The ultrafast response time of these detectors is ideal for NASA applications such as X-ray pulsar navigation, time-gated Raman spectroscopy, and planetary gamma ray spectrometers. NASA has flown a number of instruments and missions using scintillation detectors, including MESSENGER's Gamma ray and neutron spectrometer; the CGRO Energetic Gamma Ray Experiment Telescope (CGRO/EGRET); the Fermi Large Area Telescope (Fermi/LAT); and the Fermi Gamma-Ray Burst Monitor (Fermi/GBM). The unique capabilities of this subnanosecond scintillation detector are an enabling technology for NASA's Advanced Compton Telescope and other missions requiring high efficiency gamma-ray detection with excellent time resolution, such as a follow-on to the Fermi-LAT.

9915-45, Session 9

Generic integration-time hysteretic sensor response revealed in CCD photon transfer statistics and implications for high fidelity point-spread function retrieval: connecting recorded signal to incident flux distribution in high dynamic range exposures

Andrew P. Rasmussen, SLAC National Accelerator Lab. (United States); Augustin Guyonnet, Institut National de Physique Nucléaire et de Physique des Particules (France); Craig Lage, Univ. of California, Davis (United States); Pierre E. Antilogus, Institut National de Physique Nucléaire et de Physique des Particules (France); Peter E. Doherty, Harvard Univ. (United States); David K. Gilmore, SLAC National Accelerator Lab. (United States); Michael Jarvis, Univ. of Pennsylvania (United States); Ivan V. Kotov, Brookhaven National Lab. (United States); Robert H. Lupton, Princeton Univ. (United States); Andrei Nomerotski, Paul O'Connor, Brookhaven National Lab. (United States); Christopher W. Stubbs, Harvard Univ. (United States); Anthony Tyson, Univ. of California, Davis (United States); Christopher Walter, Duke Univ. (United States)

We conjoin electrostatic conversion drift calculations to CCD pixel signal covariances observed in flat field exposures. We thus constrain pixel geometry distortions present at exposure end, based on signal images recorded. We use available data from several operational astronomical sensor technologies to validate our understanding. Our primary goal is to optimize flux point spread function (FPSF) estimation quantitatively, and thereby minimize sensor-induced errors which may limit precision astronomy performance. We consider alternative compensation scenarios that will take maximum advantage of our understanding of this underlying mechanism, in data processing pipelines currently under development.

9915-46, Session 10

Properties of DePFET active pixel sensors fabricated in an industrial CMOS foundry

Stefan Aschauer, Peter Holl, PNSensor GmbH (Germany); Sascha Weyers, Julia Hauser, Fraunhofer-Institut für Mikroelektronische Schaltungen und Systeme (Germany); Robert Hartmann, David Kalok, Dieter Schlosser, Petra Majewski, Gerhard Lutz, Lothar W. Strüder, PNSensor GmbH (Germany)

Modern state-of-the-art CMOS processes offer a wide spectrum of advantages compared to research laboratory style fabrications, provided that the physical key parameters needed for a good detector performance are preserved: low leakage currents, defect free double sided handling, and a good Si-SiO2 interface quality to mention some of the relevant parameters. We developed a fabrication process in an industrial CMOS foundry which fulfills the above boundary conditions and facilitates the production of backside-illuminated DEPFET active pixel sensors on 725 μm thick, double sided polished high resistivity float-zone silicon. The foundry offers further, high process stability, smaller feature sizes, more complex additional circuitry and a higher throughput in a shorter time. Based on a technology test fabrication which yielded promising results, we have started such a detector fabrication. The first DEPFET devices ever built in an industrial-scale CMOS fab will be available early next year and their properties will be presented together with the outcome of already existing test devices. Given the customized CMOS process we have simulated the final device properties in two and three dimensions to extract the sensor relevant electrical properties, such as (a) transconductance, (b) internal gate depth, (c) clear functionality, (d) clear speed, (e) analog storage of signal charge and (f) internal gate capacitance. All those parameters are required to safely predict the performance figures of the DEPFET sensor. Based on our simulation experience, which led to a very good agreement between simulations and measurements for recent DEPFET fabrications, we derived the properties for a 50 x 50 μm? pixel design. These pixels can be realized with an amplification of more than 1.5 nA/electron with a charge handling capacity of 100.000 signal charges. Due to the CMOS process which allows for smaller DEPFET dimensions these devices can be completely cleared with moderate voltages within 100 ns. Beginning of next year these characteristics will be verified on real devices and their overall capabilities for X-ray imaging and spectroscopy will be summarized. In addition, a concept of a large, high resolution X-ray imager and its deduced characteristics will be presented. The already proven DEPFET features will be highlighted in view of the new options of the industrial fabrication process: repetitive non-destructive readout, gating, high charge handling capacity through non-linear amplification and analog signal storage.

9915-48, Session 10

Spectral performances of Kyoto's x-ray astronomical SOI pixel sensor in the frame and event-driven readout modes

Takeshi G. Tsuru, Makoto Itou, Shunichi Ohmura, Hideaki Matsumura, Ayaki Takeda, Hiroyuki Uchida, Takaaki Tanaka, Kyoto Univ. (Japan); Shinya Nakashima, Institute of Space and Astronautical Science (Japan) and Japan Aerospace Exploration Agency (Japan); Yasuo Arai, Toshinobu Miyoshi, Ikuo Kurachi, High Energy Accelerator Research Organization, KEK (Japan); Koji Mori, Ryota Takenaka, Yusuke Nishioka, Nobuaki Takebayashi, Kouki Noda, Univ. of Miyazaki (Japan); Takayoshi Kohmura, Kouki Tamasawa, Yusuke Ozawa, Tadashi Sato, Tokyo Univ. of Science (Japan); Shoji Kawahito, Keiichiro Kagawa, Keita Yasutomi, Hiroki Kamehama, Sumeet Shrestha, Shizuoka Univ. (Japan); Kazuhiko Hara, Shunsuke Honda, Univ. of Tsukuba (Japan); Craig S. Tindall, Lawrence Berkeley National Lab. (United States)

We have been developing monolithic active pixel sensors, X-ray SOIPIXs based on a Silicon-On-Insulator (SOI) CMOS technology for future X-ray astronomy satellites (eg. Tsuru et al. SPIE AS14, arXiv:1408.4556). Immediate readout of only the pixels hit by X-rays is available by an event trigger output function implemented in each pixel with its high time resolution of better than 10 usec (event-driven readout). It allows us to do fast timing observation and also reduce non-X-ray background dominating at high X-ray energy band above 5-10 keV by adopting an anti-coincidence technique.

We propose the X-ray SOIPIXs as a soft X-ray sensors of wide-band hybrid X-ray imagers of a next Japanese mission, FORCE (FOcusing Relativistic universe and Cosmic Evolution), which is characterized by broadband (1-80 keV) X-ray imaging spectroscopy with high angular resolution (<15"), reaching to about 10 times the sensitivity compared to previous missions above 10 keV (See Mori et al. in AS102).

In this presentation, we report followings subjects.

(1) Reduction of interference in the event-drive readout mode. As reported in AS14, we have already reached the readout noise of ~32e (rms) in the frame readout mode, in which all the pixels data are read out serially like CCD. However, the spectral performance is still poor in the event-driven readout mode. The readout noise is ~150e (rms) and an offset is observed in the correlation between the pulse-height and X-ray energy. They are caused by interference due to a capacitive coupling between a comparator in the circuit layer and a charge collecting node in the sensor layer of the high resistivity silicon. Thus, we newly developed X-ray SOIPIXs using a double SOI wafer having a low resistivity silicon layer between the circuit and sensor layers.

The device successfully reduces the interference and the offset.

(2) Sensitivity in the low energy X-ray band. Since the circuit layer has the thickness of ~8um, a backside illumination (BI) is essential to observed low energy X-rays. Thus, we developed BI types of X-ray SOIPIXs by using the process of ion implantation and laser annealing. X-ray measurements revealed the the thickness of the dead layer of ~2um. In order to do further reduction, we fabricated devices whose backsides were processed by the "Pizza" process developed by LBNL, in which the ion implantation is followed by a low temperature annealing. The Pizza process successfully reduced the dead layer to ~1um, which fulfills the requirements of the FORCE mission. We are now trying another process aiming at a further reduction.

(3) Large sized device. We completed in Dec. 2015 the production of 3-side buttable devices with a pixel size of 36um and the imaging area of 22mm x 14mm. It also has a new peripheral readout circuits (PGA and differential readout). We report results from initial tests of the device in the presentation.

9915-50, Session 10

The HEXITEC hard x-ray pixelated CdTe imager for fast solar observations

Wayne H. Baumgartner, Steven D. Christe, Albert Y. M. Shih, Marco Panessa, Andrew Inglis, NASA Goddard Space Flight Ctr. (United States); Jessica A. Gaskin, Colleen Wilson-Hodge, NASA Marshall Space Flight Ctr. (United States); Paul Seller, Matthew D. Wilson, Matthew C. Veale, STFC Rutherford Appleton Lab. (United Kingdom)

The HEXITEC CdTe Imager (for High Energy X-ray Imaging Technology) is an 80x80 array of 250 micron pixels sensitive in the 4--80 keV band and capable of a full frame readout rate of 10 kHz. HEXITEC is being developed in part for solar astrophysics, where observations of extremely bright solar flares often cause pileup in current detectors.

HEXITEC's small 250 micron pixels are the smallest independently read out pixels currently available, and are well matched to the few arcsecond PSF produced from current and next generation hard X-ray focusing optics. The Rutherford Appleton Laboratory has developed the ASIC used for HEXITEC, which is then bonded to 1-2 mm thick CdTe.

NASA's Goddard and Marshall Space Flight Centers are collaborating with RAL to develop these detectors for use with hard X-ray focusing telescopes for astronomy and have achieved spectral resolutions better than 1 keV at 60 keV. We present recent developments from the HEXITEC program and report on its current performance.

9915-51, Session 11

Persistence measurements and photometric impact of intra-pixel variations on a Euclid HAWAII-2RG at ESTEC

Pierre-Elie Crouzet, Ludovic Duvet, Jörg Ter Haar, Jerko Heijnen, Hans Smit, Frederic Lemmel, Visser Ivo, Bart Butler, Cornelis Van der Luijt, Gertjan Van Duinkerken, European Space Research and Technology Ctr. (Netherlands)

In the frame work of the ESA's Cosmic Vision program, the Euclid mission has the objective to map the geometry of the Dark Universe. Galaxies and clusters of galaxies will be observed in the visible and near-infrared wavelengths by an imaging and spectroscopic channel. For the Near Infrared Spectrometer instrument, the state-of-the-art HAWAII-2RG detectors will be used, associated with the SIDECAR ASIC readout electronic.To characterize the persistence performance and the photometric impact of the intra-pixel variations, a test bench in the Payload Technology Validation Section at ESTEC has been designed, tested and validated.This publication describes the test set up developed to measure the persistence by projecting flat field over a Euclid HAWAII-2RG and the associated results for different illumination level, temperature and exposure time.This publication will describes as well the set up used to project a spot on the detector to measure the photometric impact of the intra-pixel variation. The results of the sub-pixel spot scan on the photometric impact will be as well presented.

9915-52, Session 11

HgCdTe calibrated photodiodes for quantum efficiency measurements in IR spectral range

Cyril Cervera, Olivier Gravrand, CEA-LETI (France); Olivier Boulade, CEA-IRFU (France)

Absolute measurements of quantum efficiency (QE) in IR domain on focal plane arrays are extremely difficult because of the lack of calibrated photodiodes in this spectral range. Actually, the only calibrated photodiodes available commercially, with a good accuracy, are based on Silicon (Si) technology and so exhibit a cut-off wavelength close to 1.1µm.

We propose in this paper a method to calibrate the MCT photodiodes made at CEA-LETI. The aim of this method is to use the capability of MCT to be sensitive in the visible range, independently of the cut-off wavelength. Moreover we know that the Quantum efficiency is constant in the IR and visible domain. We therefore feel that it is possible to calibrate MCT IR photodiode in the visible range where Si diodes can be used as reference.

The relative spectral response of the photodiodes is measured with a FTIR system, and the absolute calibration is performed with a calibrated black body. Then, the validation of this absolute calibration is assessed by thinning a photodiode to get uniform sensitivity from the IR to the visible spectral range, measure its absolute responsivity with the black body in the IR range and again in the visible against a calibrated Si photodiode. This paper will present the experimental setup as well as results on the calibration of photodiodes at 12.5µm cutoff.

9915-53, Session 11

Persistence characterization and comparison of European large format array NIR detectors

David Gooding, Pierre-Elie Crouzet, Ludovic Duvet, Hans Smit, Jörg Ter Haar, Sander Blommaert, Ivo Visser, Frederic Lemmel, Jerko Heijnen, Cornelis Van Der Luijt, Bart Butler, European Space Research and Technology Ctr. (Netherlands)

The Payload Technology Validation Section (SRE-FV) at ESTEC has the goal of validating new technology for future or on-going missions. In this framework, a test set up to facilitate the characterisation of near-infrared (NIR) detectors has been created. A current technology development activity at ESA, the European Large Format Array (LFA), is being undertaken by a small team with the goal of creating a full NIR photon-to-SpaceWire detection system. In the context of the NIR European LFA, a number of detectors are tested in order to identify a suitable epitaxial technology and supplier. We report on the characterisation progress of the LFA detectors, for which a series of rigorous tests have been performed on four different detectors provided by CEA/LETI; two LPE and two MBE. Experimental techniques and results will be presented, in particular regarding the persistence/latency effect observed in such detectors and its dependency on temperature, illumination duration and illumination level. These effects are investigated by producing a flat field from an array of five LEDs integrated into the vacuum chamber and the results can be compared to data from HAWAII-2RG detectors from the Euclid project. Relevant conclusions will be presented and the effectiveness of mitigation strategies will be explored. Other properties and effects under investigation and discussed in this report include conversion gain, dark current and inter-pixel coupling. The impact of irradiation on the detector performance is investigated here and the results from the different detectors are then compared to support the on-going development of the LFA activity.

9915-55, Session 11

Flexible focal plane arrays for VIS/NIR wide field instrumentation

Wilfried Jahn, Emmanuel Hugot, Lab. d'Astrophysique de Marseille (France); Christophe Gaschet, Lab. d'Astrophysique de Marseille (France) and CEA-LETI (France); David Henry, CEA-LETI (France); Sabri Lemared, Lab. d'Astrophysique de Marseille (France); Laurent Mendizabal, Stephane Getin, CEA-LETI (France); Jean Luc Gach, Lab. d'Astrophysique de Marseille (France); Bertrand Chambion, CEA-LETI (France)

LAM and CEA-LETI are developing the technology of deformable detectors, for VIS or NIR applications. Such breakthrough devices will be a revolution for future wide field imagers and spectrographs, firstly by improving the image quality with better off-axis sharpness, resolution, brightness while scaling down the optical system, secondly by overcoming the manufacturing issues identified so far and by offering a flexibility and versatility in optical design.

The technology of curved detectors can benefit of the developments of active and deformable structures, to provide a flexibility and a fine tuning of the detectors curvature by thinning the substrate without modifying the fabrication process of the active pixels. We present studies done so far on optical design improvements, the technological demonstrators we developed and their performances as well as the future five years roadmap for these developments.
