Ultrashort-pulsed lasers reach from pico- to femtoseconds. In order to demonstrate which pulse duration and ablation strategy is the best for the singling of silicon wafers, the ablation threshold for pulse durations from pico- to femtoseconds is determined with the method of Liu. During the method, the diameter of the ablated geometry is measured, squared and plotted against the peak fluence in logarithmic scale. With decreasing pulse durations the surface of the silicon seems to be smoother and the ablation is characterized by a sharp ridge. With knowledge of the ablation threshold, different cutting strategies are compared in order to create a minimal cutting kerf with a reduced heat affected zone. The ablation threshold of silicon depends on the temperature, so a second laser beam for the pre-heating of the silicon material is coupled coaxially with the cutting beam, which can improve the ablation behaviour of silicon significantly.

Determination of transport parameters of organic thin film based on PTB7:PCBM mixture

Miriam Cuatecatl Tlapapatl, Nikolay Korneev, Svetlana Mansurova, Julio C. Carrillo Sendejas, Andrey Kosarev, Ismael Cosme-Bolaños, Antonio J. Olivares Vargas, Instituto Nacional de Astrofísica, Óptica y Electrónica (Mexico)

Organic semiconductors based on a mixture of poly[[4,8-bis[(2-ethylhexyl)oxy]benzo[1,2-b:4,5-b']dithiophene-2,6-diyl][3-fluoro-2-[(2-ethylhexyl)carbonyl]thieno[3,4-b]thiophenediyl]] (commonly known as PTB7) and [6,6]-phenyl-C61-butyric acid methyl ester (PCBM) give some of the highest reported efficiencies for polymer:fullerene solar cells due to the polymers extended absorption into the near infra-red and lower HOMO level.

Photoconductive properties of organic blend, and in particular its transport parameters (mobilities and diffusion lengths) are crucial factors determining the performance of photovoltaic structure based on it. As the blend of two different material types cannot be described by a simple superposition of the single properties material, a prediction of its photoconductive characteristic in a solar cell is not straightforward. In this context, the experimental data on donor/acceptor ratio dependent characteristics would have been of particular interest and a considerable amount of work has been devoted recently to this problem On the other hand, the change of photoelectric parameters of organic blend as a function of temperature is a widely used method to elucidate the material electronic structure.

In this work we present the results of detailed experimental study of photoelectric properties of organic thin film based on PTB7:PCBM bulk heterojunction for different ratios of the component. Temperature dependencies of dark and photoconductivity, as well as modulated photocurrent and non-steady-state photo-EMF technique have been used in order to elucidate materials photoelectric parameters, such as charge carriers motilities, their lifetime and the diffusion lengths.

Organic solar cells based on graphene derivatives and eutectic alloys free-vacuum deposited as cathodes

Álvaro Daniel Romero-Borja, Ctr. de Investigación en Química Aplicada (Mexico) and Centro de Investigaciones en Óptica, A.C. (Mexico); J. Oracio C. Barbosa-García, Centro de Investigaciones en Óptica, A.C. (Mexico); Enrique Pérez-Gutiérrez, Consejo Nacional de Ciencia y Tecnología (Mexico) and Benemérita Univ. Autónoma de Puebla (Mexico); Mario A. Rodríguez, Centro de Investigaciones en Óptica, A.C. (Mexico); Arxel de León, Centro de Investigaciones en Óptica, A.C. (Mexico) and Ctr. de Investigación en Química Aplicada (Mexico); Salvador Fernández, Ctr. de Investigación en Química Aplicada (Mexico); Canek Fuentes-Hernández, Georgia Institute of Technology (United States); José-Luis L. Maldonado, Centro de Investigaciones en Óptica, A.C. (Mexico)

We present the use of two graphene derivatives in organic photovoltaic devices (OPVs) based on PTB7:[70]PCBM as active layer. First, reduced graphene oxide (rGO) was compared with PEDOT:PSS as hole transport layer (HTL) [1]. Second, solution-processable functionalized graphene (SPFG) was incorporated as a third component in the active layer [2]. Furthermore, we propose the use of two eutectic alloys as non-conventional cathodes: Field's metal (FM): Bi/Sn/In and BS: Bi/Sn, that melt at 65 and 138 ºC, respectively, which are deposited at room conditions by drop coating [3]. In OPVs with rGO as HTL, thin films were prepared by reiterative spin-deposition and thermal reduction of GO after each deposition. The best results were achieved for 8-rGO as HTL, where the PCE = 6.7% was as high as 95% of the obtained in reference devices (PEDOT:PSS as HTL, PCE = 7.0%). On the other hand, ternary active layers were prepared by blending SPFG at different weight ratios (0, 2, 4, and 6 wt. %) with PTB7:[70]PCBM (1:1.5 w/w). Our results show an increment in PCE for OPVs devices with 4 wt. % of SPFG that is 10% higher than that of the reference device (0 wt. % of SPFG). Finally, FM and BS were used as novel cathodes in OPVs devices reaching very acceptable PCEs (around 7.0%), for both eutectic alloys, in comparison with the PCE of those OPVs cells fabricated with the non-stable and costly high-vacuum evaporated Al.

Hybrid perovskite/polymer composite for moisture stability in the absorber layer

John P. Murphy, Montana Tech (United States); Jessica M. Andriolo, Montana Tech (United States) and Univ. of Montana (United States); Jack L. Skinner, Montana Tech (United States)

Hybrid perovskite solar cells (PSCs) have climbed rapidly in power conversion efficiency in recent years and represent the future in low-cost photovoltaics. Facile fabrication of PSCs and the low cost of precursor chemicals have resulted many variations in materials synthesis and ultimately device design. A common goal across device architecture is the improvement of chemical stability of the hybrid perovskite material, particularly in resistance to degradation onset by moisture exposure. The research proposed herein will be directed at the improvement of moisture/UV stability in a PSC through utilization of a polymer/hybrid perovskite composite material in the active layer of the device. Perovskite

microcrystallites are synthesized via a simple solution method utilizing an organic ligand to control size and facilitate dispersion in toluene. Perovskite colloidal solutions can then be mixed into solutions of optical polymers and utilized as an active layer in a PSC. The dependency of the active-layer thickness, perovskite-crystallite size, and perovskite-crystallite loading in the composite on the device performance of PSCs will be parametrically analyzed using an AM 1.5G class ABA solar simulator and a Keithley 2450 sourcemeter. Device performance over time and in high humidity (~90% RH, ~20 °C) environments will be evaluated. Photocurrent will be minimized in the composite active layer cell due to a smaller heterojunction area. However, if device lifetime can be improved using composite active layers, PSCs may be able to reach an energy payback point necessary to allow implementation in the solar energy marketplace.

10363-110, Session PMon

Analysis of the aging/stability process of organic solar cells based on PTB7:[70] PCBM and an alternative free-vacuum deposited cathode: The effect of active layer scaling

Mirna D. Barreiro Argüelles, Gabriel Ramos-Ortiz, José-Luis L. Maldonado, Centro de Investigaciones en Óptica, A.C. (Mexico); Álvaro Daniel Romero-Borja, Centro de Investigaciones en Óptica, A.C. (Mexico) and Ctr. de Investigacíon en Química Aplicada (Mexico); Marco-Antonio Meneses-Nava, Centro de Investigaciones en Óptica, A.C. (Mexico); Enrique Pérez-Gutiérrez, Consejo Nacional de Ciencia y Tecnología (Mexico) and Benemérita Univ. Autónoma de Puebla (Mexico)

In this work the PV performance and aging/stability of organic photovoltaic (OPV) devices based on the well-known system PTB7:[70]PCBM are fully studied when the active area is scaled by a factor of 25. The cells configuration was: ITO/PEDOT:PSS/PTB7:PC71BM/PFN/Field's metal (FM), where FM is an alternative air-stable electrode deposited by doctor blade technique at room conditions. The average power conversion efficiency (PCE) for devices with the small active area of 0.09 cm2 is 7.4±0.8%, similar to that obtained for OPVs cells comprising Al as traditional cathode [1]. On the other hand, a decrease of 60% in efficiency for the scaled OPVs was measured. The aging/stability processes were also studied through single diode model, impedance spectroscopy and light-beam induced current (LBIC) measurements in accordance with the established ISOS-D1 (dark storage) and ISOS-L1 (illumination conditions) protocols [2]. Here it is found that the time to reach 50% of the initial PCE (T50) is >1500 h under ISOS-D1 protocol, which represent about 1000 h more than previously reported devices [3, 4]. In addition it was observed an improvement in stability for the scaled devices. However, for devices tested under ISOS-L1, T50 is reached in ~14 h independently of the device area. A discussion on the origin of these behaviors is presented. Finally, these results are a good indication that FM cathode works as an encapsulating material and provides excellent PV performance comparable with the common and costly high-vacuum evaporated Al cathode.

Formation and diffusion of metal impurities in perovskite solar cell material CH3NH3PbI3: implications on the choice of electrode and solar cell degradation

Mao-Hua Du, Wenmei Ming, Oak Ridge National Lab. (United States); Dongwen Yang, Lijun Zhang, Jilin Univ. (China)

CH3NH3PbI3-based solar cells have shown remarkable progress in recent years but have also suffered from structural, electrical, and chemical instabilities and the resulting degradation. It was shown recently in CH3NH3PbI3 thin film solar cells that Au atoms from Au electrode can diffuse through hole transport layer and CH3NH3PbI3 layer at 70 °C, leading to significant degradation of the solar cell. We performed density functional theory calculations to study the formation and diffusion of a number of noble and transition metal impurities (Au, Ag, Cu, Cr, Mo, W, Co, Ni, and Pd) in CH3NH3PbI3. The purpose is to find a metal that has low resistivity, an appropriate work function, and does not diffuse into CH3NH3PbI3. We find that the oxidation state of the metal impurity affects its diffusion barrier. Au, Ag, and Cu have low resistivities but their ions with the +1 oxidation state can diffuse easily into CH3NH3PbI3. In particular, Au on a Pb site induces deep levels inside the band gap, which may be efficient nonradiative recombination centers. Cr, Mo, W, Co, Ni, and Pb impurities usually take the 2+ oxidation in CH3NH3PbI3 and their diffusion barriers are much higher. Mo, W, and Co have relatively low resistivities and Co has a work function that is most appropriate for hole extraction. These metals should deserve further experimental studies for their potential as stable back contact materials for CH3NH3PbI3 solar cells.

Transparent wide bandgap metal halides for bifacial hybrid solar cells

Karunakara Moorthy Boopathi, Chintam Hanmandlu, Chih-Wei Chu, Academia Sinica (Taiwan)

The main objective of photovoltaic materials research is to find low-cost semiconductor materials with facile fabrication routes for efficient photovoltaic devices. Here, solution processable wide bandgap lead iodide semiconductor has been investigated as light absorbing material with different organic polymers as electron transport materials. Wide intrinsic bandgap of 2.6 eV was found for PbI2 thin film from Tauc plot and X-ray diffraction suggested the hexagonal crystalline structure with preferable orientation along (001) plane. Light intensity dependence of Voc and Jsc was studied to investigate the charge recombination mechanism for fabricated devices. The power conversion efficiency of 2.1% was achieved with opaque electrode (Ca/Al), while transparent electrode (BCP/Ag/MoO3) yielded 0.75% and 0.67% from bottom and top illumination, respectively. Using of wide bandgap light absorber materials opens up a new path for fabricating efficient and transparent photovoltaic devices for building integrated window applications.

Solution processable lead free antimony based perovskite materials for photovoltaic applications

Chih-Wei Chu, Karunakara Moorthy Boopathi, Anupriya Singh, Academia Sinica (Taiwan); Gang Li, The Hong Kong Polytechnic Univ. (Hong Kong, China)

Organic–inorganic metal halide perovskites have recently emerged as highly competitive light absorbing materials for low cost solution-processable

photovoltaic devices. With the high efficiency already achieved, removing the toxicity, i.e., lead-free and stability are the key obstacles for perovskite solar cell. Here, we report the synthesis of antimony (Sb)-based hybrid perovskites having the crystal structure of A3Sb2I9 [A = CH3NH3 (MA), Cs] and an investigation of their potential photovoltaic applications. The Sb-based perovskite materials exhibited attractive absorbance properties, with the band gaps of MA3Sb2I9 and Cs3Sb2I9 measured as 2.2 and 2.3 eV, respectively. The band gaps of these materials are suitable for their use in solar cells, and also make them good choices for other optoelectronics applications. X-ray photoelectron spectroscopy confirmed the formation of stoichiometric perovskites from appropriate precursor molar ratios. Planar hybrid perovskite solar cells were fabricated with the device structure of glass/ITO/PEDOT:PSS/A3Sb2I9/PCBM/C60/BCP/Al and exhibited negligible hysteresis and reproducible power output under working conditions. A power conversion efficiency of 1.11% was achieved by MA3Sb2I9 perovskite device—the highest reported to date for a Sb-based perovskite solar cell.

Phase stability of perovskite nanocrystals

Olivia Ashton, Henry J. Snaith, Univ. of Oxford (United Kingdom)

There are a wide variety of perovskite compositions, each with differing thermal and phase stability. For the bulk material, stabilising the perovskite phase has been widely researched across a range of these compositions. This has allowed for optimal materials and processing procedures to develop for photovoltaic devices.

Perovskite nanocrystals have recently shown great promise for both optoelectronic devices and photovoltaics. To date however there has been little research into the phase stability of the nanocrystals and how that could relate to device performance.

Here we present a study which investigates the phase stability of perovskite nanocrystals and how this changes relative to the composition of the material. We present emission and absorbance spectra along with structural characterisation from X-ray diffraction and transmission electron microscopy, to support our findings.

We also make a comparison to their bulk counterparts, exploring how the structural confinement that the nanocrystals undergo affects their stability in relation to an infinite lattice.

Coupled with the lifetime of carriers in these materials, extrapolation to potential device performances can be made.

10363-116, Session PMon

Improved efficiency of silicon nanoholes/gold nanoparticles/organic hybrid solar cells in both ultraviolet and visible regions

Ling Xu, Nanjing Univ. (China)

Silicon is the most widely used material for solar cells due to its abundance, non-toxicity, reliability, and mature fabrication process. We fabricated silicon nanoholes (SiNHS)/gold nanoparticles (AuNPS)/organic hybrid solar cells and investigated their spectral and opto-electron conversion properties. SiNHS nanocomposite films were fabricated by metal-assisted electroless etching (EE) method. Then, we modified the surface of the nanocomposite films by exposing the samples in the air. After that, polymer poly(3,4-ethylenedioxythiophene):poly (styrenesulfonate) (PEDOT:PSS) blended with AuNPS were spin-coated on the surface of the SiNHS nanocomposite films as a hole-transporting layer. The external quantum efficiency (EQE) values of the solar cells with AuNPS are higher than that of the samples without AuNPS in the spectral region of 600–1000 nm, which were essential to achieve high performance photovoltaic cells. The power conversion efficiency (PCE) of the solar cells incorporating AuNPS exhibited an enhancement of 27 %, compared with that of the solar cells without AuNPS. We thought that the improved efficiency were attributed to localized surface plasmon resonance (LSPR) triggered by gold nanoparticles in SiNHS nanocomposite films.

K-space optoelectronic properties of organic-inorganic hybrid methylammonium lead halide crystals

Hye Ri Jung, Trang T. T. Nguyen, Hye-Jin Jin, Bich Phuong Nguyen, Gee Yeong Kim, Seokhyun Yoon, William Jo, Ewha Womans Univ. (Korea, Republic of); Won Seok Woo, Chang Won Ahn, Shinuk Cho, Ill Won Kim, Univ. of Ulsan (Korea, Republic of)

Organic-inorganic lead halide perovskite, CH3NH3Pb(Br,I)3 is taking the spotlight with outstanding performance for photovoltaic, light-emitting, and memristic devices. Most studies of all, examination on single crystals are demanded to comprehend the intrinsic physical characteristics. Grain growth in perovskite is not fully interpreted with regards to compositions, textures, and even believed as a trapping source of ionic migration. We confirm the structural systems and phase purity by using transmission electron microscopy and Raman scattering spectroscopy. We verify the details of the crystal structure in terms of configuration of the methyl-ammonium ligands. Thus, we evaluate the exposed surface of the perovskite crystals in terms of surface potential with Kelvin probe force microscopy. Calculated work function exhibits distribution around 4.6 eV, which is a similar value with thin film perovskite thin film. We also measured its photoluminescence and temperature dependent resistivity in order to estimate electronic structure and transport behaviors of the crystals. There are the deformations of the perovskite materials to the methyl- ammonium halide and lead halide on the surface partially by the deconvolution of the surface potential and it imply the alternative electrical characteristics depending on the surface doping. Synthetically, we obtained a stereographic schematic picture for the electronic band structures, which reveal the possible semiconducting nature of the materials by consolidating the information of the band gap and work function.

10363-119, Session PMon

Implications of ferroelectric polarization on ionic migration and hysteretic behaviors on hybrid perovskite absorber solar cells with mesoscopic and planar electron transport layers

Hye Ri Jung, Bich Phuong Nguyen, Juran Kim, Hye-Jin Jin, Wiiliam Jo, Ewha Womans Univ. (Korea, Republic of)

Hybrid lead halide perovksite, MAPbX3(MA=CH3NH3+, X=Br- or I-) have risen to prominence with remarkable efficiency increasing and examination on its physical properties are of particular concern. One of the issues is hysteresis phenomenon with ionic migration. Current-voltage curves tend to differ depending on the sweep rate and

direction. Several mechanisms have been proposed including difference in trapping efficiency, ion migration, imbalance between electron and hole fluxes into an electron transfer layer and a hole transfer layer, and ferroelectricity of the perovskites. We report our observations on the piezoelectricity in the perovskite thin-films grown on TiO2 mesoscopic and planar bottom electrodes by measuring piezoelectric responses and ferroelectric property using piezoelectric force microscopy which is one of atomic force microscopy techniques. In addition, we investigated for the distribution of the surface electric potential and current transport by Kelvin probe force microscopy and conductive atomic force microscopy, respectively. We propose a device model to enhance charge transfer with in the perovskite solar cells when we have a preferred polarization in the materials through examination for the nature of the hysteresis properties.

Excited state polarizability in polymer:fullerene blends via electroabsorption

Erik D. Klump, Xueping Yi, Iordania Constantinou, Amin Salehi, North Carolina State Univ. (United States); Kin Lo, John R. Reynolds, Georgia Institute of Technology (United States); Franky So, North Carolina State Univ. (United States)

The interaction between donor polymers and fullerene in organic solar cells has been a topic of extensive study. However, detail understanding of this complex interface is still lacking. To further our understanding of the nature of the interface between fullerene and polymers, we sought to characterize the excited state polarizability and difference in dipole moment between the ground and excited states in blend films. To accomplish this, we utilized electroabsorption (EA) spectroscopy. This sensitive technique relies on modeling of the Stark effect to fit the measured EA signal at the band edge of polymer:fullerene blends. To attain the accurate absorption data necessary for good fits and confidence in the extracted parameters, we utilized photothermal deflection spectroscopy to extract the optical absorption data.

We were able to quantify the difference in excited state polarizability and dipole moment between the ground and excited states in a number of systems. We found that the charge transfer states in the polymer were greatly affected by the mixing with fullerene. Specifically, the difference in excited state polarizability was shown to significantly increase in blends with optimal morphology to several times that of the pristine polymer. This dramatic increase was found to closely correlate with exciton dissociation efficiency. Thus, we conclude that the mixing of polymer with fullerene not only creates charge transfer states, but also changes the polarizability of excited polymer states. In turn, this increased polarizability and thus delocalization of the charge transfer states facilitates the efficient exciton dissociation process necessary for highly performing organic solar cells.

10363-122, Session PMon

Optimization of regioregular polymer structure through synthesis and characterization of benzothiazole (BT)-based polymers

Na Gyeong An, Ulsan National Institute of Science and Technology (Korea, Republic of); Mohammad Afsar Uddin, Yuxiang Li, Korea Univ. (Korea, Republic of); Seyeong Song, Ulsan National Institute of Science and Technology (Korea, Republic of); Hwasook Ryu, Han Young Woo, Korea Univ. (Korea, Republic of); Jin Young Kim, Ulsan National Institute of Science and Technology (Korea, Republic of)

Three types of photoactive terpolymers (random, regular and block) were synthesized by incorporating two electron deficient and one electron-rich moieties based on two parent donor polymers, poly[(2,5-bis(2-decyltetradecyloxy)phenylene)-alt-(5,6-difluoro-4,7-di(thiophen-2-yl)benzo[c][1,2,5]thiadiazole)] (PPDT2FBTDT) and poly[(2,5-bis(2-decyltetradecyloxy)phenylene)-alt-(5,6-dicyano-4,7-di(thiophen-2yl) benzo[c][1,2,5]thiadiazole)] (PPDT2CNBT). All three terpolymers showed a broad light absorption in the range of 300-850 nm covering the absorption of two parent polymers. Their optical, electrochemical, morphological and photovoltaic properties were compared and investigated in detail. The power conversion efficiencies (PCEs) of 5.63, 4.45 and 3.13% were obtained for PPDT2FBTDTrandom-PPDT2CNBT, PPDT2FBTDT-regular-PPDT2CNBT and PPDT2FBTDT-block-PPDT2CNBT based photovoltaic devices, respectively. Through intensive investigation on charge carrier mobility, photocurrent and light intensity dependence of JSC, the random structure was proved to be most effective molecular design in this series of terpolymers to show weaker charge recombination and enhanced charge transport/extraction with well distributed blend morphology. The fine modulation of different arrangement and composition of three monomers in a main chain is crucial for optimizing the terpolymeric structures as an efficient photoactive material.

10363-125, Session PMon

Morphological characterization of fullerene and fullerene-free organic photovoltaics by combined real and reciprocal space techniques

Subhrangsu Mukherjee, Andrew A. Herzing, National Institute of Standards and Technology (United States); Donglin Zhao, Qinghe Wu, Luping Yu, The Univ. of Chicago (United States); Harald W. Ade, North Carolina State Univ. (United States); Dean M. DeLongchamp, Lee J. Richter, National Institute of Standards and Technology (United States)

The performance of a bulk heterojunction (BHJ) solar cell is sensitive to the details of the morphology that include the sub-100 nm domain size, shape, connectivity, orientation of components and composition. Recently molecular acceptors have showed promise to replace fullerene derivatives in BHJs and have achieved >10% efficiencies in single junction devices. However, a key challenge for the organic photovoltaics community has been to develop measurements of these aspects of structure for the newer systems. The similar mass/electron densities between the donor and acceptor results in poor material contrast compared to fullerene-based BHJs. Therefore, morphology characterization using techniques that rely on mass/electron density variations poses a challenge. Using two efficient fullerene-based (PTB7-Th:PC71BM) as well as a recent non-fullerene-based (PTB7-Th:a-TPB) BHJ systems it will be demonstrated that low-angle annular dark field scanning transmission electron microscopy (LAADF-STEM) and resonant soft X-ray scattering (R-SoXS) form a set of complementary tools that can provide quantitative characterization of fullerene as well as non-fullerene based organic photovoltaic systems. Excellent agreement was obtained between the Fourier analysis of LAADF-STEM images and R-SoXS profile shapes as well as size scales between the two techniques for both systems. The optimized non-fullerene blend prepared with additive DPE is found to have a higher average phase purity compared to the no additive sample. Furthermore, the strong differences between the phase separation characteristics of the identically prepared no additive fullerene and non-fullerene blends likely indicate different miscibilities of the acceptor materials in the donor (PTB7-Th) matrix and therefore different Flory-Huggins interaction parameters.

10363-126, Session PMon

Over 11%-efficiency fullerene-free organic solar cells enabled by benign solvents

Long Ye, North Carolina State Univ. (United States); Wenchao Zhao, Institute of Chemistry (China); Masoud Ghasemi, Yuan Xiong, North Carolina State Univ. (United States); Jianhui Hou, Institute of Chemistry (China); Harald W. Ade, North Carolina State Univ. (United States)

Owing to the recently developed nonfullerene small molecule acceptors, the best power conversion efficiency (PCE) of solution-processable organic solar cells (OSCs) has been boosted up to over 12%[1], which makes this technology an economically viable contender for commercialization. Along with the steady progress in PCE achieved by spin-coating photovoltaic materials with chlorinated solvents in protective atmosphere, a central issue in the development of OSCs is pursuing a greener and simpler manufacturing protocol[2], which particularly allows for large-area

processing in ambient air. Particularly, it is still a great challenge to replace halogenated solvents with halogen-free, low-toxicity solvents to achieve high-efficiency nonfullerene OSCs.

Here we show that ~11.6% efficiency is achieved in nonfullerene OSC device based on PBDB-T:IT-M[3] by using a non-halogenated solvent combination. Moreover, the device parameters were correlated to the morphology investigated by synchrotron radiation grazing-incidence wide-angle X-ray scattering (GIWAXS), resonant soft X-ray scattering (R-SoXS), and differential scanning calorimetry (DSC). We observed a monotonic correlation between the average composition variations and photovoltaic device characteristics across all processing protocols in this record-efficiency material system. This correlation is indeed universal for OSC, irrespective of acceptor materials used (fullerenes, nonfullerene molecular acceptor, or conjugated polymers) and fabrication methods used (spin-coating or blade-coating).[1-5] We believe this nonhazardous solvent approach will be also applicable in the large area roll-to-roll coating and industrial scale printing of high-efficiency OSCs in air.

Revealing the high stability of non-fullerene polymer solar cells

Masoud Ghasemi, Long Ye, Harald W. Ade, North Carolina State Univ. (United States)

The rapid increase in the power conversion efficiency (PCE) along with high stability in non-fullerene polymer solar cells (PSCs) is mostly attained through emerging novel non-fullerene acceptors. In this work we investigate the effect of vitrified morphology of non-fullerene small molecule acceptors on device stability of a binary blend comprised of a benchmark donor poly(3-hexylthiophene) (P3HT) with a non-fullerene acceptor O-IDTBR[1], as the morphological stability of such devices is an essential consideration for technological implantations. Further consideration of molecular miscibility of the polymer:non-fullerene blends provides an new insight into morphology-function correlation in non-fullerene PSCs. The diffusion experiments done with secondary ion mass spectroscopy (SIMS), and thermodynamic investigations by differential scanning calorimetry (DSC), complemented with X-ray scattering experiments together show that diffusion of non-fullerene acceptor in the polymer network is prohibited due to vitrified morphology of the non-fullerene acceptor when the temperature is below 140 °C. Furthermore, the maximum concentration of diffused O-IDBR into the polymer layer, by annealing the thin bilayer films at elevated temperatures, is found to be limited by the molecular miscibility in the blend. In conclusion, the vitrified morphology of non-fullerene acceptors well explains the excellent long-term stability of non-fullerene PSCs, due to prevention of formation of micro sizes crystals in the thin films. Our findings may pave a way to understand an important question that why non-fullerene PSCs are more stable compared with their fullerene counterparts.

10363-128, Session PMon

Critical factors that affect complex morphology and device performance of multiple cases of organic solar cells

Long Ye, Subhrangsu Mukherjee, North Carolina State Univ. (United States); Jianhui Hou, Institute of Chemistry (China); Harald W. Ade, North Carolina State Univ. (United States)

In the organic solar cell field, thousands of new polymer donors along with hundreds of emerging small molecule acceptors create an incredibly large pool of polymer:acceptor pairs that would be difficult to optimize without a complete characterization and fundamental understanding of the complex and often multi-length scale morphology[1-2]. The recent demonstration of multilength scale morphology brings many questions critical to the operation of these novel organic devices into focus: What are the critical factors that affect the complex morphology and device performance of organic solar cells? Through detailed characterizations (hard/soft X-ray scattering), we show that a linear correlation between the average composition variations at the smallest length scale and photovoltaic device characteristics in a PBDTTPD:fullerene[3] system and two state-of-the-art nonfullerene material systems[4]. The degree of molecular mixing in the amorphous mixed domains is shown to control fill factors (FFs) and needs to be precisely controlled for designing new polymer:nonfullerene acceptor pairs with even higher FFs. More significantly, we further correlate the thermodynamic interaction parameters to morphology and performance in these record-efficiency nonfullerene devices, which allows us to understand the optimal processing temperature for the 12%-efficiency PBDB-T:IT-M blend[4]. We propose that the precise determination of temperature dependent interaction parameters will aid in establishing property-performance relationships and screening new material combinations/optimal processing conditions creating a morphology that can support high performance.

Effect of immerse an organic layer in isopropyl alcohol on characteristics of hybrid photovoltaic structures

Antonio J. Olivares-Vargas, Ismael Cosme-Bolaños, Svetlana Mansurova, Andrey Kosarev, Adrian Itzmoyotl Toxqui, Instituto Nacional de Astrofísica, Óptica y Electrónica (Mexico)

Solar cells based on crystalline silicon offer high efficiency but the manufacturing process is very costly, due to requirement of high temperatures and high vacuum to produce the p-n junction. Organic materials have become very important in recent years due to their potential use for photovoltaic applications. Among the main advantages of organic

semiconductors are their functional and mechanical flexibility, as well as fabrication simplicity. However, these materials usually afford moderate efficiency. Hydrogenated amorphous silicon (a-Si:H) is another material suitable for large area fabrication of potentially flexible devices at low cost. The idea of combining organic semiconductors and amorphous silicon films in hybrid photovoltaic devices is very attractive due to the possibility to complement the useful properties of both material systems.

The photovoltaic devices that we study in this work consist of a p-i-n structure, which is also commonly used in inorganic solar cells. In such kind of structures, the light is mainly absorbed in the intrinsic silicon film and the p- and n-type films are used to create an electric field that separates electrons and holes to produce a photocurrent. In this work, we use an organic material (PEDOT:PSS) to replace the p-type inorganic film in amorphous silicon p-i-n structure. It is widely known, that PEDOT:PSS based organic film is highly transparent and its conductivity can be modified e.g. immerse in a solvent type. Here we present the results of experimental investigation of the effect of isopropanol (IPA) treatments of p-type (PEDOT:PSS) organic layer in characteristics of hybrid solar cell structure.

18% high-efficiency air-processed perovskite solar cells made in a humid atmosphere of 70% RH

Sai Wing Tsang, Yuanhang CHENG, City Univ. of Hong Kong (Hong Kong, China)

Despite the advanced progress in power conversion efficiency (PCE), developing air-processed high-efficiency perovskite solar cells (PVSCs) for future commercialization is still challenging. Here we report that, besides the general wisdom of the effect of moisture, oxygen in air has severe impact on the quality of the solution-deposited perovskite films. Interestingly, different from moisture that induces fast crystallization of PbI2 upon deposition, oxygen exacerbates the wetting of the PbI2 solution on substrates. To eliminate the impact of oxygen and moisture on the formation of PbI2, we preheat the substrate and PbI2 solution to build up a shield of organic vapor from the solvent during PbI2 film formation. Using this simple method, an air-processed PVSC made under a humid atmosphere of 70% RH has a record PCE of 18.11%. Our work not only reveals the origin of the detrimental effects on perovskite film formation in ambient air, but also provides a simple practical strategy to develop air-processed high-efficiency PVSCs for future commercialization.

On the study of exciton binding energy with direct charge generation in photovoltaic polymers

Sai Wing Tsang, Ho-Wa LI, City Univ. of Hong Kong (Hong Kong, China)

Overcoming the strong excitonic effect in organic photovoltaics (OPVs) is one of the key strategies for the design of materials and device structures. Approaches to measure the binding energy in organics are, however, not readily available. Here, we systematically studied the electrical and optical quantum efficiencies of a series of conjugated photovoltaic polymers. We find that there is generally a secondary onset in external quantum efficiency (EQE) spectrum at high excitation energy, independent of optical absorbance of the materials. Combining photoluminescence quantum yield measurement and adding a small amount (1 wt%) of fullerene acceptor in polymer blends, it further confirms the pristine polymer EQE spectrum has a transition from exciton to free-charge generation with increased excitation energy. Strikingly, by comparing the reported photoemission spectroscopy results, the secondary onsets in the EQE spectra have excellent agreement with the transport gap (Eg) in corresponding materials. Consequently, the exciton binding energies of the polymers can be obtained with the smallest 0.6 eV in PCE10 to the largest 1.2 eV in MEHPPV. Our results demonstrate a facile access to the transport gap and exciton binding energies in organic semiconductors. This provides valuable information for further understanding the strong excitonic effect in photovoltaic cells.

Understanding of electronic and ionic transport at metal halide perovskites interfaces

Ashwith Chilvery, Xavier Univ. (United States); Padmaja Guggilla, Alabama A&M Univ. (United States)

Over the past 5 years, perovskites have revolutionized optoelectronics and photonics with the discovery of organometal halide perovskite materials. These class of materials have displayed promising results for advanced and efficient photovoltaics (PV). However, some of the urgent issues associated with these materials such as hysteresis, lead toxicity, and poor stability are yet to be resolved. Hysteresis in these halide perovskite PV devices is a combination of multiple factors, that impact transport within the material. These relate to fundamental question regarding the transport of carriers and mobile ions that are of direct technological importance. In addition, the impact of non-reversible changes at interfaces under conditions of increased carrier density or field strength may couple these behaviors. In this project, we propose to examine basic interface interactions at metal halide perovskite interfaces with technological relevant contact materials. More specifically we will look at metal, metal oxide and select chalcogenide materials interfaced with solar relevant halide perovskites. This project will develop the several test structures in which these interface combinations can be examined. Specifically, to undertake this we intend to develop test structures in which contact resistance, and stability of these technologically relevant interfaces can be assessed.

Solution-processable benzo[1,2-b:4,5-b’] dithiophene-6,7-difluoroquinoxaline small molecule donors with solar cell efficiency >8%

Ru-Ze Liang, Kai Wang, Jannic Wolf, Maxime Babics, Philipp Wucher, Pierre M. Beaujuge, King Abdullah Univ. of Science and Technology (Saudi Arabia)

Solution-processable small molecule (SM) donors are promising alternatives to their polymer counterparts in bulk-heterojunction (BHJ) solar cells with fullerene and nonfullerene acceptors. In particular, SM donors benefit from favorable spectral absorption, self-assembly patterns, crystalline thin-film morphologies, and high carrier mobilities in BHJ active layers with the electron-acceptor component. Our recent developments on rational pendant-group substitutions in a broad set of SM donors, and in benzo[1,2-b:4,5-b’]dithiophene–6,7-difluoroquinoxaline SMs specifically, proves that well-chosen substituents can help narrow the optical gap (Eopt) of the SM donors, without altering their propensity to order and form favorable thin-film BHJ morphologies with fullerenes. Systematic device examinations with benzo[1,2-b:4,5-b’]dithiophene–6,7-difluoroquinoxaline SMs show that power conversion efficiencies (PCEs) >8% and open-circuit voltages (VOC) nearing 1V can be achieved with the narrow-gap SM donor analogues (Eopt= 1.6 eV). Meanwhile, our concurrent effort to find solution-processable SM donor and nonfullerene acceptor combinations indicate that BHJ solar cells PCEs >6% and VOC values >1.1V can be achieved with selected nonfullerene acceptors (to be discussed in our presentation). In general, we find that in some of the best BHJ active layers, charge transport proceeds with minimal, nearly trap-free recombination. Detailed device simulations, light intensity dependence and transient photocurrent analyses will be used to emphasize how carrier recombination impacts BHJ device performance upon optimization of active layer thickness and morphology.

Probing chemistry and structure of organic semiconductors with soft x-rays

Gregory Su, Isvar Cordova, Michael Brady, Cheng Wang, David Prendergast, Lawrence Berkeley National Lab. (United States)

Continued advances in the performance of organic electronics depends on an understanding of the connections among chemistry, structure, and device performance. These relationships are difficult to probe in these complex systems. Soft X-rays span an energy range that covers the core-level transitions of the most common elements found in organic materials, allowing for sensitivity not only to certain elements, but also specific functional groups and moieties. Additionally, scattering and microscopy at these energies provides spatial distribution information, making soft X-ray spectroscopy, scattering, and microscopy a unique set of tools that can probe both chemistry and structure in organic semiconductors. Here, we show recent advances in developing the groundwork for leveraging first-principles simulations of X-ray absorption spectroscopy that reveal details of electronic structure and molecular orientation that are needed to understand and interpret experimental results. Semiconducting polymers including polythiophenes and donor acceptor polymers poly[4-(4,4-dihexadecyl-4H-cyclopenta[1,2-b:5,4-b']dithiophen-2-yl)-alt-[1,2,5]thiadiazolo[3,4-c]pyridine], PCDTPT, and [N,N-9-bis(2-octyldodecyl) naphthalene-1,4,5,8-bis(dicarboximide)-2,6-diyl]-alt-5,59-(2,29-bithiophene), P(NDIOD-T2), will be used as examples to illustrate effects of chain length, backbone tilt and alignment, and side chains on resulting X-ray absorption spectra. Furthermore, developments to enable in situ and operando studies of organic semiconductors with soft X-rays will also be presented.

10363-137, Session PMon

Optical probes of amplitude modes in PTB7 copolymer

Shai Vardeny, College of Optical Sciences, The Univ. of Arizona (United States); Sangita Baniya, Evan Lafalce, The Univ. of Utah (United States); Nasser N. Peyghambarian, College of Optical Sciences, The Univ. of Arizona (United States); Z. Valy Vardeny, The Univ. of Utah (United States)

We measured the spectra of resonant Raman scattering (RRS) and doping induced absorption of pristine films of the ϖ-conjugated donor-acceptor copolymer, namely Thieno[3,4 b]thiophene- alt-benzodithiophene (PTB7), as well as photoinduced absorption spectrum in blend of PTB7 with fullerene PCBM molecules. We found that the copolymer contains six strongly coupled vibrational modes having relatively strong Raman scattering intensity, which are renormalized upon adding charges onto the copolymer chains either by doping or photogeneration. Since the charge polaron absorption band overlaps with the renormalized modes, the strongly coupled vibrations appear as anti-resonance lines superposed onto the induced polaron absorption band in the photo-induced absorption spectrum, but less so in the doping induced absorption spectrum. We show that the RRS, doping- and photoinduced absorption spectra of PTB7 are well explained by the amplitude mode model, where a single vibrational propagator describes the renormalized modes and their related intensities in detail. From the relative strengths of the induced infrared activity of the vibration and electronic transitions we calculated the polaron effective kinetic mass in PTB7 using the amplitude mode model to be ~3.8m*, where m* is the electron effective mass. This relatively small mass stems from the weak polaronic relaxation energy and indicates a rigid chain structure for PTB7.

10363-138, Session PMon

Fabrication of semi-transparent and flexible organic solar cells

Yeongjin Lee, Gwangju Institute of Science and Technology (Korea, Republic of); Hongkyu Kang, Imperial College London (United Kingdom) and Gwangju Institute of Science and Technology (Korea, Republic of); Nara Kim, Seok Kim, Jinho Lee, Kwanghee Lee, Gwangju Institute of Science and Technology (Korea, Republic of)

Organic solar cells (OSCs) have many advantages such as solution processability, high power-to-weight ratio, cost efficiency, transparency and flexibility. Transparency and flexibility are superior characteristics for organic solar cells than inorganic solar cells. However, semi-transparent and flexible OSCs have not get been explored because they need special electrodes which have high conductivity, transparency and flexibility at the same time. In this work, we demonstrated semi-transparent and flexible OSCs using transparent and flexible electrodes with high conductivity. Polymer-Ag (PA) electrodes were fabricated as bottom electrodes on polyethylene naphthalate (PEN) flexible substrates. Then, the H2SO4-treated PEDOT:PSS electrodes were transferred on the devices as top electrodes after coating interfacial and photoactive layers on PA electrodes. In addition, to investigate a relationship between the transmittance of PA electrodes and PCEs, we controlled the thickness of PA electrodes. Our semi-transparent and flexible solar cells achieved a PCE of 4.9% with an average transmittance (AVT) of 39%, and PCE of 7.4% with an AVT of 18% corresponding to the highest values in reported semi-transparent and flexible OSCs. Our device structure presents the guideline for promising applications of OSCs with the transparency, flexibility and high performance.

Multi-colored luminescent configuration with versatile nanopatterns for advanced photovoltaics

Minwoo Nam, Jaehong Yoo, Doo-Hyun Ko, Kyung Hee Univ. (Korea, Republic of)

The conversion and manipulation of light via luminescent down-shifting (LDS) show promise in optoelectronic applications. In this study, we introduce a novel concept of multifunctional LDS platform bearing subwavelength nanopatterns. The lanthanide complexes, such as the down-shifting dopants terbium and europium, were incorporated into a polymer derived ceramic matrix, perhydropolysilazane (PHPS). The prompt formation of nanoscale photonic structures enhanced both absorption and emission characteristics, while retaining the material's optical transparency. The LDS template was a realistic strategy to enhance the efficiency of photovoltaic devices as their performance is determined by manipulating the incident light. The organic photovoltaics (OPVs) involving the LDS ceramics exhibited considerably enhanced efficiency. The LDS ceramic protected the OPV components against UV-induced degradation, resulting in the significantly better stability compared to that of the bare OPV. Double imprint technique was devised by superpositioning two LDS nanopatterned arrays to efficiently combine two lanthanide emissions. Colors could, therefore, be coded within a single layer via the double print approach. The outcome was a large-scale spectrum-matching window that was nearly transparent in the day light, while a vivid mosaic pattern with different colors emerged under UV illumination. Combined with the multi-functionality such as prominent LDS properties, self-cleaning capability, and color tunability, the developed LDS platform offers promise for future building-integrated photovoltaics (BIPVs).

Air-stable organic solar cells using an iodine-free solvent additive

Seongyu Lee, Jaemin Kong, Kwanghee Lee, Gwangju Institute of Science and Technology (Korea, Republic of)

The organic photovoltaic cells have been researching after the discovery of charge transfer with two materials for the couple of decade. Among the many of research, the introducing additive for control of the morphology has been leading a high power conversion efficiency (PCE) over 10%, which seems to be one of powerful technique. In spite of advantages from additive for high PCE, however, the reproducibility and devices life time which fabricated from additives dramatically decrease rather than one without. Here, we found that the degradation of photoactive layer is very close to the residue of common additive, 1,8-diiodooctane (DIO), by making fullerene-Iodide intermediate compounds leading the oxidation of electron acceptor even without any illumination. By introducing iodine-free reagent 1,2,4-tricholorobenzene (TCB) as a solvent additive, photovoltaic organic layer secures the air stability showing no difference in J-V performance between processing in nitrogen filled glove box and processing in ambient air. Moreover, the device lifetime significantly extended by 10 times longer than that that by DIO without any encapsulation.

10363-303, Session Plen

The History and Progress of Halide Perovskite Photovoltaics

Nam-Gyu Park, Sungkyunkwan Univ. (Korea, Republic of)

Since the first report on the solid-state perovskite solar cell with power conversion efficiency (PCE) of 9.7% in 2012 by our group, its certified PCE now reaches 22%. It is believed that perovskite solar cell is promising next-generation photovoltaics (PVs) due to superb performance and very low cost. In this talk, the history of perovskite photovoltaics will be briefly presented along with their scientific progress. Methodologies to achieve hysteresis-free, stable and high PCE perovskite solar cells will be introduced. Lewis acid-base adduct approach has been found to be very reliable and reproducible method to get high quality perovskite layer minimizing non-radiative recombination. Non-stoichiometric precursor in adduct process demonstrated grain boundary healing effect, which further improved voltage and fill factor due to long carrier life time of perovskite and improved charge transporting at grain boundary as well. Grain boundary healing process yields PCE as high as 20.4%. Moisture was effectively protected and hysteresis was significantly reduced by introducing 2-dimensioanl perovskite at grain boundary of 3-dimensional perovskite grains. Ion migration is one of factors affecting stability and hysteresis, which can be deactivated by 2-dimensional perovskite with higher barrier energy for ion migration. Thermal stability of perovskite material was found to be stable up to 120°C in the absence of moisture, but that of full device was sensitive to selective contacts, indicating that thermally stable selective contacts are equally important. Universal method to remove hysteresis will be also given in this talk.

10363-304, Session Plen

Mesoscopic Photosystems for the Generation of Electricity and Fuels from Sunlight

Michael Grätzel, Ecole Polytechnique Fédérale de Lausanne (Switzerland)

A planetary emergency has arisen from the continued depletion of fossil fuels, producing green house warming and unprecedented environmental pollution. Future energy options for renewable and carbon-free sources will need to fill the terra-watt gap that will open up during the next few decades due to the growth of the world population. A promising development is the recent emergence of a new generation of highly efficient photovoltaic converters based on molecular dyes or perovskite pigments as light harvesters. Mesoscopic photosystem that mimic the primary process of natural photosynthesis also offer the prospect of low cost fuel generation from sunlight.

10363-5, Session 3

Hybrid metal halide perovskites: optoelectronic properties and stability *(Keynote Presentation)*

Laura Herz, Univ. of Oxford (United Kingdom)

Hybrid metal halide perovskites (stoichiometry AMX3) have recently emerged as low-cost active materials in PV cells with power conversion efficiencies in excess of 21%. We discuss how parameters essential for photovoltaic operation, such as crystallinity, photostability, charge carrier mobility and diffusion lengths are altered with substitutions of the organic A cation (e.g. methylammonium versus formamidinium), the metal M cation (e.g. Pb2+ or Sn2+) and the halide X anion (I- versus Br-). We focus on two 3D perovskite systems that have attracted interest lately, lead-free ASnI3 (optical bandgap ~1.3 eV) and the mixed organic lead iodide/bromide system APb(BryI1-y)3 whose band gap can be tailored between ~1.5 eV (FAPbI3) and ~2.3 eV (FAPbBr3). We show that unintentional hole doping in tin iodide perovskites introduces fast recombination pathways that can be moderated by crystal structure [1] and introduces a radiative quasi-monomolecular charge recombination channel [2]. In addition, we demonstrate that charge-carrier diffusion and recombination in FA1-xCsxPb(BryI1-y)3 depends on a complex interplay between changes in morphology and electronic bandstructure with bromide fraction y [3,4,5].

How are charge carriers protected in lead halide perovskite? *(Invited Paper)*

Xiaoyang Zhu, Columbia Univ. (United States)

The feverish research activity on lead halide perovskites has been fueled by their exceptional optoelectronic properties, e.g., in solar cells and light-emitting devices. Hybrid lead halide perovskites exhibit carrier properties that resemble those of pristine nonpolar semiconductors despite static and dynamic disorder, but how carriers are protected from efficient scattering with charged defects and optical phonons is unknown. We have recently put forward the large polaron model to explain the carrier protection [1-3]. We find that nascent charge carriers are screened by "solvation" or large-polaron formation on time scales ≤ 0.3 ps, leading to protected carriers with dramatic suppression of electron- LO phonon scattering. This results in long-lived energetic electrons with excess energy ~ 0.25 eV above the conduction band minimum and with lifetime on the order of 100 ps, which is ≥103 time longer than those in conventional semiconductors. The exceptionally long-lived energetic carriers lead to hot fluorescence emission. The protection of energetic carriers is directly correlated with the liquid-like motion of the lattice, as revealed by femtosecond Kerr-effect spectroscopy. In contrast to that of energetic carriers, the protection of long-lived bandedge carriers do not require the presence of organic cations and is an intrinsic property of the soft perovskite lattice [4].

A simple processing technique for the electrical doping of organic semiconductors *(Invited Paper)*

Bernard Kippelen, Georgia Institute of Technology (United States)

Organic photovoltaics (OPV) can lead to a low cost and short energy payback time alternative to existing photovoltaic technologies. However, to fulfill this promise, power conversion efficiencies must be improved and simultaneously the architecture of the devices and their processing steps need to be further simplified. In this talk we will present a simple solution-based technique that leads to the electrical doping of semiconducting polymer films over a limited depth. We will also show how that new processing technique can be employed to fabricate efficient single layer organic photovoltaic devices in which the functions of hole-and electron-collection are integrated in specific regions of the active layer near the electrodes.

Eindhoven (Netherlands); Robert Gehlhaar, IMEC (Belgium); Yulia Galagan, Herbert Lifka, Holst Ctr. (Netherlands); Ruud E. I. Schropp, Mariadriana Creatore, Technische Univ. Eindhoven (Netherlands); Tom Aernouts, IMEC (Belgium); Ronn Andriessen, Holst Ctr. (Netherlands)

Organometallic halide perovskite are extremely promising novel materials for thin-film photovoltaics, exhibiting efficiencies over 22%. This presentation will focus on the current status of one of the main challenges in the industrial development of this novel PV technology: going from small cells (~0.01 cm2) to sheet-to-sheet processed modules (6 inch2).

As a first step perovskite absorbers, contact layers and device architectures were evaluated, and a planar n-i-p structure was selected. The stack consists of: Glass/ITO/TiO2/CH3NH3PbI3/Spiro-OMeTAD/Au. The perovskite absorber layer is prepared in a single deposition step based on a mixed Pb source (Pb(CH3COO)2.3H2O and PbCl2).[1] The deposition process allows a relatively fast crystallization, leading to a high PCE. TiO2 was e-beam evaporated, Spiro-OMeTAD spin coated and gold was thermally evaporated.

Secondly, laboratory deposition methods like spin coating and atomic layer deposition (ALD)[2] were replaced by scalable deposition methods like slot die coating and spatial ALD. Care is take to identify and quantify efficiency losses caused by upscaling. The cells fabricated with slot die coated perovskite and Spiro-OMeTAD layer exhibit an average PCE of 14.6 ± 1.3 %. The Jsc measured is confirmed by EQE.

In a third step, a monolithic laser interconnection is introduced yielding modules with 95% geometrical fill factor. These modules were encapsulated with flexible water barrier and PCE on aperture area (reverse JV scan) up to 10-11% were measured.

Up-scaling perovskite solar cell manufacturing from Sheet-to-Sheet to Roll-to-Roll: Challenges and solutions

Francesco Di Giacomo, Yulia Galagan, Santhosh Shanmugam, Harrie Gorter, Fieke van den Bruele, Gerwin Kirchner, Ike de Vries, Henri Fledderus, Herbert Lifka, Holst Ctr. (Netherlands) and Solliance (Netherlands); Sjoerd C. Veenstra, Energy Research Ctr. of the Netherlands (Netherlands) and Solliance (Netherlands); Tom Aernouts, IMEC (Belgium) and Solliance (Netherlands); Pim Groen, Holst Ctr. (Netherlands) and Solliance (Netherlands); Ronn Andrissen, Solliance (Netherlands) and Holst Ctr. (Netherlands)

Organometallic halide perovskite are extremely promising novel materials for thin-film photovoltaics, exhibiting a photo conversion efficiency , PCE, of over 22% on glass and over 17% on foil [1,2]. The compatibility with flexible substrate paves the way to a roll to roll production if the coating and crystallization process can be tuned properly.

Starting from a Sheet-to-Sheet production of perovskite solar cells and modules on 152x152 mm2 substrates that involve a combination of sputtering, e-beam evaporation TiO2, slot die coating of perovskite and hole transport material (HTM) and thermal evaporation (average PCE of 14.6 ± 1.3 % over 64 devices, 14.2 ± 0.4 % with 300 s of tracking, more than 10% initial PCE on modules), the steps towards a roll-to-roll production will be analysed. First of all the stack was further optimized to make it compatible with a faster production at low temperature (max 5 minutes @ 145°C for each layer), by also keeping the PCE over a threshold value of 15%.

Two option were chosen and investigated for the electron transport layer (ETL): either a spatial Atomic Layer Deposition (R2R sALD) of TiO2 or slot die coating of a ETL ink.

A water based commercial SnO nanoparticles dispersion was used as coatable ETL, and the ink was up-scaled from spin coating on a 30x30 mm2 (with stabilized PCE of 17%+), to S2S slot die coating on 152x152 mm2 substrates to R2R coating of a 300 mm wide roll of PET/ITO without using hazardous solvent and materials.

While the S2S production is carried out in a highly controlled environment, the R2R production is often carried out in atmosphere and can consume much larger quantities of materials. Thus a first important point is the development of a green solvent and precursor system for the perovskite layer to prevent the emission of toxic compound. The use of DMSO with a surface energy modifier and the use of methylammonium free perovskite allow to have a R2R coatable ink and a safe production environment, without releasing toxic vapour in the environment (> 1 km coated so far) .

The solvent also massively influenced the film crystallization, that occur in a wet phase rather that in a dry phase as for the spin coated samples. We will show how a modification of the furnace condition (i.e. air flow and temperature profile) allowed to steer the crystallization of the layer in different manners.

The first results on device fabrication are encouraging, with R2R produced flexible PSC with stabilized PCE of 12.6%, a remarkable value for this novel devices. The perovskite layer show an high coverage of the substrate with large grain domains. This result can be considered an important milestone towards the production of efficient, low cost, lightweight, flexible PSC on large area.

Roll-to-roll production of organic solar cells *(Invited Paper)*

Christian L. Uhrich, Heliatek GmbH (Germany)

Heliatek GmbH produces organic solar cells using roll to roll processes in vacuum and inert atmospheres. In this talk, we will present the latest results from our first roll to roll manufacturing machine with a maximum size of 30cm width and a length of up to 6 meters. Tandem Solar Cells from this production line show efficiencies above 7% (active area). The solar cells are deposited on a flexible PET substrate in a continuous fully integrated vacuum process. These small molecule solar cells can be semitransparent and can be produced in various colors. Due to their low weight of only 500 g/m? and the very low thickness Heliatek's HeliaFilm® can be used in numerous fields of application such as between glass, in facades or on inflatable air domes. By using doped transport layers it is easy to stack two or more individual sub cells on top of each other.

We will report about the latest news from this production process including results on lifetime and pilot installations from around the world. Furthermore, we will discuss the progress from our labs including a detailed loss mechanism analysis of our world record 13.2% efficient multi-junction cell on glass.

Currently, Heliatek is setting up a second production line with a capacity of one million m? p.a. of solar films when fully ramped up.

High performance roll-to-roll printed PTB7-Th/PCBM solar cells

Kevin L. Gu, Stanford Univ. (United States); Xiaodan Gu, Stanford Univ. (United States) and Univ. of Southern Mississippi (United States); Yan Zhou, Stanford Univ. (United States); Hongping Yan, Stanford Univ. (United States) and SLAC National Accelerator Lab. (United States); Michael F. Toney, SLAC National Accelerator Lab. (United States); Zhenan Bao, Stanford Univ. (United States)

Despite having surpassed 10% power conversion efficiency (PCE), widely held as the threshold for commercial viability, high performance organic photovoltaics (OPVs) are still mostly constrained to lab-scale devices fabricated by spin coating. Efforts to produce scalable printed OPVs trail significantly in efficiency, highlighting the need to better understand the processing-morphology-performance relationship in the context of linear printing processes. Here we investigate the OPV system PTB7-Th/PC71BM, which has demonstrated >10% PCE via spincoating but only exhibits ~1% PCE when roll-to-roll printed. Of particular interest is the ubiquitous alcohol wash post-treatment applied to the dried active layer, which induces a significant improvement in device performance, and its crucial role for printed films. While it has been speculated that the primary utility of the alcohol post-treatment is to remove the additive 1,8-diiodooctane (DIO) residue in the dried film, we find here that the wash process itself dramatically impacts morphology in printed films regardless of the presence of DIO. Here we employ various x-ray characterization techniques to probe phase separation, crystallinity, and molecular orientation, as well as in-situ grazing-incidence x-ray diffraction (in-situ GIXD) to monitor morphological evolution during the isopropanol post-treatment process. It is discovered that isopropanol induces significant donor polymer alignment and enhanced ϖ-ϖ degree of crystallinity. Through the understanding gained in this study, we are able to achieve a roll-to-roll printed OPV with 5% PCE, which is to our knowledge the highest reported performance for a roll-to-roll printed single junction photoactive layer on a flexible substrate.

10363-13, Session 4

Self-doped n-type interfacial materials for high-performance polymer/perovskite solar cells *(Invited Paper)*

Fei Huang, South China Univ. of Technology (China)

The performance of polymer/perovskite solar cells (PSCs/PVKSCs) is highly dependent on the interfacial contact between the active layer and electrodes. Water/alcohol soluble interfacial materials, which enable orthogonal processing of high-performance multi-layer PSCs can greatly improve the interfacial contact as well as device performance. Traditional interfacial materials are not compatible with the large-area processing of PSCs using roll-to-roll techniques. Here, we present a series of self-doped interfacial materials with controlled doping properties and high mobility for the interface optimization of PSCs. Self-doped interfacial materials containing n-type conjugated backbone and polar side chains are prepared. It was shown that neutral amino groups undergo photo-induced doping process while the bromide-quaternized groups employ a self-doped mechanism.1 Further study on the counterions of the self-doped interfacial materials shows that the counterions can also induce different self-assembling and doping behavior with different strength, leading to varied charge-transporting properties. 2 More importantly, these self-doped interfacial materials can enable high-performance (>10%) PSCs and still work efficiently in varied thickness, which match well with the requirement of the fabrication of large-area PSCs. Based on the development of self-doped interfacial materials, a high-performance interconnecting layer for tandem solar cells was also developed, which can boost the power conversion efficiency (PCE) of tandem solar cells to 11.35%.3 Moreover, these interfacial materials can passivate the surface traps of perovskite to improve the electron extraction properties of PVKSC, leading to high-performance PVKSCs even when the thickness of interfacial material is more than 200 nm.4 The successful development of self-doped interfacial materials offers a better processing window for potential fabrication of PSCs/PVKSCs using large-area processing method.

A new series connection architecture for large area printed organic solar cell modules

Soonil Hong, Jinho Lee, Hongkyu Kang, Kwanghee Lee, Gwangju Institute of Science and Technology (Korea, Republic of)

The fabrication of organic photovoltaic modules via printing techniques has been the greatest challenge for their commercial manufacture. Current module architecture, which is based on a monolithic geometry consisting of serially interconnecting stripe-patterned sub-cells with finite widths, requires highly sophisticated patterning processes that significantly increase the complexity of printing production lines and cause serious reductions in module efficiency due to so-called 'aperture loss' in series connection regions. In this study, we demonstrate an innovative module structure that can simultaneously reduce both patterning processes and aperture loss. By using a charge recombination feature that occurs at contacts between electron/hole transport layers, we devise a series connection method that facilitates module fabrication without patterning the charge transport layers. With the successive deposition of component layers using slot-die and doctor-blade printing techniques, we achieve a high module efficiency reaching 7.5% with area of 4.15 cm2.

10363-15, Session 5

Fullerene-free polymer solar cells with over 12% efficiencies *(Invited Paper)*

Sunsun Li, Wenchao Zhao, Institute of Chemistry (China); Shaoqing Zhang, Univ. of Science and Technology Beijing (China); Jianhui Hou, Institute of Chemistry (China)

In polymer solar cells (PSCs), molecular design and modulation of chemical composition of the active layer materials are of critical importance for enhancing power conversion efficiencies (PCEs). In our previous work, a PCE of 11.2% was demonstrated by using a new combination of a polymer donor named PBDB-T and a small molecular acceptor (SMA) named ITIC. In order to optimized photovoltaic performance of the PBDB-T:ITIC-based PSCs, subtle chemical modifications of end-groups (EGs) were applied to precisely optimize the molecular energy level of ITIC. By successively introducing one- and two- methyl substituents, the lowest unoccupied molecular orbital (LUMO) levels of the two new acceptors (IT-M and IT-DM) were raised by 0.04 eV and 0.08 eV, respectively, compared to ITIC. Hence, improved open-circuit voltages (VOC) of 0.94 V and 0.97 V were obtained in the corresponding PSCs. Benefiting from the optimized molecular energy levels in the PBDB-T:IT-M-based blend, a PCE of 12.05% was obtained. Furthermore, we also introduced the third component Bis-PCBM[70] to enhance light absorption of the PBDB-T:IT-M blend in the short wavelength region. In the ternary PSCs based on PBDB-T:IT-M:Bis-PCBM[70], a higher PCE of 12.2% was achieved.

10363-16, Session 5

RAMP-ing the discovery of high-performance organic photovoltaic materials

Andrew J. Ferguson, Bryon W. Larson, Bertrand J. Tremolet de Villers, Wade A. Braunecker, Ross E. Larsen, National Renewable Energy Lab. (United States)

Organic semiconductors (OSCs) have found numerous applications in thin film electronic devices, including displays, sensors, lighting, and solar cells. OSCs offer the advantage that they can be modified by synthetic chemists to fulfill specific needs, and that they are not limited to being made from single elements or compositional alloys. For example, organic photovoltaics (OPVs) have reached nearly 13% power conversion efficiency (PCE) in small area devices using traditional polymer-fullerene blends, yet non-polymer and non-fullerene composites are now also showing PCEs above 10%. The flexibility offered by synthetic manipulation also presents a challenge: progress towards the discovery of next-generation, high-performance materials can be stifled by the bottleneck of device optimization through process engineering. High-throughput screening techniques that provide high fidelity performance metrics can circumvent this problem and will become important tools to accelerate material development. Here, we introduce such a tool, based on unique microwave conductivity capabilities, and illustrate a cost- and time-effective approach to evaluate the potential of promising new materials, independent of their bulk (i.e., device optimized) thin-film performance. We demonstrate the power of this approach, by correlating figures of merit from our screening tool to the OPV device performance for a library of current state-of-the-art OSCs, based on both polymer and small molecule chemical structure motifs. Finally, in the context of polymeric materials, we highlight the sensitivity of the screening process to physicochemical properties (e.g., molecular weight) and suggest that our tool can be employed for batch-to-batch quality control.

10363-17, Session 5

Charge generation in non-fullerene donor-acceptor blends for organic solar cells *(Invited Paper)*

Paul E. Shaw, Nasim Zarrabi, Dani Stoltzfus, Paul L. Burn, Paul Meredith, The Univ. of Queensland (Australia)

The continued improvement in organic solar cell efficiency has been the result of materials development and the optimization of the bulk heterojunction morphology. While a broad range of donor materials have been devised, the choice of acceptor material remains dominated by fullerenes derivatives such as PC60BM and PC70BM. Although some non-fullerene acceptors deliver blends with performance in devices approaching that of fullerene-containing blends, many do not. Given the potential benefits of non-fullerene acceptors it is important to understand what properties are required to give rise to high performance cells.

We report a photophysical study on a series of novel acceptor materials that share the same chromophore, and thus energetics, but vary in terms of their shape and chromophore number per molecule. Using ultrafast transient absorption spectroscopy, we have probed the process of singlet exciton quenching and polaron formation in blends with the polymer PTB7 across acceptor concentrations varying by two orders of magnitude and compare the results with those of PC70BM-based blends.

The results show that the structural differences between the non-fullerene acceptors had no significant impact on their performance. However, the loss of polarons to geminate recombination in the non-fullerene blends was approximately twice that of the blends containing PC70BM across a broad range of acceptor concentrations. This suggests that the choice of acceptor chromophore, which will determine the nature of the interface with the donor, is critical for minimising geminate losses and achieving high performance solar cells.

10363-18, Session 5

Impact of exciton transfer dynamics on charge generation in polymer/nonfullerene solar cells

Kenan Gundogdu, Harald W. Ade, Bhoj Gautam, North Carolina State Univ. (United States); He Yan, Hong Kong Univ. of Science and Technology (Hong Kong, China); Robert Younts, North Carolina State Univ. (United States); Shangshang Chen, Hong Kong Univ. of Science and Technology (Hong Kong, China)

The initial steps in organic photovoltaic cell (OPV) operation involve the formation of neutral excitons through photo absorption, exciton diffusion to and separation into free charges at the donor acceptor interface.1, 2As the usable solar spectrum spans a large range from the visible to the infra-red (IR), an obvious direction for improved light harvesting is to synthesize donor and acceptor materials with complementary absorption. In such devices, specifically those involving polymer donors and small molecule acceptors, both charge transfer from donor and acceptor moieties, and energy (exciton) transfer from high band gap to low band gap material are possible. Here we show that when charge and exciton transfer processes are present, the co-existence of excitons in both domains can cause a loss mechanism. Charge separation of excitons in a low band-gap polymer is hindered due to exciton population in the larger band-gap acceptor domains. Our results further show that excitons in the lower bandgap material should have a relatively long lifetime compared to the transfer time of excitons from the higher band gap material, in order to contribute to the charge separation. These observations provide significant guidance for design and development of new materials in OPV applications.

10363-19, Session 6

Perovskite tandem solar cells with greater than 25% efficiency and enhanced stability *(Invited Paper)*

Michael D. McGehee, Stanford Univ. (United States)

We have deposited perovskite solar cells with a bandgap of 1.68 eV onto heterojunction silicon solar cells that by themselves have an efficiency of 21% to create a 1 square centimeter monolithic tandem solar cell with an efficiency of 25.3%. We have also made all-perovskite tandems using a new ABX3 perovskite composition containing a mixture of tin and lead on the B site that have greater than 20% efficiency. With solar cells packaged between two sheets of glass with rubber edge seals, we have passed the industry standard 1000 hour 85°C 85% humidity damp heat test as well as 200 cycles between 85°C and -40°C. One of the keys to obtaining high efficiency and stability was optimizing the composition of cesium and formamidinium on the A site and iodine and bromine on the X site. We will show how light -induced phase separation occurs when there is too much bromine in the films. Another crucial step towards improving stability is the use of atomic layer deposition to deposit a tin oxide buffer layer on the perovskite that enables the sputter deposition of an indium tin oxide transparent electrode. ITO is less reactive with perovskites than the metals that are typically used in perovskite solar cells. The ALD layer has minimal parasitic absorption and prevents shunting. Our progress towards achieving 30% power conversion efficiency and passing even more aggressive stability tests will be presented.

10363-20, Session 6

Towards a reliable measurement protocol for perovskite solar cells

Eugen Zimmermann, Ka Kan Wong, Michael Müller, Hao Hu, Philipp Ehrenreich, Carola Ebenhoch, Thomas Pfadler, Lukas Schmidt-Mende, Univ. Konstanz (Germany)

The rapid rise of power conversion efficiency of metal-halide perovskite solar cells beyond 20 % has drawn huge attention. Recent certified efficiencies, however, have been marked as "unstabilized" as perovskite solar cells tend to show a hysteretic behaviour during current density-voltage (J-V) measurements. This leads to deviating results for varying scan parameters and conditions, which challenges reliable and comparable results. In particular, the extent of this behaviour is highly dependent on device preparation method, architecture, device history, and more importantly on measurement preconditions and scan rate. Thus, the demand for reliable stabilized values arises which are reproducible and comparable among different laboratories. Here we introduce an adaptive tracking of the maximum power point and the open circuit voltage. We compare these values with device characteristics derived from standard J-V measurements. Furthermore, we discuss the challenges of a correct efficiency determination and provide the algorithms for easy implementation in existing measurement systems.

10363-21, Session 6

Solution-processed inorganic-organic halide perovskite and charge transport layers for highly efficient and stable perovskite solar cells *(Invited Paper)*

Sang Il Seok, Ulsan National Institute of Science and Technology (Korea, Republic of)

We have analyzed microstructures of perovskite layers deposited with different composition by controlling X-ray incident angle from 0.05 to 0.5, corresponding to near-surface and full-depth from surface, respectively. The patterns in the perovskite layers will be discussed in detail by combing with a high resolution TEM. In addition, alternative materials for electron- and hole-transporting layers will be introduced, because it would be important to solve several practical issues such as stability and flexibility. Sn-based oxides for the use in electron-transporting layer (ETL) and a low temperature solution-processed copper thiocyanate (CuSCN) as an inorganic HTL were applied to PSCs

10363-22, Session 6

Perovskite materials for LED and solar cells

Ana F. Nogueira, Rodrigo Szostak, Adriano S. Marques, Emre Yassitepe, Univ. Estadual de Campinas (Brazil); Jilian N. Freitas, Ctr. de Tecnologia da Informacao Renato Archer (Brazil)

Perovskite materials have been extensively investigated as thin films or colloidal nanoparticles in several technological applications, such as photovoltaic cells (PV), lasers, photodetectors and light emitting diodes (LED).

Perovskite is the name given to materials that have the general formula ABX3 with a structure similar to the mineral CaTiO3. In perovskite materials for PV, the monovalent cation "A" is an organic cation such a methylammonium (CH3NH3+, MA) or formamidinium (CH(NH2)2+, FA). For LED applications, "A" is an inorganic cation as Cs+. In both applications, "B" is a divalent cation Pb2+ or Sn2+, and "X" a halogen anion Cl-, Br- or I-. The optoelectronic properties that make perovskites attractive are their direct and tunable band gap (that can be varied due to quantum confinement or composition), high absorption coefficient (similar to GaAs), ambipolar transport of charges, high mobility of electrons and holes compared with organic semiconductors, and electron diffusion lengths that can exceed micrometers in large crystals.

In this presentation we will discuss some aspects that limit or need to be improved in both PV and LED development.

Perovskite solar cells (PSC) are very sensitive to moisture and the highest reported efficiencies are for tiny devices assembled under very controlled conditions. A dry atmosphere found in glove boxes significantly increases equipment and operational costs for industrial processes; so ambient perovskite fabrication is much less expensive and thus more attractive. In our laboratory we prepare PSC under ambient conditions with efficiency of 13% by the intramolecular exchange method. We will discuss in more details how, by changing the deposition parameters, perovskite formation occurs immediately, or thermal annealing is required to promote the full conversion. A new formation mechanism is proposed for perovskite materials prepared at ambient conditions.

Colloidal perovskite nanocrystals are promising for LED applications., The most used synthetic method to prepare them relies on a mixture of oleylamine and oleic acid (OA) as surfactants. The resulting nanocrystals exhibit poor colloidal stability due to facile proton exchange between the oleate and amine surfactants and they readily precipitate from the crude solution. Oleylamine itself can also accelerate the degradation of the nanocrystals. We will discuss an amine-free synthesis that utilizes tetraoctylammonium halides (TOAX) for preparation of OA-capped CsPbX3 PQDs without the need of post-anion exchange methods. The nanocrystals show PLQY of 70%, narrow emission spectra and enhanced colloidal stability. We will show the results of red, green and blue (RGB) LEDs with utilizing solution-processed polymer based hole transport layers

10363-23, Session 6

Understanding the upper efficiency limit and stability in perovskite solar cells *(Invited Paper)*

Jinsong Huang, The Univ. of North Carolina at Chapel Hill (United States)

I will update the strategies in developing efficient and long lifetime perovskite solar cells in our group with material and interface engineering. I will discuss the factors which limit the enhancement of p-i-n structure perovskite solar cell efficiency, particularly the open circuit voltage in wide bandgap solar cells. The realistic upper-limit efficiency of the p-i-n structure perovskite solar cells will be discussed. I will also present the impact of material morphology, electrode materials on the stability of perovskite solar cells.

10363-24, Session 6

New low-temperature approach for forming high performance CH3NH3PbI3 solar cells with good productivity and stability

Wallace C. H. Choy, The Univ. of Hong Kong (China)

Recently, researchers have focused more to design highly efficient flexible perovskite solar cells (PVSCs), which enables the implementation of portable and roll-to-roll fabrication in large scale. Here, we demonstrated that vacuum-assisted thermal annealing can be used to control the composition, morphology, and thus the quality of the perovskite films formed from the precursors of PbCl2 and CH3NH3I. Using our vacuum-assisted thermal annealing approach to completely remove the chlorine byproduct, pure, pore-free planar CH3NH3PbI3 films with enhanced morphology can be readily formed for high efficiency PVSCs with high stability and reproducibility. In addition, we will report new room temperature approaches for forming PVSCs. Regarding the hole transport layer (HTL), NiOx is a promising material for candidate for fabricating efficient PVSCs. Here, we demonstrate the flawless and surface-nanostructured NiOx film from a simple and controllable room-temperature solution process. Meanwhile, we will propose a new room temperature scheme formation of perovskite films with the features of PbI2 residue-free, large grain-sizes, and highly crystalline. We further layout the design rules for the broad, rational extension of our scheme to form high-quality perovskite films. Using our approach, a room-temperature processed PVSC is obtained with no hysteresis, high power conversion efficiency of about 18%, which is the best of the PVSCs fabricated by low-temperature techniques to date. Additionally, the device is very stable with performance maintance of 95% after 1000 hours. This work contributes to the large-sale and low-cost production of PVSCs with high device performances.

10363-25, Session 7

Two-dimension-conjugated polymer donor materials for polymer solar cells *(Invited Paper)*

Yongfang Li, Institute of Chemistry (China)

Polymer solar cells (PSCs) have attracted great attention in the past decade, because of the advantages of simple device structure, light weight and capability to be fabricated into flexible and semitransparent devices. The key photovoltaic materials of PSCs are conjugated polymer donors and the fullerene or non-fullerene acceptors. For the conjugated polymer donor materials matching with the fullerene and nonfullerene acceptors, the two-dimension (2D)-conjugated polymers play a very important role in obtaining high power conversion efficiency (PCE) of the PSCs, because of its advantages of broad absorption and higher hole mobility. Recently, the nonfullerene n-type organic semiconductor (n-OS) (such as the low bandgap n-OS ITIC) acceptors have attracted great attention for their high photovoltaic performance. To match with the low bandgap ITIC acceptor, we developed a series of medium bandgap 2D-conjugated D-A copolymer donors based on bithienyl-benzodithiophene (BDTT) as donor unit and fluorobenzotriazole (FBTA) as acceptor unit. The D-A copolymer donors possess complementary absorption spectra and matching electronic energy levels with ITIC acceptor. By side chain engineering (alkyl, alkylthio or trialkylsilyl substitution) on the thiophene conjugated side chains of the medium bandgap polymers, the power conversion efficiency (PCE) of the PSCs with the polymers as donor and ITIC as acceptor reached 9~11%. By side chain isomerization of ITIC, the PCE of the nonfullerene PSCs was further improved to 11.77%. The results indicate that the side chain engineering of the 2D-conjugated polymer donors and n-OS acceptors are efficient way to improve photovoltaic performance of the nonfullerene PSC.

10363-26, Session 7

Electron-donating polymers containing pyrrolo[3,4-f]benzotriazole-5,7-dione unit for all-polymer solar cells

Lei Ying, South China Univ. of Technology (China)

We report a series of wide bandgap conjugated polymer consisting of a new electron-deficient building block of 4,8-di(thien-2-yl)-6-alkyl-2-alkyl-5H-pyrrolo[3,4-f]benzotriazole-5,7(6H)-dione (TzBI). This building block allows for incorporating solubilizing alkyl side chains into both triazole or imide moiety, both of which will not disturb the electronic structure of conjugated backbone. The resulting copolymers exhibited relatively wide bandgap of about 1.8 eV, with relevant absorption onset of 650-700 nm. The relatively short absorption profile provide an interesting opportunity to integrating this polymer with various recently emerged non-fullerene acceptors, presenting a remarkable power conversion efficiency over 10%. This series of copolymers can pair with electron-accepting polymer to fabricate the all-polymer solar cells with a remarkable power conversion efficiencies over 8%. Of particular interest is that these copolymers allow for the processing of high-quality films from non-chlorinated solvent, exhibiting dramatically improved stability with respect to the fullerene based devices. Detailed morphology studies on the blend film indicated that a fibrillar network can be formed and the extent of phase separation can be manipulated by thermal annealing. These results indicated the great potential of utilizing TzBI as a new building block for polymer solar cells.

10363-27, Session 7

UV-visible-near-infrared absorption dimeric porphyrin donor for highly efficient organic solar cell applications

Song Chen, Hong Kong Baptist Univ. (Hong Kong, China)

In our previous works, a serial of porphyrin-based small molecules substituted with a strongly electron-withdrawing group were exhibited a high cell performance of >8%.[1] Therefore, we have designed and synthesized an efficient push-pull A?ϖ?D?D?ϖ?A type dimeric porphyrin (CS-Dimer) based on an highly efficient porphyrin-based small molecule (4c) through coupling of two zinc porphine cores via an acetylene bridge at the meso-position to extend the absorption spectrum effectively into the near infrared region. To overcome the aggregation state caused by its nearly co-planar structural nature, the key structural feature of CS?Dimer involves long alkyl side-chains attached to the peripheral porphyrin ring so as to decrease the degree of disordered aggregation and enhanced solubility in organic solvent. This dimeric porphyrin-based small molecule possesses exceptional light harvesting capability with high extinction coefficients (?2.65?105 M?1 cm?1 in solutions) and broad absorption spectra up into the near-infrared region. The light-harvesting ability of the device exhibits a panchromatic IPCE action spectrum in the region from 300 nm to 1000 nm, and the devices displayed power conversion efficiencies as high as 8.23% with JSC/mA cm−2=15.14, VOC/mV=0.781 and FF=69.8% under AM 1.5G solar irradiation. This performance is superior to what is obtained from the individual near-infrared small molecule based single-layer devices systems.

10363-28, Session 7

Low bandgap conjugated polymers with high hole mobility for efficient thick-film polymer solar cells

Junwu Chen, South China Univ. of Technology (China)

Polymer solar cells (PSCs) are one of the most attractive ways to use solar energy – an inexhaustible renewable clean energy. Large area roll-to-roll printing is a remarkable advantage of PSCs. Low reliance of power conversion efficiency (PCE) of PSCs on large thickness variations of active layer should be a major concern toward good quality or yield control. We developed low bandgap polymer donors with high hole mobility to accelerate hole transport in thick active layer, so as to decrease recombination of holes and electrons and maintain high fill factor for highly efficient thick-film PSCs. A series of D-A conjugated polymers comprising oligothiophenes as the D-units and 5,6-difluorobenzothiadiazole (FBT), dithienobenzothiadiazole (DTfBT), and dithienobenzooxadiazole (DTfBO) as the A-units were synthesized. The polymers could show very strong interchain aggregation and result in high hole mobility. For example, field-effect hole mobilities based on neat polymer films could be higher than 2 cm2/(V s). The polymers also displayed high SCLC hole mobilities. PSCs were fabricated with varied thickness of the active layers. Delightedly, the PSCs based on the polymer donors exhibited very power conversion efficiency (PCE) with thick active layers of 200 nm or beyond. The PCE variations were relatively small for different thickness of active layers. For some FBT-based polymer, PSCs with over 400 nm thick active layer could show PCE higher than 10%. The polymers would be promising for large area printing with high speed and supply big potential for PSC modules with good quality or yield control.

10363-29, Session 7

Regioregular narrow bandgap conjugated polymers for solar cell and field effect transistor applications *(Invited Paper)*

Guillermo C. Bazan, Univ. of California, Santa Barbara (United States)

Regioregular conjugated polymers typically exhibit better pi-stacking than their regiorandom counterparts. A classic example involves regioregular poly(3-alkylthiophene), for which higher crystallinity, red-shifted optical absorption, and larger charge carrier mobilities are observed when the monomers are arranged in a head-to-tail configuration. This presentation will cover the synthesis and design of regioregular narrow bandgap conjugated polymers with donor/acceptor structural units with asymmetric acceptor units. Specifically, regioregular polymers with the pyridyl[2,1,3] thidiazole (PT) unit can be readily accessed because of the preferential reactivity of substituents in the electron-poor heterocycle. The resulting polymers have been used to fabricate thin film transistors with high hole mobilities ~6 V/cm s). Specific regioregular polymer systems have also been prepared that perform much better than their regiorandom counterparts with respect to the power conversion efficiencies (PCEs) of bulk heterojunction (BHJ) solar cells. For example, a regioregular narrow-band-gap (Eg ~1.5 eV) conjugated polymer (PIPCP) comprised of CPDT-PT-IDT-PT repeat units (CPDT = cyclopentadithiophene, IDT = indacenodithiophene) and strictly organized PT orientations, such that the pyridyl nitrogen atoms point toward the CPDT fragment was prepared. We find that PIPCP:PC61BM blends yield devices with an open circuit voltage (Voc) of 0.86 V, while maintaining a PCE of > 7%. Comparison against a range of analogous narrow band-gap conjugated polymers reveals that this Voc value is particularly high for a BHJ system with band-gaps in the 1.4-1.5 eV range thereby indicating a very low Eg-eVoc loss. We will discuss mechanistic insights into how PIPCP functions under a low enthalpic driving force for charge carrier generation and how structural variations impact solar cell performance.

10363-30, Session 8

Stable perovskite solar cells by 2D/3D interface engineering *(Invited Paper)*

Mohammad Khaja Nazeeruddin, Giulia Grancini, Cristina Roldán Carmona, Iwan Zimmermann, Ecole Polytechnique Fédérale de Lausanne (Switzerland)

Despite the impressive photovoltaic performances, perovskite solar cells are poorly stable under operation, failing by far the requirements for a widespread commercial uptake.1-3 Various technological approaches have been proposed to overcome the instability problem, which, while delivering appreciable improvements, are still far from a market-proof solution.4-5 In this talk we demonstrate stable perovskite devices by engineering an ultra-stable 2D/3D HOOC(CH2)2NH3)2PbI4/CH3NH3PbI3 perovskite junction. The 2D/3D composite delivers an exceptional gradually organized multidimensional structure that yields up to 12.9% photovoltaic efficiency in a low cost, hole-conductor free architecture and 17% in standard mesoporous solar cells. To demonstrate the up-scale potential of this technology we fabricate 10x10 cm2 solar modules by a fully printable, industrial-scale process delivering 11.2% efficient devices which are stable for >8,500 hours with zero efficiency loss measured under controlled standard conditions. This innovative architecture will likely enable the timely commercialization of perovskite solar cells.

Interlayer engineering for high Voc perovskite solar cells

Paul L. Burn, Qianqian Lin, Dani Stoltzfus, Ardalan Armin, Ravi Nagiri, Wei Jiang, Shanshan Zhang, Paul Meredith, The Univ. of Queensland (Australia)

Lead-based organohalide perovskites are promising for thin film solar cell technologies as they can be solution processed or deposited by low-temperature evaporation techniques, their opto-electronic properties can be tuned, and they have been shown to be capable of power conversion efficiencies (PCEs) of >20%. A factor that has led to the improvement in perovskite solar cell efficiency has been the use of interfacial engineering to control the open-circuit voltage (Voc). In principle, perovskites can work efficiently in a very simple device architecture – a high quality absorbing layer sandwiched between work function modified anodes and cathodes. In an inverted architecture the holes are collected at the transparent conducting electrode. For inverted solar cells, the hole transport/interlayer material needs to modify the anode such that its work function is close to the ionisation potential of the organohalide perovskite junction to maximise Voc. Poly(3,4-ethylenedioxythiophene):poly(styrenesulfonate) (PEDOT:PSS) can act as an anode work function modifier and is a sufficiently hydrophilic hole transport material to enable the deposition of good quality perovskite films. However, PEDOT:PSS has a relatively low work function, which limits the open-circuit Voc. In this presentation, we will discuss two different methods to modify the work function of the ITO anode to increase the Voc as well as providing a surface energy suitable for depositing a good quality perovskite film. Using these methods Vocs > 1 V and and PCEs of up to 16.5% can achieved for simple solution processed perovskite cells.

10363-32, Session 8

Pushing the lifetime of perovskite solar cell beyond 4500 h by the use of impermeable tin oxide electron extraction layers

Kai Oliver Brinkmann, Bergische Univ. Wuppertal (Germany); Jie Zhao, Ting Hu, Bergische Univ. Wuppertal (Germany) and Nanchang Univ. (China); Tim Becker, Neda Pourdavoud, Bergische Univ. Wuppertal (Germany); Selina Olthof, Klaus Meerholz, Univ. zu Köln (Germany); Lukas Hoffmann, Tobias Gahlmann, Ralf Heiderhoff, Bergische Univ. Wuppertal (Germany); Marek Oszajca, Nanograde (Switzerland); Detlef Rogalla, Ruhr-Univ. Bochum (Germany); Norman A. Lüchinger, Nanograde (Switzerland); Yiwang Chen, Baochang Cheng, Nanchang Univ. (China); Thomas J. Riedl, Bergische Univ. Wuppertal (Germany)

Perovskite solar cells (PSCs) suffer from decomposition of the active material in the presence of moisture or heat. In addition, the corrosion of metal electrodes due to halide species needs to be overcome.[1,2]

Here, we introduce ALD-grown tin oxide (SnOx) as impermeable electron extraction layer (EEL), which affords air resilient and temperature stable MAPbI3 PSCs. Being conductive, SnOx is positioned between the metal electrode and the perovskite. Its outstanding permeation barrier properties protect the perovskite against ingress of moisture or migrating metal atoms, while simultaneously the metal electrode is protected against leaking halide compounds.[2] Therefore, SnOx is also excellently suited to sandwich and protect ultra-thin metal layers (Ag or Cu) as cost efficient Indium-free semitransparent electrodes (SnOx/metal/SnOx) in PSCs. Using photoelectron spectroscopy, we unravel the formation of a PbI2 interfacial layer between a SnOx EEL and the perovskite. The resulting interface dipole between SnOx and the PbI2 depends on the choice of oxidant for ALD (water, ozone, oxygen plasma). SnOx grown by using ozone affords hysteresis-free devices with a stable efficiency of 16.3% and a remarkably high open circuit voltage of 1.17 V.[3] Finally, we fabricated semitransparent PSCs with efficiency >11% (Tvis = 17%) and an astonishing stability > 4500h under ambient conditions (>50% RH) or elevated temperatures (60°C).[4]

10363-33, Session 8

Tailored interfaces in halide perovskite thin films and nanocrystals *(Invited Paper)*

David S. Ginger, Univ. of Washington (United States)

Halide perovskite are being explored for optoelectronics applications ranging from solar cells to LEDs. Recent work suggests that electrical heterogeneity in both the perovskite active layer, as well as the perovskite/electrode interface can affect carrier diffusion and non-radiative recombination processes within perovskite active layers. In this talk, we will discuss both ligand exchange, and cation exchange experiments, for tailoring the properties of halide perovskite thin films and nanocrystals. We show that with controlled Lewis base passivation of the perovskite surfaces that we are able to obtain carrier lifetimes and PL intensities in thin films that rival those in the best single crystals, achieving quasi-Fermi level splittings that approach the Shockley-Queisser limit under illumination. In addition to controlling surface chemistry, we also demonstrate facile control over the perovskite chemical composition through metal B-site cation exchange of the ABX3 lattice, a process which enables control over composition of the perovskite lattice in perovskite nanocrystals, as well as perovskite thin films.

10363-34, Session 8

Enhancement of efficiency for mixed metal Sn/Pb perovskite solar cells from the view point of hetero-interface traps

Yuhei Ogomi, Daiki Yamasuso, Ayumu Yonaha, Kengo Hamada, Daiki Yamasuso, Erina Yamaguchi, Kyushu Institute of Technology (Japan); Qing Shen, Taro Toyoda, The Univ. of Electro-Communications (Japan); Kenji Yoshino, Univ. of Miyazaki (Japan); Takashi Minemoto, Ritsumeikan Univ. (Japan); Shuzi Hayase, Kyushu Institute of Technology (Japan)

Absorption edge of perovskite (PVK) solar cells consisting of MAPbI3 is 800nm. According to our simulation, light harvesting in the area of near IR is also necessary for enhancing the efficiency more. We have already reported that mixed metal perovskite (MAPbSnI3) shows photo-conversion in IR region (1-6). The short circuit current (Jsc) was high, reaching to 30 mA/cm2 because of the wide range of light harvesting. However, the open-circuit voltage (Voc) was lower than 0.3 V and the estimated voltage loss was 0.6-0.7 V, which was much larger than that of MAPbI3 (0.4 V), suggesting the presence of high density charge recombination center. We found that Ti-O-Sn bonds formed at the interface between Tiania and MAPbSnI3 layer, create trap states, resulting in increasing charge recombination at the interfaces. The surface trap density and the trap depth was quantitatively monitored by thermally stimulated current methods. When the Ti-O-Sn linkage was formed at the interface between TiO2 and PVK, the trap density increased by one order of magnitude. The interface was analyzed by XPS and confirmed that Ti-O-Sn linkage was formed. After removing the Ti-O-Sn bond at the interface between TiO2 and MAPbSnI3, the efficiency drastically increased from 4.0 % to 13.8 % and the stability was improved. It was proved that interface architecture is quite important for enhancing the MAPbSnI3 solar cells.

Interface engineering for large-area planar perovskite solar cells

Jinho Lee, Soonil Hong, Eunhag Lee, Hongkyu Kang, Kwanghee Lee, Gwangju Institute of Science and Technology (Korea, Republic of)

The formation of pinhole-free perovskite photoactive films with full surface coverage has been a tremendous challenge for up-scaling planar perovskite solar cells (PSCs) while maintaining their high power conversion efficiencies (PCEs). Particularly, a significant mismatch between the surface energies of a hydrophilic perovskite precursor solution and a hydrophobic organic charge transport layer (CTL) has been a major cause for the poor and random surface coverage of perovskite photoactive films, which drastically reduces the scalability and reproducibility of PSCs. Here, we report a universal method to create extremely compact perovskite photoactive films on a variety of hydrophobic CTLs. By introducing an amphiphilic conjugated polyelectrolyte as an interfacial compatibilizer, we succeed in improving the wettability of perovskite precursor solutions on hydrophobic CTLs and fabricating perovskite photoactive films over large areas. Our approach enables the scalable fabrication of planar PSCs with large areas (1 cm2, PCE of 17%) while preserving nearly 90% of the PCEs of the corresponding small-area devices (PCE of 19%).

10363-36, Session 8

Advanced plasmonic and perovskite solar cells

Dong-Ha Kim, Ewha Womans Univ. (Korea, Republic of)

Plasmonics have also been recognized as promising platform that may premise the enhanced performance of next-generation photovoltaic devices. Plasmonic effects have been proposed as a solution to overcome the limited light absorption of thin film photovoltaic devices and diverse types of plasmonic solar cells have been developed. Recently, we made a comprehensive overview of the state-of-the-art progress on the design and fabrication of plasmonic solar cells as well as the understanding of the enhancement mechanism (Chem. Rev. 2016). In this presentation, we propose a few strategies to develop viable plasmonic DSSCs and OPVs based on metal-graphene oxide core-shell nanostructures (ACS Energ. Lett. 2017) or lithographically-induced plasmonic nanopatterns (ACS Nano 2016).

Very recently metal halide perovskites have been attractive as solar energy harvesters due to efficient ambipolar transport and strong light absorption. They have rapidly advanced thin film photovoltaic performance; as a result, the observed instabilities urgently require a solution. We report the reduced-dimensionality (quasi-2D) perovskite films that exhibit improved stability in solar cell performance while retaining the high performance of conventional three-dimensional perovskites. We achieve the first certified hysteresis-free solar power conversion in a planar perovskite solar cell, obtaining a 15.3% PCE, and observe greatly improved performance longevity (J. Am. Chem. Soc. 2016). The quasi-2D perovskites were also employed to develop limiting emitting diodes with the most bright and highest EQE (Nat. Nanotech. 2016).

10363-37, Session 9

Relating material properties to charge recombination mechanisms in solution processed solar cells *(Invited Paper)*

Jenny Nelson, Imperial College London (United Kingdom)

In any photovoltaic device, efficient energy conversion results from a competition between light harvesting, charge separation and transport, and charge recombination. Devices based on disordered materials such as solution processed molecular, inorganic and hybrid semiconductors, despite showing impressive advances in performance recently, typically show greater recombination losses than traditional crystalline semiconductor devices. The impact of non-radiative recombination on open-circuit voltage can be quantified precisely using luminescence techniques, but the method does not indicate the microscopic origin of the recombination nor its impact on overall solar cell performance. In this work, we use a variety of complementary experimental techniques and simulation to correlate the measured voltage losses to the underlying recombination mechanism in different types of solar cell including organic heterojunctions, lead halide perovskites and solution processed inorganic devices. We will focus on the impact of structural and energetic disorder, selectivity of contacts, density and energy of defect states and the competition of charge separation with recombination. We will comment on the extent to which disorder controls the losses to recombination, and address the question of whether large recombination losses are unavoidable in molecular materials.

10363-38, Session 9

Reducing voltage losses in multilayer organic solar cells while keeping high external quantum efficiencies

Vasileios C. Nikolis, Johannes Benduhn, Felix Holzmueller, TU Dresden (Germany); Fortunato Piersimoni, Dieter Neher, Univ. Potsdam (Germany); Christian Körner, Donato F. Spoltore, Koen Vandewal, TU Dresden (Germany)

High photon energy losses (Eloss) constitute a major performance limiting factor for organic solar cells (OSCs), limiting significantly their open-circuit voltage (Voc) and power conversion efficiency (PCE). Reduction of Eloss, while a keeping a high external quantum efficiency (EQE), can lead OSCs into a new PCE regime, beyond 12%.

In this work, we report a multilayer cascade device architecture which increases Voc through the insertion of discontinuous interlayers between electron donor (D) and electron acceptor (A). We systematically study the influence of adding various interlayers in a sequentially deposited ?-6T/interlayer/SubNc/SubPc cascade OSC, resulting in a Voc which increases from 0.98 V to 1.16 V. We show that this remarkable Voc-increase of 0.18 V is due to the suppression of non-radiative recombination, as a consequence of a reduced physical contact between ?-6T (D) and SubNc (A). The electroluminescence quantum yield of 0.9??-4 for our highest voltage device corresponds to non-radiative losses of 0.23 eV, which are the lowest reported for OSCs. Comprising the sum of non-radiative and radiative losses, we achieve an Eloss of 0.58 eV from the optical gap (Eopt) to Voc. The loss from the low energy peak of the EQE spectrum to Voc is 0.61 eV, due to a steep absorption onset. Most importantly, the low energy (700 nm) EQE peak remains high at 79%, despite a minimal driving force for charge transfer of less than 10 meV.

Our work shows that a low Eloss can be efficiently combined with a high EQE in organic photovoltaic devices.

10363-39, Session 9

Intrinsic non-radiative voltage losses in fullerene-based organic solar cells

Johannes Benduhn, TU Dresden (Germany); Kristofer Tvingstedt, Julius-Maximilians-Univ. Würzburg (Germany); Fortunato Piersimoni, Univ. Potsdam (Germany); Sascha Ullbrich, TU Dresden (Germany); Dieter Neher, Univ. Potsdam (Germany); Donato F. Spoltore, Koen Vandewal, TU Dresden (Germany)

For organic solar cells (OSCs), the open-circuit voltage is low as compared to the optical gap of the absorber molecules, indicating high energy losses per absorbed photon. These voltage losses arise only partly due to necessity of an electron transfer event to dissociate the strongly bound excitons. A large part of these voltage losses is due to recombination of photo-generated charge carriers, including inevitable radiative recombination. In this work, we study the voltage losses caused by non-radiative recombination and we find that they increase when the energy difference between charge transfer (CT) state and ground state decreases. This observed trend is in agreement with the "Energy-Gap Law for non-radiative transitions", which implies that a non-radiative decay of a CT state is facilitated by skeletal molecular vibrations. This intrinsic loss mechanism, which until now has not been thoroughly considered for OSCs, is different in its nature as compared to the commonly considered inorganic photovoltaic loss mechanisms of defect, surface, and Auger recombination. As a consequence, the theoretical upper limit for the power conversion efficiency of a single junction OSC reduces by ~25% as compared to the Shockley-Queisser limit for an optimal optical gap of the main absorber between (1.45-1.65) eV.

10363-40, Session 9

Transport and recombination considerations for charge generation efficiency in organic solar cells *(Invited Paper)*

Paul Meredith, Swansea Univ. (United Kingdom); Ardalan Armin, The Univ. of Queensland (Australia); Martin Stolterfoht, Safa Shaoi, Univ. Potsdam (Germany); Ivan Kassal, The Univ. of Sydney (Australia); Paul L. Burn, The Univ. of Queensland (Australia)

The efficiency with which photogenerated free carriers are extracted in excitonic solar cells is governed by the interactions between a number of material specific and device level properties and parameters: recombination dynamics, faster and slower carrier mobilities, contact potentials, etc. This complexity is inherent in disordered excitonic semiconductors, and understanding the underlying structure-property relationships is an ongoing endeavour in the field of organic solar cells. Questions such as – do higher mobility semiconductors necessarily deliver improved charge collection; how does supressed bimolecular recombination lead to fill factor maintenance especially at higher input irradiances [1]; or, how do we achieve high fill factors and efficiencies in thick junctions more suited to viable manufacturing [2]?

In my talk I will examine some of the latest thinking in this area [3], and present data from a suite of emerging experimental techniques such as intensity dependent photocurrent, resistant dependent photovoltage and related extraction methodologies. I will also discuss recent findings on the interrelationship between the efficiency with which free charges are extracted and charge separated state formation – the two possibly connected through entropic considerations [4].

10363-41, Session 9

Carbon dangling bonds in photodegraded polymer:fullerene solar cells

Fadzai Fungura, William Robin Lindemann, Joseph Shinar, Ruth Shinar, Iowa State Univ. of Science and Technology (United States)

Intrinsic photodegradation of organic solar cells, theoretically attributed to C-H bond rearrangement/breaking, remains a key commercialization barrier. This work presents, via dark electron paramagnetic resonance (EPR), the first experimental evidence for metastable C dangling bonds (DBs) formed by blue/UV irradiation of polymer:fullerene blend films in nitrogen. The DB density increased with irradiation and decreased ~4 fold after 2 weeks in the dark. The dark EPR also shows increased densities of other spin-active sites in photodegraded polymer, fullerene, and polymer:fullerene blend films, consistent with broad electronic measurements of fundamental properties, including defect/gap state densities. The EPR and electronic measurements enable identification of defect states, whether in the polymer, fullerene, or at the donor/acceptor (D/A) interface. Importantly, the EPR results indicate that the DBs are at the D/A interface, as they were present only in the blend films. The role of polarons in interface DB formation will also be discussed.

10363-42, Session 9

Limits for photocurrent generation in polymer solar cells consisting of near-IR polymers

Yasunari Tamai, Shun Yamaguchi, Kota Tsujioka, Hideo Ohkita, Kyoto Univ. (Japan)

Near-IR polymers with the bandgap Eg below 1.5 eV have recently attracted considerable attention. Since achievable short-circuit current density JSC

increases with lowering the Eg, polymer solar cells (PSCs) consisting of the near-IR polymers potentially overcome state-of-the-art PSCs based on conventional low-bandgap polymers with Eg ~1.5–1.6 eV. Various near-IR polymers with the Eg around 1.2 eV have been developed and tested for PSCs. Nevertheless, PSCs consisting of the near-IR polymers routinely lagged in JSC behind their conventional low-bandgap polymer based analogues. Here, we study limits for photocurrent generation in PSCs consisting of near-IR polymers with the Eg around 1–1.2 eV. We performed transient absorption measurements for these polymer films, and find that exciton lifetimes of these polymers are very short. This finding suggests that PSCs consisting of the near-IR polymers suffer from poor exciton harvesting to the heterojunctions. We will discuss the origin of the short exciton lifetimes for the near-IR polymers.

10363-43, Session 10

Lead halide perovskites of different dimensionalities: growth, properties, and applications in optoelectronics *(Invited Paper)*

Osman M. Bakr, King Abdullah Univ. of Science and Technology (Saudi Arabia)

Three-dimensional (3D) lead halide perovskites exhibit impressively long carrier diffusion lengths and low trap densities, while reduced-dimensionality perovskites, such as two-dimensional (2D) and zero-dimensional (0D) perovskite derivatives, possess large exciton binding energies and high photoluminescence quantum yields. These characteristics make the diverse class of perovskite materials ideal for photovoltaics, photodetection, and light emission. Here we discuss our latest advances in growing and understanding the properties of monocyrstalline 3D perovskites, as well as 0D and 2D perovskite derivatives. We also demonstrate the integration of these materials in a range of optoelectronic applications including: monocrystalline perovskite solar cells; simultaneously fast and sensitive photodetectors that can operate in both broadband and narrow-band regimes; and efficient light-emitting diodes. Thus, in these device prototypes, we showcase the importance of crystallinity, dimensionality, and composition for tailoring materials properties, and realizing novel and efficient perovskite optoelectronics.

10363-44, Session 10

Mapping structural properties of lead halide perovskites by scanning nanofocus x-ray diffraction

David G. Lidzey, The Univ. of Sheffield (United Kingdom)

To date, the most widely employed technique to investigate the crystal structure and morphology of perovskite films have been SEM and X-ray diffraction. Most perovskite films are highly polycrystalline and thus traditional imaging techniques cannot easily isolate single crystallites or determine the statistics of lateral grain size or crystal size and morphology. A further limitation is that both SEM and other scanning probe microscopy techniques are surface-sensitive, with the bulk of the material being largely inaccessible using conventional imaging methods.

To gain better insight into a perovskite film, we scan an X-ray beam focused to 400 nm across a sample, while simultaneously recording wide-angle X-ray scattering patterns. Such scanning nanofocus x-ray diffraction (nXRD) techniques have been employed to resolve local variations in structure across a broad range of materials and research fields, however this is the first time they have been applied to a perovskite film.

We describe a method to in which each scattering pattern is analysed, allowing a classification to be made of individual perovskite grains according to a specific Miller plane. Using this method, we show that nXRD is able to resolve the extent of individual perovskite grains buried within a polycrystalline film (grain segmentation). We then use nXRD and SEM to demonstrate that the perovskite film coverage can be controlled by varying the temperature of the substrate during spin-coating. We conclude by showing that solar cells with a perovskite layer cast on a substrate held at a relatively high temperature result in devices with higher PCE.

10363-45, Session 10

Introduction of benzoquinone additive for efficient and stable planar perovskite solar cells

Chuanjiang Qin, OPERA Ctr. for Organic Photonics and Electronics Research (Japan) and Japan Science and Technology Agency, ERATO (Japan); Toshinori Matsushima, OPERA Ctr. for Organic Photonics and Electronics Research (Japan) and Kyushu Univ. (Japan) and Japan Science and Technology Agency, ERATO (Japan); Takashi Fujihara, Institute of Systems, Information Technologies and Nanotechnologies (ISIT) (Japan); Chihaya Adachi, OPERA Ctr. for Organic Photonics and Electronics Research (Japan) and Kyushu Univ. (Japan) and Japan Science and Technology Agency, ERATO (Japan)

Organic-inorganic perovskites have emerged as an interesting class of materials that have excellent photovoltaic properties for application to solar cells. The power conversion efficiency of perovskite solar cells over 20% has already been realized through systematic optimization of materials and fabrication processes. However, the long-term stability of perovskite solar cells still need to be improved for practical applications. In this study, we introduced a multifunctional benzoquinone (BQ) additive into a precursor solution containing methylammonium iodide (MAI) and lead iodide (PbI2) used for spin-coating of perovskite films. Resulting spin-coated perovskite films containing BQ had the improved perovskite morphology and crystal quality because of intermolecular interaction between MAI and BQ slowing the rate of perovskite crystal formation. Therefore, we obtained the greatly enhanced power conversion efficiency from 10.7% to 15.6%. The reduced charge recombination loss by electron transfer from perovskite to BQ is another source of the improved efficiency. In addition to the efficiency enhancement, the BQ addition led to the extended lifetime about twenty-six times. The lifetime, at which efficiency reduces to 80% of the initial under the one-sun condition (100 mW/cm2 and AM1.5G), reached about 4000 h, one of the longest lifetimes ever reported in perovskite solar cells. The extended lifetime can be explained by the reduced formation of carrier traps originating from metallic lead during solar irradiation as the results of thermally stimulate current measurements. We believe that the present findings offer insight to help obtain efficient, stable organic-inorganic perovskite solar cells for future applications.

10363-46, Session 10

A surface science approach to perovskite material and solar cell research *(Invited Paper)*

Yabing Qi, Okinawa Institute of Science and Technology Graduate Univ. (Japan)

In recent years, perovskite solar cells have been attracting enormous attention from academia as well as industry. To fabricate high performance perovskite solar cells, surfaces and interfaces are of paramount importance. My group at OIST is making concerted efforts to investigate relevant surfaces and interfaces in these materials and devices and to develop innovative strategies to improve their performance [1]. In this talk, I will introduce our research progress on real-space atomic-scale imaging of organic-inorganic hybrid perovskite [2], the vapor-based methods that can be used to fabricate large-area perovskite solar cells and modules [3-5], and degradation of perovskite [6, 7].

10363-47, Session 10

Unraveling the improved electronic and structural properties of methyl ammonium lead iodide deposited from acetonitrile

Alexandra Ramadan, Nakita Noel, Univ. of Oxford (United Kingdom); Sarah Fearn, Imperial College London (United Kingdom); Neil Young, Univ. of Oxford (United Kingdom); Marc Walker, The Univ. of Warwick (United Kingdom); Luke Rochford, The Univ. of Birmingham (United Kingdom); Henry J. Snaith, Univ. of Oxford (United Kingdom)

Perovskite-based photovoltaics are an emerging solar technology, with device efficiencies of up to 22.1 % and significant steps are being made towards their commercialisation. The conventional high efficiency active layers of perovskite solar cells are fabricated using solution film growth techniques employing high boiling point, polar aprotic solvents with N,N-dimethylformamide (DMF) one of the most frequently used solvents. However, toxicity associated with the use of each of such solvents on an industrial scale represents an insurmountable barrier to large scale manufacturing, thus the substitution of these solvents is vital for industrial upscaling of perovskite solar cells to be realised. Our recent work has established acetonitrile (ACN), in the presence of methylamine, as a viable alternative for fabrication of methylammonium lead iodide (MAPbI3) photovoltaic devices with efficiencies of >18%.

Films prepared from ACN and DMF based processing routes have been investigated using X-ray photoemission spectroscopy (XPS), ultraviolet photoemission spectroscopy (UPS), secondary ion mass spectrometery (SIMS), low energy ion scattering (LEIS) and scanning probe microscopy (SPM). The ACN processing route results in MAPbI3 based devices with higher efficiencies than those formed using DMF routes. Significant differences in the composition and electronic structure of MAPbI3 films, formed via the two different solvent routes, are observed. These differences suggest that the use of ACN as a solvent produces films with improved electronic and structural properties thereby resulting in more efficient photovoltaic devices.

10363-48, Session 10

Understanding the role of titanium dioxide (TiO2) surface chemistry on the nucleation and energetics of hybrid perovskite films

R. Clayton Shallcross, The Univ. of Arizona (United States); Selina Olthof, Klaus Meerholz, Univ. zu Köln (Germany); Neal R. Armstrong, The Univ. of Arizona (United States)

We demonstrate how amino-terminated silane monolayers alter the chemical and energetic composition of the TiO2 surface, which controls the interfacial nucleation, growth and energetics of device-relevant, hybrid perovskite (PVSK) thin films. The surface chemistry and energetics of compact TiO2 thin films are modified with a 3-aminopropyltriethoxysilane (APTES) monolayer that can either weakly coordinate Pb2+ ions (–NH2/free base form) or act as a surrogate organic cation (–NH3+/acid form) at the TiO2/PVSK interface, providing for significant differences in the nucleation free energy for the PVSK active layer as a function of NH3+/NH2 ratio. XPS spectra of amine-modified TiO2 surfaces (N 1s core level) demonstrate that we can achieve NH3+/NH2 ratios of between 3:1 and 1:3 depending upon subsequent acid and base treatment, respectively. Methylammonium lead triiodide (MAPbI3) films are incrementally co-evaporated on TiO2, TiO2/APTES-NH3+ and TiO2/APTES-NH2 interfaces, and the chemical composition, growth dynamics and energetics are systematically investigated using in situ X-ray photoelectron spectroscopy (XPS) and UV photoelectron spectroscopy (UPS). The XPS and UPS results reveal that initial nucleation and subsequent growth of the MAPbI3 PVSK film strongly depends on the chemical functionality of the TiO2 surface. The evaporated films display island-like growth on the bare TiO2 surface, which hinders nucleation of the PVSK phase until ca. 15 nm of precursor material is deposited. Conversely, film growth is more layer-by-layer on the amine-modified TiO2 interfaces, which promote nucleation of the PVSK phase within the first ca. 5 nm of deposition. In addition to vacuum evaporated thin films, we show how these TiO2 surface modifications control the morphology and crystallinity of solution-processed PVSK films based on formamidinium and methylammonium organic cations. These studies elucidate the role of TiO2 surface chemistry on the formation mechanism of hybrid PVSK active layers and the interfacial and bulk energetics, which have significant consequences related to the processing and operation of next-generation optoelectronic device platforms.

10363-49, Session 11

Molecular orientation-dependent photovoltaic performance in organic solar cells *(Invited Paper)*

Kilwon Cho, Pohang Univ. of Science and Technology (Korea, Republic of)

Photovoltaic performance of organic solar cells is highly dependent on the anisotropic nature of optoelectronic properties of photoactive materials. Here, we demonstrate an approach for highly efficient planar heterojunction solar cells by tuning the molecular orientation of the organic semiconducting materials. A monolayer graphene inserted at anode interface served as a template for quasi-epitaxial growth of pentacene crystals with lying-down orientation, which was favorable for overall optoelectronic properties including light absorption, exciton diffusion, charge transport, and interfacial energetics. The lying-down orientation persisted until ~100 nm in thickness, significantly enhancing the photon harvesting within the photoactive layer due to its increased absorption range and exciton diffusion length. The resultant photovoltaic performance showed a remarkable increase in Voc, Jsc, FF and consequently a 5 times increment in power conversion efficiency than the devices without graphene layers. The effect of molecular orientation at donor-acceptor interface was further investigated by using a planar heterojunction structure with orientation-controlled P3HT thin films. In this case, even though the P3HT layers showed similar optoelectrical properties regardless of the orientation, the photocurrent generation was more efficient in the case of the face-on donor-acceptor interface than the edge-on interface. Photophysical analyses revealed that the charge pair dissociation at the face-on interface was more efficient and resulted in smaller geminate recombination loss. These results imply that the molecular orientation in photoactive layers is a critical factor that should be elaborately controlled for future high performance organic solar cells.

Innovative architecture design for high performance organic and hybrid multi-junction solar cells

Ning Li, i-MEET (Germany); George D. Spyropoulos, Bayerisches Zentrum für Angewandte Energieforschung e.V. (Germany); Christoph J. Brabec, i-MEET (Germany) and Bayerisches Zentrum für Angewandte Energieforschung e.V. (Germany)

The multi-junction concept is especially attractive for the photovoltaic (PV) research community owing to its potential to overcome the Schockley-Queisser limit of single-junction solar cells. Tremendous research interests are now focused on the development of high-performance absorbers and novel device architectures for emerging PV technologies, such as organic and perovskite PVs. It has been predicted that the multi-junction concept is able to boost the organic and perovskite PV technologies approaching the 20% and 30% benchmarks, respectively, showing a bright future of commercialization of the emerging PV technologies.[1]

In this contribution, we will demonstrate innovative architecture design for solution-processed, highly functional organic and hybrid multi-junction solar cells.[2-4] A simple but elegant approach to fabricating organic and hybrid multi-junction solar cells will be introduced. By laminating single organic/hybrid solar cells together through an intermediate layer, the manufacturing cost and complexity of large-scale multi-junction solar cells can be significantly reduced.[3] Moreover, hybrid triple-junction solar cells based on organic and perovskite absorbing layers are exploited and analysed. In this hybrid triple-junction configuration, solution-processed silver nanowires are served as an intermediate electrode to efficiently extract the charge carriers from both organic and perovskite sub-cells.[4] This smart approach to balancing the photocurrents as well as open circuit voltages in multi-junction solar cells will be demonstrated and discussed in detail.

Ternary blend polymer solar cells with wide-range light harvesting *(Invited Paper)*

Hideo Ohkita, Ryosuke Shimizu, Yasunari Tamai, Kyoto Univ. (Japan)

Polymer-based solar cells have made rapid progress in the last decade and are currently attracting a great deal of attention as a next-generation solar cell. Very recently, they have shown a power conversion efficiency (PCE) of more than 10%, which is comparable to that reported for amorphous silicon solar cells. However, it is still required to improve the photovoltaic performance furthermore for practical applications. In this talk, I will demonstrate ternary blend polymer solar cells, which are a new approach to improving the photocurrent generation. We have recently developed ternary blend polymer solar cells based on a wide-bandgap polymer, poly(3-hexylthiophene) (P3HT), a fullerene derivative (PCBM), and a near-IR dye molecule such as a silicon phthalocyanine derivative (SiPc). Such near-IR dye addition can easily expand the light-harvesting wavelength range up to the near-IR region, and hence can boost the photocurrent furthermore. I will demonstrate how molecular design of near-IR dye molecules can control the location in ternary blend solar cells to improve the photocurrent generation effectively. We also have fabricated ternary blend polymer solar cells based on a wide-bandgap polymer, a low-bandgap polymer, and PCBM. This two-donor polymer blend can also expand the light-harvesting wavelength and hence can boost the photocurrent effectively. Efficient exciton harvesting and charge collection can be designed by combining a wide-bandgap crystalline polymer and a low-bandgap amorphous polymer.

10363-52, Session 11

Flexible polymer solar cells with synergistic light harvesting enhancement

Yanqing Li, Jianxin Tang, Soochow Univ. (China)

To fully unlock the potential of metallic electrodes in flexible polymer solar cells (PSCs), tuning their optical properties is urgently required. Here we report an efficient light harvesting scheme involving the combination of silver mesowire grid-based front transparent electrode and plasmonic meta-mirror-based back reflector electrode. As an alternative to the indium-tin-oxide transparent conductor, the silver mesowire grid on plastic substrate enables the reduced Ohmic loss with competitive mechanical, electrical and optical properties, verifying its superiority in large-area flexible devices. The further implementation of plasmonic meta-mirror back reflector allows the broadband enhancement of light harvesting efficiency over the entire visible wavelength range, yielding a power conversion efficiency of 9.5% due to a 23.2% increase in photocurrent compared to the reference flat device. Experimental and theoretical analysis of light propagation in PSCs elucidates that the optical harvesting enhancement benefits from the synergistic effects of wide-area redistribution of optical field induced by silver mesowire grid electrode and broadband recovery of photon loss via surface plasmon and scattering enabled by the meta-mirror back reflector. This method provides a convenient and scalable way for developing high-performance flexible PSCs towards the future photovoltaic applications.

10363-53, Session 12

The importance of molecular packing, orientation and morphology control in performance and stability of all-polymer solar cells *(Invited Paper)*

Bumjoon Kim, KAIST (Korea, Republic of)

Non-ideal bulk-heterojunction morphology (BHJ) of all-polymer solar cells (all-PSCs), i.e., large-scale polymer domain size, reduced ordering of polymer chains, is one of the critical hurdles for producing efficient all-PSCs. To address this issue, we focused on developing the correlation between the polymer microstructure, BHJ morphology and the photovoltaic properties of high performance all-PSCs. As model systems of modulating the molecular weight and the alkyl side chain of polymers, the polymer microstructure and the BHJ blend morphology of all-PSCs are systematically controlled, and thereby we produced high-performance all-PSCs system with 6.7% efficiency, which is the highest value reported to date. More importantly, our all-PSCs exhibited dramatically enhanced strength and flexibility compared with polymer/PCBM devices, with 60x and 470x improvements in elongation at break and toughness, respectively. The superior mechanical properties of all-PSCs afford greater tolerance to severe deformations than conventional polymer-fullerene solar cells, making them much better candidates for applications in flexible and portable devices.

10363-54, Session 12

Enhanced thermal stability of ternary bulk-heterojunctions

Dominik Landerer, Adrian Mertens, Dieter Freis, Robert Droll, Daniel Bahro, Alexander Schulz, Tobias Leonhard, Alexander Colsmann, Karlsruher Institut für Technologie (Germany)

After enhancing the power conversion efficiencies of organic solar cells beyond 10%, their long term stability became the most urgent challenge in order to eventually integrate organic solar cells into end-user products. Even worse, the devices have to endure harsh conditions when fabricating tiles or façade elements, typically requiring lamination temperatures up to 120°C for 2 hours.

In this work, we demonstrate ternary high-performance bulk-heterojunctions with significantly enhanced thermal stability at 120°C, clearly outperforming the thermal stability of common binary polymer/fullerene bulk-heterojunctions. All solar cells were deposited from eco-compatible solvents as required by industry standards. [1] The binary bulk-heterojunctions comprise either of the BDT donor polymers PTB7 or PTB7-Th as well as the industrially more relevant (less expensive) fullerene acceptor PC61BM. The binary blends exhibit only moderate thermal stability by losing more than 30% of their initial performance, originating from crystallization and aggregation of the fullerene. In contrast, binary polymer:fullerene blends with the infrared absorber polymer PDTP-DFTB show practically no degradation but retain their initial performance. We found that the PTB7-Th:PC61BM bulk-heterojunctions can be stabilized by including 10 wt% of PDTP-DFTB (or more), thereby inheriting the thermal stability of PDTP-DFTB:PC61BM bulk-heterojunctions.

Besides the superior energy conversion of the ternary bulk-heterojunction over binary bulk-heterjunction, this device concept demonstrates how to suppress unfavourable morphological changes by using ternary blends. After 2 hours of thermal annealing at 120°C, the respective solar cells still exhibit 90% of their initial performance, here yielding PCEs of 6%.

10363-55, Session 12

Estimating the surface recombination velocity at contacts in organic devices using charge extraction by linearly increasing voltage

Oskar J. Sandberg, Mathias Nyman, Staffan Dahlström, Ronald Österbacka, Åbo Akademi Univ. (Finland)

The kinetics at contacts plays a crucial role in sandwich-type thin-film devices based on organic semiconductors. This is of particular importance in organic and perovskite solar cells where selective contacts that are able to efficiently collect majority carriers, simultaneously blocking minority carriers, are desired. Despite the vast progress made, a comprehensive understanding, needed for developing new electrode materials to improve and optimize device performance is still lacking.

A key parameter for obtaining information about processes taking place at the contacts is the effective surface recombination velocity.[1] However, means to quantitatively measure surface recombination velocities at contact interfaces in sandwich-type thin-film devices based on organic semiconductors are lacking.

The Charge Extraction by a Linearly Increasing Voltage (CELIV) technique is one of the most common methods to measure the charge transport properties in organic semiconductor devices. In this work, we show how CELIV can be used to determine surface recombination velocities at selective and/or blocking contacts in thin-film devices. The analytical framework behind the method is presented, and confirmed by numerical drift-diffusion simulations. We furthermore demonstrate the method on organic semiconductor devices, employing TiO_2 and SiO_2 as cathode buffer layers. The method allows for an increased understanding of contact properties in sandwich-type thin-film devices based on organic semiconductors.

10363-56, Session 12

Stabilizing organic solar cells using antioxidants, radical scavengers and light stabilizers

Vida Engmann, Univ. of Southern Denmark (Denmark); Sebastian Engmann, National Institute of Standards and Technology (United States); Nikos Tsierkezos, Technische Univ. Ilmenau (Germany); Harald Hoppe, Friedrich-Schiller-Univ. Jena (Germany); Uwe Ritter, Gerhard Gobsch, Technische Univ. Ilmenau (Germany); Morten Madsen, Horst-Günter Rubahn, Univ. of Southern Denmark (Denmark)

Record efficiencies of OPV devices nowadays reach well above 10%. However, their organic nature makes them strongly sensitive to oxygen, light, heat and humidity.

We report on long-term stabilization by ternary blending the active layers with small amounts of stabilizing compounds of different classes of antioxidants[1,3], radical scavengers[1] and light stabilizers[2]. Lifetime testing was conducted under ISOS3-degradation conditions on bulk-heterojunction cells containing a wide selection of stabilizers. Microscopic and spectroscopic methods were applied to monitor chemical degradation over time, and the observed differences are discussed in terms of energetic trap states formation within the HOMO/LUMO gap of the photoactive material, morphological and structural changes.

Both antioxidants and UV absorbers yielded an increase of the accumulated power generation by over a factor of 3 compared to the reference devices without additive. In both cases, stability improvement was caused by significant reduction of radicals within the photoactive layer, which in turn stabilizes the performance by decreasing exciton recombination. However, stabilization mechanisms of these two classes are quite different, as reflected in the burn-in. While antioxidant-stabilized cells manifested a simultaneous increase of the burn-in period and decrease of decay magnitude, UV-absorber-stabilized cells retained the same burn-in period as the reference.

Conference 10364: Organic Sensors and Bioelectronics X

Sunday - Monday 6 –7 August 2017

Part of Proceedings of SPIE Vol. 10364 Organic Sensors and Bioelectronics X

10364-1, Session 1

Pushing the detection limit of organic and hybrid perovskites detectors to light and x-ray *(Invited Paper)*

Jinsong Huang, Univ. of North Carolina at Chapel Hill (United States)

I will present two materials and device structures which can further push down the detection limit of existing solution process non-cooled photodetectors. In one case, a modified organic phototransistor architecture for detecting ultraviolet–visible light down to 100 fW/cm^2 at room temperature is demonstrated. The exceptional sensitivity stems from an amplification process triggered by incident light. A responsivity of ≈10^7 A/W is achieved. The other type of detectors use the perovskite single crystals as absorber for incident visible and x-ray photons. The interfacial engineering allows the great suppress of noise, and thus the combination of high gain and low noise enabled the sensitivity enhancement by 10 to 1000 times over the state-of-the-art photodetectors and X-ray detectors based on perovskite materials. The imaging capability of the perovskite detector array will be reported.

10364-2, Session 1

Organic plasmonic Schottky barrier photodetectors

Ji-Ling Hou, Axel Fischer, Sheng-Chieh Yang, Johannes Benduhn, Daniel Kasemann, Johannes Widmer, Robert Brückner, Ronny Timmreck, Koen Vandewal, Karl Leo, TU Dresden (Germany)

Organic near-infrared (NIR) photodetectors are in the focus for developing low-cost optical-sensing devices.[1] In this work, a new device architecture for organic photodetectors is demonstrated to overcome the lack of efficient NIR absorbing organic semiconductors. We propose an organic Schottky barrier photodetector with an integrated plasmonic nanohole electrode. [2] Photons with energies below the gap of the organic semiconductor are detected via internal photoemission processes (IPE) over a metal/organic Schottky barrier, generating photocurrent. The intrinsically low IPE yield is significantly improved through the use of a nanohole electrode, enabling the excitation of surface plasmon resonances. Within the nanohole-metal/organic/metal device configuration, these SPRs are found to couple with the out-of-plane Fabry-Pérot cavity, further enhancing the responsivity. The responsivity can be easily modulated by an external field to affect the Schottky barrier, enabling selective control of individual pixels. A large (>1000) on/off ratio and a responsivity of 0.1 mA/W at 830 nm is achieved by forming a Schottky contact between Ag and a wide energy-gap (3.3 eV) organic semiconductor. Photodetection based on this mechanism allows tuning of the detector wavelength, for example by manipulating the nanohole geometry, independent of the absorption properties of the organic semiconductors used. This concept opens up new design and application possibilities for organic NIR photodetectors.

10364-3, Session 1

Organic infrared photodiodes with charge blocking layers

Gijun Seo, Vishal Yeddu, Do Young Kim, Oklahoma State Univ. (United States)

Organic infrared photodetectors are attractive because of compatibility with flexible substrates, low-cost process, and large area applications. On the other hand, a low dark current is quite important in photodetector for obtaining high detectivity. In this study, we report infrared organic photodetectors with various charge blocking structures for reducing a dark current, thus resulting in enhancement in detectivity. Tin(IV) 2,3-naphthalocyanine dichloride (SnNcCl2) with an absorption band in the 650 ~ 1200 nm of the spectrum was used for infrared sensing. Various hole transporting materials including N,N?-Bis(naphthalen-1-yl)-N,N?-bis(phenyl)benzidine (NPB) and 4,4?,4??-Tris[phenyl(m-tolyl)amino] triphenylamine (m-MTDATA) were used as the electron blocking layer, and various electron transporting materials including bathocuproine (BCP) and Bathophenanthroline (BPhen) were used as the hole blocking layer. With both electron and hole blocking layer structure, the dark current density decreases significantly without sacrificing the photo-generated charge carrier extraction, thus resulting in the enhancement in detectivity. A systematic study of these devices and the underlying mechanism will be presented.

10364-4, Session 1

Characterization of novel organic short wavelength infrared photosensors

Weichuan Yao, Zhenghui Wu, Univ. of California, San Diego (United States); Jason D. Azoulay, The Univ. of Southern Mississippi (United States); Tse Nga Ng, Univ. of California, San Diego (United States)

Short wavelength infrared (SWIR) sensors are important to applications in environmental monitoring, medical diagnosis and optical communications, but there are only a few organic semiconductors that show optoelectronic response in the SWIR region. Recently we demonstrated a family of novel donor-acceptor polymers with narrow bandgap responsive in the SWIR region, and the bulk heterojunction photodiodes based on these polymers show detectivity up to 1E11 Jones at a wavelength of 1.37 micron, with absorption edge extending out to 1.7 micron. A SWIR photodiode was incorporated into the etalon-array reconstructive spectroscopy system to demonstrate its imaging capabilities.

As the initial performance is very promising, we proceed to investigate the stability of the encapsulated devices and to infer the degradation mechanisms. The performance of photodiodes were monitored by IV measurement, external quantum efficiency (EQE) and electrochemical impedance spectroscopy. The IV measurement and electrochemical impedance spectroscopy were conducted both in the dark and under illumination, to track over several weeks the change in charge generation and recombination processes under the short circuit and open circuit conditions. The characteristics from band-to-band absorption and from absorption in charge-transfer states were compared to quantify the lifetime and recombination losses of photogenerated carriers in these devices.

10364-5, Session 1

Photoresponse characteristics of small molecule organic photodetectors for image sensor applications *(Invited Paper)*

Dong-Seok Leem, Gae Hwang Lee, Kwang-Hee Lee, Sungyoung Yun, Seon-Jeong Lim, Younhee Lim, Hye Sung Choi, Moon Gyu Han, Kyung-Bae Park, Yeong Suk Choi, Yong Wan Jin, Sangyoon Lee, Samsung Advanced Institute of Technology (Korea, Republic of)

Organic photodetectors (OPDs) are attracting interest as various sensing platforms such as photo/chemical sensors, healthcare sensors, x-ray scanner, and image sensors. In particular, a distinct advantage of organic materials, i.e., orthogonal photosensitivity to the specific wavelength such as blue (B), green (G), red (R), and even infrared has recently facilitated promising applications to organic full colour image sensors. For instance, vertical stacks of G-wavelength selective organic photoconversion layers on conventional Si CMOS imagers with B/R color filters have been made to realize highly sensitive image sensors by doubling the light detecting area compared to the planar R/G/B pixel structure.

Our recent investigations on small molecule OPDs with bulk heterojunction structure have shown high peak external quantum efficiencies over 60% and extremely low dark current densities below 0.1 nA/cm2 at reverse bias of 3V, which are comparable to the typical performance of Si-based PDs. On the other hand, their photoresponse characteristics have not been systematically studied. For example, the Si PD exhibited the rising time of photoresponse speed as fast as 10 us at 99.9% of the peak photocurrent, whereas the OPD showed 20 times slower response time plausibly due to the reduced charge carrier mobility. Thus, in order to investigate the practical use of OPDs as image sensor applications, we will present the current status of dynamic characteristics of OPDs in terms of photoresponse speed, frequency response, and transient photocurrent. Further, the possible origin of photoresponse characteristics of OPDs will be described.

10364-6, Session 2

Microvolt-signal amplification circuitsbased on organic thin-film transistors *(Invited Paper)*

Tsuyoshi Sekitani, Osaka Univ. (Japan)

Organic thin-film transistors (OTFTs) are promising electrical components for biomedical applications because of their unique properties for lightweight, mechanical flexibility and cost effective processability. To realize a precise biosignal detecting, flexible and biocompatible electrodes should be tightly placed to the biological target surface. Also, it is desired to amplify the detected small signals nearby the electrodes for minimizing background noise. For this reason, ultra-flexible organic amplifier circuits combined with biocompatible electrodes are suitable for a reliable biosignal sensing.

We have developed ultra-flexible voltage amplifier system using an organic pseudo-CMOS inverter, which consists of four p-type OTFTs. The TFTs show the mobility is 1.5 cm2/Vs, the subthreshold slope is 92 mV, and the on/off ratio is 10^8. The voltage amplifier system, which includes a pseudo-CMOS inverter, feedback resistance, and input capacitor. Small input voltage for 10 μVpp at 3 Hz sine wave is amplified to 10 mVpp, which means the voltage gain is 60 dB. The large voltage gain is quite beneficial for detecting small biological signals. Especially, since the signal amplitude for electroencephalogram (Brain wave) is in the order of μV, which is three orders smaller than the other biological signals, the voltage amplifier system is effective for precise sensing of the electroencephalogram.

10364-7, Session 2

High sensitive biosensors based on water-stable organic field-effect transistors

Amir Foudeh, Raphael Pfattner, Celine Liong, Desheng Kong, Chao Wang, Wen-Ya Lee, Stanford Univ. (United States)

There is a big need for electronic biosensors that can be operated in water for biomedical applications and environmental monitoring. Devices based on organic materials are currently attracting great attention for applications where low-cost, large area coverage and flexibility are required. Water is an aggressive medium and due to its chemical activity the operational voltage window for stable sensor operation is limited. Related to that, in the past, degradation under both ambient and aqueous environments have limited their application in bio sensors for portable, label-free detection in the field of healthcare and environmental monitoring.

Quite recently, our group has demonstrated stable FET device operation based on organic active materials directly exposed to water and more interestingly, even sea water.[1-3] By pattering an array of gold nano-particles on top of the organic semiconductor but close to the transistor channel, the developed structure was able to sense low concentrations of mercury ions in sea water.[2,3]

Here we would like to present the second generation of this highly sensitive bio-sensor platform based on organic field-effect transistors developed in our group able to operate at even lower voltages which is a necessary condition for stable device operation in water based environments.[4,5] Functionalization is a powerful tool to attach receptor units close to the transistor channel which are able to detect its corresponding analytes. This methodology allows preparing a scalable, easy producible and high performing sensor platform suitable for portable biosensing in aqueous media.

Rylenediimide derivatives as a new molecular platform for n-type WG-OFETs: the role of thin-film 3D growth modality in engineering the electrolyte-semiconductor interface

Stefano Toffanin, Federico Prescimone, Emilia Benvenuti, Marco Natali, Andrea Lorenzoni, Istituto per lo Studio dei Materiali Nanostrutturati (Italy); Zhihua Chen, Northwestern Univ. (United States); Franco Dinelli, Istituto Nazionale di Ottica (Italy); Fabiola Liscio, Silvia Milita, Institute for Microelectronics and Microsystems (Italy); Francesco Mercuri, Michele Muccini, Istituto per lo Studio dei Materiali Nanostrutturati (Italy); Antonio F. Facchetti, Northwestern Univ. (United States)

The Water-Gated Organic Field-Effect Transistor (WGOFET) is one of the most promising device architecture for stimulating and recording cell electrophysiological activity given the possibility of biofunctionalization of the organic/electrolyte interface [1]. Here we present for the first time the use of two electron-transporting PDI derivatives, named PDIF-CN2 and PDI8-CN2 [2], as active materials in WGOFETs. The two materials have identical solid-state arrangement but show two different growth mechanisms: almost-2D layer by layer for PDIF-CN2 and 3D for PDI8-CN2. The electron mobility of PDI8-CN2 shows a saturation with increasing the semiconductor layer thickness (~10-4 cm2/Vs at 10-15 nm). Differently from other semiconductors used in WGOFETs, whose mobility saturates after 1-2 monolayers from the interface, the PDIF-CN2 mobility increases unexpectedly with the semiconductor film thickness up to 35 nm while preserving an almost-2D growth modality, thus reaching values comparable to state-of-the-art p-type semiconducors (~10-3 cm2/Vs). From the cross-correlation of experimental and theoretical investigations, we can suggest that the charge mobility increase is likely correlated to a bulk conduction contribution to the field-effect charge transport. Moreover, the electron-rich end-substituents of PDIF-CN2 organize into an ordered and dense interlayer at the interface with the electrolyte, which increases the surface hydrophilicity while avoiding water molecules percolation. These insights may enable the definition of a new material paradigm for the realization of performing WGOFETs for use in biological signal transduction.

Prototype all solid state bioelectronic interfaces *(Invited Paper)*

Paul Meredith, Swansea Univ. (United Kingdom); Albertus B. Mostert, Margarita Sheliakina, The Univ. of Queensland (Australia); Adam P. Micolich, Damon J. Carrad, The Univ. of New South Wales (Australia)

One of the critical tasks in realising a bioelectronic interface is the transduction of ion and electron signals at high fidelity, and with appropriate speed, bandwidth and signal-to-noise ratio [1]. This is a challenging task considering ions and electrons (or holes) have drastically different physics. For example, even the lightest ions (protons) have mobilities much smaller than electrons in the best semiconductors, effective masses are quite different, and at the most basic level, ions are 'classical' entities and electrons 'quantum mechanical'. These considerations dictate materials and device strategies for bioelectronic interfaces alongside practical aspects such as integration and biocompatibility [2].

In my talk I will detail these 'differences in physics' that are pertinent to the ion-electron transduction challenge, and outline how DC and AC electrical measurements can isolate the different 'timescales' of transport. From this analysis, I will summarise the basic categories of device architecture that are possibilities for transducing elements, and give recent examples of their realisation including a novel all-solid-state electrochemical transducer that operates by so-called volumetric gating. Ultimately, transducing elements need to be combined to create 'bioelectronic logic' capable of signal processing at the interface level. In this regard, I will extend the discussion past the single element concept, and discuss our recent progress in delivering all-solids-state logic circuits based upon transducing interfaces [3].

Sensing of non-nitro group containing explosive vapours *(Invited Paper)*

Paul L. Burn, Shengqiang Fan, Paul E. Shaw, The Univ. of Queensland (Australia)

Detection of explosives can play an important role in combating terrorism and humanitarian de-mining in war-torn countries. Many detection systems used for identifying the presence of explosives are cumbersome or not portable. Luminescent conjugated polymers have been successfully used in portable detectors where the presence of the analyte is detected by a decrease in the luminescence. We have also discovered that light-emitting dendrimers can be used for effective detection of nitro-containing explosive analytes with them showing rapid and selective sensing. However, there are other explosives that are also important to detect. In this presentation we will discuss the development of sensing materials for non-nitro containing group explosives. We will show the properties of the materials and explain the method of sensing.

10364-11, Session 3

Nitroaromatic explosive vapor detection using a digitally printed sensor array *(Invited Paper)*

Carsten Eschenbaum, Karlsruher Institut für Technologie (Germany) and InnovationLab GmbH (Germany) and Institut für Mikrostrukturtechnik, Karlsruher Institut für Technologie (Germany); Nico Bolse, Karlsruher Institut für Technologie (Germany); Ralph Eckstein, Karlsruher Institut für Technologie (Germany) and InnovationLab GmbH (Germany); Tobias Rödlmeier, Karlsruher Institut für Technologie (Germany) and InnovationLab GmbH (Germany); Anne Habermehl, Karlsruher Institut für Technologie (Germany); Gerardo Hernandez-Sosa, Karlsruher Institut für Technologie (Germany) and InnovationLab GmbH (Germany); Ulrich Lemmer, Karlsruher Institut für Technologie (Germany) and InnovationLab GmbH (Germany) and Institut für Mikrostrukturtechnik, Karlsruher Institut für Technologie (Germany)

We report on a fluorescent optoelectronic nose for the trace detection of nitroaromatic explosive vapors. The sensor arrays, fabricated by aerosol-jet printing, consist of six different polymers as transducers. We demonstrate the nose's ability to discriminate between several nitroaromatics including nitrobenzene, 1,3-dinitrobenzene and 2,4-dinitrotoluene at three different concentrations using linear discriminant analysis (LDA). We assess the within-batch reproducibility of the printing process and we report that the sensor polymers show efficient fluorescence quenching capabilities with detection limits of a few parts-per-billion in air.

Our approach enables the realization of highly integrated optical sensor arrays in optoelectronic noses for the sensitive and selective detection of nitroaromatic explosive trace vapors using a potentially low-cost digital printing technique suitable for high-volume fabrication. An important challenge is temperature-dependence which is often neglected even though organic emitters are strongly affected by temperature. For some materials, even small changes of a few Kelvin can lead to large changes in the emission intensity making a temperature-control for sensing applications inevitable. Therefore, the temperature-dependence of these sensors is investigated via a heated transparent thin film on the back of such sensors allowing the active layer to be temperature controlled. All of these led to the development of a portable system.

10364-12, Session 3

Poly(dendrimers) for explosives sensing

Kinitra Hutchinson, Paul E. Shaw, Dani Lyons, Paul L. Burn, The Univ. of Queensland (Australia)

Trace detection of explosives and explosive-related compounds is crucial for countering terrorism and providing homeland security. Current technologies for doing this include ion mobility spectrometry , mass spectrometry, colorimetric detectors, electrochemical sensing, and surface acoustic wave devices. However, the best way to detect explosives is to use a stand-off detection method so as to minimize physical contact and risk to personnel. One method of achieving this goal is to use a luminescence-based system to detect explosive vapours. Luminescent conjugatged polymers and dendrimers have been developed for the detection of explosives in handheld sensors. Recently, luminescent dendrimers that incorporate triarylamine units have been shown to have good selectivity for nitro-containing explosives and taggants.[1]

In this presentation a new class of sensing material, namely luminescent poly(dendrimers), will be introduced. The poly(dendrimers) consist of triarylamine-based chromophores (dendrons) linked via a non-conjugated polymeric backbone. Such a structural motif combines the versatile

processability of polymeric materials as well as an alternative route to controlling the packing of the luminescent chromophores and thus reducing intermolecular ϖ-ϖ interactions that can cause quenching of the luminescence. Furthermore, the poly(dendrimer) can in principle give rise to a less dense film structure, which would facilitate diffusion of analytes into the sensing film. We discuss the synthesis of the materials as well as the sensing performance for the detection of nitroaromatics, such as 2,4-dinitrotoluene, and the nitroaliphatic taggant 2,3-dimethyl-2,3-dinitrobutane (DMNB) by fluorescence quenching. Stern-Volmer measurements show enhanced quenching of the poly(dendrimers) relative to the monomers. We will also discuss the potential for using poly(dendrimers) as a sensing material in a handheld detector.

10364-13, Session 3

Organic semiconductor sensing of explosives *(Invited Paper)*

Ifor D. W. Samuel, Ross Gillanders, James Glackin, Paulina Morawska, Graham A. Turnbull, Univ. of St. Andrews (United Kingdom)

The fluorescence of conjugated polymers is quenched by electronegative materials such as explosives. This can be used to make a sensor for explosive vapor, which can then give chemical information to help identify explosive devices, and complements other approaches such as metal detectors and ground penetrating radar. Whilst the principle has been known for some time, its practical implementation requires considerable development of instrumentation and materials. We will report our work to address these challenges, with particular emphasis on humanitarian demining.

10364-14, Session 4

Organic temperature sensor using 3D printed polymer surfaces

Kyu-Sung Lee, Electronics and Telecommunications Research Institute (Korea, Republic of) and Korea Univ. of Science and Technology (Korea, Republic of); Yong Suk Yang, Ji-Young Oh, Electronics and Telecommunications Research Institute (Korea, Republic of); Seung Eon Moon, Electronics and Telecommunications Research Institute (Korea, Republic of); Myoung-Woon Moon, Korea Institute of Science and Technology (Korea, Republic of); ChangWoo Lee, Korea Institute of Machinery & Materials (Korea, Republic of)

Recent development of 3D printing technologies would provide the variety of electronic devices including environmental sensors and bio-applications. Polymer-based sensors are compatible with human-body parts or prostheses to monitor the body status of surfaces or surroundings such as temperature, humidity, and pressure. Conventional 1D or 2D fabrication processes are effective for mass production. However, specific shapes such as curvy or 3D pathways would require the 3D printed sensors to expand the possible applications.

In this study, organic temperature sensors fabricated on 3D printed surfaces are investigated to improve the device properties. 3D structures were fabricated using a DLP (direct light processing) 3D printer with photo-polymers. Sensor electrodes based on conductive carbon materials were printed on 3D shape structures. The resistances of organic temperature sensors were measured by the temperature variations. As the environmental temperature increased from 29 to 54?, the resistance was decreased from 8.57 to 8.23 k? with the certain linearity, respectively. To further improvements, polymer composites comprising the inorganic nanoparticles were introduced to control the interfacial properties and the conductivity of composite carbons were improved.

10364-15, Session 4

Active matrix type large area flexible sensor arrays *(Invited Paper)*

Emil J. W. List-Kratochvil, Humboldt-Univ. zu Berlin (Germany)

Electrically tunable resistors realized in two terminal structures seem to be one of the most versatile innovations in the semiconductor industry with many possible applications such as logic circuitry or neuromorphic systems. In particular, inorganic resistive switching devices utilized as non-volatile memory are close to commercialization. Also, resistive switching effects in organic and hybrid devices have been presented in a multitude of devices and novel materials. [1] Recently the fabrication of organic resistive switches using environmentally friendly inkjet-printing methods and their integration into fully functional hybrid crossbar array structures has been demonstrated. [2]

10364-16, Session 4

Synthesis and characterization of bioinspired organic nanowires and nanoribbons *(Invited Paper)*

Alon Gorodetsky, Univ. of California, Irvine (United States)

One-dimensional organic nanowires and nanoribbons represent idealized model systems for investigating charge transport mechanisms at molecular length scales. However, there are significant difficulties associated with the synthesis of organic nanowires and nanoribbons with precisely defined sequences, lengths, geometries, and terminal functionalities. By drawing inspiration from biological systems, we have developed facile strategies for the covalent assembly of organic semiconductor building blocks into well-defined one-dimensional ensembles. We have investigated the properties of these nanowires with a suite of spectroscopic, electrochemical, and computational techniques, discovering unique emergent properties for our constructs. Such findings hold significance both for fundamentally understanding nanoscale charge transport phenomena and for the ultimate development of next-generation molecular electronic devices.

10364-34, Session 4

Graphene electronic tattoo sensors *(Keynote Presentation)*

Nanshu Lu, The Univ. of Texas at Austin (United States)

Tattoo-like epidermal sensors are an emerging class of truly wearable electronics owing to their thinness and softness. While most of them are based on thin metal films, silicon membrane, or nanoparticle-based printable inks, we report the first demonstration of sub-micron thick, multimodal electronic tattoo sensors that are made of graphene. The graphene electronic tattoo (GET) is designed with filamentary serpentines and fabricated by a cost- and time-effective “wet transfer, dry patterning” method. It has a total thickness of 463 ± 30 nm, an optical transparency of ~85%, and a stretchability of more than 40%. GET can be directly laminated on human skin just like a temporary tattoo and can fully conform to the

microscopic morphology of the surface of skin via just van der Waals forces. The open mesh structure of GET makes it breathable and its stiffness negligible. Bare GET is able to stay attached to skin, for several hours, without fracture or delamination. With liquid bandage coverage, GET may stay functional on skin up to several days. As a dry electrode, GET-skin interface impedance is on par with medically used silver/silver-chloride (Ag/AgCl) gel electrodes, while offering superior comfort, mobility and reliability. GET has been successfully applied to measure electrocardiogram (ECG), electromyogram (EMG), electroencephalogram (EEG), skin temperature, and skin hydration. Graphene represents a new facile route for ultra-conformable multifunctional electronic tattoos, and paves the path for the introduction of other two dimensional materials for future advanced tattoo systems.

10364-17, Session 5

Ultra-sensitive bio-markers detection with an electrolyte gated organic transistor *(Keynote Presentation)*

Luisa Torsi, Univ. degli Studi di Bari Aldo Moro (Italy)

Organic bio-electronics represents one of the most exciting directions in printable electronics, promising to deliver new technologies for healthcare and human well?being. Among the others, organic field-effect transistors have been proven to work as highly performing sensors.1 Selectivity is achieved by integrating a layer of functional biological recognition elements, directly coupled with an electronic interface.

In this lecture novel developments in the field of organic and printable electronics implemented to probe biological interfaces will be discussed. It will also be shown that applications can lead to label-free electronic biosensors with unprecedented detection limits and selectivity. Notably, the extremely good sensing performance level can be rationalized by quantifying electrostatic and capacitance contributions characterizing the surface confined biological recognition elements interacting with their affinity ligands. Examples of the detection of clinical relevant biomarkers will be provided too.

10364-18, Session 5

Sulphonated mesoporous silica as proton exchanging layer in solid state organic transistors for bio-sensing

Soniya D. Yambem, Queensland Univ. of Technology (Australia)

Electronic devices that can interface with the human body are highly desirable for sensing of physiological parameters and for smart prosthetics. This is particularly challenging since the mechanism of signalling in most electronic materials is different from the mechanism of signalling in the human body. Most electronic devices in our daily life send signals through flow of electrons while body signals are carried via the exchange of ions and protons. There is a considerable interest in developing bioinspired proton conducting materials and solid-state devices for bio-electronic applications [1, 2, 3].

In this work, we will present a new class of proton conducting gate materials, sulphonated mesoporous silica nanoparticles (SMSN) [4], that are able to sense conduction of protons in all solid state, low voltage operating organic thin film transistors (OTFTs). Ordered mesoporous silica nanoparticles with various functional groups have been investigated for applications in catalysis, gas adsorption and drug delivery. SMSN have also been successfully investigated for applications in fuel cell membranes [4]. In this presentation, we will describe the OTFT operation of solution processable SO3H-MCM-41 films that have highly ordered pore structures. The OTFTs fabricated maintained low voltage transistor output characteristics for operating source-drain voltages 0 > Vds > -1.25 V.

We will also present results that demonstrate the application of our low voltage operating OTFTs in sensing proton exchange, where a drop of H2O2 dropped on top of the SO3H-MCM-41 gate electrode captures strong modulation in the current flow. H2O2 breaks down to oxygen, protons and electrons when a voltage above a threshold voltage is applied between source and drain. The Ids increases immediately by ~ 3-fold and continues to increase to a maximum value of ~ 5-fold, demonstrating that these OTFTs are highly applicable in advanced biomedical sensing applications.

10364-19, Session 5

Low voltage organic charge modulated FETs: A flexible approach for the fabrication of high sensitive biosensors *(Invited Paper)*

Piero Cosseddu, Andrea Spanu, Fabrizio Viola, Stefano Lai, Univ. degli Studi di Cagliari (Italy); Brunella Tedesco, Sergio Martinoia, Univ. degli Studi di Genova (Italy); Annalisa Bonfiglio, Univ. degli Studi di Cagliari (Italy)

Charge Modulated OTFTs represent a versatile tool for the realization of a wide range of sensing applications. The architecture is based on a floating gate organic transistor whose sensitivity to a specific target is obtained by properly functionalizing a part of the floating gate with a sensing layer that can be chosen according to the specific external stimulus to be sensed.

In this work we will show that such devices can be routinely fabricated on highly flexible, ultra-conformable thin films and that they can be employed, with no need of any chemical modification of the sensing area, for monitoring pH variations featuring a super-nernstian sensitivity. Interestingly, we will also show that the proposed approach has been applied for monitoring cell metabolic activity, demonstrated with a preliminary validation. In addition this device can be used for monitoring electrical activity of excitable cells, thus giving rise to a new family of highly sensitive, reference-less, and low-cost devices for a wide range of bio-sensing applications.

Finally, we will also demonstrate that using a different sensing layer it is possible to employ the same device architecture for the realization of matrices of multimodal tactile transducers capable to detect at the same time temperature and pressure stimuli, and that being fabricated on sub-micrometer thin film can be conformably transferred on whatever kind of surface allowing the reproduction of the sense of touch.

10364-20, Session 6

Large-scale organic neural interface devices *(Invited Paper)*

Dion Khodagholy, Columbia Univ. (United States)

As our understanding of the brain's physiology and pathology progresses, increasingly sophisticated technologies are required to advance discoveries in neuroscience and develop more effective approaches to treating brain disease. There is a tremendous need for advanced materials solutions at the biotic/abiotic interface to improve the spatiotemporal resolution of neuronal recording. Organic electronic devices offer a unique approach to these challenges, due to their mixed ionic/electronic conduction, mechanical flexibility, enhanced biocompatibility, and capability for drug delivery. We designed, developed, and characterized conformable organic electronic devices in the form of transistors and electrodes to efficiently interface with the brain and acquire neurophysiological activity not previously accessible with recordings from the brain surface. These devices have facilitated large-scale rodent neurophysiology experiments and uncovered a novel hippocampal-cortical oscillatory interaction. The biocompatibility of the devices allowed intra-operative recording from patients undergoing epilepsy surgery, highlighting the translational capacity of this class of neural interface devices

This multidisciplinary approach will enable the development of new devices based on organic electronics, with broad applicability to the understanding of physiologic and pathologic network activity, control of brain-machine interfaces, and therapeutic closed-loop devices.

10364-21, Session 6

A printed electronic platform for the specific detection of biomolecules

Amadou Doumbia, Michelle Webb, Michael L. Turner, The Univ. of Manchester (United Kingdom); Jonathan Behrendt, Richard J. Wilson, Cambridge Display Technology Ltd. (United Kingdom)

The rapid detection of disease specific biomarkers in a clinically relevant range using a low cost sensor can facilitate the development of individual treatment plans for a given patient, known as the precision, personalized or genomic medicine. In the recent decade Electrolyte Gated Organic Field Effect Transistors (EGOFETs), a subtype of OFETs where the dielectric is replaced by an electrolyte, have attracted a great deal of attention from both industry and academia for sensing applications. This is due to their capacity to operate at low voltage (< 1 volt) in physiological like media (water, phosphate saline solution, etc.) with high sensitivity and specificity. Although EGOFET based biosensors have demonstrate their capacity to specifically detect biomolecules with high sensitivity; the stability, reproducibility and performance required to reach the desired market are not yet achieved. In this contribution we describe a platform for the fabrication of stable and reproducible EGOFET sensors that are able to detect biomolecules rapidly with high selectivity and sensitivity in real time. Facile and scalable techniques are used to prepare arrays of these devices with patterned active layers. The influence of the electrode geometry (channel length to width ratio) on the device performance and sensitivity is examined. The selectivity of individual EGOFETs is investigated by immobilization of specific ligands to the target molecule of interest on the gate electrode or the active layer within a microfluidic flow cell. Finally calibration and control experiments show how the developed sensor arrays are capable of specifically determining the analyte concentration in real time

10364-22, Session 6

Microfluidics and BIO-encapsulation for drug- and cell-therapy *(Invited Paper)*

Rosaria Rinaldi, Univ. del Salento (Italy) and Istituto per la Microelettronica e Microsistemi, CNR (Italy); Alessandra Aloisi, Istituto per la Microelettronica e Microsistemi (Italy); Chiara Toma, Univ. del Salento (Italy)

We present the construction and the application of biocompatible micro- and nano-structures that can be administered systemically and transport in a targeted and effective way drugs, small molecules, stem cells or immune system cells. These polymeric nano-systems represent a primary goal for the treatment of a wide family of neurological/systemic disorders, as well as tumors and/or acute injuries As natural, biocompatible, biodegradable and non-immunogenic building blocks, alginate and chitosan are been currently exploited. Ionotropic pre-gelation of the alginate core, followed by chitosan polyelectrolyte complexation, allow to encapsulate selected active molecules by means of physical entrapment and electrostatic interactions within sub-micron sized hydrogel vesicles. Here we present a microfluidic-assisted assembly method of nano- and micro-vesicles -under sterile, closed environment and gas exchange adjustable conditions- a critical issue, when the cargo to be upload is very sensitive. Polymer/polymer and polymer/drug mass ratio relationship are crucial in order to attain the optimum in terms of shuttle size and cargo concentration. By modulating polymer reticulation conditions, it become possible to control drug loading efficiency as well as drug delivery dynamics. Recent results on the application of the vesicles for the encapsulation and delivery of Inhibin-A and Decorin secreted by Human Adult Renal Stem/Progenitor Cells for Renal tubular cell regeneration will be presented.

Finally, the impact of these polysaccharide sub-micron vesicles on Human Immune cells and the metabolic activity of cells embedded in the micro vesicles will be presented and discussed.

10364-23, Session 6

Microfluidic methods in organic electronics and organic bioelectronics *(Invited Paper)*

John C. de Mello, Imperial College London (United Kingdom)

Microfluidic methods have a critical role to play in the production of electronic and bioelectronic materials and their subsequent deployment in analytical devices. Here we describe several different aspects of microfluidic technology that are relevant to organic electronics research in general and organic bioelectronics research in particular, focusing on the optimisation and manufacturing of functional materials at scale, and their integration into self-contained analytic devices.

10364-24, Session 7

Vertical organic transistors for optoelectronic and ferroelectric applications *(Invited Paper)*

Hyeonggeun Yu, Franky So, North Carolina State Univ. (United States)

Direct integration of an infrared-sensing quantum dot film and an organic light-emitting diode (OLED) offers pixel-free infrared imaging. However, the infrared-to-visible conversion efficiencies of the devices are low due to the low photon-to-electron conversion efficiency of the quantum dot photodetector. Here, we report a novel vertical infrared phototransistor with 105 % external quantum efficiency (EQE). By integrating a phosphorescent OLED with this phototransistor, an infrared-to-visible up-conversion light-emitting phototransistor with an EQE over 1,000% is demonstrated. In addition, by employing a ferroelectric gate insulator for the vertical transistor, a flexible low voltage non-volatile memory is demonstrated with 10 years of retention extrapolated.

10364-25, Session 7

Effect of water adsorption on ionic and electronic transport in PEDOT:PSS

Eric S. Muckley, Christopher B. Jacobs, Rajeev Kumar, Ilia N. Ivanov, Oak Ridge National Lab. (United States)

Progress in bionic sensing and bio-electronic interfacing requires a thorough understanding of electronic and ionic transport in functional bio-compatible materials. The well-known polymer mixture poly(3,4-ethylenedioxythiophene) polystyrene sulfonate (PEDOT:PSS) is central to many optoelectronic applications which necessitate flexible, transparent biocompatible materials. While PEDOT:PSS is traditionally studied for its hole transport properties and resistive H_2O response, research interest has recently turned to ionic transport in the context of bio-electronic interfacing and sensing. Cations Na^+ and K^+ are often present in PEDOT:PSS as byproducts from industrial production. Uptake of water into PEDOT:PSS disrupts hydrogen bonding that maintains rigidity of the PSS matrix, causing film swelling and hydronium production due to water interaction at the hydrophilic SO_3^- moiety. As water uptake increases, mobility of Na^+, K^+, H_3O^+ and other ions may become hindered due to the formation of

electrical double layers and hydration shells around ions. At the same time, water-induced swelling of the PSS matrix increases the distance between adjacent conductive PEDOT domains, which reduces electronic mobility. Despite its widespread use as a hole transport material in a variety of organic optoelectronic devices, the effect of water on electronic and ionic transport in PEDOT:PSS remains unclear. To probe both electronic and ionic response during water uptake, we perform ultra-wide range dielectric spectroscopy from sub-Hz to optical frequencies while changing humidity conditions in a controlled environment. We correlate the frequency-dependent measurements with those of a PEDOT:PSS-coated quartz crystal microbalance (QCM) to estimate the mass of adsorbed H2O in the film. We show that the presence of water has an effect on electronic and ionic mobility in the film and both electronic and ionic transport play a role in defining the optoelectornic properties of PEDOT:PSS under a wide range of humidities.

10364-26, Session 7

Designing organic mixed conductors for bioelectronic applications *(Invited Paper)*

Jonathan Rivnay, Northwestern Univ. (United States)

Direct measurement and stimulation of electrophysiological activity is a staple of neural and cardiac health monitoring, diagnosis and/or therapy. Such bi-directional interfacing can be enhanced by the low impedance imparted by organic electronic materials that show mixed conduction properties (both electronic and ionic transport). Many high performance bioelectronic devices are based on conducting polymers such as poly(3,4-et hylenedioxythiophene):poly(styrenesulfonate), PEDOT:PSS. By investigating PEDOT-based materials and devices, we are able to establish a set of design rules for new formulations/materials. Introducing glycolated side chains to carefully selected semiconducting polymer backbones, for example, has enabled a new class of high performance bioelectronic materials that feature high volumetric capacitance, transconductance >10mS (device dimensions ca. 10um), and steep subthreshold switching characteristics. A sub-set of these materials outperform PEDOT:PSS and shows significant promise for biocompatible, low power in vitro and in vivo biosensing applications.

10364-27, Session PMon

An enzyme-based lactate sensor incorporating a three-dimensional complementary inverter for high sensitivity

Sanghoon Baek, Jimin Kwon, Pohang Univ. of Science and Technology (Korea, Republic of); Hiroyuki Matsui, Shizuo Tokito, Yamagata Univ. (Japan); Sungjune Jung, Pohang Univ. of Science and Technology (Korea, Republic of)

Enzyme-based biochemical sensors based on organic field-effect transistor (OFET) have gained attention for their potential applications as low-cost, disposable, wearable sensors. They take advantage of inducing drain current change in OFET from enzymatic reaction, however, the induced current signal is not stable and signal-to-noise ratio is not large enough to be easily detected. In this study, we propose a new strategy of an extended-gate type inverter incorporating three-dimensional complementary organic field-effect transistors (3D-COFETs) for lactate detection with higher sensitivity. In the device structure of 3D-COFETs, a bottom-gate p-type OFET is vertically integrated on a top-gate n-type OFET with the gate shared in-between, and complementary inverter is implemented with this transistor-on-transistor structure. For lactate detection, enzyme-functionalized gold electrode is used as an extended-gate of complementary inverter, and it composes biofuel cell with Ag/AgCl reference electrode in aqueous media. We have observed that the enzymatic redox chain reaction of lactate occurring in the biofuel cell causes potential difference between the two electrodes which results in switching voltage shift in the complementary inverter. The proposed 3D-COFETs structure itself has advantages in sensing applications within complementary integrated circuit systems thanking to its higher transistor density. The output signal from the detection of lactate levels using the proposed 3D-COFETs inverter is expressed in voltages which is more stable than current signals and sensitivity is higher compared with that of single OFET-based biochemical sensors because the voltage shift induced from enzymatic reaction is amplified by the gain of the inverter. It is expected that the proposed biochemical sensor incorporating 3D-COFETs is a promising candidate for highly sensitive biosensors in practical applications.

10364-28, Session PMon

Porous silicon photoluminescence biosensor for rapid and sensitive detection of toxins

Yuliia Melnyk, Karyna Pavlova, Valerii Myndrul, Valentyn Smyntyna, Odessa I.I. Mechnikov National Univ. (Ukraine); Roman Viter, Univ. of Latvia (Latvia); Igor Iatsunskyi, Adam Mickiewicz Univ. (Poland)

Mycotoxins are toxic secondary metabolites produced by some fungal species. Among all mycotoxins, ochratoxin A (OTA) and aflatoxin (AF) have received much attention due to severe health effects in animals and humans. Porous silicon (PSi) has become one of the most popular materials for the biosensor technology in the last years. In the present study, we have developed a sensitive, cost-effective, and comparatively fast method for OTA and AF detection. PSi samples fabricated by metal-assisted chemical etching (MACE) were used to develop photoluminescence (PL) biosensor for OTA/AF detection. PSi samples were characterized by X-ray diffraction (XRD), scanning electron microscopy (SEM), reflectance and PL spectroscopy. The main structural and chemical parameters of PSi were obtained. We explored the ability of PSi samples, as a new material to enhance the performance of optical biosensors for OTA and AF detection. This biosensing system using PSi and PL signal analysis was proposed in our knowledge for the first time for OTA/AF detection. The PL biosensor exhibited a wide detection range from 0.094 to 100 ng/mL (linear range from 0.001 to 100 ng/mL) of toxins. Immobilization of the biosensitive layer onto PSi surface was found to decrease the intensity of PL. A phenomenon of changes in PL of PSi samples upon the interaction with toxins was proposed to be used as a platform for the optical biosensor development.

10364-29, Session PMon

Au-Ag alloy nanoislands for high-sensitive localized surface plasmon resonance biochemical analytes detection

Guangyu Qiu, Siu Pang Ng, Chi-Man L. Wu, City Univ. of Hong Kong (Hong Kong, China)

Nanoislands of Au and Ag alloy were synthesized by self-assembly thermal annealing method. The nanoparticles show not only the combination of plasmonic properties related to the presence of two individual metal elements, but also have improved and tunable plasmonic sensing performance. The Au-Ag alloy nanoislands were optimized in two aspects: 1) the atomic ratio of Au and Ag, and 2) the size of synthesized nanoislands. UV-visible absorption spectroscopy was utilized to investigate the plasmonic effect of transmitted light, and achieved tunable light absorption ranging from 420 nm to 570 nm by changing the atomic ratio of Au and Ag. Among the various atomic ratios investigated, the Au60Ag40 (in atomic ratio) nanoislands exhibited the sharpest and strongest absorption. In virtue of the common-path interferometric sensing system, the optimized Au60Ag40 nanoislands showed improved refractive index sensitivity than pure Au nanoislands, together with better corrosion resistance properties over pure Ag nanoparticles.

The synthesized Au-Ag alloy nanoislands were successfully functionalized with various protocols, i.e. 1) conventional Au functionalization protocol with 11-Mercaptoundecanoic acid (11-MUA); 2) dielectric functionalization method to immobilized organic receptors onto glass substrate; and

3) direct functionalization with synthetic copolymer such as poly(m-Phenylenediamine-co-Aniline-2-sulfonic acid) nanoparticles. The functionalization efficiency and biochemical sensing performance toward various analytes of synthetic homodispersed Au60Ag40 nanoislands were compared with previously reported Au nanoislands. Further, it was demonstrated that the self-assembly Au-Ag alloy nanoislands showed improved plasmonic sensing performance. These results indicated that the Au-Ag alloy nanoislands have great potential for its sensing applications.

10364-30, Session PMon

Development of fully organic moisture sensor

Aramis A. Sanchez Juárez, Univ. Técnica Particular de Loja (Ecuador)

A fully organic moisture sensor was developed, the active substance is a natural organic dye contained in the species Hibiscus Sabdariffa and the support material is a natural biopolymer made from three different species Canna indica, Cavendish Valery and Arracacia xanthorrhiza. Characterization and accuracy results depending on the biopolymer are presented in this paper. The sensor was characterized by the correlation between color changes ranging from violet to blue and humidity levels varying from 5% to 100%, another study was the lifetime of the sensor under different storage conditions. An important result for an organic moisture sensor is that it exhibits reversibility when exposed to extreme moisture values. Additionally, the effects of temperature, UVA exposure and ionizing radiation on sensor performance with respect to time are studied.

10364-31, Session PMon

Fully organic pH sensor development

Aramis A. Sanchez Juárez, Johanna E. Jaramillo Q., Univ. Técnica Particular de Loja (Ecuador)

A fully organic pH sensor was developed, the active substance is a natural organic dye contained in the species Prunus Salicifolia and the support material is a natural biopolymer by an independent study carried out for the manufacture from three different species Canna indica, Cavendish Valery and Arracacia xanthorrhiza. Characterization and accuracy results depending on the biopolymer are presented in this paper. The sensor was characterized by the correlation between color changes ranging from green to red and pH levels varying from 1 to 12, another study was the lifetime of the sensor under different storage conditions. An important result for an organic moisture sensor is that it exhibits reversibility when exposed to extreme pH values. Additionally, the effects of temperature, UVA exposure and ionizing radiation on sensor performance with respect to time are studied.

10364-32, Session PMon

Novel biomimetic light-harvesting molecular architecture based on porphyrin-peptoid conjugates

Jiwon Seo, Gwangju Institute of Science and Technology (Korea, Republic of)

The energy flow during natural photosynthesis is controlled by maintaining the spatial arrangement of pigments, employing ?-helices as scaffolds. The natural photosynthetic mechanism can be better elucidated by developing a synthetic molecular system that can establish a pigment array with the precision of natural systems. Herein, we have developed porphyrin-peptoid conjugates that can tune the donor-acceptor energy transfer efficiency with exceptional precision by controlling the inter-porphyrin distances and orientations. Peptoids, or oligo-N-substituted glycines, with ?-helical conformation were used as scaffolds for porphyrin display; two porphyrins can have strong to minimal intramolecular excitonic couplings depending on their relative placement in the helix. The unique structural characteristics and synthetic accessibility of peptoids can be further utilized to develop artificial light-harvesting proteins and tunable photosensitizers.

10364-33, Session PMon

Fabrication and characteristics of composite metals for 3D printed electronics

Yong Suk Yang, Hyun-Woo Dang, Bonjin Koo, Electronics and Telecommunications Research Institute (Korea, Republic of); ChangWoo Lee, Korea Institute of Machinery & Materials (Korea, Republic of)

- This presentation contains the materials and processes of 3D printing for printed sensors and transistors.

- The metals for the 3D printing were based on eutectic materials such as GaIn, InAg, SnBi, and SnAgCu

and were utilized to achieve 3D printing.

- The 3D printed metals were applied to electrodes and wirings.

Conference 10365: Organic Field-Effect Transistors XVI

Monday - Wednesday 7 –9 August 2017

Part of Proceedings of SPIE Vol. 10365 Organic Field-Effect Transistors XVI

10365-1, Session 1

Programmable and coherent crystallization of semiconductors *(Invited Paper)*

Aram Amassian, King Abdullah Univ. of Science and Technology (Saudi Arabia)

Crystalline order determines the electronic properties of semiconducting materials, determining their functionality, performance and technological utility. Polycrystalline thin films are typically grown directly from vapour or solution phases, but crystalline films can also be formed by annealing a disordered film. We demonstrate that the stochastic nucleation of crystallites within disordered media proceeds via homogeneous nucleation. A key implication of this finding is that unlike heterogeneous nucleation, the crystallization behavior is proportional to the volume of material and thus to local variations in film thickness. We utilize this breakthrough to harness the nucleation and growth of the crystalline phase by creating deliberate thickness variations. This leads to fully programmable crystallization behavior which we utiize to fabricate organic thin film transistors (OTFTs) with superior transport properties as well as dramatically improved device to device reproducibility. This method provides significant new pathways for controlling material structure and patterning functional properties for use in electronic devices, circuits and beyond.

10365-2, Session 1

Formation and growth of organic semiconductors with mm-scale grains *(Invited Paper)*

Barry P. Rand, Princeton Univ. (United States)

While record mobilities have been reported for organic semiconductors in their single crystal form, the bulk nature of such crystals prohibit their practical application. Here, we discuss our efforts to realize pinhole free films of the organic semiconductor rubrene with grains of up to 1 mm in extent. We will show our efforts to understand their formation, epitaxy, and transistors. Homoepitaxial studies uncover evidence of point and line defect formation in these films, indicating that homoepitaxy is not at equilibrium or strain-free. Point defects that are resolved as screw dislocations can be eliminated under closer-to-equilibrium conditions, whereas we are not able to eliminate the formation of line defects. We are, however, able to eliminate these line defects by growing on a bulk single crystal of rubrene, indicating that the line defects are a result strain built into the thin film template, indicating that, in general, organic crystalline thin films may not adopt the exact lattice of a bulk crystal.

10365-3, Session 1

Large-area solution-processed monolayer single crystals for organic field-effect devices

Anastasia V. Glushkova, M.V. Lomonosov Moscow SU (Russian Federation); Elena Y. Poimanova, Donetsk National Univ. (Ukraine); Vladimir V. Bruevich, M.V. Lomonosov Moscow SU (Russian Federation); Yuriy N. Luponosov, Sergei A. Ponomarenko, Institute of Synthetic Polymeric Materials (Russian Federation); Dmitry Y. Paraschuk, M.V. Lomonosov Moscow SU (Russian Federation)

Single-crystal organic filed effect transistors (OFETs) can provide electrical performance exceeding that of a-Si devices. Solution-processed devices could be more advantageous enabling low production costs. For industrial applications of organic single crystals, their high morphological homogeneity and thickness uniformity on large areas are needed. As charge transport in OFETs occurs within a few monolayers of organic semiconductor, ultrathin devices are beneficial from the viewpoint of low material consumption, mechanical flexibility and optical transparency. Herein, we report on solution-processed oligothiophene-based monolayer single crystals with sizes up to a few mm and study their performance as OFET active layers. As materials, we used oligothiophenes and oligothiophene-phenylenes with five conjugated rings and different terminal linear alkyl substituents, which were proved to be crucial for 2D crystallization in monolayers. The monolayer single crystals were grown on various surfaces, both with high and low surface energies, and studied by optical polarization microscopy, atomic-force microscopy, spectroscopic ellipsometry, and x-ray diffraction. Our in situ studies of crystal growth allowed us to suggest a possible growth mechanism. The OFET mobility was tenfold higher for the oligomers with longer alkyl substituents. The best devices showed the charge mobility exceeding by an order of magnitude the highest reported mobilities for oligothiophene-based monolayer OFETs [1]. We discuss correlation between the OFET performance and the oligomers molecular structure. We conclude that large-area solution-processed monolayer single crystals can be a promising platform for ultrathin organic electronic field-effect devices.

10365-4, Session 1

Robust design and fabrication of three-dimensional printed dual-gate organic circuits on a flexible plastic film

Jimin Kwon, Pohang Univ. of Science and Technology (Korea, Republic of); Yasunori Takeda, Rei Shiwaku, Shizuo Tokito, Yamagata Univ. (Japan); Sungjune Jung, Pohang Univ. of Science and Technology (Korea, Republic of)

The direct printing of organic thin-film transistors (TFTs) gives us a facile and fast route to fabrication of freeform electronic applications on a flexible substrate. However, despite the significant improvement in the performances of organic semiconductors, electronics industry still has not adopted the printed organic TFTs for manufacturing electronic applications. The low resolution, large feature size and variation of inkjet printing have limited the implementation of organic integrated circuits with reasonable transistor densities and uniformity. To overcome these problems, we have developed a robust inkjet design rule optimized for high-yield circuit patterning, and fabricate a three-dimensional (3D) printed dual-gate (DG) organic TFT where n- and p-type TFTs are stacked in transistor-on-transistor manner halving the transistor foot print. In this work, all the functional layers including electrodes and semiconductors are fully printed except a parylene dielectric that is formed by chemical vapor deposition. The design rule has been developed via a systematic study on the influence of inkjet printing parameters such as substrate temperature, drop spacing) on the minimum width, smoothness, and reproducibility of vertically or horizontally printed metal lines. The stacked DG TFTs showed average carrier mobilities of around 0.2 and 0.7 cm?/(V·s) for the n-type and p-type, respectively, showing exceptional uniformity and long-term stability at 5 V operation voltage. We successfully demonstrated 7-stage ring-oscillator on a flexible PEN film with the maximum frequency of 200 Hz and a gate delay of 340 ?s. Our 3D printing approach provides a path for achieving high transistor density, high yield, high uniformity, and long-term stability, which are critical for the realization of printed organic electronics applications.

10365-5, Session 1

High-density polyethylene, an inert additive stabilizing organic field-effect transistors *(Invited Paper)*

Natalie Stingelin, Georgia Institute of Technology (United States)

Polymer blends and in general multicomponent systems represent an interesting platform for organic electronics. Semiconducting:insulating polymer blends can, for instance, be useful to address specific mechanical requirements in addition to fulfilling the required electronic performance. Here we will focus on how addition of an 'inert' additive polymer can increase the stability of thin-film transistors subjected to bias-stress. It also allows to minimise high and parasitic off-currents. Stabilization of n-type operation for usually p-type materials will be demonstrated. We will discuss the interplay within structure, property and processing providing guidelines on how to further develop blend systems and electronic devices in the area of organic electronics. Future challenges and opportunities will be addressed.

10365-6, Session 2

All-printed organic transistors: integrating devices for flexible circuits *(Invited Paper)*

Mahsa Sadeghi, Lilian Cardoso, Ana Claudia Arias, Univ. of California, Berkeley (United States)

Over the past several decades, conventional electronic circuits have been used for both analytical and digital logic circuits. Printed electronics has the potential to reduce fabrication complexity of electronic circuits and using lower-cost and large area manufacturing techniques. The performance of film transistors (OTFTS) has also improved and these devices could be applied to circuit applications where the high performance, high speed, and high energy consumption offered by conventional electronics is not needed. Amongst many factors that govern circuit design, the scale factor (W/L) serves as a crucial variable for tuning a circuit performance. Here we present printing techniques developed in order to adjust aspect ratios of printed transistors using solution processed electronic materials on to flexible substrates. By combining high-speed doctor blade and surface energy patterning we can demonstrate arrays of OTFTs that are later integrated to form circuits. In the surface energy patterning process, a hydrophobic self-assembled monolayer is deposited on a plastic substrate, and plasma etching is used to create hydrophilic regions. The desirable ink is deposited on the hydrophilic regions using doctor blading and only hydrophilic regions are patterned with the ink. Device aspect ratios are increased and controlled by patterning intermitted SD electrodes and controlling the size of the semiconductor island. We utilize screen printing method to interconnect devices to demonstrate several circuit designs such as enhancement-load Inverter, NAND and NOR on the same printing batch. We will discuss how machine learning is used to train this circuits and applied to sensing applications.

10365-7, Session 2

Printed organic short wavelength infrared photo-transistors

Moran Amit, Hyunwoong Kim, Zhenghui Wu, Univ. of California, San Diego (United States); Jason D. Azoulay, The Univ. of Southern Mississippi (United States); Tse Nga Ng, Univ. of California, San Diego (United States)

Low-cost infrared photo-transistors with improved detectivity (i.e. higher signal-to-noise ratio) could find further use in spectral analysis, which is important for chemical identifications, as well as other applications from environmental monitoring to optical communications. Accordingly, the main goal of this research is to advance printed, flexible photo-transistors by using a family of novel donor-acceptor polymers with narrow bandgap that are responsive in the short wavelength infrared (SWIR) region. In particular, the transistors show optical response extending out to a wavelength of 1.8 micrometer. The external quantum efficiency and the rectification ratio are used to characterize the performance of devices with different polymer layer thickness, in order to optimize detectivity. The individual transistors could further be exploited for the fabrication of integrated arrays for bio-medical and/ or robotic applications. It paves the way to large-area, conformal designs that are currently not achievable with conventional inorganic SWIR materials.

10365-8, Session 2

Organic thin-film transistor fabrication using a laser printer

Peter J. Diemer, Angela F. Harper, Wake Forest Univ. (United States); Muhammad Rizwan Khan Niazi, King Abdullah Univ. of Science and Technology (Saudi Arabia); John E. Anthony, Univ. of Kentucky (United States); Aram Amassian, King Abdullah Univ. of Science and Technology (Saudi Arabia); Oana D. Jurchescu, Wake Forest Univ. (United States)

Organic electronic materials are desirable due to facile and low-cost manufacturing through solution deposition. However, the inherit difficulties of reproducibility and solvent compatibility, as well as the hazards associated with the solvents, have stifled the progress of realizing practical solution-deposition methods. As a result, organic thin-films used in industry are typically produced by thermal evaporation techniques, which largely negate the benefits due to the higher cost and complexity of vacuum and evaporation equipment. Here we report the use of a conventional office laser printer to electrophotographically deposit the organic semiconductor layer in thin-film transistors. We have successfully used this solvent-free, low-cost method to produce the first laser-printed organic semiconductor layer in thin-film transistors. We printed on flexible and transparent polyethylene terephthalate (PET) substrates. We used the highly hydrophobic fluoropolymer Cytop as the dielectric in a bottom-gate, bottom-contact configuration, a feat that is not possible with traditional solution-deposition. The organic semiconductor layer consisted of a toner powder based on triisopropylsilylethynyl pentacene (TIPS Pn). Grazing incidence wide-angle X-ray scattering (GIWAXS) images indicated both edge- and face-on orientations of the semiconductor for these devices while electrical measurements revealed field-effect mobilities up to 10-3 cm2V-1s-1 and on/off current ratio of 103.

Our method has the combined advantages of low temperature and ambient pressure deposition while eliminating the drawbacks of solvents or the high cost of evaporation equipment. Further, as a digital printing method, the laser-printed layer is easily patternable as designed by any convenient graphics software. Since the powder is transferred in a dry state, surface dewetting is no longer an issue, which opens the door to even more substrate/dielectric materials that would otherwise reject solutions from adhering.

10365-9, Session 2

Inkjet-printed intrinsically stretchable conductors and interconnects

Ulrike Kraft, Francisco Molina-Lopez, Chenxin Zhu, Yue Wang, Zhenan Bao, Boris Murmann, Stanford Univ. (United States)

Future electronics will be wearable and in close contact to the skin. However, to accommodate for deformations such as twisting and stretching, these next-generation electronics need to be stretchable. One viable approach towards stretchable electronics is the development of intrinsically stretchable electronic materials, devices and circuits. Recently, the first

intrinsically stretchable transistors have been demonstrated. However, for the realization of stretchable circuits, stretchable interconnects that connect the circuit components, such as transistors or capacitors, are very important. Therefore, intrinsically stretchable, conductive films based on doped PEDOT:PSS are also being investigated (Y. Wang, Z. Bao et al., Science Advances, accepted). Ionic additives act as dopants and plasticisers in this approach.

For the deployment of highly stretchable materials as interconnects and electrodes, patterning is crucial. Therefore, we developed a process for inkjet printing of intrinsically stretchable PEDOT:PSS-based interconnects and conductors and also via holes. A customized ink was printed on stretchable polymeric substrates (SEBS, styrene-ethylene-butadiene-styrene) and optimized to achieve a smooth morphology of the printed features by adjusting the surface tension and suppressing the coffee stain effect. The printed interconnects have a conductivity of 700 S/cm, sustain strains above 100% and show good stability in 1000-cycle stretching experiments. Besides the morphology, the electrical properties and the stretchability, we also investigated the bias-stress stability, the long-term stability in ambient air and the cycling stability.

With these findings, we will be able to connect individual transistors and build intrinsically stretchable circuits, such as health monitoring devices that can be directly attached to the skin.

10365-10, Session 2

Organic vapor-jet printing with reduced heat transfer for low-cost flexible organic electronics

Sungyeon Kim, Jung-Min Choi, Hanul Moon, Hyukyun Kwon, Jaehyeok Park, Seunghyup Yoo, KAIST (Korea, Republic of)

Organic vapor-jet printing (OVJP) is a promising organic thin-film deposition method that combines the advantages of mask-free, on-demand printing technologies and field-proven vacuum thermal evaporation techniques for small molecules [1]. However, its applications have been limited mostly to rigid substrates due to the excessive heat transfer from the heated nozzle head to the substrate. Hence, this study aims at reducing the radiative heat transfer to the underlying medium and thus broadening the use of OVJP even to temperature-sensitive cases. In particular, we focus on high-resolution flexible device fabrication, in which a small substrate-to-nozzle gap is necessary. To this end, we apply a low-emissivity coating on the nozzle via electrochemical deposition. It turns out that the proposed method can exert a significant effect on mitigating the deformation of plastic films, while maintaining temperature conditions and the substrate-to-nozzle distance. Using the proposed nozzle, we have succeeded in fabricating devices on plastic substrates. As an example, we demonstrate a fabrication of flexible active-matrix sensor arrays and flexible signage-type organic light-emitting diodes (OLEDs) on polyethylene terephthalate (PET) substrates. Both devices showed performances comparable to devices fabricated with vacuum thermal evaporation. We believe the results shown in the present study indicate that OVJP can be used also in devices or systems involving flexible substrates or heat-sensitive elements, providing one with an opportunity to unlock its full potential as a reliable additive fabrication technology for low-cost flexible electronics.

A lattice-strained organic single-crystal nanowire array fabricated via solution-phase nanograting-assisted pattern transfer for use in high-mobility organic field-effect transistors

Kyunghun Kim, Yebyeol Kim, Pohang Univ. of Science and Technology (Korea, Republic of); Se Hyun Kim, Yeungnam Univ. (Korea, Republic of); Chan Eon Park, Pohang Univ. of Science and Technology (Korea, Republic of)

Crystal orientation and polymorphism of organic semiconductors (OSCs) are crucial factors in determining the electrical performance of organic field-effect transistors (OFETs). Herein, uniaxially-aligned and lattice-strained organic single crystal nanowire (NW) array is fabricated via a straightforward solution processing technique called as ‘nanograting-assisted pattern transfer’. 50 nm-wide 6,13-bis(triisopropylsilylethyn yl) pentacene (TIPS-PEN) NWs are grown while the solution is confined between a substrate and a flexible nanograted template. From UV-vis absorption and grazing incidence wide angle X-ray scattering experiments, NWs are found to be single crystalline and adopt an anisotropic crystal orientation for efficient charge transport. Notably, the crystal growth under nano-confined spaces results in lattice-strained packing motif of NWs with close ϖ-ϖ stacking distance. TIPS-PEN NW OFETs yield extremely high field-effect mobilities (?FETs) up to 9.71 cm2/(V?s) with narrow ?FET distribution. In addition, the nanograting-assisted pattern transfer technique is applied on flexible substrates, demonstrating high-performance flexible OFETs. From these findings, it is expected that the nanograting-assisted pattern transfer technique provides a general method for realization of high ?FET OFETs, and also a facile soft lithographic method for nanoscale patterning of well-grown crystallites.

Understanding doped organic field-effect transistors

Shiyi Liu, Akram Al-Shadeedi, Vikash Kaphle, Changmin Keum, Björn Lüssem, Kent State Univ. (United States)

Organic field-effect transistors (OFETs) have the potential to become the basic building block of a flexible electronics technology used e.g. in displays with novel form factors or low-cost or wearable sensors systems. Doping these transistors can make them not only more reliable and reproducible [Applied Physics Letters 104, 013507 (2014)], but opens new ways to tune their characteristics or even realize novel transistor concepts [Nature communications 4, 2275 (2013)].

To realize the full advantages of doping, a detailed understanding of the influence of doping on the flatband voltage, the pinch-off voltage, and the threshold voltage of the OFET has to be developed. In this presentation, pentacene-based organic field effect transistors (OFETs) and metal insulator semiconductor (MIS) junctions are studied by current-voltage (I-V) and capacitance-voltage (C-V) measurements. Based on the experimental results, a new analytical model of doped OFETs is presented that describes the influence of a shift in the flatband voltage due to doping on the pinch-off voltage and saturation in OFETs quantitatively.

Meanwhile, it is shown that OFETs become much less sensitive to gate bias stress by inserting a doped layer in the channel region of OFETs. By a series of carefully designed transistors, it is shown that this increase in stability originates from a change at the organic semiconductor/gate insulator interface.

Overall, the presented results provide for a detailed understanding of doping related effects on OFET behavior. It opens new approaches to optimize OFETs or even develop new organic transistor concepts.

10365-39, Session PMon

Enhanced performance in n-type organic field-effect transistors using non-conjugated polyelectrolytes

Yu Jung Park, Dong-A Univ. (Korea, Republic of)

To enhance electron injection in n-type organic field-effect transistors (OFETs), a non-conjugated polyelectrolyte (NPEs) layer was interposed between a [6,6]-phenyl-C61-butyric acid methyl ester (PCBM) layer and Au electrodes. Novel NPEs with various counterions (Cl-, Br-, I-) improved the electron mobilities up to ~10-2 cm2V-1s-1 and on-off ratios (Ion/Ioff) of 105. Ultraviolet photoemission spectroscopy (UPS) indicates that reduced electron injection barrier at NPE/metal interface was induced by dipole formation and led the improved electron injection and transport. These findings are important for understanding how NPEs function in devices, improve the device performance, and design of new materials for use in optoelectronic devices.

10365-41, Session PMon

Submicron-channel-length n-channel organic thin-film transistors fabricated by stencil-mask lithography

Ute Zschieschang, James W. Borchert, Max-Planck-Institut für Festkörperforschung (Germany); Florian Letzkus, Joachim N. Burghartz, Institut für Mikroelektronik Stuttgart (Germany); Hagen Klauk, Max-Planck-Institut für Festkörperforschung (Germany)

Using high-resolution stencil-mask lithography, we have fabricated bottom-gate, top-contact (inverted staggered) n-channel organic thin-film transistors that have a channel length of 0.3 μm, gate-to-source and gate-to-drain overlaps of 20 μm and channel widths ranging from 5 to 100 μm. As the semiconductor we used the commercially available small-molecule material Polyera ActivInkTM N1100 (bis(heptafluorobutyl)-dicyano-perylene tetracarboxylic diimide). The gate dielectric is a combination of oxygen-plasma-grown aluminum oxide and a fluoroalkylphosphonic acid self-assembled monolayer with a total thickness of 5.7 nm. Owing to the small channel length, the transistors have a large channel-width-normalized transconductance of 0.09 S/m, despite the relatively small electron mobility of 0.03 cm2/Vs. The transistors also have an on/off current ratio of 5?107 and a subthreshold slope of 160 mV/decade, which are to our knowledge the largest on/off ratio and the steepest subthreshold slope reported to date for submicron-channel-length n-channel organic transistors.

10365-42, Session PMon

Optimization of a hydroxyl-containing polymer mixture as gate dielectric for low-temperature, solution-processed organic thin-film transistors and logic circuits on a flexible substrate

Hyunjin Park, Jimin Kwon, Sungjune Jung, Pohang Univ. of Science and Technology (Korea, Republic of)

A polymer gate dielectric is one of the key elements of high-performance solution-processed organic thin-film transistors (OTFTs) for low-cost, large-area, flexible electronic applications. For decades, a hydroxyl-containing mixture of poly(4-vinylphenol) (PVP) and poly(melamine-co-formaldehyde) (PMF) has been widely used as gate dielectric in OTFTs due to its low gate leakage current, high dielectric constant, and good chemical compatibility. However, the polymer mixture has been compatible only with suitably engineered expensive plastic substrates due to its high curing temperature for crosslinking (typically higher than 175 °C) to remove hydroxyl groups that might cause hysteretic device characteristics. In this work, we report OTFTs with negligible hysteresis, low gate leakage current, and high on/off drain current ratio, even though the dielectric film was cured at 100 °C. We investigated the influence of various PVP:PMF mixture conditions such as weight ratio (0.2:1 to 5:1) and curing temperature (100 to 200 °C) on the performances of 6,13-bis(triisopropylsilylethynyl) OTFTs. We found that the OTFT using a PVP:PMF mixture with the weight ratio of 0.5:1 cured at 100 °C showed the best device performance for hysteresis, gate leakage current, and on/off drain current ratio. Fourier transform infrared spectroscopy results provided the evidence that device performances were influenced by PVP:PMF mixture related to non-hydrogen-bonded hydroxyl groups which might evoke water absorption.. Finally, we demonstrated OTFTs and diode-connected inverters on a 3-?m-thick flexible parylene film. This work shows that PVP:PMF mixture is a suitable dielectric material to fabricate flexible electronic devices and circuits on inexpensive plastic substrates.

10365-43, Session PMon

Thermal annealing effect on the stability of C60 thin-film transistor with a lithium fluoride protective layer

Bo Yao, Yan Li, Zebo Fang, Shaoxing Univ. (China)

Organic thin-film transistors (OTFTs), compared to the traditional inorganic transistors, demonstrate attractive advantages of light-weight, low cost and flexibility, and are the best candidates for large-scale flexible display, sensors and organic integrated circuit. A high-performance complementary logic circuit requires p-type and n-type transistors with high and balanced hole and electron mobilities. However, stable n-type organic semiconductors are rare and the current level of electron mobility of n-type organic semiconductors remains much lower than that of p-type organic semiconductors. At present, the field-effect mobility of single crystal C60 TFTs has reached 6 cm2/Vs, which has already exceeded than that of amorphous silicon TFTs. However, the air stability of C60 based n-type TFTs needs to be improved for possible industrial applications. In this paper, bottom-gate top-contact C60 TFTs with a lithium fluoride (LiF) protective layer was investigated. It is shown that the performances of C60 TFT with a LiF protective layer has been improved by vacuum annealing at 120 ? during various long-time annealing treatments. With the increase of annealing time, the saturated drain current and the on/off current ratio of the devices are significantly increased, the output characteristics are more stable. This shows that n-type OTFTs' stable performance can be enhanced by encapsulated a LiF protection layer with an appropriate annealing treatment.

10365-11, Session 3

Exploring disorder and polymorphism in small-molecule organic semiconductors *(Invited Paper)*

John E. Anthony, Univ. of Kentucky (United States)

Along with the precise orientation of crystals in the solid state determined from the crystal structure, the electronic performance of small molecule organic semiconductors is also influenced by a variety of disorder parameters common to soft materials. In chromophores of reduced symmetry, variations in orientations of the chromophore can yield subtle changes in intermolecular interactions that impact both crystal packing and the quality of films grown from such materials. Using weakly interacting supramolecular synthons, we can tune chromophores to enhance or diminish these subtle forms of disorder, to explore their impact both on calculated electronic coupling and on the transport properties observed in organic field-effect transistors. More recently, we have shown how certain vibrational modes can be highly detrimental to transport properties in materials functionalized across the short axis of a high-aspect-ratio chromophore. I will present our recent approaches to mitigate these vibrations, to determine whether short-axis functionalization strategies can yield processable ultra-high-mobility organic semiconductors.

10365-12, Session 3

Electronic and morphological traps in conjugated polymers *(Invited Paper)*

Alberto Salleo, Stanford Univ. (United States)

Efficient charge transport is needed in all electronic devices. For instance, the fill factor of solar cells is lowered when charge extraction is not efficient. In transistors, carrier mobility is directly linked to the transit time across the channel and therefore to switching speed. Carrier mobility is adversely affected by electronic traps, which are regions where charge delocalization is suppressed. By combining sensitive spectroscopy in the IR with theory, we can infer the degree of delocalization of the polarons and relate it to microstructural features. The delocalization of the polaron depends on charge density, as fixed by the gate voltage in a transistor architecture. A second type of trap, which is purely morphological, is unique to macromolecules. The polymer conformation dictated by the rigidity of the chain, induces kinks. When these kinks push charges against the direction of the field, a morphological trap is created. I will show how these traps affect charge transport. The effect of field and molecular weight will be described in more detail.

10365-13, Session 3

Highly reproducible single-crystalline organic thin-film transistors by minimizing morphological defects in crystalline templating layers

Robby Janneck, IMEC (Belgium) and KU Leuven (Belgium); Nicolas Pilet, Paul Scherrer Institut (Switzerland); Satya P. Bommanaboyena, IMEC (Belgium); Benjamin Watts, Paul Scherrer Institut (Switzerland); Paul Heremans, Jan Genoe, IMEC (Belgium) and KU Leuven (Belgium); Cedric Rolin, IMEC (Belgium)

Organic thin films transistors based on single-crystalline thin films offer great potential for the realization of high-performance, low-cost large area electronics. The fabrication of these films directly on the substrate with limited morphological defects pose one of the biggest challenge for their commercial application. Even though tremendous progress has been made in optimizing fabrication techniques, the resulting layers nevertheless typically show defects such as cracks, voids or ribbon-like growth. Here we employ a two-step fabrication method that yields single-crystalline layers with negligible morphological defects. We use a commonly used solution coating technique to fabricate a crystalline layer showing the typical ribbon-like growth. This layer acts as a templating layer for the subsequent deposition step, which repairs most of the morphological defects. In our case this results in a mobility increased by a factor of three and a relative spread in device characteristics improved by almost half an order of magnitude. In particular, for the case of C8-BTBT, we reproducibly achieved average thin film mobilities of 10cm2/Vs with device-to device parameter spreads of only 10%. This double step method is easily adoptable to different coating techniques and small molecules, enabling a route towards the fabrication of highly reproducible, high-performance large area electronics.

10365-14, Session 3

1D versus 2D growth of TIPS-pentacene in TIPS-pentacene/insulating polymer blends

Wi Hyoung Lee, Konkuk Univ. (Korea, Republic of)

Organic semiconductor/insulator polymer blends have been widely used in the manufacturing process of field-effect transistors (FETs) to overcome the disadvantages of FETs based on organic semiconductor. In this study, phase-separation characteristics and structural developments of 6,13-bis(triisopropylsilylethynyl)-pentacene (TIPS-pentacene)/insulating polymers were examined to enhance electrical properties of their blends for uses in active layers of FETs. Especially, phase-separation characteristics of TIPS-pentacene/insulating polymer blends were greatly affected by the processing condition such as spin coating time. Although TIPS-pentacene-top/insulating polymer-bottom vertically phase separated structures were formed onto the substrate regardless of spin-time, spin coating time governed growth mode of phase-separated TIPS-pentacene onto phase-separated insulating polymer. Excess residual solvent in short spin-coating time induces convective flow in a drying droplet, thereby resulted in one-dimensional (1D) growth of TIPS-pentacene crystals. On the other hand, optimum residual solvent in moderate spin coating time led to two-dimensional (2D) growth of TIPS-pentacene crystals. These 2D spherulites onto insulating polymer was quite advantageous for increasing field-effect mobility of FETs because of higher perfectness and coverage of TIPS-pentacene crystals compared to those of 1D crystals. In addition, when TIPS-pentacene was blended with various types of insulating polymers, critical spin-coating time was changed due to the different surface energy of the insulating polymers. Insulating polymer with lower surface energy was advantageous for increasing film formation time, thereby increasing time for phase-separation and crystallization.

10365-15, Session 3

Transport pathways in organic semiconducting polymers *(Invited Paper)*

Michael L. Chabinyc, Univ. of California, Santa Barbara (United States)

Thin film transistors with semiconducting polymers can exhibit high hole and electron carrier mobilities. There is a clear connection between microstructure and carrier mobility because of the need for carriers to move along and between single polymer chains. While local order is readily observed by methods such as wide angle X-ray scattering, significantly less is known about the detailed structure on longer length scales (100s nm) in thin films. We have studied the structural order in well-performing p-type semiconducting polymers using high resolution transmission electron microscopy (HR-TEM) to reveal how regions of ordered chains are connected. In a series of N-alkylthieno[3,4-c]pyrrole-4,6-dione (TPD)-based polymers, examination of the structure of nanoscale domains reveals multiple polymorphic structures, rather than typically assumed paracrystalline domains. The structure of the crossings of ordered domains observed in HR-TEM also suggests a rationale for changes, or lack thereof, in texture of the conjugated backbone upon thermal annealing in these systems. We will discuss a new computational framework that improves the analysis of HR-TEM images of soft materials and provides statistically robust information about percolation pathways for charge transport.

10365-16, Session 4

Multi-component organic blend semiconductors for transistor applications *(Invited Paper)*

Thomas D. Anthopoulos, King Abdullah Univ. of Science and Technology (United Kingdom)

The increasing demand for thin-film transistors (TFTs) technologies with improved carrier mobility and operating stability has been the driving force behind the tremendous progressed witnessed in recent years in the field of organic TFTs (OTFTs). A common approach towards this goal has been the development of new compounds with improved electronic and processing characteristics. In this presentation I will discuss an alternative strategy to materials, and ultimately OTFT and integrated circuits, development based on the use of molecular additives in combination with semiconducting blends. I will describe how the incorporation of different types of additives can lead to semiconducting systems and OTFTs that combine highly attractive features such as solution processability, high carrier mobility and enhanced bias stability. The role of the molecular additives and the

underlying mechanism responsible for the performance enhancement observed in several different blend systems will also be discussed.

10365-17, Session 4

Polarization-induced transport in organic field-effect transistors: the role of ferroelectric dielectrics *(Invited Paper)*

Suchi Guha, Amrit Laudari, Univ. of Missouri (United States)

The tuning of the dielectric constant in polymer-ferroelectric dielectrics with temperature offers a platform for monitoring changes in interfacial transport with the polarization strength in organic field-effect transistors (FETs). The charge transport mechanism in an organic semiconductor often occurs at the interface of bandlike coherent motion and incoherent hopping through localized states. By choosing two small molecule semiconductors, pentacene and 6,13 bis(triisopropylsilylethynyl)pentacene (TIPS-pentacene), which have distinct differences in their bulk transport properties, we show that ferroelectric dielectrics such as poly(vinylidene fluoride-co-trifluoroethylene) (PVDF-TrFE) allow an observation of bandlike transport with a negative temperature coefficient of the mobility in FETs, when the semiconductor shows discrete-trap space-charge-limited conduction. Pentacene-based FETs show a weak temperature dependence of the charge carrier mobility in the ferroelectric phase of PVDF-TrFE, which is attributed to polarization fluctuation driven transport resulting from a coupling of the charge carriers to the surface phonons of the dielectric layer [1]. By comparing single layer PVDF-TrFE pentacene FETs with stacked PVDF-TrFE/inorganic dielectric FETs, the contribution from Froehlich polarons is extracted. TIPS-pentacene based FETs using PVDF-TrFE show bandlike transport beyond 200 K. The polarization fluctuation dominant transport inherent to a ferroelectric dielectric, in conjunction with the nature of traps, results in an effective de-trapping of the shallow-trap states into more mobile states in TIPS-pentacene [2].

10365-19, Session 4

Significance of the double-layer capacitor effect in solution-processable polymeric dielectrics and exceptionally stable low-voltage organic transistors

Raphael Pfattner, Amir Foudeh, Celine Liong, Chao Wang, Wen-Ya Lee, Desheng Kong, Zhenan Bao, Stanford Univ. (United States)

High-performance FETs based on organic active materials are of particular interest due to their compatibility with low-cost, high-throughput processing and mechanical compliance with soft tissues. Due to the relatively low charge carrier mobilities of organic materials, often high operational voltages have to be applied and result in severe limitations. To overcome these issues high gate capacitance materials are needed. One appealing approach is the fabrication of ultra-thin dielectric layers, which, however, are technologically very challenging to make and suffer often from high leakage problems.

Here, we discovered that a polar fluorinated PVDF-HFP dielectric, despite of a low ion concentration, is able to induce an electric double-layer charging effect under an applied gate voltage. This polymer dielectric is solution-processable with a high static capacitance of about 0.3 ?F/cm2, even at a thickness of several micrometers. Furthermore it is highly compatible with solution processing of various organic semiconductors. Remarkably, the resulting devices showed both high current output and low bias stress in both ambient and aqueous conditions making it the ideal candidate for low-voltage and stable device operation.[1,2] Furthermore, based on this novel dielectric material, some proof of concept BioSensor devices with the capability of working in complex physiological liquids have been developed.

10365-20, Session 5

Developing theory-driven approaches to design organic semiconducting materials *(Invited Paper)*

Chad Risko, Univ. of Kentucky (United States)

Semiconducting materials derived from organic, ϖ-conjugated molecules or polymers have drawn the attention of materials chemists for decades because of the potential to modulate material (opto)electronic properties through well-established synthetic chemistry methods. Unfortunately, materials design remains highly Edisonian, due to limited knowledge among the intimate relationships that connect chemical composition and molecular architecture, material processing, and the solid-state packing arrangements that define the underlying physicochemical processes that determine material performance. We seek to address these connections through the development and application of multiscale, theoretical materials chemistry approaches that build upon principles from organic and physical chemistry, condensed matter physics, and materials science. In this presentation, we will focus on how these models can reveal the striking influence of seemingly modest changes in chemical structure on the solid-state packing of organic semiconducting active layers and resulting characteristics of importance to charge-carrier transport. The chemical insight developed through these investigations is beginning to refine and offer novel design paradigms essential to the development of next generation organic semiconducting active layers, and is opening new pathways for in silico materials development.

10365-21, Session 5

Indolo-naphthyridine-6,13-dione thiophene building block for conjugated polymer electronics: Molecular origin of ultrahigh n-type mobility *(Invited Paper)*

Kealan Fallon, Univ. College London (United Kingdom); Nilushi Wijeyasinghe, Imperial College London (United Kingdom); Eric Manley, Tobin Marks, Northwestern Univ. (United States); Thomas D. Anthopoulos, King Abdullah Univ. of Science and Technology (Saudi Arabia); Hugo A. Bronstein, Univ. College London (United Kingdom)

We present the synthesis and characterization of four conjugated polymers containing a novel chromophore for organic electronics based on an indigoid structure. These polymers exhibit extremely small band gaps of ?1.2 eV, impressive crystallinity, and extremely high n-type mobility exceeding 3 cm2 V s–1. The n-type charge carrier mobility can be correlated with the remarkably high crystallinity along the polymer backbone having a correlation length in excess of 20 nm. Theoretical analysis reveals that the novel polymers have highly rigid nonplanar geometries demonstrating that backbone planarity is not a prerequisite for either narrow band gap materials or ultrahigh mobilities. Furthermore, the variation in backbone crystallinity is dependent on the choice of comonomer. We find that electron mobility can be correlated to the degree of order along the conjugated polymer backbone. Finally, we use this novel system to begin to understand the complicated effect of alkyl chain variation on the solid state packing in all 3 dimensions.

10365-22, Session 5

Truxenones on coinage metal surfaces: structure and epitaxial templating

Luke A. Rochford, The Univ. of Birmingham (United Kingdom); Alexandra J. Ramadan, Univ. of Oxford (United Kingdom); Christian Nielsen, Queen Mary, Univ. of London (United Kingdom)

The interface between organic molecules and metallic surfaces is integral to the performance of organic optoelectronic devices. Considerable efforts have been focused on the synthesis and processing of novel donor and acceptor materials for high performance devices. Despite this, there is little understanding of the fundamental behaviour of these molecules at relevant metallic surfaces. The truxenone family of small molecule semiconductors exhibit three-fold symmetry, have stabilised lowest unoccupied molecular orbital (LUMO) energy levels, independently conjugated branches from the core and have been shown to exhibit promising properties as electron acceptors in organic solar cells. Our recent work has demonstrated that Truxenones self-assemble to form epitaxial open-pored structures on Cu (111), a highly unusual observation in semiconducting organic molecules. This assembly is affected by the choice of metal substrate and data from analogous Ag (111) and Au (111) interfaces will be compared and contrasted. In addition the use of a commensurate epitaxial truxenone template to direct the growth of commensurate epitaxial C60 layers will be shown. This strategy imparts the structural symmetry and in-plane structural order of the substrate into the molecular template and subsequent C60 layers and has implications for the growth of single-crystalline organic interfaces and devices.

10365-23, Session 5

Organosilicon derivatives of BTBT for monolayer organic field effect transistors

Sergey A. Ponomarenko, Institute of Synthetic Polymeric Materials (Russian Federation) and M.V. Lomonosov Moscow State Univ. (Russian Federation); Oleg V. Borshchev, Elena V. Agina, Marina S. Polinskaya, Alexey S. Sizov, Askold A. Trul, Institute of Synthetic Polymeric Materials (Russian Federation); Viktoria P. Chekusova, Bauman Moscow State Technical Univ. (Russian Federation) and Institute of Synthetic Polymeric Materials (Russian Federation); Maxim A. Shcherbina, Institute of Synthetic Polymeric Materials (Russian Federation) and Russian Research Ctr. Kurchatov Institute (Russian Federation); Sergei N. Chvalun, Russian Research Ctr. Kurchatov Institute (Russian Federation) and Institute of Synthetic Polymeric Materials (Russian Federation)

Development of efficient self-assembled monolayer field-effect transistors (SAMFETs) is a great challenge for organic electronics. Recently we reported organosilicon derivatives of oligothiophenes capable to monolayer formation on the water-air interface, which were used for fast and efficient SAMFETs fabrication by Langmuir-Blodgett (LB) and Langmuir-Schaefer (LS) techniques [A.S. Sizov, et al., Langmuir, 2014, 30, 15327; E.V. Agina, et al., Proc. SPIE, 2015, 9568, 95680Z]. In this work we synthesised novel organosilicon derivatives of mono- and dialkyl substituted [1] benzothieno[3,2-b][1]-benzothiophene (BTBT) containing flexible aliphatic spacers linked to chlorosilane or disiloxane anchor groups [O.V. Borshchev, et al., Chem. Commun., 2017, 53, 885]. They were successfully used for LB and LS SAMFETs preparation, which showed the charge carrier mobilities up to 0.02 cm2/Vs, threshold voltage close to 0 V and On/Off ratio up to 10,000. The results obtained confirmed that the presence of covalent bonds between a semiconducting monolayer and a substrate is not crucial for the monolayer OFETs performance. In this report, influence of the chemical structure of the molecules synthesized (type of the anchor group, spacer length, presence or absence of hexyl end-group) on the morphology, molecular 2D ordering in the monolayers and their semiconducting properties will be considered. Different methods of the ultrathin layer preparation, such as LB and LS, as well as spin coating and doctor blade, and their effect on the OFET performance will be compared and discussed.
This work was supported by Russian Foundation for Basic Research (grants 16-29-05321 and 17-03-00222).

10365-24, Session 5

On the importance of alkyl chains in organic semiconductors *(Invited Paper)*

Bob C. Schroeder, Queen Mary, Univ. of London (United Kingdom)

Organic semiconductors are an intriguing class of materials because of their facile processability and good charge carrier properties. In order to employ conventional large scale printing techniques such as roll-to-roll or inkjet printing, it is important to understand how the viscosity of conjugated polymer solutions can be tweaked in order to be suitable for a wide variety of printing techniques. In many organic semiconductors the processability and the electronic properties are intimately intertwined, making it difficult to change one without negatively affecting the other. Decorating high performing conjugated polymers with long alkyl side chains is one of the most popular approaches to enhance the material's processability, however often at the expense of lower charge carrier mobilities. Gaining a fundamental understanding on how alkyl side chains affect transport characteristics is a key requirement to develop more processable and ye high performing semiconducting polymers suitable for industrial printing techniques.

In this talk, we will present a series of alternative approaches to incorporate electrically insolating alkyl side chains into semiconducting polymers, whilst maintaining excellent charge carrier mobilities. Our findings highlight that a better understanding of side chain geometry and architecture, cannot only lead to significantly enhanced material properties, but also allows to control the molecular packing and orientation down to the nanoscale.

10365-25, Session 6

Fast unipolar and complementary circuits based on organic thin-film transistors on flexible substrates *(Invited Paper)*

Hagen Klauk, Max-Planck-Institut für Festkörperforschung (Germany)

Organic thin-film transistors (TFTs) can typically be fabricated at temperatures below 150 °C and thus not only on glass, but also on unconventional substrates, such as plastics and paper. This makes organic TFTs potentially useful for flexible, large-area electronics applications, such as rollable or foldable displays and conformable sensor arrays. In some of the more advanced applications envisioned for organic TFTs, the TFTs have to control electrical signals of a few volts at frequencies of several megahertz. The first requirement for achieving high switching frequencies is efficient charge transport in the semiconductor. This requirement can be met by choosing organic semiconductors that provide good molecular ordering and large carrier mobilities, even when processed at low temperatures. Examples are the thienoacene DNTT and its alkylated or phenylated derivatives for p-channel TFTs and the core-cyanated perylene diimide derivative Polyera ActivInk N1100 for n-channel TFTs. The second requirement is a small channel length. To meet this requirement, we have developed a process in which the TFTs are patterned using high-resolution silicon stencil masks. With this process, bottom-gate, top-contact organic TFTs with a channel length of about 1 μm can be fabricated on plastic substrates. For 11-stage complementary and unipolar ring oscillators based on TFTs with a channel length of 1 μm, signal propagation delays per stage as short as 6.6 μs and 420 ns have been measured at a supply voltage of 3 V.

10365-26, Session 6

Understanding and improving the operational stability of polymer field-effect transistors *(Invited Paper)*

Thuc-Quyen Nguyen, Univ. of California, Santa Barbara (United States)

Polymer field effect transistors (PFETs) have potential applications in large-area flexible displays, sensors, radiofrequency identification tags, and logic circuits with low-cost processability. However, they are still inadequate for commercialization and practical implementation due to their operational instability. We investigated the mechanism of the electrical instability of high performing PFETs that show a certain degree of ambipolarity and unraveled the effect of electron conduction on the stability of hole current and the double-slope behavior. The model polymer used in this study is regioregular D-A copolymer poly[4-(4,4-dihexadecyl-4H-cyclopenta[1,2-b:5,4-b']dithiophen-2-yl)-alt-[1,2,5]thiadiazolo[3,4-c]pyridine] (PCDTPT). While performing current-voltage measurement, we found that consecutive sweeping of gate voltage changed the shape of the transfer curves. We conducted a thorough study of bias-stress of the system and found that electron trapping at the gate dielectric/polymer interface greatly alters the device characteristics including the occurrence of the double-slope. We provide several solutions to improve the device operational stability.

10365-27, Session 6

Understanding the working mechanisms of organic permeable-base transistors

Akram Al-Shadeedi, Changmin Keum, Shiyi Liu, Vikash Kaphle, Kashi Subedi, Björn Lüssem, Kent State Univ. (United States)

Organic Permeable Base Transistors (OPBTs) [J. Phys.: Condens. Matter 27, 443003 (2015)] show excellent performance, which make them a viable option for high-speed flexible electronics. They operate at low voltages (<2V), reach large ON-state currents (>1A/cm2), and can be processed without the need for high-resolution patterning techniques [Appl. Phys. Lett. 101, 213303 (2012); Adv. Mater. 27, 7734 (2015)]. However, despite some progress during the last years [J. Appl. Phys. 120, 094501 (2016)], the precise working mechanism of is still under discussion, in parts due to a lack of systematic experimental data.

In this presentation, we discuss the influence of the device area, thickness of base electrode, and annealing conditions on the OPBT performance. Based on a thorough optimization of the individual diodes the OPBT consists of, the ON/OFF ratio, transconductance, and amplification of the devices is optimized. Best devices reach an ON/OFF ratio of larger than 10^6, a transconductance above 2 S/cm^2, and an amplification of 10^2.

Based on this larger experimental effort, a 2D numerical model is developed that describes the experimental trends correctly. Strategies are presented to improve the performance of OPBTs further. In particular, it is argued that the current gain of the OPBT can be significantly increased without reduction in device performance by a reduction of charge injection at the base electrode. Experimental strategies to reduce base currents are proposed and first experimental data that validates these strategies is presented

10365-28, Session 6

Probing the origins of temperature dependence of charge transport in organic single crystal transistors

Emily G. Bittle, Adam J. Biacchi, Lisa Fredin, Andrew A. Herzing, Thomas Allison, Angela Hight Walker, David J. Gundlach, National Institute of Standards and Technology (United States)

Low temperature transport measurements of classical semiconductors are a well-defined method to determine the physics of transport behavior. These measurements are also used to evaluate organic semiconductors, though physical interpretation is not yet fully developed. The similar energy ranges of the various processes involved in charge transport in organic semiconductors, including excitonic coupling, charge-phonon coupling, and trap distributions, result in ambiguity in the interpretation of temperature dependent electrical measurements. The wide variety of organic semiconductors, ranging from well-ordered small molecule crystals to disordered polymers, manifest varying degrees of "ideal" device behavior and require intensive studies in order to capture the full range of physical mechanisms involved in electronic transport in this class of materials. In addition, the physics at electrical contacts and dielectric material interfaces strongly affect device characteristics and results in temperature dependent behavior that is unrelated to the semiconductor itself. In light of these complications, our group is working toward understanding the origins of temperature dependent transport in single crystal, small molecule organic semiconductors with ordered packing. In order to disentangle competing physical effects on device characterization at low temperature, we use TEM and Raman spectroscopy to track changes in the structure and thermal molecular motion, correlated with density functional theory calculations. We perform electrical characterization, including DC current-voltage, AC impedance, and displacement current measurements, on transistors built with a variety of contact and dielectric materials in order to fully understand the origin of the transport behavior. Results of tetracene on silicon dioxide and Cytop dielectrics will be discussed.

10365-29, Session 7

Interplay between processing and doping of organic semiconductors *(Invited Paper)*

Christian Müller, Chalmers Univ. of Technology (Sweden)

Molecular doping of organic semiconductors is an important tool for the optimization of electronic devices ranging from field-effect transistors to solar cells and thermoelectric generators. In this talk the interplay between processing and the solid-state nanostructure of molecularly-doped conjugated polymers will be discussed, and relevant structure-property relationships will be established. Design criteria that permit to mitigate the often encountered poor compatibility of molecular dopants and organic semiconductors will be introduced. As an example, co-processing of a polythiophene and common molecular dopants will be discussed, resulting in thermally stable films with a high electrical conductivity of 100 S/cm. Finally, the use of insulating matrix polymers will be revisited, which can be used to adjust the rheological and mechanical properties of electrically conducting plastics.

10365-30, Session 7

Thiol-treated palladium and platinum in pentacene bottom contact thin-film transistors *(Invited Paper)*

Marco R. Cavallari, Columbia Univ. (United States) and Univ. de São Paulo (Brazil); Jiho Yoon, Amrita V. Masurkar, Columbia Univ. (United States); Fernando J. Fonseca, Univ. de São Paulo (Brazil); Ioannis Kymissis, Columbia Univ. (United States)

The performance of organic Thin-Film Transistors (TFTs) with bottom contact electrodes is mostly limited by injection energy barrier and semiconductor thin-film lack of crystallinity from electrodes to conducting channel. This is often translated into series resistance effects. Despite its scarcity and cost, thiol-treated gold thin-films are widely-used as source and drain electrodes due to the lack of reliable alternatives. In this work, platinum and palladium noble metals were investigated to replace gold contacts. Furthermore, the effect of a pentafluorobenzothiol (PFBT) monolayer on top of these noble metals in pentacene transistor performance was investigated for the first time. A self-assembled monolayer was formed on both Pt and Pd, demonstrated by atomic force microscopy (AFM), ellipsometry, X-ray photoelectron spectroscopy, contact angle and Kelvin Probe techniques. Even though work function and surface energy varied, differences in pentacene morphology on top of electrode and channel areas persisted even after treatment. In the case of an untreated interface between semiconductor and dielectric, performance of TFTs from alternative metals was comparable to thiol-Au. However, after octadecyltrichlorosilane treatment of SiO2, the presence of a PFBT monolayer could further increase current modulation while achieving a hole mobility beyond amorphous silicon while decreasing series resistance.

10365-31, Session 7

A rational design of polymer semiconductors for high-resolution solution tandem electronics

Han Wool Park, Keun-Yeong Choi, Haejung Hwang, Soongsil Univ. (Korea, Republic of); Boseok Kang, Pohang Univ. of Science and Technology (Korea, Republic of); Kyung Ah Nam, Soongsil Univ. (Korea, Republic of); Yun-Hi Kim, Gyeongsang National Univ. (Korea, Republic of); Kilwon Cho, Pohang Univ. of Science and Technology (Korea, Republic of); Moon Sung Kang, Hojin Lee, Do Hwan Kim, Soongsil Univ. (Korea, Republic of)

Organic electronics has recently attracted a great deal of interest because of its solution-processed potential applications in flexible, wearble and even stretchable devices. Dissolvability of semiconducting organic materials in typical solvents potentially provides these materials with unique opportunities to acheive the electronics with cheaper and simpler manufacturing processes. This opportunity, however, serves as a trade-off when one tries to implement these processes in assembling practical electronic devices, since the as-deposited tandem layers would be defenceless to following solution processes. As a result, this controversial issue remains valid not only while applying advanced printing processes, but also while applying photolithography for semiconducting polymers.

Herein, we describe a whole new type of polymer semiconductors based on sol-gel chemistry, which is capable of remarkably showing chemical and mechanical reliability during sequential photolithography processes. The critical step in a sol-gel reaction is the formation of a highly cross-linked network out of molecular precursors through hydrolysis and condensation reactions. By carefully manipulating this step, we could prepare an orthogonal polymer semiconductor gel thin film with heterogeneous inter-penetrated polymer network (HIPN). The resulting structures yielded films that are highly tolerant against harsh external stimuli. Consequently, formation of high resolution patterns of various semiconductor polymers as well as fabrication of tandem devices and circuits based on multiple semiconducting materials could be readily attained using conventional photolithography processes, and finally fabricate high-resolution CMOS circuits with micron n- and p-type organic channels.

10365-32, Session 7

Self-organized (macro)molecular semiconducting materials for organic electronics and ambipolar charge transport *(Invited Paper)*

Yiming Xiao, Xiaolu Su, Univ. Pierre et Marie Curie (France); Martin Brinkmann, Institut Charles Sadron (France); Benoît Heinrich, Bertrand Donnio, Institut de Physique et Chimie des Matériaux de Strasbourg (France); Ji-Seon Kim, Imperial College London (United Kingdom); Jeong Weon Wu, Ewha Womans Univ. (Korea, Republic of); Jean-Charles Ribierre, EWHA Univ. (Japan); Emmanuelle Lacaze, Institut des NanoSciences de Paris (France); Thierry Barisien, David Kreher, André-Jean Attias, Fabrice Mathevet, Danli Zeng, Univ. Pierre et Marie Curie (France)

The self-organization of ϖ-conjugated organic materials forming highly ordered supramolecular architectures has been extensively investigated in the last two decades in view of optoelectronic applications. Indeed, the control of both the mesoscopic and nanoscale organization within thin semiconducting films is the key issue for the improvement of charge transport properties and achievement of high charge carrier mobilities. These well-ordered materials are currently either self-organized semiconducting polymers or liquid crystals.

In this context, we endeavored to investigate the self-organization of semiconducting liquid crystalline materials incorporating different kind of ϖ-conjugated systems in unique molecular or macromolecular architectures. Here we describe the design and synthesis of (i) dyads and triads combining discotic or calamitic ϖ-conjugated mesogens, and (ii) side-chain liquid crystal semiconducting polymers where the backbone is a ϖ-conjugated polymer and the side groups are ϖ-conjugated discotic mesogens.

In this work, we will give the details on the synthesis, structural characterization and morphology studied by Polarized-light Optical Microscopy (POM), Differential Scanning Calorimetry (DSC), Temperature-dependent small-angle X-ray diffraction, Grazing-incidence X-ray scattering (GIXS) and Atomic Force Microscopy (AFM). Moreover, their charge transport properties studied in OFET configuration will also be depicted.

10365-33, Session 8

Tailoring organic electrochemical transistors through form factor and materials selection *(Invited Paper)*

Jonathan Rivnay, Northwestern Univ. (United States)

Organic electrochemical transistors (OECTs) have gained considerable interest for applications in bioelectronics, neuromorphic computing, and logic circuitry. Their defining characteristic is the bulk-modulation of channel conductance owing to the facile penetration of ions into the (semi) conducting polymeric channel. In the realm of bioelectronics, OECTs have shown promise as amplifying transducers due to their stability in aqueous conditions and high transconductance. These devices can be fabricated in conformable form factors for in vivo stimulation/recording, and for cutaneous EEG and ECG recordings in human subjects. The performance of these devices, their operating conditions, and suitability for certain applications is linked intimately with their form factor and the transport properties of the active materials. In this work we show how thickness can be used to design optimal devices for a range of electrophysiological recording applications. Scaling of device performance with geometry reveals

the importance of the active material's mobility and charge storage capacity (per unit volume) in benchmarking new materials. Such findings have led to the development of a new class of polymers which outperform prototypical conducting polymers (i.e. PEDOT:PSS), and can potentially open new paths for the utility of OECTs in a number of application areas.

10365-35, Session 8

Anomalous behaviors of FeFETs based on polar polymers with high glass temperature

Vasileia Georgiou, National Institute of Standards and Technology (United States) and George Mason Univ. (United States); Dmitry Veksler, Jason P. Campbell, National Institute of Standards and Technology (United States); Pragya R. Shrestha, National Institute of Standards and Technology (United States) and Theiss Research (United States); Jason T. Ryan, National Institute of Standards and Technology (United States); Dimitris E. Ioannou, George Mason Univ. (United States); Kin P. Cheung, National Institute of Standards and Technology (United States)

The low processing temperature of polymeric materials and their wide range of applications make polar polymer based ferroelectric memory very promising and attractive. The typical configuration of the ferroelectric memory cell is the FeFET (Ferroelectric field-effect-transistor) with the polar polymer incorporated in the gate dielectric stack. The memory effect in these devices originates from the polarization of the ferroelectric polymer film and results in a hysteresis of the Id-Vg characteristics. In this study, we fabricated FeFETs based on ultrathin poly-Si channel and CP1-polymer (glass-transition temperature (Tg ~260 C) as the gate dielectric. We investigated the hysteresis of the Id-Vg curves over a wide range of temperatures and frequencies. We observed the effects of thermocycling on the device, such as the change of the hysteresis loop direction at temperatures close to Tg (associated with the change of the dominant hysteresis mechanism), and the simultaneous significant decrease in gate leakage current (which may indicate significant reduction of active defects in the polymer layer). The reversibility of the observed phenomena was also investigated through consecutive thermocycles. Soaking the chip in warm water (60 C) for 3 hours changes the magnitude of the hysteresis loop without changing the direction. The gate leakage current also remains very low. Thus, humidity may play some role in the hysteresis magnitude but not the loop direction, nor does it play any role in the leakage current. In this paper, we will discuss possible explanations of these observations.

Conference 10366: Hybrid Memory Devices and Printed Circuits 2017

Thursday 10–10 August 2017

Part of Proceedings of SPIE Vol. 10366 Hybrid Memory Devices and Printed Circuits 2017

10366-1, Session 1

Organic neuromorphic devices based on electrochemical concepts *(Invited Paper)*

Paschalis Gkoupidenis, Ecole Nationale Supérieure des Mines de Saint-Étienne (France) and Max-Planck-Institut für Polymerforschung (Germany); Dimitrios Koutsouras, Thomas Lonjaret, Shahab Rezaei-Mazinani, Esma Ismailova, Ecole Nationale Supérieure des Mines de Saint-Étienne (France); Jessamyn A. Fairfield, National Univ. of Ireland, Galway (Ireland); George G. Malliaras, Ecole Nationale Supérieure des Mines de Saint-Étienne (France)

Neuroinspired device architectures offer the potential of higher order functionalities in information processing beyond their traditional microelectronic counterparts. In the actual neural environment, neural processing takes place in a complex and interwoven network of neurons and synapses. In addition, this network is immersed in a common electrochemical environment and global parameters such as ionic concentrations and concentrations of various hormones regulate the overall behaviour of the network. Here, various concepts of organic neuromorphic devices are presented based on organic electrochemical transistors (OECTs). Regarding the implementation of neuromorphic devices, the key properties of the OECT that resemble the neural environment are also presented. These include the operation in liquid electrolyte environment, low power consumption and the ability of formation of massive interconnections through the electrolyte continuum. Showcase examples of neuromorphic functions with OECTs are demonstrated, including short-, long-term plasticity and spatiotemporal or distributed information processing.

10366-2, Session 1

Adaptive 2D memory-like devices with molecules and nanoparticles for unconventional computing *(Invited Paper)*

Dominique Vuillaume, Ctr. National de la Recherche Scientifique (France)

We have previously studied the photo-switching performances of azobenzene dithiophene derivative (AzBT) (1) inserted in nanoparticle self-assembled networks (NPSAN) nanodevices.(2) Here, we integrate AzBT-NPSAN in sub-100 nm 6-terminals devices (2 inputs, 4 outputs) and we demonstrate optically-driven reconfigurable Boolean operations associated to the light controlled switching of the molecules. Depending on the conductance pathways inside the AzBT-NPSAN, we identify 3 main output functions with a reconfiguration yield of 65%.(3) Contrary to previous results,(4) the devices work at room temperature and fully exploit the functionality of the molecules (and not Coulomb blockade in NPs). In addition, redox molecule NPSANs exhibit giant NDR (negative differential resistance) and memory effect.(5)

We also investigate how complex non-linearity in the AzBT-NPSAN leads to High Harmonics Generation (HHG), one of the prerequisites of reservoir computing (RC) approaches.(6,7) We show that HHG can be modified by UV illumination which paves the way for the processing of multi-input signals through a device that acts as a reservoir computer. Finally, temperature dependent measurements (4K) demonstrate light-driven increase of co-tunneling into these molecular networks.

10366-4, Session 1

The role of embedded nanoparticles in organic-based resistive nonvolatile memory devices

Giovanni Ligorio, Humboldt-Univ. zu Berlin (Germany); Sebastian Nau, Stefan Sax, NanoTecCenter Weiz Forschungsgesellschaft mbH (Austria); Marco Vittorio Nardi, Humboldt-Univ. zu Berlin (Germany); Norbert Koch, Humboldt-Univ. zu Berlin (Germany) and Helmholtz Zentrum Berlin für Materialien und Energie GmbH (Germany); Emil J. W. List-Kratochvil, Humboldt-Univ. zu Berlin (Germany)

Novel non-volatile memory devices are currently investigated to overcome the limitation of traditional memory technologies. New materials and architectures are being considered to address high-density, high-speed, low-fabrication costs and low power-consumption. Among the candidates competing for new-generation memories, resistive switching non-volatile memory (R-NVM) devices based on hybrid inorganic/organic materials (metal nanoparticles embedded in a conjugated organic host) are emerging. A R-NVM is a simple two-terminal device formed by two electrodes, separated by an active material, where the resistivity can be reversibly switched between two (high/low) states. Bistable electrical switching has been reported for a wide range of material combinations. Nonetheless, the switching mechanism is still under debate.

In unipolar R-NVMs, two distinct classes of switching mechanism have been proposed: one highlights the role of a space?charge field, controlling the current flowing in the device, thus the switching between the different conductive states is due to charging/discharging of the embedded metal NPs. A second reported mechanism is based on filamentary formation/destruction. The electrical switching is explained by the formation of highly conductive localized paths (filaments) within the organics.

In this contribution, we report on a series of carefully conducted experiments to rationalize the role of metal nanoparticles embedded into conjugated organic materials, and address whether the NPs' charging/discharging plays a role in the resistive switching of R-NVMs. The electronic and electric behaviour of the hybrid NP/organic materials was investigated via ultraviolet photoemission spectroscopy, as well as impendence spectroscopy.

Our results provide evidence that the most commonly proposed charging/discharging mechanisms can be excluded as the working mechanism, and there is solid evidence that resistive switching is due to the formation/rupture of filaments.

10366-5, Session 1

Spatial summation of pulse responses of a pair of organic heterogeneous junctions

Fei Zeng, Tsinghua Univ. (China)

Recent studies have found that responses to electrical stimulations in organic semiconductors and/or electrolytes heterogeneous junctions possess features in common with neural synaptic plasticity. Thus, we explore spatial summation of short-term plasticity by using a pair of such junctions. A simple integration of parallel connection displayed frequency selectivity

in the weight modification of charging peaks but not for discharging peaks. Significantly, the weight modification could be linearly summed from those of the two source devices though the absolute peak currents could not. Our system is feasible for synaptic computation including spatial summation and direction selectivity in artificial neural network.

10366-6, Session 2

Printed read-only memories and their operation in mobile readout system *(Invited Paper)*

Xiaojun Guo, Ruolin Wang, Sujie Chen, Wenjiang Liu, Shanghai Jiao Tong Univ. (China)

Printed read-only memory (ROM) would be a key component for many envisioned printed electronics applications such as item identification, anti-counterfeiting, brand protection and supply chain management. This paper will firstly introduce the electrical requirements on the memories to be operated in power constrained mobile readout systems for these targeted applications. Then, two types of printed ROMs, including polymer resistive type ROM and fuse-type electrically programmable write-once-read-many (WORM) ROM, will be presented. For the former, the instability issues associated with the conventional PEDOT: PSS and its interface with contact electrodes will be revealed. This work proves that, by removing the hydrophilic acidic groups in conventional PEDOT: PSS, these instability issues can be well addressed. The ROM tags fabricated based on the modified PEDOT: PSS of neutral pH and inkjet printed silver electrodes present extremely stable performance under both aging and electrical stress tests in air ambient. For the latter, fuse-type WORM ROMs are fabricated using a common material inkjet printer to form both the contact pads and the resistor tracks with the same silver ink and process settings. Based on the dependence of the fusing voltage on the length of the printed resistor track, a new cell structure is proposed to achieve multi-bit memories with greatly saved contact pad numbers for easier external electrical connections than the conventional design. The memory cells also present excellent long-term storage and operation stabilities. The function of the printed ROMs are finally demonstrated with mobile readout hardware systems.

10366-7, Session 2

Towards all inkjet printed electronics *(Invited Paper)*

Piero Cosseddu, Giulia Casula, Stefano Lai, Silvia Conti, Univ. degli Studi di Cagliari (Italy); Annalisa Bonfiglio, Univ degli Studi di Cagliari (Italy)

Organic electronics has been thoroughly investigated as technology for the fabrication of flexible devices enabling a wide range of applications including disposable electronics, smart cards, flexible displas, wearable electronics and sensors. However, in order to make such technology suitable for real applications, reliable, cost efficient approaches for large area fabrication, such as inkjet printing, have to be properly optimized. Moreover, in order to increase the final system portability, and as a consequence, its application range, such devices must be also operated at relatively low voltages.

In this work we present the different solutions we have developed for the routinely fabrication of inkjet printed organic transistors, operating a very low voltages and we report about their employment in the realization of different kinds of sensor devices for monitoring physical (pressure/temperature) and biochemical (eg. pH and/or DNA) stimuli and/or ionizing radiations.

Moreover, the development of organic electronics systems requires also the integration of such smart sensing systems with reliable data storage devices. Among several possible solutions, we will demonstrate that inkjet printing can be employed for the fabrication of high performing memory devices using different approaches, based on printed transistors and resistive switching elements, and that, such devices, can be easily integrated with electrical sensors for the fabrication of printed, flexible smart tags.

10366-8, Session 2

Non-volatile memory diodes based on organic ferroelectrics *(Invited Paper)*

Kamal Asadi, Paul W. M. Blom, Dago M. de Leeuw, Max-Planck-Institut für Polymerforschung (Germany)

Organic electronics has emerged as a promising technology for large-area micro-electronic applications, such as foldable displays, electronic papers, contactless identification transponders, and smart labels. Storing information is a key factor in many of the envisioned applications. A memory element is needed that retains its data in the absence of external power, hence non-volatile, and that further can be programmed, erased, and read-out electrically.

Organic ferroelectric memory diodes are promising candidates. A microstructure is needed that consists of bicontinuous columns of a semiconducting polymer embedded in the matrix of ferroelectric copolymer of vinylidenefluoride with trifluoroethylene (P(VDF-TrFE)). This microstructure can be realized either using a phase separated blends of a semiconducting polymer and P(VDF-TrFE) or using imprint patterning. Memory diode is realized by deliberately choosing an injection limited contact. Depending on the ferroelectric polarization, the current density is high and the diode is in the on-state or the current density is low and the diode is in the off-state. In this contribution we discuss state-of-the-art understanding of the device physics of the ferroelectric memory diodes by taking into account polarization dynamics, and confer the limits for the upscaling.

10366-9, Session 2

Organolead halide perovskites for low voltage resistive switching memories *(Invited Paper)*

Ho Won Jang, Seoul National Univ. (Korea, Republic of)

We report multilevel resistive switching using an organolead halide perovskite (OHP). Solution-processed 400 nm thick $CH_3NH_3PbI_3$ films with Ag top and Pt bottom electrodes exhibited electroforming-free resistive switching with a low SET voltage of ~0.13 V and high ON/OFF ratios of ≈10^6 under ±0.15 V pulses. Based on these extraordinary properties, four-level storage capability of the $CH_3NH_3PbI_3$-based devices was demonstrated. We attributed the high performance resistive switching behavior of the $CH_3NH_3PbI_3$-based devices to the energetically benign migration of anions defects, but further studies are needed to identify the mechanism responsible for the ultralow electric field resistive switching. Enhancements in switching speed, endurance, and retention are also necessary and may be achieved by controlling the doping concentration, crystallinity, and large area compositional uniformity of the OHP film. The inherent structural flexibility and the number of possible combinations for ABX_3-type OHPs will support intensive studies for other electronic device applications beyond resistive switching memories. Finally, we believe that the solution-processed $CH_3NH_3PbI_3$-based cells are promising for microelectronics built on flexible substrates.

10366-10, Session 2

Organic field-effect transistor nonvolatile memories: From fundamental understanding to prototype applications *(Invited Paper)*

Sui-Dong Wang, Soochow Univ. (China)

Organic nonvolatile memories can be key components toward future low-cost, light-weight, flexible and portable electronic products. The memories based on organic field-effect transistors (OFETs) possess advantages of nondestructive reading, capability to integrate data processing and storage,

and compatibility with various substrates. OFET nonvolatile memories face the challenge of simultaneously achieving large memory window, high air stability, long retention time and good rewritable endurance. We firstly elucidate the charge trapping/detrapping mechanism in the memories by a variety of approaches [1-9], including (1) in-situ surface potential mapping, (2) design and tailoring of nano-floating-gate, (3) characterization on memory ambient stability, (4) light response of memory behaviors and (5) probing of current transition point. The charge trapping/detrapping mechanism turns out to be a complex process dependent on both external electrical/optical fields and internal material properties. Secondly, the OFET nonvolatile memories are demonstrated to be promising in the applications of multibit data storage and solar-blind photodetection.

10366-11, Session 3

Hybrid electronic systems powered by printed thermoelectric generators *(Invited Paper)*

Ulrich Lemmer, Karlsruher Institut für Technologie (Germany); André Gall, Matthias Hecht, Karlsruher Institut für Technologie (Germany) and Otego GmbH (Germany); Silas Aslan, Karlsruher Institut für Technologie (Germany); Frederick Lessmann, otego GmbH (Germany) and Karlsruher Institut für Technologie (Germany); Verena Schendel, Karlsruher Institut für Technologie (Germany)

Thermoelectric generators (TEGs) transform heat to electricity without any movable parts. These devices are considered to be an important means of energy harvesting for wearables and sensor nodes for the Internet-of-Things (IoT). Organic semiconductors have recently demonstrated ZT-values approaching the same order of magnitude of those of the best established inorganic materials. Conjugated polymers as well as printable inorganic nanomaterials offer the unique advantage of being processable on printing machines. This opens a pathway for the fabrication of thermoelectric generators with unprecedented low costs thus enabling mass consumer applications. We have developed novel printable PEDOT formulations and a device layout which allow for a roll-to-roll printing process on ultrathin plastic foils. The TEGs are then subsequently fabricated by an automated folding process which allows to adapt the geometry of the devices such that the desired thermal resistance is optimum for the specific thermal boundary condition. Using this approach in combination with designed low power electronics forms the basis for several wireless sensor nodes.

10366-12, Session 3

Methods for fabrication of flexible hybrid electronics *(Invited Paper)*

Yong Zhang, Brent S. Krusor, Ping Mei, David E. Schwartz, Steve E. Ready, Robert A. Street, PARC, A Xerox Co. (United States)

Printed electronics (PE) is an emerging technology with potential applications in flexible displays, smart labels, wearable electronics, soft robotics, and prosthetics. While conventional electronics are fabricated on rigid, inorganic substrates, solution processed materials are compatible with plastic film substrates that are flexible, soft, and stretchable, thus enabling conformal integration with curvilinear objects. In addition, manufacturing by printing is scalable to large areas and is amenable to low-cost sheet-fed and roll-to-roll processes.

PE includes display and sensory components to interface with users and environments. On the system level, PE also requires electronic circuits for power, memory, signal conditioning, and communications. Those electronic components can be integrated onto a flexible substrate by either assembly or printing. PARC has been developing systems and processes for realizing both of these approaches. This talk will present PE fabrication methods with an emphasis on techniques recently developed for the assembly of off-the-shelf chips. A few examples of PE systems fabricated with this approach will also be described.

10366-13, Session 3

Printed soft-electronics for remote body monitoring *(Invited Paper)*

Matti Mantysalo, Tiina Vuorinen, Mahmoud Mosallaei, Vala Jeihani, Antti T. Vehkaoja, Tampere Univ. of Technology (Finland)

Wearable electronics has emerged into the consumer markets over the past few years. Wrist devices and textile integration are common technologies for unobtrusive measuring in sport and wellbeing sectors. Disposable bandages represents a paradigm shift in wearable electronics. Soft-electronics can conform to temporary transfer tattoo and deform with the skin without detachment or fracture.

In this presentation, we focus on printed soft-electronics for remote body monitoring. We will present fabrication and characterization of electrode bandage and temperature sensor. Components are fabricated on thin polyurethane film. Screen-printed interconnects for electrodes have sheet resistances of 36 m?/?, with a standard deviation of 4.5 m?/?, and it can be stretched up to 70% (single pull), and more than 1000 cycles (20% elongation). Stretchable interconnects are demonstrated in disposable electrode bandage. The measured ECG signals is fully satisfactory to compute important cardiac parameters. Temperature sensors are fabricated with inkjet-printed graphene/PEDOT:PSS ink. Sensor characterization was conducted both in inert and ambient atmosphere and the graphene/PEDOT:PSS temperature sensors (thermistors) were able reach higher than 0.06% per degree Celsius sensitivity in an optimal environment exhibiting negative temperature dependence.

10366-14, Session 3

Printed and Flexible Dual-color polymer light-emitting diodes (PLEDs) for optoelectronic sensors *(Invited Paper)*

Donggeon Han, Jonathan Ting, Ana Claudia Arias, Univ. of California, Berkeley (United States)

Here we demonstrate blade coated polymer light-emitting diodes (PLEDs) with different colors on a flexible substrate for optoelectronic sensor applications. Flexible electronics conform well to human body, which makes

them favorable for wearable application. Blade coating is an attractive printing scheme to fabricate electronic devices, in that it is simple to configure and has high throughput. Here, surface energy patterning (SEP) is used to blade coat solution at desired areas. This technique reduces the amount of solution wasted through the sides of the blade, as compared to bladecoating without SEP, which leads to highly homogeneous active layer film and relatively consistent device performance. Using this technique, PLEDs with individual colors, red, green and near infrared (NIR) which are known colors that can be used to detect the condition of haemoglobin, are separately fabricated with blade coating. Luminous Efficacy and EQE of the PLEDs at 1Wsr-1m-2 were 42.7mW/W, 10% for Red, 31.2mW/W, 6.3% for Green, and 8.6mW/W, 3.1% for NIR. Also, SEP is further utilized to bladecoat two PLEDs with different colors on one substrate with no significant changes in the performance of the PLEDs. Before fabricating PLEDs for optoelectronic sensors we assessed design parameters such as minimum required flux and ideal distance between the light source and the detector using solid-state components. Based on the experiment, the PLEDs are fabricated to be used in conjunction with a photodiode to perform pulsating photoplethysmogram (PPG) measurements. Furthermore, with the multicolor PLEDs we successfully demonstrate oxygenation measurement.

10366-15, Session 4

Development of printed large area organic transistors and integrated circuits *(Invited Paper)*

Yong-Young Noh, Dongguk Univ. (Korea, Republic of)

For at least the past 10 years, printed electronics has promised to revolutionize our daily life by making cost-effective electronic circuits and sensors available through mass production techniques, for their ubiquitous applications in wearable components, rollable and conformable devices, and point-of-care applications. In this presentation, I will give a talk on the recent progressive of my group on development of printed organic integrated circuits. I will mainly talk about on development of high performance inkjet printed unipolar and ambipolar polymer field-effect transistors (FETs), and applications to elementary organic complementary logic circuits by applying novel polymer dielectrics, new organic semiconducting and design new printing processes. In particular, we engineered and introduce new concept based for solution processed solid-state electrolyte gate insulators (SEGIs) by precise blending of P(VDF-TrFE) solution and P(VDF-HFP)-[EMIM][TFSI] gel solution resulting, after deposition of a thin film solid gate dielectric FETs, in ultrahigh field-effect mobility (?FET) and stable devices operating at low-voltage for several classes of unconventional semiconductors including ?-conjugated polymers, metal-oxides and other carbonaceous materials. By adding a minute amount (3% volume ratio for the optimal composition) of P(VDF-HFP)-[EMIM][TFSI] to the bulk fluorinated P(VDF-TrFE), high areal capacitance of > 4 µFcm-2 is reached thanks to the combined polarization of the -C-F interface dipoles and electrical double layers formation. To eliminate the integral complexity in differentiating field induced charge carriers from any possible carriers resulting from electrochemical doping of the semiconducting layer, we systematically measured the specific capacitance for each semiconductor/dielectric FET combination to avoid overestimation of the ?FET extraction in our SEGI devices - a major common issue in several publications. For instance, with our engineered SEGIs, unprecedented hole mobility increase from ~10-2 to 5 cm2V-1s-1 (corresponding ~37 cm2V-1s-1 by commonly used method) at ≤ 2 V operation is reached in commercially available poly(3-hexylthiophene-2,5-diyl) (P3HT) FETs, and ?FET exceeding 10 cm2V-1s-1 in others semiconductors.

10366-16, Session 4

Optogenetic electronic skins *(Invited Paper)*

Benjamin Tee, Institute of Materials Research and Engineering (IMRE) (Singapore)

Electronic sensor skins is an active area of research for many groups over the world due to its potential to enable dramatic changes in how we interact with the digital environment. For example, 'robots' can don on sensor active skins to shake human hands with comfortable pressure, measure our health biometrics and possibly aid in wound healing. In my talk, I will discuss the development of electronic sensor skins with some historical context, followed by showcasing of several force sensitive electronic skin technologies with high sensitivity, stretchability and bio-mimetic self-healing abilities. More recently, we demonstrated a power-efficient frequency encoded artificial mechano-receptor system inspired by biological mechano-receptors4. We further used a channelrhodopsin with fast kinetics and large photocurrents as an optical interface to neuronal systems for next generation opto-tactile prosthetic interfaces.

10366-17, Session 4

Large area processing and printing of conducting copper structures for use in (opto)electronics

Felix Hermerschmidt, David Burmeister, Humboldt-Univ. zu Berlin (Germany); Stefan Sax, Karl Popovic, JOANNEUM RESEARCH Forschungsgesellschaft mbH (Austria); Gerburg Schider, NanoTecCenter Weiz Forschungsgesellschaft mbH (Austria); Christine Boeffel, Fraunhofer-Institut für Angewandte Polymerforschung (Germany); Efthymios Georgiou, Stelios A. Choulis, Cyprus Univ. of Technology (Cyprus); Frank Peuckert, 3D-Micromac AG (Germany); Graham Gray, Richard Ward, Intrinsiq Materials Ltd. (United Kingdom); Emil J. W. List-Kratochvil, Humboldt-Univ. zu Berlin (Germany)

Most current electronics manufacturing technologies utilise subtractive processing that is expensive, wasteful and energy intensive. Printed electronics is revolutionising the electronics industry by enabling additive processing that significantly reduces expense, waste and energy consumption.

The EU-funded PLASMAS project demonstrates the capability of printed electronics based on novel nanoparticle Cu inks with favourable cost to performance ratios, through development of large area printed circuit boards and printed logic as well as OLED and OPV elements with printed Cu nanoparticle electrodes.

However, a number of challenges need to be overcome when printing these metal nanoparticle inks – the typical feature height of printed structures of several 100 nm tend to exhibit a rough surface, which can lead to shorts in the device after subsequent overcoating of the organic active layer materials. Furthermore, the sintering temperature of the nanoparticle inks needs to be low (< 130 °C) in order to allow deposition and curing on transparent flexible substrates such as PET.

We therefore present the process development of solution-processed electrodes based on inkjet-printed Cu grids, by embedding the inkjet-printed metal grids to yield ITO-free optoelectronic devices. Secondly, we present roll-to-roll inkjet-printed RFID antennas based on Cu inks. Finally, we demonstrate a truly low-temperature sintering route for a Cu nanoparticle ink by using a reducing atmosphere of formic acid, yielding stable highly conducting layers.

The results of the project highlight overall parameters for solution processing and implementation of novel metal nanoparticle materials and architectures in printed electronics.

10366-18, Session 4

Printed thin film transistors for flexible and transparent electronics applications *(Invited Paper)*

Yongtaek Hong, Seoul National Univ. (Korea, Republic of)

Printed electronics has been one of the hottest topics due to its potential low-cost, low-temperature, and facile fabrication of thin film transistors (TFTs) and circuits on various flexible platforms. Therefore, several types of the solution-process semiconducting materials, such as organic, oxide, single-walled carbon nanotube (SWCNT), have been widely studied. In addition, when organic conductor and dielectric are used, transparent TFTs and circuits can be also fabricated by using several printing processes. In this talk, technical issues of all inkjet-printed TFTs, including improvement of the source/drain (S/D) contacts for organic semiconductor and short channel printing process, will be addressed. Organo-compatible, single-step interface engineering with dimethylchlorosilane-terminated polystyrene (PS) (PS–Si(CH3)2Cl) has much improved the S/D contact properties of the bottom-contact organic TFTs with a poly(4-vinyl phenol) (PVP) gate dielectric, for both silver and poly(3,4-ethylenedioxythiophene):polystyre ne sulfonate (PEDOT:PSS) S/D electrodes. High transparency of the organic and SWCNT semiconducting thin films renders them feasible in transparent electronics applications. However, it should be noted that stability of TFT performances under illumination is key requirement in such applications. In fact, different behavior was observed for each semiconducting material under the visible light illumination and details of the illumination stability will be further discussed. Furthermore, by combining high-k aluminum oxide (Al2O3) and n-type indium gallium zinc oxide (IGZO), we obtained low voltage (< 5V) printed hybrid complementary metal oxide semiconductor (CMOS) circuits. This work was supported by the Center for Advanced Soft-Electronics funded by the Ministry of Science, ICT and Future Planning as Global Frontier Project (CASE-2015M3A6A5065309).

10366-19, Session 4

Toward solution processed magnetic nanoparticles for non-volatile memory applications

Hamed Sharifi Dehsari, Anielen Halda Ribeiro, Kamal Asadi, Max-Planck-Institut für Polymerforschung (Germany)

Iron oxide nanoparticles (IONPs) are among the most promising candidates for nano-scale magnetic memory applications due to their excellent magnetic properties. The information can be stored depending on the magnetization of the particles. The general drawback of IONPs however is the lack of ferromagnetism in IONPs at room temperature. To overcome this issue, doping of IONPs with cobalt is suggested. In this contribution we present a systematic study of Co doped IONPs using heat-up synthesis methods (thermal decomposition), wherein different synthesis parameters are surveyed and their effect on the particle size, stoichiometry of cobalt within the spinel ferrite nano crystals (CoxFe3-xO4) and magnetic properties are investigated. The synthesis was optimized to obtain sub-20 nm highly crystalline and monodisperse ferromagnetic nanoparticles with optimum magnetization and coercivity values. The particles were further modified by grafting polymerization from the surface of nanoparticles. Polymeric shells of different molecular weight are obtained, which allowed well dispersion of the ferromagnetic nanoparticles in common organic solvents. Nanoparticles can be solution processed to form a ferromagnetic thin-film. Solution processable magnetic films can open a new avenue in the low-cost non-volatile memory application.

10366-20, Session 4

Elucidation of light effects in organic nano-floating-gate nonvolatile memories

Xu Gao, Zhong-Da Zhang, Xiao-Jian She, Sui-Dong Wang, Soochow Univ. (China)

Organic nonvolatile memory based on OFET is an essential element in organic electronics, which integrates nondestructive data processing and reliable data storage [1,2]. It is reported the memory window is sensitive to light illumination. However, the fundamental of the light-assisted program, especially the photon energy dependence of memory performance, needs to be clarified with a clear physical picture. In our work, the charge trapping process in the organic nano-floating-gate memory was comparatively studied by light response measurements, where light sources with different wavelengths of 408 nm, 532 nm, and 652 nm were employed. The positive threshold voltage shift was observed for all lights and increased up raising the light intensity, while the negative threshold voltage shift was only observed under 408 nm light illumination. It is proposed that the light with photon energy higher than the HOMO–LUMO gap of pentacene can induce the minority multiplication effect, which leads to significant positive threshold voltage shift but no obvious impact on negative threshold voltage shift. Whereas the light with photon energy in excess of the injection barriers at the pentacene/PS interface can additionally cause the excitation-induced injection effect, corresponding to hole injection into floating gate from the HOMO of pentacene, which realizes further negative threshold voltage shift [3]. The photon-energy-dependent light effects could be utilized to reduce the operation voltage of organic nano-floating-gate nonvolatile memories, and motivate the development of organic energy-resolved photosensors.

Conference 10367: Light in Nature VI

Monday 7 –7 August 2017

Part of Proceedings of SPIE Vol. 10367 Light in Nature VI

10367-1, Session 1

Momentum of light

Michael Mazilu, Univ. of St. Andrews (United Kingdom)

There are many ways to calculate the optical forces acting on scattering particles such as Maxwell's stress tensor, Lorentz forces, gradient and scattering forces, Lorenz-Mie formalism, T-matrix. All these approaches use the electromagnetic field and define the amount of linear momentum transferred to the scattering particles. The resulting momentum transferred is proportional to the intensity of the incident fields, however, the momentum of single photons (hbar k) does not naturally appear in these classical expressions. Here, we discuss an alternative Maxwell's stress tensor based formalism that renders the classical electromagnetic field momentum compatible to the quantum mechanical one. This is achieved through the introduction of the quantum conversion which allows the transformation, including units, of the classical fields to wave-function equivalent fields.

10367-2, Session 1

Enhanced high-harmonic generation in photonics crystal: theoretical and experimental studies

Evgeny Gorbunov, Kirill I. Zaytsev, Egor Yakovlev, Arsen Zotov, Bauman Moscow State Technical Univ. (Russian Federation); Vladimir M. Masalov, Gennadi A. Emelchenko, Institute of Solid State Physics RAS (Russian Federation); Nikita Kruchkov, Stanislav O. Yurchenko, Bauman Moscow State Technical Univ. (Russian Federation)

The effect of strong localization of electromagnetic field in colloidal photonic crystals (PCs) is considered in our talk. It is shown theoretically that due to lateral modulation of dielectric permittivity of PC the sharp peaks of light's intensity arise at the band-gap pumping, and light field decays parametrically with depth. The light itself localises at the near-surface volume of the PC and enhances nonlinear light conversion. Theoretical model to explain generic physical picture is presented for two-dimensional PC, and the analytical results are compared with numerical simulations by finite-difference time-domein method to solve the Maxwell's equations. The fingerprints of enhanced high harmonic generation, which are observed in our experimental studies with globular opal PCs, justifyes the main theoretical predictions.

10367-3, Session 1

2D and 3D graphical representation of the propagation of electromagnetic waves at the interface with a material with general effective complex permittivity and permeability

Andres Diaz, Univ. Metropolitana (United States); Jonathan S. Friedman, Univ. Metropolitana (United States) and Arecibo Observatory (United States); Jose G. Ramos, Univ. Metropolitana (United States); Sarah C. Luciano, College of Optical Sciences, The Univ. of Arizona (United States)

One of the fundamental phenomena we need to understand about the nature of light is how it interacts with different types of materials and how it changes as it is reflected, absorbed, and refracted at an interface. With the collaboration of students in the Computer Science undergraduate program at Universidad Metropolitana, we developed a web-based instructional and research tool that addresses the need to visualize this physical phenomenon - usually only considered from a mathematical viewpoint - and that bridges the gap of inadequate or overly costly software in this area. From first-principle physics based on Maxwell's equations, the program analytically and graphically demonstrates the behavior of electromagnetic waves as they propagate through a homogenous medium and through an interface where the second medium can be characterized by an effective complex permittivity and permeability. Either p- or s-polarization wave components can be chosen, allowing a complete analysis of wave interaction with regular dielectric, ferromagnetic, metallic, and double-negative materials. Parameters such as amplitude, wavelength, frequency, direction of propagation, intensity, and phase velocity can be visualized. The graphical interface includes two-dimensional wave representation and three-dimensional component representations enabling the study of continuity (or lack thereof) of EM components, normal incidence, critical angle, Brewster angle, absorption and amplification, subunity and negative refractive indices, parallel and antiparallel behaviors of Poynting vector to phase velocity, and positive and negative Goos-Hänchen shifts.

10367-4, Session 1

Spectroscopic composition of corona discharge and some effects on materials

Jorge A. García-Macedo, Univ. Nacional Autónoma de México (Mexico); Giulio Fanti, Univ. degli Studi di Padova (Italy)

Corona-discharge CD is just the point at which the air breakdown begins to happen. This phenomenon is usually present when high voltage is applied between a needle and a metallic plate. The air molecules begin to ionizate, separation of their positive and negative charges occur and any minimum voltage increment produces a suddenly discharge between the electrodes. At this critical non-equilibrium point, some of the opposite separated charges are recombined and a light violet-blue emission is produced at the tip of the needle. The released energy can cause some kind of chemical transformation on the materials nearby. In this work we reported the composition of this emission captured from tip of the needle. We show the kind of change that this Corona-discharge produced on fabrics of cotton and linen. CD has been considered as one of the most probably effect that generate the image in the so called Turin Shroud. We present some image produced by controlled CD. Some discussion is given.

10367-5, Session 1

The generation, propagation, and absorption of photons

Nithin Kumar Goona, Priya Singh, Saidi Reddy Parne, Venugopal Reddy Barry, National Institute of Technology, Goa (India)

Photon can be treated as both particle and wave. Photon can also be treated as a spherical shell of information with its radius increasing with a rate of speed of light. It is equally likely for all other charges surrounding the charge to register this information with certain strength even when those are separated by huge distances. And so presence of photon at many places at same time in a double slit experiment can be explained which can also be extended to matter waves. Based on mutual separation between all charges and inverse square law, this paper discusses strength of information i.e quanta of energy to be registered at each charge, generation of new information after registering old information and its strength. This paper also discusses on the factors resulting in attenuation of information while it is propagating, maximum absorption of photon, single photon detector and the applications for renewable energy devices.

10367-6, Session 2

Not all butterflies have colorful wings *(Invited Paper)*

Akhlesh Lakhtakia, The Pennsylvania State Univ. (United States)

Fluttering from flower to flower, butterflies are nature's mobile flowers. Having evolved from moths, which are usually drab, butterflies must have developed brilliantly colorful wings some way down the evolutionary path. Pigments must have become brighter and scales must have developed ribbed reinforcements that doubled as diffraction gratings to produce structural color. Today, however, several species of glasswinged butterflies exist. Conspicuously large portions of their wings are transparent and colorless. Where did the colors go? Therein hangs a fascinating tale.

10367-7, Session 2

Nanophotonic structures discovered in wild comet moth

Norman Shi, Cheng Chia Tsai, Columbia Univ. (United States); Catherine Craig, Harvard Univ. (United States); Nanfang Yu, Columbia Univ. (United States)

This paper studies in detail the optical properties of the cocoons produced by a wild moth from the northern rainforest of Madagascar, the comet moth. Through detailed optical analysis and morphology studies of cocoon fibers, the first half of the paper demonstrates how the cocoon provides thermal regulation for the pupae through optical reflection in the visible and near-infrared, and radiative heat transfer in the mid-infrared. Cross sectional images prepared by focused ion beam milling show that the cocoon fibers contain a densely packed, random distribution of filamentary air voids with cross-sectional sizes ranging from 100 to 600 nm. Hemispherical reflection measurements at normal incidence on the cocoon shells show high reflectivity in the visible and near-infrared, and high emissivity in the mid-infrared. These properties allow the cocoon to act as a passive radiative cooling object that efficiently reflects solar radiation and meanwhile radiates heat away from the cocoon walls. The second half of the paper delves into the cocoon fibers' capabilities in waveguiding through transverse Anderson localization. Due to the unique longitudinal invariance (over tens of microns) of the filamentary voids inside these cocoon fibers, shorter-wavelength light (400-600 nm) that is launched from one end of the fiber is confined spatially through transverse Anderson localization as it propagates through the fiber. At times, there are strong confinements of certain propagating modes inside the localized region.

10367-8, Session 2

Light scattering optimization of chitin random network in ultrawhite beetle scales

Francesco Utel, LENS - Lab. Europeo di Spettroscopie Non-Lineari (Italy); Lorenzo Cortese, ICFO - Institut de Ciències Fotòniques (Spain); Lorenzo Pattelli, LENS - Lab. Europeo di Spettroscopie Non-Lineari (Italy); Silvia Vignolini, Univ. of Cambridge (United Kingdom); Matteo Burresi, Istituto Nazionale di Ottica (Italy); Diederik S. Wiersma, Univ. degli Studi di Firenze (Italy)

Among the natural white colored photonics structures, a bio-system has become of great interest in the field of disordered optical media: the scale of the white beetle Chyphochilus. Despite its low thickness, on average 7 ?m, and low refractive index, this beetle exhibits extreme high brightness and unique whiteness. These properties arise from the interaction of light with a complex network of chitin nanofilaments embedded in the interior of the scales. As it's been recently claimed, this could be a consequence of the peculiar morphology of the filaments network that, by means of high filling fraction (0.61) and structural anisotropy, optimizes the multiple scattering of light.

We therefore performed a numerical analysis on the structural properties of the chitin network in order to understand their role in the enhancement of the scale scattering intensity.

Modeling the filaments as interconnected rod shaped scattering centers, we numerically generated the spatial coordinates of the network components. Controlling the quantities that are claimed to play a fundamental role in the brightness and whiteness properties of the investigated system (filling fraction and average rods orientation, i.e. the anisotropy of the ensemble of scattering centers), we obtained a set of customized random networks. FDTD simulations of light transport have been performed on these systems, determining the values of the parameters that optimize brightness and whiteness. Moreover we demonstrated how the anisotropy is indeed a parameter that can strongly influence the system reflectance, even at such a low thickness.

10367-9, Session 2

Butterflies regulate wing temperatures using radiative cooling

Cheng Chia Tsai, Norman Nan Shi, Crystal Ren, Columbia Univ. (United States); Julianne Pelaez, Univ. of California, Berkeley (United States); Gary D. Bernard, Univ. of Washington (United States); Nanfang Yu, Columbia Univ. (United States); Naomi Pierce, Harvard Univ. (United States)

Butterfly wings are live organs embedded with a network of mechanical and temperature sensory neurons. For some butterfly species, their wings are equipped with pheromone-producing organs called scent pads or patches, which are filled with live cells. The proper function of butterfly wings thus demands a suitable range of temperatures. However, the wings have a small thermal capacity and correspondingly a very short time constant of temperature changes. Therefore, the wings are extremely thermally sensitive and can overheat quickly under exposure to strong solar radiation, while the head, thorax, and abdomen with much larger thermal capacities are still in their operation range of temperatures. We investigated the morphology of the butterfly wing scales and found that the non-uniform thickness of the wings and diverse wing scale nanostructures lead to a highly inhomogeneous distribution of radiative cooling, which determines the temperature distribution on butterfly wings. We developed an infrared technique to map butterfly wing temperatures by considering the spectral thermal emissivity distribution of butterfly wings. We discovered that despite the diverse visible colors and patterns, regions of wings that contain live cells are always the coolest. We also conducted a series of behavioral studies on live butterflies to show that their wings can function as sensitive and fast sensors of temperatures, and that the butterflies use a number of behavioral traits to prevent overheating and overcooling of their wings.

10367-10, Session 3

Contributions of early Arab scholars to color science and the role of Ibn al Haytham

Vasudevan Lakshminarayanan, Univ. of Waterloo (Canada)

The Islamic world made important discoveries in the field of color science during the medieval era. For example, al-Kindi proposed that it is the object rather than the medium that produces color (contrary to Aristotle). Ibn Sina, al Tusi and Nishaburi developed a two dimensional color order and described the partial hue scale. To Ibn al Haytham (whose publication of Kitab al Manzir, Book of Optics was celebrated during the International Year of Light) color was a percept and light and color were ontologically distinct. Al Haythm even discussed topics such as color contrast. Other contributions by these scholars include descriptions of the rainbow, color mixtures, color tops, etc. These contributions will be presented and discussed in this talk.

10367-11, Session 3

Effects of color in the learning of science

Aramis A. Sanchez Juárez, Johanna E. Jaramillo Q., Univ. Técnica Particular de Loja (Ecuador)

The teaching of science is a global problem, general studies have been carried out which take into account the effects of color in the educational environment and have had revealing results, however a study has not been made to measure the effects of color in the learning of the sciences, in this specific case of Physics and mathematics. A study of the effects of color on science teaching was conducted, controlling color of various materials such as slides used in class, markers on blackboard, pens, paper sheets, laboratory materials and teacher's clothing color. In this paper we present results of student academic performance, opinion about the subject, development of logical abilities and a comparison with the teaching of science in a free way, that is to say, without control of color. There is also a study of color effects in science education distinguishing between genders and finally comparing the general results in the educational field with those obtained in this work.

10367-12, Session 3

Non-visual biological effects of light on human cognition, alertness, and mood

Huaye Li, Huihui Wang, Junfei Shen, Peng Sun, Siman Zhang, Ting Xie, Zhenrong Zheng, State Key Lab. of Modern Optical Instrumentation, Zhejiang Univ. (China)

Light exerts non-visual effects on a wide range of biological functions and behavior apart from the visual effect. Light can regulate human circadian rhythms, like the secretion of melatonin and cortisol. Light also has influence on body's physiological parameters, such as blood pressure, heart rate and body temperature. However, human cognitive performance, alertness and mood under different lighting conditions have not been considered thoroughly especially for the complicated visual task like surgical operating procedure. In this paper, an experiment was conducted to investigate the cognition, alertness and mood of healthy participants in a simulated operating room (OR) in the hospital. A LED surgical lamp was used as the light source, which is mixed by three color LEDs (amber, green and blue). The surgical lamp is flexible on both spectrum and intensity. Exposed to different light settings, which are varied from color temperature and luminance, participants were asked to take psychomotor vigilance task (PVT) and Karolinska sleepiness scale (KSS) for alertness measurement, alphabet sheet test for cognitive performance measurement, positive and negative affect schedule (PANAS) for mood measurement. The result showed the participants' cognitive performance, alertness and mood are related to the color temperature and luminance of the LED light. This research will have a guidance for the surgical lighting environment, which can not only enhance doctors' alertness and efficiency during the operations, but also create a positive and peaceful surgical lighting environment.

10367-13, Session 4

Observing halos through airplane windows

Joseph A. Shaw, Montana State Univ. (United States)

A halo is one of the most frequent and impressive optical phenomena easily observable through an airplane window. Halos and related phenomena vary from a single spot of light formed by reflection of the sun from the tops of plate-shaped ice crystals to large rings with splashes of colors, caused by a combination of reflection and refraction in ice crystals. Even with extreme heat at the ground, an airplane quickly rises through sufficient altitude to find ice crystals in the clouds, enabling an alert passenger (or pilot) to see ice-crystal optical phenomena. This talk will briefly review these phenomena and explain them with photographs and diagrams. Photographs will include commonly seen halos, as well as one photo of Bottlinger's rings, which is a rare halo that is still not explained fully. The presentation will conclude with tips for how audience members can enhance their chances of seeing halos and understand them when they do.

10367-14, Session 4

Identifying the optical phenomena responsible for the blue appearance of veins

Spencer R. Van Leeuwen, Gladimir V. G. Baranoski, Univ. of Waterloo (Canada)

Blue in nature is often associated with beauty. It can be observed all around us, from captivating blue eyes to iridescent blue butterfly wings. While colours in nature are often the result of pigmentation, the majority of natural blue is produced by structural coloration. The colour of the sky, for example, is primarily caused by Rayleigh scattering. In this paper, we examine a single occurrence of blue in nature, specifically the blue appearance of veins near the surface of human skin. The most comprehensive investigation of this coloration to date showed that the blue light reflected by skin with an underlying vein is strongly dominated by the reflected red. Since these results imply that the vein should appear red, the authors suggested that we observe blue due to colour constancy, a feature of the visual perception system. However, in this previous work, the reflectance was only measured at three wavelengths which does not provide the full picture. In this paper, we employ in silico experiments, performed using first-principles light interaction models for skin and blood, to investigate the net effect of skin and vein optical properties on their aggregate reflectance across the visible range. We demonstrate that the blue coloration of veins results from Rayleigh scattering occurring within the skin. Furthermore, we show that veins can appear blue without considering colour constancy. The results of this paper, in addition to answering an old open question, have practical implications for performing non-invasive measurements of the physiological properties of skin and blood.

10367-15, Session PMon

Color vision tests comparison: Farnsworth D-15 versus Lanthony D-15

Marta A. Szmigiel, Malwina Geniusz, Wroclaw Univ. of Science and Technology (Poland)

Disorder of color vision in humans is the inability to perceive differences between some or all of the colors that are normally perceived by others. Color blindness is usually a birth defect, a genetically determined, inherited recessive in engagement with the chromosome X. For this reason it is much more common in men (approx. 8%) than women (approx. 0.5%). Different types of disorders color recognition are due to faulty or complete lack of functioning of the conesThe problem with color vision can be divided into: dichromacy - total absence of one of the types of cones, trichromacy - the difference of sensitivity to the color of one of the types of suppositories, or monochromacy - total inability to recognize colors.

This paper presents the results of the test FarnsworthD-15 and Lanthony D-15 on a group of volunteers, both adults and children. The study was conducted to compare the results of both tests, as well as the way of their execution (eg. the execution time of each test).

There is no known cure for color blindness. An essential part of adapting to the perceived defect is a change in the processing information about the world, eg. remembering the order and not the color of traffic lights on the road. It is very important that in the process of education to adapt teaching methods (eg images illustrating the contents of tasks) to a limited ability of recognizing colors.

10367-16, Session PMon

Color effect + motivation = learning and teaching

Darwin P. Castillo Malla, Aramis A. Sánchez Juárez, Univ. Técnica Particular de Loja (Ecuador)

The present work shows the teaching and motivation of children to study optics and color effects. The methodology consists of studying the different optical phenomena that occur through the sunsets and then do a correlation of this information with the phenomena and optical effects of the color of class presentations; to determine the motivation and attention of students.

Determination of better protective eyeglasses depending on the shape and material

Aramis A. Sánchez Juárez, Johanna E. Jaramillo Q., Univ. Técnica Particular de Loja (Ecuador)

In the equatorial zone of the planet one suffers of a high degree of ultraviolet radiation, this is related to diseases of the skin and of the eyes, the solar blockers already do their part protecting the exposed skin and one has enough detailed information about the best one Sun cream protection, however when choosing sunglasses for sun protection, you end up choosing by style rather than utility. This study presents a study of the levels of protection offered by various products on the market, making a direct correlation between the shape of the glasses and the materials of the lenses. Also included are glasses for vision correction and spectacle performance on sunny days and cloudy days.

The results show small differences between expensive eyeglasses and cheap sunglasses regarding sun protection.

10367-18, Session PMon

Color vision deficiencies and the child's willingness for visual activity: preliminary research

Malwina Geniusz, Marta A. Szmigiel, Maciej Geniusz, Wroclaw Univ. of Science and Technology (Poland)

After a few weeks a newborn babys can recognize high contrasts in colors like black and white. They reach full color vision at the age of ca. six months. Matching colors is the next milestone. Most children can do it at the age of two. Good color vision is one of the factors which indicate proper development of a child.

The color vision of a group of children aged 3-8 was examined with saturated Farnsworth D-15 and desaturated Lanthony D-15. Fransworth test was performed twice - in a standard version and in a magnetic version. The time of completing standard and magnetic tests was measured. Furthermore, parents of subjects answered questions checking the children's visual activity in 1 - 10 scale. Parents stated whether the child is willingly to watch books, to color coloring books, to put puzzles or whether they like to play with blocks etc. Presented research shows the correlation between color vision and visual activity.

10367-19, Session PMon

Temporary effects of alcohol on color vision

Maciej Geniusz, Malwina Geniusz, Marta A. Szmigiel, Wroclaw Univ. of Science and Technology (Poland)

Color vision is an amazing and complex phenomenon. Despite numerous studies we still do not understand all the processes that affect the interpretation of colors. The concept of color itself is disputable: our brains create the perception of color from the spatial and temporal patterns of the wavelength and intensity of light.

It is well known that color vision seems to be very sensitive to several chemicals. This paper reviews the published literature that is concerned with color vision impairment from alcohol.

In general, most cases of congenital color vision impairment are red-green, and blue-yellow impairment is extremely rare. However, most of the acquired color vision impairment that is related to age, alcohol or environmental factors is blue-yellow impairment. Therefore, many studies have been performed to identify this relationship between alcohol addict and color impairment.

The present research reviews the published literature that is concerned with color vision impairment due to alcohol. Most of this research considers people under long-term effects of alcohol. However, there is little information about temporary effects of alcohol on color vision. A group of volunteers aged 20-40 was studied. During the study levels of alcohol in the body were tested with a standard breathalyzer while color vision were studied using Farnsworth and Lanthony D-15 Color Vision Tests. The extent of color vision loss was quantitatively assessed based on Bowman's color confusion index (CCI). The defect due to alcohol itself soon disappears during desintoxication.

10367-21, Session PMon

Six years of vision screening tests in pre-school children of Wroclaw

Ireneusz Szmigiel, Marta A. Szmigiel, Malwina Geniusz, Wroclaw Univ. of Science and Technology (Poland)

Detection of vision defects of a child without professional knowledge is not easy. Very often, the parents of a small child does not know that their child sees incorrect. Also the youngster, not knowing any other way of seeing, does not know that it is not the best.

While the vision of a small child is not yet fully formed, it is worth checking them very early. Defects detected early opportunity to give the correction anomalies, which might give the effect of the normal development of vision.

According to the indications the American Optometric Association (AOA) control eye examination should be performed at the age of 6 months, 3 years, before going to school and then every two years.

Members of SPIE Student Chapter, in cooperation with the Visual Optics Group working on the Department of Optics and Photonics (Faculty of Fundamental Problems, Wroclaw University of Science and Technology) for 6 years offer selected kindergartens of Wroc?aw performing visual screening test of children. Depending on the number of involved members of the student chapter and willing to cooperate students of Ophthalmology and Optometry, vision screening test was carried out in up toeight kindergartens every year.

The basic purpose of screening vision test is to detect visual defects to start the correction so early in life as possible, while increasing the efficiency of the child's visual potential. The surrounding community is in fact more than enough examples of late diagnose vision problems, which resulted in lack of opportunity or treatment failure.

Conference 10368: Next Generation Technologies for Solar Energy Conversion VIII

SPIE. OPTICS+ PHOTONICS OPTICAL ENGINEERING+ APPLICATIONS

Monday - Tuesday 7 –8 August 2017

Part of Proceedings of SPIE Vol. 10368 Next Generation Technologies for Solar Energy Conversion VIII

10368-201, Session Plen

A Brief History of Photovoltaics: Yesterday, Today, and Tomorrow

Charles Gay, U.S. Dept. of Energy (United States)

What can happen over the next 15 years, as photovoltaic (PV) power costs continue to decrease and markets expand? This talk will cover the range of opportunities associated with changes in energy supply in developed and developing economies. We will review the history of solar and discuss the key role of professionals in communicating a vision for the future. Our efforts to inform and educate a wide range of stakeholders will be essential to seeing the potential for wide adoption of PV become a reality. This talk will endeavor to convey some of the stories essential to enabling our outreach.

10368-202, Session Plen

Photovoltaics Moving into the Terawatt Age

Eicke R. Weber, Berkeley Education Alliance for Research in Singapore BEARS (Singapore) and Univ. of California, Berkeley (United States)

In the last few years, PV electricity became cost-competitive with electricity produced by conventional sources. Global PV production capacity will double within the next five years to 100-120 GWp/a, bringing PV installations into the Terawatt range. A key factor for this growth will be continuous technology advances aimed at higher efficiencies at reduced cost. In addition, cell efficiency will be even more important than lowest cost, to optimize energy harvest from a given area. Crystalline Silicon technology currently represents 90% of the global PV market. This technology is approaching a ceiling of 29% efficiency for a single-bandgap semiconductor. New approaches for higher efficiencies require heterojunctions, and several approaches will be discussed. These include heterojunctions on silicon, allowing to combine well-established large-scale Silicon PV technology with new technologies, such as low-cost III/V or Perovskite layers.

10368-203, Session Plen

Bankability of Novel Energy Technologies

Ralph Romero, Black & Veatch (United States)

New technologies are helping energy system owners improve performance and service to their customers while creating a sustainable energy future. But many of these new tools and processes are unproven and costly, which may hinder their large scale deployment. This talk will address the topic of new technology bankability and how owners, technology providers and financial institutions assess their risk exposure before embarking on significant projects. The talk will focus on the lessons learned from the rapid growth of the photovoltaic industry and discuss areas where technology risk should be further reduced.

10368-20, Session PMon

Power saving using amorphous transformers

Sarhan H. Hasan, Univ. of Denver (United States)

The large number of distribution transformer through any electrical network in any country result in a significant amount of losses .Low efficiency transformers effect the environment by requiring increased generation to supply increased transformer losses. The wasted generation causes increased carbon dioxide in the air and contribute to so called greenhouse effect. Alternatively, energy efficient transformers like amorphous transformers (AMDT) reduce the required generation and reduce the emission into the air. The purpose of this paper is to introduce amorphous material as alternative transformer core material in place of traditional silicon steel core, as it has excellent magnetic characteristics compared to silicon steel material. By using Amorphous as a transformer core material 70 % percent of transformer no load losses could be reduced due to amorphous low sheet thickness and its high resistivity. The economics of transformer replacement should be determined before replacement decision. The total owing cost (TOC) of both transformers the replacement and continuing operation transformer should be compared then the decision could be made. The total owing cost (TOC) is the transformer first price levelized over the life of transformer plus the cost of future transformer losses (no load losses and load losses) discounted to present value and levelized over the life of the distribution transformer. The electrical network in Libya is considered as case study in this paper where it contains about 5570 distribution transformer. The total owing cost (TOC) of some of them based on the data received from economical study center at the electrical department in ministry of energy in Libya is calculated to determine the replacement option, and then the power saving due to this replacement of the number of transformers that allowed to replace in the network is calculated.

14.66%-efficient printing CIGS solar cells on stainless steel foil

Tung-Po Hsieh, Yu-Kuang Liao, Lung-Teng Cheng, Chia-Ming Chang, Wei-Sheng Lin, Chou-Cheng Li, Yu-Yun Wang, Wei-Tse Hsu, Jen-Chuan Chang, Sheng-Wen Chan, Song-Yeu Tsai, Industrial Technology Research Institute (Taiwan)

Efficiency of Cu(In,Ga)Se2 (CIGS) solar cells is pushing closer to silicon-based photovoltaic, outperforming silicon-based solar cells by its low material consumption, light weight, roll-to-roll production and wide variety of applications. In this work, we demonstrate a high quality, flexible CIGS absorber via mixed oxide particle ink for high efficiency flexible CIGS module. The ink was coated by Doctor Blade coator on a 2-?m-thick p-type contact metal (Mo/Cr), which was sputtered on stainless steel foils. The precursor film was prepared by the ink followed by hydrogen reduction. Sulfurization after selenization process are used for formation of CIGS absorber, which is followed by deposition of a CdS buffer layer on CIGS absorber by chemical bath deposition, and sputtering of an intrinsic ZnO, and a transparent conducting oxide (Al:ZnO). The device fabrication was terminated at top electrode prepared by screen printing of silver paste, and an MgF2 layer on AZO as anti-reflection layer.

Each CIGS absorber has been processed into CIGS module with two isolated CIGS solar cells, each with area of 100 cm2. From production of 56 devices, the yield rate of these 100 cm2 CIGS solar cells has reached 71 % for efficiency above 13 %, and 25 % for efficiency above 14 %. The champion 100 cm2 CIGS solar cell has reached 14.66 % efficiency. By series connection of these two devices, a 200 cm2, flexible CIGS mini-module has been successfully fabricated, and achieved 13.93 % efficiency.

10368-22, Session PMon

Fabrication of p-type monocrystalline germanium thin films on silicon wafer by magnetron sputtering

Cheng-Wei Luo, National Central Univ. (Taiwan)

The particular is p-type monocrystalline germanium thin films on silicon wafer by magnetron sputtering investigated in this research. Among the many types of solar cells, the conversion efficiency of III-V multi-junction solar cell is still the highest records of all kind of solar cells. But solar cell market gradually declining, we need to develop new battery technologies or structure. A silicon-based tandem solar cell is one of the possibility developments in the future. The III-V material is not suitable to grown on the silicon substrate, because the lattice constant is too different between III-V and Si, it will make the lattice mismatch to cause the threading dislocation density (TDD). Therefore, fabricating the epitaxial growth of Ge thin film on Si wafer substrate and applies it on tandem junction of Si and III-V group solar cells have great research potential to solve the problem of TDD. In order to overcome the current mismatch problem between the tandem junction of Si and III-V group solar cells, the single crystalline Ge thin film must have high carrier concentration as tunneling junction property.

This study, we use magnetron sputter system with B/Ge alloyed target to grow the p-type doped single crystal Ge films on Si (100) wafer. And the post annealing process was chosen to improve the Ge thin film qualities. For analysis of germanium film material analysis, we use XRD measurement verify crystallization of the single crystal Ge thin films. We also use Hall to measure the doped concentration and mobility of p-type Ge thin films.

10368-23, Session PMon

Using sputter epitaxial growth of SiGe films on mono-crystalline silicon substrate

Chiu-Yi Shih, National Central Univ. (Taiwan)

Monolithic integration is viewed as the most promising technique for the eventual realization of commercial wafer scale integration of III-V compound semiconductors on silicon. However, the large mismatches in lattice constant (~4.1%) and thermal expansion coefficient (~63%) , antiphase domains APDs and auto doping create difficulty for GaAs grown directly on Si negates the advantages of III–V/Si systems by generating large densities of dislocations in the III–V device layers. To reduce the dislocation density, We grown GexSi1-x thin films between Si and Ge as buffer layer since by increasing the Ge content (x) during growth of a GexSi1-x epitaxial layer on Si, the lattice constant can be increased from that of Si to Ge, providing a close lattice match for subsequent GaAs-based device growth. The general fabrication methods for epitaxial growth Ge were chemical vapor deposition (CVD) method and molecular beam epitaxy (MBE) method, however, the equipment costs of those methods were very expensive and needs use of extremely toxic raw materials in the CVD deposition processes. We use sputter meth to reduce hazardous substances and the cost. And improve competitiveness in the market.

This study we use sputter to epitaxy GexSi1-x on mono-crystalline silicon substrate. To measure

And analyze by X-ray diffraction (XRD) spectra, Raman spectra, and Electron backscatter diffraction (EBSD).

10368-1, Session 1

Energy migration, exchange and dissipation in ensembles of semiconductor nanocrystals for photovoltaic applications *(Invited Paper)*

Tom Gregorkiewicz, Univ. van Amsterdam (Netherlands)

The band structure of semiconductor nanocrystals (NCs) is modified by several effects which appear due to quantum confinement and surface eminence. When in an ensemble, individual NCs can couple with each other, depending on their proximity. In a dense dispersion of NCs, exchange of energy between proximal NCs can take place, profoundly influencing properties of the ensemble. In my presentation, I will discuss different processes of energy transfer between optically excited NCs in dense ensembles as induced by exciton concentration and/or bandgap gradients and facilitated by photon reabsorption, Förster and Dexter mechanisms, and specifically:

1. Exciton diffusion between Si NCs in SiO2 due to the Förster mechanism. I will show direct evidence of this process taking place in structures of different characteristics and evaluate the relevant transfer rates.

2. Dexter coupling between excited Si NCs. I will show that a highly excited NC can transfer energy to its neighbors, due to effective overlap of the highly delocalized character of the "hot" electron/hole states.

3. For a solid-state dispersion of Si NCs and Er3+ ions in SiO2, I will show how a combination of Förster and Dexter mechanisms operating in parallel facilitates efficient extraction of hot carrier excess energy.

4. Finally, I will discuss coupling between NCs of all-inorganic perovskite CsPbBr3. I will discuss how the bandgap energy of a particular NC is modified by the close proximity of its neighbors.

10368-2, Session 1

A metamaterial sunlight down-converter for improved photovoltaics

Antonio Capretti, Arnon Lesage, Tom Gregorkiewicz, Univ. van Amsterdam (Netherlands)

We tackle the requirements of sunlight down-conversion for improved photovoltaics by integrating semiconductor quantum-dots and dielectric nanocylinders, into a highly-optimized hierarchical metamaterial. Specifically, we utilize silicon nanocrystals (Si-NCs) supporting a form of multiple-exciton generation called space-separated quantum cutting, and embed them in SiO2 nanocylinders. We demonstrate that: i) total absorption can occur for photons with energy E > 2 Egap and ii) total transmission of photons with E < 2 Egap, where Egap is the cell bandgap (Egap ~ 1.11 eV for Si). This achievement solves the spectral selectivity needed for an effective down-conversion scheme.

Our efficient design supports metamaterial absorption peaks, whose spectral positions are tailored by geometrical design parameters. This peaks are due to both Mie resonances in the nanocylinders and grating resonances in the array. Our calculation predicts that the absorption can go up to 50% for a free-standing metamaterial, and it can reach total absorption by using an impedance-matched substrate. We experimentally prove that that the increased absorption directly couples to the Si-NC optical transitions, resulting in an enhancement of the photoluminescence intensity.

Although in this work we propose and use a specific material platform, the principle demonstrated is general and can be applied to other semiconductor quantum dots and emitting species, such as rare-earth ions and organic molecules. We envision the application of this principle to other applications in solar energy conversion, such as spectral shaping for photovoltaics, but also photocatalysis and artificial photosynthesis with higher efficiency.

10368-3, Session 1

Optical modeling of nanowire array tandem solar cell

Yang Chen, Johannes Svensson, Lund Univ. (Sweden); Oliver Höhn, Nico Tucher, Fraunhofer-Institut für Solare Energiesysteme (Germany); Mats-Erik Pistol, Lars-Erik Wernersson, Nicklas Anttu, Lund Univ. (Sweden)

A tandem solar cell consisting of a III-V nanowire top cell on a planar silicon bottom cell is a promising candidate for next generation photovoltaics. Here, we modeled the optical response of a III-V nanowire array on a silicon substrate with emphasis on varying processing layers. A conformal indium tin oxide (ITO) top contact lead to a 50% drop in the short-circuit current in the silicon cell. By instead using a planar ITO layer, this ITO absorption loss could be reduced by 90%. However, a ≈25% reflection loss showed up in such a planarized design. These reflection losses could be reduced by 80% with a 100 nm thick SiO_2 anti-reflection coating on top of the ITO layer and a 90 nm Si_3N_4 layer on top of the silicon surface between the nanowires. Regarding the absorption in the silicon bottom cell, we show that different approximate models can lead to a 15% variation in the estimated short-circuit current in the silicon subcell. Finally, we addressed the issue of weak absorption in small-diameter nanowires caused by electrostatic screening. We placed 16 nanowires in a cluster and coupled the nanowires optically with a dielectric coating. In this way, the clusters showed resonant absorption, and the absorption in the small-diameter nanowires was boosted by a factor of 200. Such a cluster design opens the door for using small-diameter nanowires for efficient absorption, while at the same time allowing for the inherent materials science benefits of small diameter nanowires like efficient strain relaxation in heterostructures.

10368-4, Session 1

Photovoltaic characteristics of organic-inorganic hybrid silicon quantum dot solar cell

Mitsuru Inada, Nozomi Isobe, Tomoki Miyake, Tadashi Saitoh, Kansai Univ. (Japan)

The sample structure is ITO/CuPc(20nm)/Si QDs(11nm)/C60(40nm)/BCP(5nm)/Al. The mean diameter of Si QD is 5nm. An indirect- and direct-optical band gap of Si QD obtained from UV-VIS absorption spectroscopy are 2.0eV and 3.5eV, respectively. An open-circuit voltage of 0.3V, a short-circuit current density of 0.032mA/cm2 and fill-factor of 0.23 are obtained from current-voltage measurements under AM1.5G sunlight irradiation. The result shows that the sample acts as a solar cell though the performance is not so good. Photocurrent characteristics are investigated by spectral responsivity measurements. The clear enhancement of resposivity at a photon energy of 3.5eV are observed, compared with a reference CuPc/C60 solar cell which does not include Si QD. These results shows that this inorganic-organic QD solar cell structure has a one of a new type of candidates of the QD solar cells.

10368-5, Session 1

Optimization of charge-carrier generation in amorphous-silicon thin-film tandem solar cell backed by two-dimensional metallic surface-relief grating

Benjamin J. Civiletti, Thomas H. Anderson, Univ. of Delaware (United States); Faiz Ahmad, The Pennsylvania State Univ. (United States); Peter B. Monk, Univ. of Delaware (United States); Akhlesh Lakhtakia, Pennsylvania State Univ. (United States)

The rigorous coupled-wave approach was used to calculate the three-dimensional charge-carrier-generation rate in an amorphous-silicon, thin-film tandem solar cell. The solar cell comprised a front coating, designed to reduce the reflection of incident light; three p-i-n junctions in tandem; and a periodically corrugated metallic back reflector (PBR). Indium-tin-oxide was chosen for the front coating. The p-i-n junctions were taken to be made from hydrogenated amorphous silicon alloyed with carbon or germanium. The silver PBR was assumed to possess hexagonal hillock texturing in order to couple the incident light with wave guide modes and surface-plasmon-polariton waves. The total charge carrier-generation rate in the three junctions, under illumination by the AM1.5G solar spectrum, was calculated at both normal and oblique incidence. The differential evolution algorithm was used to maximize this rate throughout the three junctions, with the design-parameter space including the PBR relief, the PBR duty cycle, front coating thickness, and the thicknesses of each of the i-layers. A one-dimensional, finite-element drift diffusion model, implemented in COMSOL, was used to predict the efficiency of the tandem solar cell at various locations in the parameter space. Each of the p-i-n junctions comprising the tandem solar cell was assumed to be electrically isolated.

10368-6, Session 2

Optimal indium-gallium-nitride Schottky-barrier thin-film solar cells

Thomas H. Anderson, Peter B. Monk, Univ. of Delaware (United States); Tom G. Mackay, The Univ. of Edinburgh (United Kingdom); Akhlesh Lakhtakia, Pennsylvania State Univ. (United States)

A two-dimensional model was developed to simulate the optoelectronic properties of indium-gallium-nitride (InGaN), thin-film, Schottky-barrier-junction solar cells. The solar cell comprises a front coating designed to reduce the reflection of incident light, Schottky and ohmic front contacts, an n-doped InGaN-wafer, and a periodically corrugated metallic back reflector. The ratio of indium to gallium in the wafer varies periodically in the thickness direction, and thus the optical and electrical properties also vary periodically. Empirical models for indium nitride and gallium nitride, combined with Vegard's law, are used to calculate the optical and electrical properties of these alloys. This material nonhomogeneity could be physically achieved by varying the fractional composition of indium and gallium during deposition. The periodic nonhomogeneity aids charge separation and, in conjunction with the periodically corrugated back reflector, enables incident light to couple to multiple surface plasmon-polaritons. The resulting charge-carrier-generation rate profile when the solar cell is illuminated by the AM1.5G spectrum was calculated using the rigorous coupled-wave approach. The steady-state drift-diffusion equations were solved using COMSOL, which employs finite-element methods, to calculate the current density as a function of the voltage. Mid-band Shockley-Read-Hall, Auger and radiative recombination rates were taken to be the dominant methods of recombination. This model was used to study the effects of the solar-cell geometry and the shape of the periodic material nonhomogeneity on efficiency. The solar-cell efficiency was optimized using the differential evolution algorithm.

10368-7, Session 2

Silicon-based infrared photodetectors enabled by hot electrons

Seok Jun Han, Sang Eon Han, The Univ. of New Mexico (United States)

Conventionally, photonic infrared (IR) detectors employ low band gap materials such as InGaAs, InSb, or HgCdTe. However, these materials include elements that are rare, expensive, or toxic. Past research indicates that crystalline Si (c-Si), which is a much cheaper and more abundant element, could be used for IR detection when metal electrodes are cleverly nanostructured. In this type of photodetection systems, the IR light with energies below the c-Si band gap is strongly absorbed by the metal

structures, rather than by c-Si. The photoexcited electrons in the metal can then be injected into the conduction band of c-Si before being thermalized and electric current can be generated. These non-thermalized electrons, called hot electrons, enable the detection of IR light with energies below the c-Si band gap. For efficient transport of electrons in the metal before thermalization, the metal layer should be as thin as approximately the electron mean free path. Accordingly, the metal layer thickness should be only a few tens of nanometers. To induce strong optical absorption in such a thin metal layer, surface plasmon polaritons (SPPs) can be excited at the metal surface. Previous studies on hot electron photodetection utilized small-scale metamaterials or deep trench resonators to have strong resonant absorption of SPPs in thin metal films on c-Si at the desired frequencies. However, these structures should be fabricated with a high precision because the metal structure sizes determine resonances. Accordingly, in many cases, expensive techniques such as electron beam lithography have been commonly used to fabricate the structures. However, for mass production, it is important to obtain metallic structures that do not require expensive techniques and tolerate practical fabrication errors. In this study, we use metal metasurfaces that can be fabricated by scalable, inexpensive techniques and achieve a broad-band IR absorption of over 95% in 15-nm-thick metal films. This unprecedented strong absorption, in terms of both the absorptance magnitude and the band width, is enabled by a new scheme where the light takes multiple passes within the c-Si substrate. During the passage, light is preferentially absorbed by the thin metal layer that is on one side of the substrate. Absorption on the other side is efficiently eliminated by using a dielectric layer. In our effort, the surface of the c-Si substrate where thin meal film is deposited is structured by a simple optical lithography. The structured surface admits the incident light into the substrate and prevents the light from leaking out of the substrate. In our scheme of multiple light passes, extremely strong resonances are not necessary and fabrication errors would not destroy the optical properties appreciably. In this talk, we will discuss the details of the optical absorption in our scheme. We will also present our experimental results on the electronic characteristics of our hot electron devices.

10368-8, Session 2

Highly efficient organic photovoltaics enabled by polymeric additives

Taeshik Earmme, Brian J. Worfolk, Kathy A. Repa, Hualong Pan, Alyssa B. Chinen, Kathy B. Woody, Phillips 66 (United States)

Organic photovoltaics (OPVs) are of current interest for providing a low-cost, scalable solar energy conversion technology. A typical photoactive layer for OPV consists of a light absorbing donor polymer and fullerene acceptor in a bulk heterojunction binary blend, where free charge carriers are generated by absorbed photons. Recently, the use of a ternary component in the active layer is emerging as a promising strategy to enhance device performance. The third component could be a quantum dot, small molecule or polymer. In addition to a complementary absorption with the primary donor material in the solar spectrum and cascade energy levels between HOMO and LUMO energy levels of the dominating donor polymer and fullerene acceptor to facilitate charge transport, improved nanomorphology over the binary device has been also reported.

In this study, incorporation of a non-conjugated polymeric additive to the polymer:PC70BM photoactive layer is demonstrated to enhance device performance. OPV devices with different ratios of polymeric additive were fabricated and investigated. The increase in the photovoltaic parameters by using polymeric additive is successfully demonstrated showing over 10% power conversion efficiency with very high current density (>19.0 mA/cm2). Results of a thermal stability test show that the additive suppressed a decrease in the fill factor, indicating the potential ability to stabilize morphological changes in the active layer caused from heat stress.

10368-9, Session 2

Enhanced optical absorption of amorphous silicon films modulated by silicon nitride (Si3N4) nanostructures

Hong Liu, Suzhou Univ. of Science and Technology (China) and Suzhou Thermoelectric Technology Co. (China)

The optical absorption of amorphous silicon (??-Si) films is enhanced by silicon nitride (Si3N4) nanostructures deposited on the films. The reflection of amorphous silicon (??-Si) films at the long wavelength side of localized phonon polaritons (LPPs) resonance originated from silicon nitride nanostructures is significantly decreased, i.e. the optical absorption is enhanced. The results show that the frequency of localized phonon polaritons depend on the sizes and shapes of cylindrical silicon nitride nanoparticles , and the average reflectivity of the amorphous silicon films in the wavelength range of 900–1200nm could be decreased by 20.5%. Moreover, the reduction of the reflection is found to be mainly dependent on the sizes and shapes of the silicon nitride nanostructures, which is related to nanoparticles sizes and shapes which result in the LPP's resonance peak position. The above results indicate that amorphous silicon films modulated by Si3N4 Nanostructures will be a ideal material for photo-thermal absorption.

Reactive colloidal optics for passive tracking of the sun

Ido Frenkel, Avi Niv, Ben-Gurion Univ. of the Negev (Israel)

The growing need for cost effective renewable energy is hampered by the stagnation in solar cell technology. Concentrating photovoltaics (CPV) is a possible mean for increasing the module efficiency. CPV, however, requires cumbersome active tracking that reduces much of its cost effectiveness. Here we propose a passive tracking scheme based colloidal optical device. Here, tracking is achieved by exploiting the capacity of a new kind of colloidal material for light activated binary switching from opacity to transparency, switching that is based a new kind of opto-mechanical force. Being based on phase transition in water this approach is both cost-effective and efficient. We further show that combining this passive tracking approach with an external cavity results in what is possibly a groundbreaking optical approach for solar power conversion. Being external to the cell itself, the proposed approach is indifferent to the type of semiconducting material that is used, as well as to other aspects of the cell design. This, in turn, liberates the cell from optical constraints thus paving the way to higher efficiencies at lower module price.

10368-12, Session 3

Volume holographic lens spectrum splitting photovoltaic system for high energy yield with direct and diffuse solar illumination

Benjamin D. Chrysler, Yuechen Wu, Raymond K. Kostuk, The Univ. of Arizona (United States)

A flat-panel Volume Holographic Lens system is designed to 1) achieve

high conversion efficiency of sunlight at normal incidence, 2) convert diffuse sunlight, and 3) minimize system thickness. Spectrum splitting with a holographic lens is accomplished by focusing a transition wavelength to the junction between two solar cells. Longer wavelength light is dispersed to a narrow bandgap cell (Silicon) and shorter wavelength light to a wide bandgap cell (GaAs) allowing each spectral component to be more efficiently converted. Diffuse sunlight is not Bragg matched and is transmitted through the hologram, and converted to electricity by solar cells. This approach also allows flat-panel module configurations with depths less than 2.5cm. Two holographic lenses are cascaded to achieve efficient diffraction over a broad spectrum (450nm). The diffraction properties of the cascaded elements are optimized to maximize spectral bandwidth while minimizing cross-coupling effects. The holographic elements were fabricated in dichromated gelatin by ‘stitching’ or forming multiple holograms side by side to obtain the desired aperture. A prototype spectrum splitting system shows an increase in conversion efficiency relative to the more efficient cell in the system (GaAs). Experimental results are compared to simulation using non-sequential ray tracing and rigorous coupled wave analysis.

10368-15, Session 4

Transparent solar cell material processing using laser induced thin film epitaxial growth using laser beam holographic patterning and monitoring using RHEED

Mohammad Masum Anwar, Forever Living Products (Bangladesh)

Solar cell material processing is very important for generating efficient power supply from solar energy and this paper will focus on some kind of transparent solar cell that can be used as solar energy emf source and the material processing will be using laser beam induced thin film epitaxial growth by using holographic 3 d patterning and the epitaxial growth mode will be monitored using reflection high energy electron diffraction (RHEED) technique for precision and more efficiency in thin film growth. There are three different thin film epitaxial growth such as island growth , layer growth and island plus layer growth , we will use any mode of crystal growth suing vacuum technique where we will use laser beam holographic technique for crystal growth mode change and patterning and the process of thin film epitaxial growth will be monitored using reflection high energy electron diffraction technique.

10368-17, Session 4

Graphene for thermoelectronic solar energy conversion

Dilip De, Covenant Univ. (Nigeria) and Sustainable Green Power Technologies (United States); Olukunle C. Olawole, Covenant Univ. (Nigeria)

Graphene is a high temperature material which can stand temperature as high as 4600 K in vacuum. Even though its work function is high (4.6 eV) the thermionic emission current density at such temperature is very high. Graphene is a wonderful material whose work function can be engineered as desired. Kwon et al1 reported a chemical approach to reduce work function of graphene using K2CO3, Li2CO3, Rb2CO3, Cs2CO3. The work functions are reported to be 3.7 eV, 3.8 eV, 3.5 eV and 3.4 eV. Even though they did not report the high temperature tolerance of such alkali metal carbonate doped graphene, their works open a great promise for use of pure graphene and doped graphene as emitter (cathode) and collector (anode) in a solar thermionic energy converter. This paper discusses the dynamics of solar energy conversion to electrical energy using thermionic energy converter with graphene as emitter and collector. We have considered parabolic mirror concentrator to focus solar energy onto the emitter so as to achieve temperature around 4300 K. Our theoretical calculations and the modelling show that efficiency as high as 55% can easily be achieved if space-charge problem can be reduced and the collector can be cooled to certain proper temperature. We have discussed methods of controlling the associated space-charge problems. Richardson-Dushman equation modified by the authors have been used in this modeling. Such solar energy conversion would reduce the dependence on silicon solar panel and has great potential for future applications in enery conversion.

10368-18, Session 4

A solar powered device for chlorine generation

Enrico Chinello, Ecole Polytechnique Fédérale de Lausanne (Switzerland); Miguel Antonio Modestino, New York Univ. (United States); Laurent Coulot, Mathieu Ackermann, Insolight Sàrl (Switzerland); Christophe Moser, Ecole Polytechnique Fédérale de Lausanne (Switzerland)

The chlor-alkali process is employed to produce 60 million tons of chlorine each year, accounting for 1% of the overall global energy consumption. Currently, the process involves an electrochemical apparatus fed by almost exclusively grid electricity. Here we present a solar powered chlor-alkali device potentially able to decrease drastically the external energy demand. An innovative solar concentrator is utilized to focus sunlight on multi-junction solar cells, whose output voltage is sufficient to drive the reaction. The electrolyzer is constituted by a nickel-based cathode and a dimensionally-stable-anode (DSA), separated by a cation exchange membrane. The device shows a continuously stable operation when exposed to natural sunlight illumination, with performances that closely match the predictions based on the nearest weather station. Under the tested experimental conditions 16.1% sun-to-chlorine (STC) efficiency was recorded. The device was also tested in absence of direct sun. A typical summer day is reproduced in terms of illumination direction and intensity for each hour of the day; results show the capability of employing the innovative tracking strategy without angular limitations. Despite the relatively small input area of the device tested (5 square-centimeters), it holds the potential to be easily scaled up and be practically implemented.

10368-19, Session 4

A study of the penetration of photovoltaic generation into the Libyan power system

Abdulmunim Guwaeder, Oklahoma State Univ. (United States); Sarhan H. Hasan, Univ. of Denver (United States); Ibrahim Aldaouab, Univ. of Dayton (United States)

Current remarkable tendency in the cost of photovoltaic (PV) modules on a large scale has enhanced their deployment around the world. This paper presents a study of the penetration of photovoltaic generation on the Libyan power system. Further, it also presents a brief description of the Libyan power system with its past and current state of generation and transmissions infrastructure and potential solar power plans.

10369-1, Session 1

Nanostructured materials for selective solar absorbers and thermal emitters *(Invited Paper)*

Sheng Shen, Carnegie Mellon Univ. (United States)

In this talk, I will give two examples about utilizing nanostructured materials to develop selective solar absorbers and thermal emitters. First, I will demonstrate large-scale three-dimensional (3D) nanophotonic solar selective absorbers for solar thermal energy conversion. Compared with traditional photovoltaics, one major advantage of solar thermal energy conversion is the utilization of nearly the entire solar spectrum, enabling higher energy conversion efficiency. To maximize the conversion efficiency of the incident solar flux to heat, one important strategy is to employ spectrally selective solar absorbers that need to exhibit a near-blackbody absorption in the solar spectrum while suppressing infrared emission from the absorbers at elevated temperatures. The novel 3D nanophotonic solar selective absorbers developed in this work can significantly facilitate transformative advancements in the performance and design of solar thermal systems. Second, I will discuss our recent theoretical and experimental work about thermal emission from optical antennas. By carefully designing the thermal emission from optical antennas, we experimentally demonstrate a new type of perfect selective thermal emitters, which can be potentially used for thermal radiation control, high-performance infrared thermal sources and detectors.

10369-2, Session 1

Analysis of monthly solar radiation in Libya

Abdulmunim Guwaeder, Rama Ramakumar, Oklahoma State Univ. (United States)

The development of renewable energy sources generation capacity has increased rapidly over the years, as one of the most widely deployed renewable energy technologies, such as solar photovoltaic (PV), which is considered to be a promising energy source. In order to develop renewable energy sources technology such as photovoltaic, it's necessary to provide analysis at any area of suitability in its employment. Moreover the cost of renewable energy sources has decreased significantly in the last three decades. The amount of solar radiation data received for a specific area is one of the most important meteorological parameters for many application fields. This paper discusses the probability distribution functions (PDF) of a monthly insolation for four locations in Libya based on analysis of 30 years of historical weather data calculated by National Renewable Energy Laboratory (NREL), in order to get appropriate frequency distribution that best fits the data for a given month of the year. The frequency distributions used for solar irradiation data include Weibull, Normal, Lognormal and Gamma functions. The observed radiation at four locations in Libya on a monthly basis are analyzed to evaluate the suitability of the probability distribution functions based on mean square errors. The analysis showed all the probability functions are appropriate for all the locations where weather conditions are relatively steady throughout the year. From the analysis it is concluded that Normal and Weibull distribution give the best fit for observed solar radiation.

10369-3, Session 1

Tailoring nanomaterials for solar driven interfacial steam generation

Jia Zhu, Nanjing Univ. (China)

Water scarcity is one of the most pressing global challenges. Nanomaterials with carefully tailored properties can be used to manipulate the flow of phonons, electrons and photons, to enable unconventional solution to addressing this issue. In this talk, I will present our recent progress in solar steam generation for water treatment.

We report a plasmon-enhanced solar desalination device. This most efficient and broad-band plasmonic absorber is fabricated through self-assembly of metallic nanoparticles onto a nanoporous template by one step deposition process. Because of its efficient light absorption and strong field enhancement, it can enable very efficient and effective solar desalination by using low cost aluminum nanoparticles.

Inspired by the transpiration process in plants, we report an artificial transpiration device with a unique design of two dimensional water path. With efficient two dimensional water supply and suppressed heat loss, it can enables an efficient (80% under one-sun illumination) and effective (four orders salinity decrement) solar desalination device. More strikingly, the energy transfer efficiency of this artificial transpiration device is independent of water quantity and can be achieved without extra optical or thermal supporting systems, therefore significantly improve the scalability and feasibility of this technology.

10369-4, Session 1

Spectrum splitting for thermal management in photovoltaic concentrators

Harry N. Apostoleris, Matteo Chiesa, Ibraheem Al-Mansouri, Masdar Institute of Science & Technology (United Arab Emirates)

Spectrum splitting between two or more cells of different band gaps is a well established way of enhancing the output of a photovoltaic system. Less widely explored is the impact of spectrum splitting on thermal management in PV concentrator systems. By dividing light between multiple cells, or between cells and thermal absorbers, cell heating can be significantly reduced. This is particularly relevant in certain proposed tracking-integrated systems, where the inclusion of internal sun-tracking mechanisms may require that cells be free to move within the module, and therefore be thermally isolated to only poorly contacted to a heat sink. We model several spectrum-splitting scenarios for a low-concentration trough-receiver and investigate the effects of different spectrum-splitting concepts on cell temperature and performance, using a combination of optical, thermal and PV-modeling software tools to capture the full process of solar energy collection, conversion and extraction. To corroborate the theoretical analysis we realize a spectrum-splitting system in an experimental prototype based on the 3D-printed trough concentrators that we have previously demonstrated, and compare the receiver temperature and cell performance for both split and broad band spectra. Finally we discuss in general terms the design principles that lead to the most effective thermal management in split-spectrum systems, and further steps that can be taken to minimize cell heating in unconventional module configurations.

10369-5, Session 2

Metasurfaces for angular and spectral control of thermal radiation *(Invited Paper)*

Luke A. Sweatlock, Katherine T. Fountaine, Northrop Grumman Aerospace Systems (United States)

Design of perfect absorbers and emitters has been a primary focus of the metamaterials community owing to their potential to enhance device efficiency and sensitivity in energy harvesting and sensing applications, specifically photovoltaics, thermal emission control, bolometers and photodetectors, to name a few. While reports of perfect absorbers/emitters for a specific frequency, wavevector, and polarization are ubiquitous, a broadband and polarization- and angle-insensitive perfect absorber remains a particular challenge. In this work, we report on directed optical design and fabrication of sparse III-V nanowire arrays as broadband, polarization- and angle-insensitive perfect absorbers and emitters. Specifically, we target response in the UV-Vis-NIR and NIR-SWIR-MWIR via two material systems, InP (Eg=1.34 eV) and InSb (Eg=0.17 eV), respectively.

Herein, we present results on InP and InSb nanowire array broadband absorbers, supported by experiment, simulation and analytic theory. Electromagnetic simulations indicate that, with directed optical design, tapered nanowire arrays and multi-radii nanowire arrays with 5% fill fraction can achieve greater than 95% broadband absorption (?InP=400-900nm, ?InSb=1.5-5.5μm), due to efficient excitation and interband transition-mediated attenuation of the HE11 waveguide mode. Experimentally-fabricated InP nanowire arrays embedded in PDMS achieved broadband, polarization- and angle-insensitive 90-95% absorption, limited primarily by reflection off the PDMS interface. Addition of a thin, planar VO2 layer above a sparse InSb nanowire array enables active thermal tunability in the infrared, effecting a 50% modulation, from 87% (insulating VO2) to 43% (metallic VO2) average absorption. These concepts and results along with photovoltaic and other optical and optoelectronic device applications will be discussed.

10369-6, Session 2

Thermal radiation management by metasurfaces

Sandeep Inampudi, Mohammad Mahdi Salary, Hossein Mosallaei, Northeastern Univ. (United States)

Controlling and confining the flow of thermal radiation is one of the key factors in most of the current nano-scale to macro-scale devices. While the existing principles of metasurfaces originally designed for coherent sources are not directly applicable here, we present by combining the principles of electromagnetic theory with the fluctuation-dissipation theorem, engineered nanostructures to manipulate thermal radiation emission from hot bodies. Utilizing the developed formulation, we design a composite structure consisting of both metamaterials and metasurfaces that simultaneously controls both the emission magnitude and direction of thermal radiation.

10369-7, Session 2

High temperature ENZ plasmonics and thermal graphene metamaterials *(Invited Paper)*

Zubin Jacob, Purdue Univ. (United States)

No Abstract Available

10369-8, Session 3

Amorphous metamaterials for large scale day-time radiative cooling *(Invited Paper)*

Xiaobo Yin, Univ. of Colorado Boulder (United States)

We demonstrate a 300-mm-wide, amorphous, organic-inorganic hybrid metamaterial manufactured on a roll-to-roll extruder for effective day-time radiative cooling. It has an infrared emissivity greater than 0.93 across the entire atmospheric window (8-13μm) while being fully transparent to solar irradiance, approaching the theoretical limit of spectroscopic performance for day-time radiative cooling. We also demonstrated an averaged noon-time (11 am-2 pm) radiative cooling power of 93 W/m2 and greater than 110 W/m2 averaged cooling power during a continuous three-day field test. The scalably manufactured metamaterial shows potential for large-scale cooling applications, such as cool roofs and the cooling of solar cell panels to improve cell efficiency.

10369-9, Session 3

Super-cool paints: Optimising composition with a modified four-flux model

Marc A. Gali Labarias, Matthew D. Arnold, Angus R. Gentle, Geoffrey B. Smith, Univ. of Technology, Sydney (Australia)

Optimization approaches to formulating paint able to create cool roofs is examined. Such paints maintain a roof under summer sun at temperatures close to or below ambient to reduce cooling demand in buildings and help to reduce peak urban air temperatures (the UHI problem). The aim is albedos in the range 90% to 96% so maximised spectral reflectance R(?) across the solar spectrum is required. 95% is easy to achieve at visible wavelengths but achieving best values also in the NIR remains a major challenge. Low cost for materials and a fast application process is also needed for city scale impacts and very large areas. At NIR wavelengths typical low cost, cool painted surfaces reduce NIR backscattering and raise NIR absorption. Composite structures that retain high visible reflectance while producing high NIR reflectance are possible. A variety of composite structures are studied and ranked according to their albedo.

Models and some data include impact of fill factors, particle size and material, size mix, and possible binder materials. The model used is a variation of the classical four-flux method, a differential method that solves the energy transfer problem through four balance equations. We use a different approach to the characteristic differential parameters to define the absorptance and scattering of the complete complex composite. This generalization allows extension to consider size dispersion of each type of particle used and various binders.

10369-10, Session 3

3D printable optical structures for sub-ambient sky cooling

Angus R. Gentle, Altay Nuhoglu, Matthew D. Arnold, Geoffrey B. Smith, Univ. of Technology, Sydney (Australia)

There has been continued recent interest in radiative sky cooling of flat surfaces, due to the ability to passively attain sub-ambient temperatures. As the clearest sky (lowest incoming infrared radiation) occurs at the zenith, ideally a surface will see this region of the sky, while limiting the view of the near horizon which has significantly more incoming radiation. Two approaches to this are angular selectivity, which limits outgoing as well as incoming radiation, and macroscopic reflectors which limit incoming sky radiation, while maximising the outgoing emitted radiation. This work focuses on the second of these techniques. Here we maximise the cooling potential via coated 3D printed structures which can passively maintain a thermal reservoir below ambient temperature throughout the night and day. We demonstrate novel design methods, to fabricate and test structures which maximise outgoing thermal radiation from a surface, while

minimising incoming radiation from the sky and sun. Preliminary results gave 10°C below both ambient both day and night during a Sydney summer. 3D printing allows the production of complex designed mirror cones with relatively low thermal conductivity. Post processing of the 3D printed structures allows the desired surface textures and optical properties to be created.

10369-11, Session 4

The superradiant effect in thermal emission *(Invited Paper)*

Zongfu Yu, Univ. of Wisconsin Madison (United States)

When wave effects of thermal photons become significant, thermal emitters can exhibit intriguing coherent effects. Here, we show that the superradiant emission, which was originally found in quantum emitters, can be realized in resonant thermal emitters. Similar to the superradiance in quantum emitters, the in-phase oscillation of resonant emitters reduces the lifetime of thermal photons in the emitters. Unlike the atomic superradiance, one remarkable consequence of the thermal superradiance is the anomalous power scaling, where the emission power can scale inversely with the number of thermal emitters. More thermal emitters generate less power due to the coherent interference of thermal photons.

10369-12, Session 4

Radiative cooling for concentrating photovoltaic systems

Yubo Sun, Zhiguang Zhou, Xingshu Sun, Muhammad Ashraful Alam, Peter Bermel, Purdue Univ. (United States)

Radiative cooling, merging as a unique but not widely used passive cooling method for devices operating outdoors, has been studied and demonstrated to be effective for photovoltaic thermal management. In this work, we investigate the effect of radiative cooling as a complementary to existing passive cooling methods like convective cooling for a system with much higher heat load, a concentrating photovoltaics (CPV) system, where severe thermal management challenges are encountered. A feasible radiative cooling enabled CPV system is proposed with its theoretical cooling limit calculated. Compared with a CPV system cooled via convective cooling only (with zero emittance), radiative cooling enables another temperature drop over ~36 K with an area ratio of ~800 at 1000 suns concentration and limited convection. A systematic simulation with realistic cooler design is then performed. The radiative cooler proposed in this work consists of low-iron soda-lime glass with a porous layer on top as an anti-reflection coating. It is found that a simple structure as proposed has strong mid-IR emittance as well as spectral selectivity that resembles an ideal cooler. Subsequently, the geometry of the radiative-cooled CPV system is optimized. The net result for a crystalline silicon PV is a relative increase in power production of at least 18% via radiative cooling and substantially higher reliability. Furthermore, the associated cooler volume can be substantially reduced relative to a finned convective heat sink.

10369-13, Session 4

Structure optimization of metallodielectric multilayer for high-efficiency daytime radiative cooling

Takahiro Suichi, Atsushi Ishikawa, Yasuhiko Hayashi, Kenji Tsuruta, Okayama Univ. (Japan)

Engineered metallodielectric nanostructures offer a new platform for controlling thermal emission in a desired manner, thus promise potential applications in passive cooling devices. Here, we present optimization design of metallodielectric multilayer structures for high-efficiency daytime radiative cooling and experimentally characterize their cooling performance. The device structure consisted of alternating layers of SiO2 and PMMA on an Al mirror, which worked as a selective thermal emitter at 8-13 μm with a high reflectance for sunlight. Automated design scheme based on simulated annealing method combined with photonic-thermal analysis was developed and applied to search the optimized number and thickness of each layer. The evaluation function in the optimization process was predefined such that a net emission power would be maximized at the ambient temperature of 300 K under the sunlight irradiation of AM1.5. The numerical results proved efficient radiative cooling to 2.5 K below the ambient temperature, corresponding to 13.5 K below the bare Al mirror temperature. Based on the optimized design, the device was fabricated on an Al mirror by using SiO2 deposition and spin-coating process over an area of 25 mm ? 25 mm. The reflectance and absorption properties of the fabricated device were characterized to demonstrate the selective thermal emission at the mid-infrared region. The equilibrium temperature of the device was also investigated to demonstrate the cooling performance under the direct sunlight irradiation.

10369-14, Session 5

High performance incandescent light bulb using a selective emitter and nanophotonic filters *(Invited Paper)*

Arny Leroy, Bikram Bhatia, Kyle Wilke, Evelyn N. Wang, Massachusetts Institute of Technology (United States)

While traditional incandescent light bulbs (ILB) are inefficient – reaching a luminous efficiency of just about 2% as most of the energy is radiated as infrared, they are still often preferred over alternatives because of their low price and high color rendering index (CRI). Previous approaches to improve the efficiency of ILBs have relied on tailoring the emitted spectrum using cold side interference filters that reflect the infrared energy back to the filament while transmitting the visible light. While this approach has, in theory, potential to surpass light-emitting diodes (LEDs) in terms of luminous efficiency while conserving the excellent CRI, system-level losses and challenges such as low view factor, high filament (>2800 K) and filter temperatures and tungsten evaporation have significantly limited the maximum efficiency. In this work, we propose combining a cold side filter with a selective emitter to further enhance the efficiency while preserving a near-perfect CRI. In particular, we analyze the effect of non-idealities of the cold side filter and the selective emitter on the luminous efficiency. On the cold side filter, we show that high reflectivity in the infrared and near unity view factor is critical. On the emitter side, we demonstrate that high emissivity in the visible combined with low emissivity in the infrared can lead to efficiencies higher than ILBs and even LEDs. Finally, we show that this approach can match the efficiency of LEDs while operating at much lower temperatures (2350 K) than conventional ILBs, thus alleviating the system-level challenges due to high temperatures.

10369-15, Session 5

Nanostructure enhanced near-field radiative heat transfer and designs for energy conversion devices

Bingnan Wang, Chungwei Lin, Koon Hoo Teo, Mitsubishi Electric Research Labs. (United States)

Near-field radiative heat transfer can exceed the blackbody limit, and this property has been explored toward energy transfer and conversion applications, such as thermophtovoltaic (TPV) devices, radiative cooling devices, and thermoradiative (TR) devices. The coupling of resonant modes between two surfaces is important in near-field heat transfer and near-field TPV systems. Recently, coupled-mode theory has been developed for the analysis and optimal design of TPV systems. In this paper, we show that all important parameters, including near-field emissivity of an emitter, the transmissivity from an emitter to an absorber, the radiation power from the emitter, the electric power generated by the photovoltaic (PV) cell, and eventually the power conversion efficiency of a near-field TPV system, can

be calculated from the resonant modes that are supported by the system. The calculation can be applied to both planar configurations, as well as nanostructured systems. While the frequency of surface plasmon polariton (SPP) resonance is fixed for a planar emitter, a nanostructured emitter supports additional resonances such as SPP or cavity modes with lower frequencies that are closer to the bandgap energy of a typical TPV cell. We show that this significantly improves the near-field radiative power transfer and electric power output for a TPV system.

10369-16, Session 5

Fabrication and thermal analysis of micro thermocouples for energy harvesting

Brhayllan Mora-Ventura, Gabriel González, Francisco Javier González, Univ. Autónoma de San Luis Potosí (Mexico)

We present the thermal study of micro thermocouples fabricated by electron beam lithography process, the micro thermocouples (MTCs) are based on a recently discovered thermoelectric effect in single-metal nanostructures with cross-sectional discontinuity, single-metal MTCs would simplify the fabrication process and allow the large-scale production of these devices using fabrication technologies such as nanoimprint lithography. In this work, we have investigated the temperature difference between the asymmetric unions of the micro thermocouples using Optotherm EL InfraSight 320 thermal imaging camera. Results show that single-metal MTCs are promising structures that could be used to harvest thermal radiation and generate electric energy through the Seebeck effect.

10369-17, Session 5

Demonstration of 24% efficient thermophotovoltaic energy conversion using 1055 C selective emitter

David Woolf, Physical Sciences Inc. (United States); Emil A. Kadlec, Don Bethke, Eric A. Shaner, Sandia National Labs. (United States); Joel Hensley, Physical Sciences Inc. (United States)

We demonstrated thermophotovoltaic (TPV) energy conversion using a selective thermal emitter whose emissivity was designed to match the external quantum efficiency of a 0.6 eV bandgap photovoltaic (PV) cell. Additional filtering of the transmitted radiation was achieved using a dielectric filter between the emitter and the PV cell. With the emitter at 1055 C, we measured 0.189 Watts/cm2 of power out of the PV cell. From a series of experiments, we were able to determine that the PV cell converted 24% of the power incident upon it into electricity.

Conference 10370: Reliability of Photovoltaic Cells, Modules, Components, and Systems X

SPIE. OPTICS+ PHOTONICS OPTICAL ENGINEERING+ APPLICATIONS

Sunday - Monday 6 –7 August 2017

Part of Proceedings of SPIE Vol. 10370 Reliability of Photovoltaic Cells, Modules, Components, and Systems X

10370-1, Session 1

Comparison of higher irradiance and black panel temperature UV backsheet exposures to field performance *(Invited Paper)*

Thomas C. Felder, William J. Gambogi, Steven W. MacMaster, Bao-Ling Yu, T. John Trout, DuPont Photovoltaic Solutions (United States)

Current IEC standard 61215 was adopted in 2005 and has been useful in revealing design flaws and manufacturing defects, but does not address long-term durability. The IEC is now developing a Weathering Technical Standard for backsheet qualification, IEC 62788-7-2, and an important component of this proposal is a higher irradiance and higher black panel temperature UV Xenon exposure (0.8W/sqm-nm and 90C BPT). Comparing results with field data is needed. We have tested polyester-based and PVF-based backsheets according to the proposed standard. Along with exposure, several specimen stuctures based on glass / EVA laminates are proposed to mimic the backsheet service environment. Samples were exposed as glass / EVA / EVA / backsheet laminates, and in the same structure with a transparent separator sheet between the backsheet and the EVA. Samples were exposed on both the airside and glass side.We find PET yellowing with no mechanical loss at the current 0.55 W/sqm-nm 70C BPT exposure condition. Increasing irradiance alone has no effect on yellowing, but leads to an observable drop in % elongation in the PET backsheets. Increasing black panel temperature with the higher irradiance increases both PET yellowing and mechanical loss. Comparative field results taken from a database of panels in the field 4 - 14 years. Results from the new exposure are closer to field data

10370-2, Session 1

Degradation analysis of field exposed photovoltaic modules with non-fluoropolymer-based backsheets

Andrew Fairbrother, National Institute of Standards and Technology (United States); Scott Julien, Kai-Tak Wan, Northeastern Univ. (United States); Liang Ji, Kenneth P. Boyce, Underwriters Labs. Inc. (United States); Sebastien Merzlic, Amy A. Lefebvre, Greg O'Brien, Arkema Research Ctr. (United States); Yu Wang, Laura S. Bruckman, Roger H. French, Case Western Reserve Univ. (United States); Michael D. Kempe, National Renewable Energy Lab. (United States); Xiaohong Gu, National Institute of Standards and Technology (United States)

The polymeric components of photovoltaic (PV) modules have changed little since the inception of the PV industry, with ethylene-vinyl acetate and fluoropolymer-based laminates being the most widely adopted encapsulant and backsheet materials, respectively. The backsheet in particular must serve as electrical insulation and to protect the solar cells from weathering. Due to continued downward pressure on cost, non-fluoropolymer-based materials are being modified to withstand outdoor exposure, including polyester- and polyamide-based backsheets. Because of their relatively recent deployment, less is known about their reliability and if they can stand up to the 25+ year warranty rated lifetimes of PV modules.

In that context this work presents a degradation analysis of field-exposed modules with polyester- and polyamide-based backsheets. Modules were exposed for up to five years in different geographic locations: USA (Ohio), Italy, China, and unexposed. Surface and cross-sectional analysis included visual inspection, colorimetry, gloss, Raman and Fourier-transform infrared spectroscopies, and scanning electron microscopy. Each module experienced different types and profiles of degradation depending on the exposure site, even for the same material and module brand. For instance, the polyamide-based backsheet experienced microcracking and greater yellowing in China, while in Italy it underwent macroscopic cracking and higher changes in gloss. Spectroscopic studies led to identification of degradation products and changes in polymer structure over time. Comparisons will be made to fielded modules with fluoropolymer-based backsheets, as well as materials in accelerated laboratory exposures. Implications for the service life prediction of the non-fluoropolymer-based backsheets will be discussed.

10370-3, Session 1

Comparison of PV module backsheet materials under multi-factor accelerated UV light exposures

Addison G. Klinke, Case Western Reserve Univ. (United States); Abdulkerim Gok, Case Western Reserve Univ. (United States) and Gebze Technical Univ. (Turkey); Roger H. French, Laura S. Bruckman, Case Western Reserve Univ. (United States)

Long term outdoor durability of photovoltaic module backsheets is critical to the module's power output over lifetime. The use of fluoropolymer-based backsheets or the addition of stabilizers to polyethylene-terephthalate (PET) and polyamide (PA) type backsheets can help extend the lifetime of these backsheets. In this study, the performance of 20 different types of backsheets under ASTM G154 Cycle 4 accelerated light exposures are presented. The backsheets were subjected to 4000 hours of high irradiance UVA light at 1.55 W/m2/nm at 340 nm at 70 oC with or without condensing humidity cycle. Backsheets were evaluated, with repeated measurements, using various evaluation techniques to identify and assess potential degradation mechanisms. These evaluations included the change in yellowness index (YI), gloss, UV-Vis absorbance, and Infrared spectroscopy. Fluoropolymer-based backsheets were found to withstand these exposure with only slight changes; however, PET and PA based backsheets showed serious yellowing and cracking under indoor exposures, and the stabilizer additives only helped protecting the polymers to some extent. Semi-supervised, generalized, network structural equation modeling (netSEM) analytics was then applied in order to explore statistically significant relationships describing the degradation of materials. In this stress | mechanism | response (< S|M|R>) framework, the type and level of multiple stressors (UV light, heat, humidity) and the observed physical and chemical responses are connected with statistical models to discover a network of mechanistic degradation pathways identifying factors contributing to overall degradation.

10370-4, Session 1

Characterizing the weathering induced changes in the optical performance and properties of poly(ethylene-terephthalate) via MaPd:RTS spectroscopy *(Invited Paper)*

Devin A. Gordon, Case Western Reserve Univ. (United States); Lin DeNoyer, Deconvolution & Entropy Consulting (United States); Corey W. Meyer, Noah W. Sweet, Case Western Reserve Univ. (United States); David M. Burns, 3M

Co. (United States); Laura S. Bruckman, Roger H. French, Case Western Reserve Univ. (United States)

Poly(ethylene-terephthalate) (PET) film is widely used in photovoltaic module backsheets for its dielectric breakdown strength, and in applications requiring high optical clarity for its high transmission in the visible region. However, PET degrades and loses optical clarity under exposure to ultraviolet (UV) irradiance, heat, and moisture. Stabilizers are often included in PET formulation to increase its longevity; however, even these are subject to degradation and further reduce optical clarity. To study the weathering induced changes in the optical performance and properties in PET films, samples of a UV-stabilized grade of PET were exposed to heat, moisture, and UV irradiance as prescribed by ASTM-G154 Cycle 4 for 168 hour time intervals. In a previous study it was found that material yellowing is dominant under exposure to UV light, while the addition of moisture to the exposure increases the light scattering behavior of the samples. UV-Vis reflection and transmission spectra were collected via Multi-Angle, Polarization-Dependent, Reflection, Transmission, and Scattering (MaPd:RTS) spectroscopy after each exposure interval. The resulting spectra were used to calculate the complex index of refraction throughout the UV-Vis spectral region via an iterative optimization process based upon the Fresnel equations. The index of refraction and extinction coefficient were found to vary throughout the UV-Vis region with time under exposure. The spectra were also used to investigate changes in light scattering behavior with increasing exposure time. The intensity of scattered light was found to increase at higher angles with time under exposure.

10370-5, Session 2

Comparison of modeled and experimental PV array temperature profiles for accurate interpretation of module performance and degradation

Teri Elwood, Kelly Simmons-Potter, The Univ. of Arizona (United States)

Quantification of the effect of temperature on photovoltaic (PV) module efficiency is vital to the correct interpretation of PV module performance under varied environmental conditions. However, previous work has demonstrated that PV module arrays in the field are subject to significant location-based temperature variations associated with, for example, local heating/cooling and array edge effects. Such thermal non-uniformity can potentially lead to under-prediction or over-prediction of PV array performance due to an incorrect interpretation of individual module temperature de-rating. In the current work, a simulated method for modeling the thermal profile of an extended PV array has been investigated through extensive computational modeling utilizing ANSYS, a high-performance computational fluid dynamics (CFD) software tool. Using the local wind speed as an input, simulations were run to determine the velocity at particular points along modular strings corresponding to the locations of temperature sensors along strings in the field. The point velocities were utilized along with laminar flow theories in order to calculate Nusselt's number for each point. These calculations produced a heat flux profile which, when combined with local thermal and solar radiation profiles, were used as inputs in an ANSYS Thermal Transient model that generated a solar string operating temperature profile. A comparison of the data collected during field testing, and the data fabricated by ANSYS simulations, will be discussed in order to authenticate the accuracy of the model.

10370-6, Session 2

Artifact-free coring of solar modules

Helio R. Moutinho, Steve Johnston, Bobby To, Chun-Sheng Jiang, Chuanxiao Xiao, Peter Hacke, John Moseley, Jerry Tynan, National Renewable Energy Lab. (United States); Neelkanth G. Dhere, Univ. of Central Florida (United States); Mowafak M. Al-Jassim, National Renewable Energy Lab. (United States)

Traditionally, researchers have studied solar panel performance and degradation by analyzing parameters such as efficiency and output power, which are measures of bulk properties. However, manufacturers would find it useful to know how these properties are related to local degradation that is associated with microscopic defects. The first requirement in performing this type of research is to develop procedures for removing (coring) small specimens from a solar panel without changing their properties during the process. Indeed, little information is available in the literature on this subject. In this work, we will describe our development of two coring procedures applied to Si, CdTe, and CIGS solar panels.

We developed the first procedure to accommodate most solar panels, which use tempered glass that shatters into small pieces when cut. In this case, we first shattered the glass and then cut the cores. Finally, we used a process to dissolve the ethylene vinyl acetate to obtain small pieces of the panel.

In the second procedure, we did a partial coring, i.e., we cored part of the panel, excluding the tempered glass. Then we attached a post with glue to the cored part of the panel and removed the sample from the panel.

To locate specific areas to be cored, we used electroluminescence and dark lock-in thermography. To investigate possible damage of structural and electro-optical properties during coring, we evaluated material quality by different analytical techniques, such as scanning electron microscopy, energy-dispersive X-ray spectroscopy, electron backscatter diffraction, scanning Kelvin probe force microscopy, and electron-beam induced current. In particular, to investigate changes in the defect structure, we analyzed some samples before coring by electroluminescence, and after coring by photoluminescence—on exactly the same area.

In this work, we describe in detail the two coring procedures applied to different kinds of modules, and show results of different analyses that prove the efficacy and reliability of our coring procedures.

10370-22, Session 2

Temperature coefficient of power (Pmax) of field aged PV modules: Impact on performance ratio and degradation rate determinations

Farrukh Mahmood, Hatif Majeed, Haider Agha, Saddam Ali, USPCAS-E, National Univ. of Sciences and Technology (Pakistan); Sai Tatapudi, Telia Curtis, GovindaSamy TamizhMani, Arizona State Univ. (United States)

The determinations of performance ratio (per IEC 61724 standard) and degradation rate (using slope of performance ratio over time) of photovoltaic (PV) modules in a power plant are computed based on the power (Pmax) temperature coefficient data of the unexposed modules or the exposed modules during the commissioning time of the plant. The temperature coefficient of Pmax is typically assumed to not change over the lifetime of the module in the field. Therefore, this study was carried out in an attempt to investigate the validity of this assumption and current practice. Several 15-20 years old field aged modules from four different manufacturers underwent baseline light I-V measurements and dark I-V measurements to determine the power temperature coefficient and series resistance for each module. Using the dark I-V and light I-V data, the series resistances (Rs) and shunt resistances (Rsh) were calculated in order to determine their impact on fill factor (FF) and hence on Pmax. The result of this work indicates a measurable drop in fill factor (FF) as the series resistance (Rs) increased which in turn increases the temperature coefficient of Pmax. This determination goes against the typical assumption that the temperature coefficient of (Pmax) for aged modules does not change over time. The outcome of this work has a significant implication on the performance ratio and degradation rate determinations based on the temperature coefficient of Pmax of new modules which is not an accurate practice for analyzing field aged modules.

10370-7, Session 3

Exposure of CIGS solar cells to negative, zero and positive electrical biases in a damp-heat Illumination environment *(Invited Paper)*

Mirjam Theelen, TNO (Netherlands) and Solliance (Netherlands); Klaas Bakker, Energy Research Ctr. of the Netherlands (Netherlands) and Solliance (Netherlands); Henk Steijvers, Gabriela De Amorim Soares, Soheyl Mortazavi, TNO (Netherlands) and Solliance (Netherlands); Jeroen Vink, ReRa Solutions B.V. (Netherlands); Nicolas Barreau, Institut des Matériaux Jean Rouxel (France); Erik Haverkamp, ReRa Solutions B.V. (Netherlands)

In earlier studies, unencapsulated CIGS solar cells were exposed to damp heat and illumination in an hybrid degradation setup, while their electrical parameters were real-time determined. In these studies, solar cells were kept under open circuit voltage, while operating solar cells perform at the maximum powerpoint, while shading can lead to negative voltages. Since it is known that exposure to small and large (reverse) bias voltages can modify [1,2,3] device performance, electrical loads were installed in the hybrid degradation setup.

Unencapsulated CIGS solar cells were exposed to damp heat and illumination, combined with open circuit, maximum powerpoint, short circuit and negative (-0.5V) voltage biases. In a preliminary study, differences could not be observed for the zero and positive voltages, while the solar cells under negative bias degraded faster. This was mostly caused by a more rapid decrease of the open circuit voltage of these cells.

In a second experiment, CIGS solar cells were exposed to the same conditions, which were changed after ~73 hours. Cells previously exposed to zero or positive biases, were set to -0.5V, while the cells exposed to -0.5V were exposed to -1.5V. These changes led to efficiency decreases of over 1 % point. It was therefore concluded that sudden negative bias exposure of these unencapsulated cells had a strong negative effect on their performance.

Ultrashort pulsed laser ablation for decollating of solid state lithium-ion batteries

Christian J. Hördemann, Hemanth Anand, Arnold Gillner, Fraunhofer-Institut für Lasertechnik (Germany)

Rechargeable lithium-ion batteries with liquid electrolytes are the main energy source for many electronic devices that we use in our everyday lives. But there are drawbacks of this energy storage technology as the liquid electrolyte impose a great danger to the user and the environment. Also lithium-ion batteries are limited in voltage, energy density and the range of operating temperature. One novel and promising battery technology are Solid-State Lithium-Ion Batteries (SSLBs) that can be produced without limitations to the geometry, are bendable in contrast to conventional batteries, have a high volumetric and gravimetric energy density and are intrinsically safe since no liquid electrolyte is used. However, manufacturing costs are still high and existing production-technologies are comparable to the processes used in the semiconductor industry. Single cells are produced in batches with masked-deposition at low rates. In order to decrease manufacturing costs and to move towards continuous production, Roll2Roll production methods offer the possibility to produce large quantities of substrates with deposited SSLB-layers. From this coated substrate, single cells can be cut out. For the flexible decollation of SSLB-cells from the substrate, new manufacturing technologies have to be developed since blade-cutting, punching or conventional laser-cutting lead to short circuits between the layers. Here, ultra-short pulsed laser ablation and cutting allows the flexible decollating of SSLBs. By selective ablation of individual layers, an area for the cutting kerf is prepared so that a shortcut-free decollation is possible. The approach can easily be transferred to the decollating of flexible electronics and flexible solar modules since the production process is similar.

10370-9, Session 4

Impact of PID on industrial roof-top PV-installations

Claudia Buerhop-Lutz, Frank W. Fecher, Tobias Pickel, Tirth Patel, Bayerisches Zentrum für Angewandte Energieforschung e.V. (Germany); Cornelia Zetzmann, Rauschert GmbH (Germany); Christian Camus, Jens A. Hauch, Bayerisches Zentrum für Angewandte Energieforschung e.V. (Germany); Christoph J. Brabec, Bayerisches Zentrum für Angewandte Energieforschung e.V. (Germany) and i-MEET (Germany)

Potential induced degradation (PID) causes severe damage and financial losses even in modern PV-installations. In Germany, approximately 19% of PV-installations suffer from PID [1] and resulting power loss. This paper focuses on the understanding of PID generation in real installations.

What promotes the unexpected inhomogeneous and fast development of PID on rooftop installations of industrial buildings? How does PID impact the module performance?

The analysis focuses exemplarily on a 314 kWp PV-installation in the Atlantic coastal climate. IR-imaging [2, 3] is used for identifying PID without operation interruption. Continuous historic electric performance data are available from a monitoring system on string level as well as punctually measured string IV-curves. Both data sets are combined for understanding the PID behavior of this PV plant.

The number of PID affected cells within a string varies strongly between 1 to 22% with the string position on the building complex after an operation period of just 3 years. With increasing number of PID-affected cells the performance ratio (PR) decreases down to 60%. Local differences in PID evolution rates are identified. A PR-reduction of 3.65% per year is found for the PV-plant.

The analysis reveals that PID generation and progress in rooftop installations on industrial buildings can be fairly complex. The results yield that local conditions, e. g. ambient weather conditions (solar irradiance, temperature, humidity, wind) as well as shading and influence of distinct roof installations, e. g. heat or dust emissions on an industrial building, seem to have a dominating impact on the PID degradation rate.

10370-10, Session 4

Effect of bias application or light irradiation during PID tests of CIGS modules and crystalline silicon modules

Keiichiro Sakurai, Kinichi Ogawa, Hajime Shibata, Atsushi Masuda, National Institute of Advanced Industrial Science and Technology (Japan); Hiroshi Tomita, Darshan Schmitz, Shuuji Tokuda, Solar Frontier K.K. (Japan)

We experimentally studied the effects of forward bias application or light irradiation during PID tests of CIGS, as well as of some crystalline silicon (c-Si) modules. 96 hours of PID tests were conducted on modules after

300~1000 hours of damp heat testing. Some modules have shown lesser degradation by irradiating white LED (blue+yellow) light during PID tests. We would also report on effects of forward bias voltage during PID tests.

10370-21, Session 4

Mitigation of PID in commercial PV modules using current interruption method

Birinchi Bora, National Institute of Solar Energy (India) and TERI Univ. (India); Jaewon Oh, Sai Tatapudi, Arizona State Univ. (United States); Oruganty Sastry, Rajesh Kumar, National Institute of Solar Energy (India); Basudev Prasad, TERI Univ. (India); Govindasamy Tamizhmani, Arizona State Univ. (United States)

Potential induced degradation (PID) is known to have a very severe effect on the reliability of PV modules. PID is caused due to the leakage of current from the cell circuit to the grounded frame under humid conditions of high voltage PV systems. There are multiple paths for the current leakage. The most dominant leakage path is from the cell to the frame through encapsulant, glass bulk and glass surface. This dominant path can be prevented by interrupting the conductivity at the glass surface. In our previous works related to this topic, we demonstrated the effectiveness of glass surface conductivity interruption technique using one-cell PV coupons. In this work, we demonstrate the effectiveness of this technique using a full size commercial module susceptible to PID. The interruption of surface conductivity of the commercial module was achieved by attaching a narrow, thin flexible glass strips, from Corning, called Willow Glass® on the glass surface at the inner edges of the frame. The flexible glass strip was attached to the module glass surface by heating the glass strip with an ionomer adhesive underneath using a handheld heat gun. The PID stress test was performed at 60°C and 85% RH for 96 hours at ?600V. Pre- and post-PID characterizations including I-V and electroluminescence were carried out to determine the performance loss and affected cell areas. This work demonstrates that the PID issue can be effectively addressed by using this technique. An important benefit of this approach is that this interruption technique can be applied after manufacturing the modules and after installing the modules in the field as well.

10370-11, Session 5

Development of calibration standards for extremely low permeation measurement *(Invited Paper)*

Michael D. Kempe, Matthew O. Reese, Arrelaine A. Dameron, Dylan L. Nobles, Talysa R. Klein, Byron McDanald, National Renewable Energy Lab. (United States)

Flexible photovoltaic applications are typically made using thin film devices that are sensitive to moisture ingress. Because of this, there is a need to develop flexible barrier materials with permeation rates less than 10-4 g/m?/day. To put this in perspective, a permeation rate this low would be expected to pass enough water for a layer that is only 1 micron thick after 20 years. There are many methods suitable for measuring permeation rates this low but unfortunately, previously calibration standards suitable for validating these measurement methods below around 10-3 g/m?/day were not available.

In this work we demonstrate the development of a calibration standard suitable for measurement much less than 10-4 g/m?/day. These calibration standards are constructed by first drilling a ~2.3 mm diameter hole, inserting a glass capillary into the hole and sealing it using a low melting point glass solder creating a hermetic seal. The glass capillaries have an outer diameter of 2 mm and an inner diameter ranging between 0.025 mm and 1 mm. To further restrict moisture ingress through the capillary, it is filled with a polydimethyl siloxane elastomer. The moisture permeation properties of the silicone are known from transient permeation studies using conventional permeation equipment so that geometric considerations allow us to predict the moisture permeation rate through these standards and control it in the range from 1 g/m?/day to ~8·10-7 g/m?/day. This range of permeation rates is needed because it overlaps with conventional methods and NREL's custom method able to measure less than 10-6 g/m?/day to allow some inter-comparison with known and unknown permeation measurements.

10370-12, Session 5

Conducting paste based soldering process for thin crystalline silicon photovoltaic module

Hyung-Jun Song, Woo Gyun Shin, Ga Eon Jin, Gi-Hwan Kang, Korea Institute of Energy Research (Korea, Republic of)

Thin crystalline silicon photovoltaic (c-Si PV) module (< 100 um) will be dominant market owing to its low cost. However, high temperature soldering process for PV module to connect PV cells in serial and parallel induces bowing and crack of cells owing to different thermal expansion coefficient between silicon and ribbon. Moreover, it is expected that thermo-mechanical stress issues will deteriorate the performance of thin c-Si PV module. Thus, in this study, we demonstrated a low temperature soldering method based on conducting pastes (CP) for joint ribbon to C-Si PV. During the lay-up process, ribbon barely adhered to high viscosity CP printed busbar of PV cell. The temporally attached busbar and ribbon are securely connected each other at a low temperature (~ 150 °C) during the lamination process. The efficiency of module fabricated by our suggested method was similar to that of device based on high temperature process with soldering flux and tabbing. Especially, cell to module loss arising from increased resistance during the module process were at the same range in both cases. Furthermore, it was observed that bowing and micro-crack losses occurred in soldering process were suppressed in CP based module. Therefore, low temperature processed thin C-Si module with CP will reduce the losses and manufacturing cost without deteriorating its performance.

10370-13, Session 5

Data acquisition and PV module power production in upgraded TEP/AzRISE solar test yard

Whit Bennett, Asher Fishgold, Barrett G. Potter Jr., Kelly Simmons-Potter, The Univ. of Arizona (United States)

The Tucson Electric Power (TEP) and University of Arizona AzRISE (Arizona Research Institute for Solar Energy) solar test yard is continuing efforts to improve standardization and data acquisition reliability throughout the facility. Data reliability is ensured through temperature insensitive data acquisition (DAQ) devices with battery backups in the upgraded test yard. Software improvements allow for real-time analysis of collected data, while uploading to a web server. With no data failures over 365 days of data collection, the new loggers have proven to be both reliable and durable. In addition to improved DAQ systems, precision temperature monitoring has been implemented so that PV module backside temperatures are routinely obtained. Type-T thermocouples, shown to provide high measurement accuracy, have been applied in a standard, three-per-module sensor configuration. Sample data illustrates high fidelity monitoring of the burn-in period of a polycrystalline silicon photovoltaic module test string. Weather station data acquired at the test yard provide local ambient temperature, humidity, wind speed, and irradiance measurements that have been utilized to enable characterization of PV module performance over an extended test period.

10370-14, Session 5

Analyzing the degradation of pre-damaged PV-modules *(Invited Paper)*

Claudia Buerhop-Lutz, Sven Wirsching, Tobias Pickel, Christian Camus, Jens A. Hauch, Bayerisches Zentrum für Angewandte Energieforschung e.V. (Germany); Christoph J. Brabec, Bayerisches Zentrum für Angewandte Energieforschung e.V. (Germany) and i-MEET (Germany)

The presence of pre-damaged modules, especially with cell cracks and fractures, can be observed frequently in contemporary PV-installations which have been in service for some years [1, 2]. Up to now, most investigations, standards and test procedures focus on degradation of new, defect-free modules [3, 4]. Unknown/unclear is the degradation and lifetime of pre-damaged, cracked modules at real operating conditions.

This study highlights a twofold approach for the analysis of lifetime and degradation of pre-damaged PV—modules with cell cracks from a landslide claim: 1) Field monitoring and inspection data reveals information about real-life degradation of pre-damaged modules during 1 year of enduring outdoor exposure with highly temporarily resolved weather and performance data. Punctual EL-images visualize the new cracks – if observed - and their propagation. 2) For accelerated stress test a newly developed set-up for load testing is used. It allows the experimental simulation of planar load by under- or overpressure, which is typical for snow and wind loads. Simultaneous EL-imaging precisely records crack initiation and growth as well as crack opening under load and crack closure at unloaded stage.

This unique study yields information about load conditions on the degradation of pre-damaged modules, like load thresholds, crack orientation, most-affected cell positions, and statistics for crack appearance as well as the impact on the module performance.

Numerical simulation of wind flow over a photovoltaic solar panel using RANS equations

Andre Luiz Tenorio Rezende, Instituto Militar de Engenharia (Brazil) and Ctr. Univ. Augusto Motta - UNISUAM (Brazil); Katherine B. M. Leitão, Univ. Veiga de Almeida (Brazil); Neelkanth G. Dhere, Univ. of Central Florida (United States)

The aim of this study is the numerical simulation of wind flow over solar photovoltaic panels. At present there are 113 schools in Florida that use similar 10-kW photovoltaic (PV) solar energy systems installeds on their campus. The PV electricity is fed to the grid and reduces the consumption of grid electericity of the schools. Moreover, these schools serve as disaster relief shelters. During hurricanes or other disasters the grid electricity to the shelters may be cut for few weeks. The PV electricity can then serve to provide the minimum critical necessities during such periods. Because of strong winds and hurricanes in this region, it is essential to study the effect of flow of wind on photovoltaic panels. Such study can also be useful to design efficient protectors and supports to guard the panels. ypicals flows phenomena such as vortex shedding and boundary layer separation may influence the distribution of wind load on PV panels. Because of the similar PV system design and construction, the geometry of the solar panel installations and wind conditions would be similar in the PV systems in 113 Florida schools. The wind speed in critical conditions can reach 50 m/s. This work consists of a steady state and incompressible flow numerical simulation through the Reynolds Averaged Navier-Stokes equations (RANS). The turbulence closure model uses the shear stress transport (kw-SST).

The main results of the simulations are the pressure and velocity fields that are involved in loads that panels are being subjected to.

10370-16, Session PMon

Image analysis of PV module electroluminescence

Teh Lai, Claudia Ramirez, Barrett G. Potter Jr., Kelly Simmons-Potter, The Univ. of Arizona (United States)

Electroluminescence imaging can be used as a non-invasive method to spatially assess performance degradation in photovoltaic (PV) module. Cells, or regions of cells, that do not produce an infra-red luminescence signal under electrical excitation indicate potential damage in the module. In this study, an Andor iKon-M camera and an image acquisition tool provided by Andor have been utilized to obtain electroluminescent images of a full-sized multicrystalline PV module at regular intervals throughout an accelerated lifecycle test (ALC) performed in a large-scale environmental degradation chamber. Computer aided digital image analysis methods were then used to automate degradation assessment in the modules. Initial preprocessing of the images was designed to remove both background noise and barrel distortion in the image data. Image areas were then mapped so that changes in luminescent intensity across both individual cells and full module could be identified. Two primary techniques for image analysis were subsequently investigated. In the first case, pixel intensity was averaged over each individual PV cell and changes to the intensities of the cells over the course of an ALC test were evaluated. In the second approach, intensity line scans of each of the cells in a PV module were performed and variations in line scan data were identified during the module ALC test. In this presentation, both the image acquisition and preprocessing technique and the contribution of each image analysis approach to an assessment of degradation behavior will be discussed.

10370-18, Session PMon

Model development of degradation of PV modules backsheet with locating place of module

Yu Wang, Case Western Reserve Univ. (United States); Sebastien Merzlic, Arkema Research Ctr. (United States); Andrew Fairbrother, National Institute of Standards and Technology (United States); Lucas Fridman, Case Western Reserve Univ. (United States); Scott Julien, Northeastern Univ. (United States); Amy A. Lefebvre, Arkema Research Ctr. (United States); Xiaohong Gu, National Institute of Standards and Technology (United States); Liang Ji, Kenneth P. Boyce, Underwriters Labs. Inc. (United States); Michael D. Kempe, National Renewable Energy Lab. (United States); Kai-Tak Wan, Northeastern Univ. (United States); Roger H. French, Laura S. Bruckman, Case Western Reserve Univ. (United States)

Performance of photovoltaic modules under outdoor exposure is tightly related with the micro-environment around the module. The irradiance, temperature and humidity varies within a single array of modules. It is found that the position of a photovoltaic module within an array influences the yellowing and gloss-loss of its associated PV module backsheet, with PET outer layer, under exposure in Dfa climatic zone (Gaithersburg, MD). In this study, similar evaluation is conducted on modules with different backsheet materials exposed in the same climatic zone (Cleveland, OH). Stress/ Response models of yellowing and gloss-loss as function of module position, backsheet material and other related variables are under development. The chemical change of backsheet materials is investigated with FTIR spectroscopy and quantified with the intensity of selected peaks of normalized FTIR spectra. The selected peaks are also used as mechanistic variables to develop a Stress/ Mechanism/ Response model.

10370-20, Session PMon

Comparison of efficiency degradation in polycrystalline-Si and CdTe thin-film PV modules via accelerated lifecycle testing

Teh Lai, Barrett G. Potter Jr., Kelly Simmons-Potter, The Univ. of Arizona (United States)

Thin-film solar cells normally have the shortest energy payback time due to their simpler mass-production process compared to polycrystalline-Si photovoltaic (PV) modules, despite the fact that crystalline-Si-based technology typically has a longer total lifetime and a higher initial power conversion efficiency. For both types of modules, significant aging occurs during the first two years of usage with slower aging over the module lifetime. The PV lifetime and the return-on-investment for local PV system installations rely on long-term panel performance. Understanding the efficiency degradation behavior under a given set of environmental conditions is, therefore, a primary goal for experimental research and economic analysis. In the present work, in-situ measurements of key electrical characteristics (J, V, Pmax, etc.) in polycrystalline-Si and CdTe thin-film PV modules have been analyzed. The modules were subjected to identical environmental conditions, representative of southern Arizona, in a full-scale, industrial-standard, environmental degradation chamber, equipped with a single-sun irradiance source, temperature, and humidity controls, and operating an accelerated lifecycle test (ALT) sequence. Initial results highlight differences in module performance with environmental conditions, including temperature de-rating effects, for the two technologies. Notably, the thin film CdTe PV module was shown to be approximately 15% less sensitive to ambient temperature variation. After exposure to a five-month equivalent compressed night-day weather cycling regimen the efficiency degradation rates of both PV technologies were obtained and will be discussed.

10371-1, Session 1

Adhesive bonds for optics: analysis and trade-offs

John G. Daly, Vector Engineering (United States); Matthew D. Hawk, M. Hawk Consulting (United States)

Adhesives, normally epoxies are one of the most common solutions to mounting optical elements. This design decision can be considered a simple, low-cost fastening technique where a critical optical element must be attached to a metal (or plastic) structure. In most cases, especially commercial (room temperature) applications problem-free performance can be expected. However, in many cases a wide range of failures do occur. These include: adhesion failure, outgassing problems, movement during cure, movement after cure, optical distortion, stress birefringence, and even fracture of the lower strength optical element.

This paper will briefly touch on all aspects of the selection and application of an adhesive for fastening an optical element. The approach will attempt to derive a “rules of thumb” approach with general calculations to determine strength and predict stress situations. This provides set of analysis techniques that can be applied in each case to justify the proposed adhesive bond.

To support this analysis, 3D mechanical models are employed with finite element analysis where movement or distortion as well as stress can be predicted. Temperature changes are addressed where differential CTE (coefficients of thermal expansion) become a major concern. Shock and vibration loads as well as gravitational effects are also included. An accurate model is dependent upon not only the number of elements employed in the model, but also knowledge of all the mechanical properties and their changes with temperature.

The comparison using analysis and finite modeling will show trade-offs in selection of the optical material, the substrate, and the adhesive. This will be followed by bond geometry comparisons, that will lead into compensation designs with athermal bonds, monolithic designs, and flexure mechanical mounts.

10371-2, Session 1

Advancements in adhesive mounting of optics

Brian M. McMaster, Corning Tropel Corp. (United States)

Historic implementations of this method carried risk of UV degradation, photo contamination, long term stability, and long assembly cycle times. Others have developed non-adhesive friction/contact approaches to mount lenses but with significant compromises in durability and product cost. These two methods are contrasted and an optimal approach to achieve high lens mounting durability, low cycle time and negligible photo-contamination is demonstrated. Durability of this adhesive mounting solution will be established with examples including shock and vibration, mechanical stress decoupling factors, and optical stability over a wide range of shipping temperatures.

10371-3, Session 1

Use of composite housing materials in high-shock optical firearm environment

Rosa Seda, Leupold & Stevens, Inc. (United States)

Composite housing materials are available for many different optical applications but are not as common in optics for firearms. They are more prevalent in some night vision and thermal sights, but not as much in reflex or daytime optics. Reflex sight and daytime optics tend to use aluminum and magnesium housing due to their material and machining properties. Firearm optics need to pass a myriad of requirements including thermal, shock, drop and sealing. The challenges associated with composite housing are with bonding/adherence and molding. In this paper, the issues with bonding and mounting optics in a firearm reflex sight are studied, analyzed and tested.

In this study, two carbon fiber reinforced thermoplastic materials were studied and tested. The materials investigated were short carbon fiber reinforced PEEK (Polyether ether ketone) and PEI (Polyetherimide) materials. The first challenge associated with these materials was bonding them with optical material, electronic and other structural materials. The surface treatment of the composite was of great importance to increase bonded joint strength. In high shock environments, it is desirable to have good joint strength. In addition to this, other consideration were how absorbent the material was to UV, linear shrinkage, thermal coefficients and other mechanical properties. The second challenge is chemical compatability to firearm chemical cleaners and its effects on the composite. Other challenges included strength issues associated with shock. The optic needs to survive shock and drop test. To mitigate issues, finite element analysis with use of crack propagation theory was used to estimate stresses. The shock values are particularly high in this application, which will be tested and compared to the calculated values.

10371-4, Session 1

ZERODUR - bending strength: review of achievements

Peter Hartmann, SCHOTT AG (Germany)

Increased demand for using the glass ceramic ZERODUR with high mechanical loads called for strength data based on larger statistical samples. Design calculations for failure probability target value below 1: 100 000 cannot be made reliable with parameters derived from 20 specimens samples. The data now available for a variety of surface conditions, ground with different grain sizes and acid etched for full micro crack removal, allow stresses by factors four to ten times higher than before. The large sample revealed that breakage stresses of ground surfaces follow the three parameter Weibull distribution instead of the two parameter version. This is more reasonable considering that the micro cracks of such surfaces have a maximum depth which is reflects in the existence of a threshold breakage stress below which breakage probability is zero. This minimum strength allows calculating minimum lifetimes. Fatigue under load can be taken into account by using the stress corrosion coefficient for the actual environmental humidity. For fully etched surfaces Weibull statistics fails. The precondition of the Weibull distribution, the existence of weakest links, is not given anymore. ZERODUR with fully etched surfaces free from damages introduced after etching endures easily 100 MPa tensile stress. The possibility to use ZERODUR for combined high precision and high stress application was confirmed by the successful launch and continuing operation of LISA Pathfinder the precursor experiment for the gravitational wave antenna satellite array eLISA .

10371-5, Session 2

2-um optical time domain reflectometry measurements from novel Al-, Ge-, CaAlSi-doped and standard single-mode fibers

Jose Rodriguez-Novelo, Ctr. de Investigación e Innovación Tecnológica (Mexico); Abel Sanchez-Nieves, Instituto Politécnico Nacional (Mexico); Abraham Sierra-Calderon, Jose A. Alvarez-Chavez, Ctr. de Investigación e Innovación Tecnológica (Mexico)

The development of novel Al-, Ge- doped and un-doped standard single mode fibers for future optical communication at 2μm requires the integration of an optical time domain reflectometry (OTDR) technique for precise spectral attenuation characterization, including the well-known cut-back method. The integration of a state of the art OTDR at 2μm could provide valuable attenuation information from the aforementioned novel fibers. The proposed setup consists of a 1.7 mW, 1960nm pump source, a 30-dB gain Thulium doped fibre amplifier at 2μm, an 0.8mm focal length lens with a 0.5 NA, a 30 MHz acusto-optic modulator, a 3.1 focal length lens with a 0.68NA, an optical circulator at 2μm, an InGaAs photodetector for 1.2nm-2.6nm range, a voltage amplifier and an oscilloscope. The propagated pulse rate is 50KHz, with 500ns, 200ns, 100ns and 50ns pulse widths. Attenuation versus novel fibers types for lengths ranging from 400- to 1000- meter samples were obtained using the proposed setup.

Full description of the proposed state of art OTDR setup at 2μm, full reflectometry spectral results, and the spectral attenuation results of all fibers will be included in the presentation.

10371-6, Session 2

Large area of MCP electronic rinse system design

YaFeng Qiu, ChengXin Song, Nanjing Univ. of Science and Technology (China)

Through the reasonable arrangement of imported molecular pump and ion pump in vacuum System, to ensure that in 40 minutes to reach the vacuum degree of Pa to meet the requirement of electron rinse and test and to reach the ultimate vacuum degree of Pa. In this system, an efficient pumping device ensures that the vacuum system to reach the working environment for electron rinse as soon as possible. While the use of four-station design greatly improves efficiency of electron rinse and test of large area MCP.

An electronic surface-emitting source was redesigned in this system. The way it works is that the ultraviolet light source emits a uniform ultraviolet light on the gold cathode with voltage of several hundred volts, thus numerous uniform electrons are emitted from the surface of gold cathode. At the same time,0V ~ 700V adjustable high voltage is adopted between the gold cathode and the standard MCP(diameter of 105mm) to generate an accelerating electric field. After electrons are accelerated by the electric field, the high energy is obtained, and the standard MCP is bombarded. The number of electrons can be exponentially increased and controlled by the voltage applied between the input and output surface of the standard MCP.200v voltage is applied between the output surface of standard MCP and input surface of the MCP to be rinsed to lead the uniform electron beam to bombard the MCP to be rinsed, then the gas molecules and related impurities are cleared out in this process. In the original electron rinse system, which is suitable for the MCP with the diameter of 30mm,uniform emitted electrons are obtained by heating the planar spiral tantalum filament in the thermal electronic surface-emitting source in vacuum System. The largest effective emitting diameter of uniform electrons produced by such a thermal electronic surface-emitting source is 50mm, and it cannot meet the size requirement of the electron rinse of large area MCP. Meanwhile, prolonged use of this thermal electronic surface-emitting source causes the filament oxidation and deformation problems. And complexity of the tantalum filament production process and the design of the accelerating field makes difficult to guarantee the reliability of the uniformity of emission electrons. This successful design of the electronic surface-emitting source in the system not only overcomes the limitation of the thermal electronic surface-emitting source based on tantalum filament in use, but also the analysis of the results of the electronic uniformity testing experiment indicates the electronic uniformity of the electronic surface-emitting source has reached 98%,which is 5% higher comparing to the thermal electronic surface-emitting source based on tantalum filament in use.

10371-7, Session 3

LLIMAS: Revolutionizing integrated modeling and analysis at MIT Lincoln Laboratory

Keith B. Doyle, Gerhard P. Stoeckel, Justin J. Rey, MIT Lincoln Lab. (United States)

MIT Lincoln Laboratory is involved in the development of a broad array of optical systems including laser communications, directed energy, radiometric detectors, chemical sensing, laser radar, and imaging systems in support of science discovery and National security. LLIMAS (Lincoln Laboratory's Integrated Modeling and Analysis Software) was developed to optimize designs and enable new prototype systems to meet challenging SWaP and performance requirements while operating in harsh environments. LLIMAS utilizes a development philosophy that envelopes industry standard engineering tools in a unified framework. The software is highly extensible to provide custom analysis capabilities to support new program and technology needs. Current capabilities include the coupling of structural, thermal, optical, stray light, and CFD tools to provide unique insight into engineering performance and the interdisciplinary behavior typically unrealized by uncoupled simulations. Applications of LLIMAS on several optical system development efforts will be discussed.

10371-8, Session 3

The diffraction grating in Ivory's optomechanical constraint equations

Alson E. Hatheway, Alson E. Hatheway Inc. (United States)

The author's previous work (Proceedings of SPIE, 8840-16) describes the diffraction grating when the plane of incidence at the grating is orthogonal to the lay of the grating. This work develops the equations for the general case where the lay of the grating is rotated with respect to its surface normal so the direction of the desired diffraction order is a compound angle in the grating's coordinate system. The optomechanical constraint equations are developed and an example of their application is shown.

10371-9, Session 3

Linear analysis using secants for materials with temperature dependent nonlinear elastic modulus and thermal expansion properties

John W. Pepi, L-3 SSG (United States)

Thermally induced stress is readily calculated for linear elastic material properties using Hooke's law in which, for situations where expansion is constrained, stress is proportional to the product of the material elastic modulus and its thermal strain. When material behavior is nonlinear, one needs to make use of nonlinear theory. However, there are some situations in which we can avoid that complexity. For situations in which both elastic modulus and coefficient of thermal expansion vary with temperature, solutions can be formulated using secant properties. A theoretical approach is thus presented to calculate stresses for nonlinear, neo-Hookean, materials. This is important for high acuity optical systems undergoing large temperature extremes. The approach taken may not be new, but little information is available in the literature. While use of the secant coefficient of thermal expansion is well known, it is often misunderstood, and use of the secant modulus is even less understood and rarely used. The theoretical use defines a neo-Hookean law which can be used in a linear sense, making input for finite element analysis simplified, precluding the need for nonlinear modeling.

10371-10, Session 4

System engineering of complex optical systems for mission assurance and affordability

Anees Ahmad, Raytheon Missile Systems (United States)

Affordability and reliability are equally important as the performance and development time for many optical systems for military, space and commercial applications. These characteristics are even more important for the systems meant for global markets, where the competition from international suppliers is very real and intense, especially when it comes to total lifecycle costs. Most global customers are looking for high performance optical systems that are not only affordable but are designed with "no doubt" mission assurance, reliability and maintainability in mind. Both US military and commercial customers are now demanding an optimum balance between the performance and affordability. We must employ a disciplined systems design approach to meet the performance, cost and schedule targets while keeping affordability and reliability in mind. The Missile Defense Agency (MDA) now requires all of their systems to be engineered, tested and produced according to the Mission Assurance Provisions (MAP). These provisions/requirements are meant to ensure the system designs of large and expensive weapon systems are executed, designed, integrated, tested and produced with the reliability and total lifecycle costs in mind. This presentation will describe a system design approach based on the MAP document for developing sophisticated optical systems that are not only cost-effective but also deliver superior and reliable performance during their intended missions.

10371-11, Session 4

Optoelectronic methods and tools for pipeline's internal surface diagnosis

Radda A. Iureva, Evgenii O. Raskin, Nadezhda K. Maltseva, ITMO Univ. (Russian Federation); Alexandr V. Ilinsky, S.I. Vavilov State Optical Institute (Russian Federation)

Laser profiler includes a laser module, optical system, which deploys its radiation in the profile analysis' plane, and photodetector system with matrix detectors. The optical axis of the photodetector's lens system is located at a certain angle (viewing angle) to the analysis of the plane, so the photodetector array is formed by a distorted image of the profile of the analyzed surface. Under profile is meant the middle luminous tape's line, occurring at the surface under study by laser radiation. Obviously, the distortion of the picture profile will be minimal at an observation angle equal to 90 °. Computing system profiler on the distorted image profile can generate profilogram analyzed surface in digital form. Accuracy compliance profilograms profile particularly depends on the quality of laser illumination. Glowing tape investigated surface brightness may be asymmetrical in the transverse direction. This asymmetry can be caused by reflection ???? the heterogeneity investigated surface.

10371-12, Session 4

HabEx primary mirror trade studies

Jacqueline M. Davis, H. Philip Stahl, William R. Arnold Sr., W. Scott Smith, NASA Marshall Space Flight Ctr. (United States)

The Habitable Exoplanet (HabEx) is a NASA flagship mission to be considered for the 2020 Decadal Survey in Astronomy and Astrophysics. The concept is to develop an imaging system to detail the characteristics of planetary systems surrounding solar-type stars. The system must provide high contrast imaging and spectroscopy with a high signal-to-noise ratio and high stability. In this paper, we will present a point design for a 4 meter, off-axis, monolithic primary mirror to be used in the HabEx imaging system. An initial optimization of design parameters was performed to minimize distortions due to vibration while also maintaining a low areal density. Finite Element Models (FEM) of mirrors were created with varying mounting configurations, materials, depths, rib thicknesses, cell sizes, facesheet thicknesses, and depths. A harmonic analysis was performed on each model, and the corresponding displacements were output from the optical surface. The data from each model was imported into MATLAB and the distortion on the optical surface of each model was analyzed. Thus, the optimal design parameters were chosen based on the vibration performance of each design. The analysis and the chosen point design will be discussed further throughout the paper.

10371-13, Session 5

Design and test of precision vertical and horizontal linear nanopositioning flexure stages with centimeter-level travel range for x-ray instrumentation

Deming Shu, Barry Lai, Steven P. Kearney, Argonne National Lab. (United States); Jayson Anton, Argonne National Lab. (United States) and Univ. of Illinois at Chicago (United States); Wenjun Liu, Jörg Maser, Christian Roehrig, Argonne National Lab. (United States); Jonathan Z. Tischler, Oak Ridge National Lab. (United States)

The ever-increasing spatial resolution of nanofocusing hard x-ray optics, coupled with the need for long working distances and spectroscopic imaging, requires translating of optics and sample stages over millimeters with trajectory errors of 10 nm or less. To overcome the performance limitations of precision ball-bearing-based or roller-bearing-based linear stage systems, compact vertical and horizontal linear nanopositioning flexure stages, with centimeter-level travel range, have been designed and tested at the Advanced Photon Source (APS) for x-ray instrumentation applications. The mechanical design and finite element analyses of the flexural stages, as well as its detailed test results with laser interferometers are described in this paper.

10371-14, Session 5

Trajectory error analysis of a flexure pivot-type guide for linear nanopositioning

Steven P. Kearney, Deming Shu, Argonne National Lab. (United States)

With the current drive towards diffraction limited storage rings, hard x-ray optics will require subsequent increases in positioning accuracy over large travel ranges. Nanometer-level precision positioning requires the use of compliant mechanisms to remove friction and backlash type errors. Ideally, the compliant mechanism is compliant in the direction of desired travel and rigid in all other directions. However, in reality, there is still compliance in these other directions, particularly for flexure pivots, which lead to parasitic trajectory errors. In this paper we analyze the trajectory errors of a linear guiding mechanism, composed of commercially available C-FlexTM flexure pivots, using finite element analysis and experimental measurements. The guide is designed as an assembly of double parallel 4-bar type deformation compensated linear guiding mechanisms, and incorporates a novel 2:1 stabilizer unit to control the floating bar. The focus of the analysis is on the trajectory errors caused by rotation center shift, manufacturing tolerances, flexure pivot size, assembly tolerances, and includes a discussion of methods to mitigate these errors.

10371-15, Session 5

The development of alignment turning system for precision lens cells

Chien-Yao Huang, Cheng-Fang Ho, Wang Jung-Hsing, Lin Yi-hao, Chien-Kai Chung, Jun-Cheng Chen, Keng-Souo Chang, Kuo Ching-Hsiang, Wei-Yao Hsu, Instrument Technology Research Ctr. (Taiwan)

In general, the drop-in and cell-mounted assembly are used for standard and high performance optical system respectively. The optical performance is limited by the residual centration error and position accuracy of the conventional assembly. Recently, the poker chip assembly with high precision lens barrels that can overcome the limitation of conventional assembly is widely applied to ultra high performance optical system. ITRC also develops the poker chip assembly solution for high numerical aperture objective lenses and lithography projection lenses. In order to achieve high precision lens cell for poker chip assembly, an alignment turning system (ATS) is developed. The ATS includes measurement, alignment and turning modules. The measurement module including a non-contact displacement sensor and an autocollimator can measure centration errors of the top and the bottom surface of a lens respectively. The alignment module comprising tilt and translation stages can align the optical axis of the lens to the rotating axis of the vertical lathe. The key specifications of the ATS are maximum lens diameter, 400mm, and radial and axial runout of the rotary table < 2 ?m. The cutting performances of the AST are surface roughness Ra < 1 ?m, flatness < 2 ?m, and parallelism < 5 ?m. After measurement, alignment and turning processes on our ATS, the centration error of a lens cell with 200mm in diameter can be controlled less than 10 arcsec. This paper also presents the thermal expansion of the hydrostatic rotating table. A poker chip assembly lens cell with three sub-cells is accomplished with average transmission centration error in 12.45 arcsec by fresh technicians. The results show that ATS can achieve high assembly efficiency for precision optical systems.

10371-16, Session 5

Lithography lens mounting flexure design and aberration analysis

Ming-Ying Hsu, Ting-Ming Huang, Instrument Technology Research Ctr. (Taiwan)

The refraction lithography lens has many units, which are easily deformed by gravity forces. However, the lens mount flexure design can relieve lens surface gravity deformation. The lithography lens generically has more than 10 lens units, so with each unit, the gravity deformation sum will create large aberrations in the system. The flexure number can generate a relative aberration, such as trefoil, tetrafoil, and high-order aberrations. In addition, the lens flexure orientation can compensate for non-symmetric to symmetric aberrations from effects of gravity deformation. Thus, symmetric aberrations must resist magnitude in one or two lens units through the measurement data. This study attempts to calculate and predict lens gravity deformation; the results can assist with optical design and reoptimize system performance, as well as reduce the rework risk by measurement data.

10371-17, Session 5

Double Arm Linkage precision Linear motion (DALL) carriage: A simplified, rugged, high-performance linear motion stage for the moving mirror of an FTS (Fourier Transform Spectrometer) or other system requiring precision linear motion

Kendall B. Johnson, Greg Hopkins, Space Dynamics Lab. (United States)

The DALL (Double Arm Linkage precision Linear motion) carriage has been developed as a simplified, rugged, high performance linear motion stage. Initially conceived as a moving mirror stage for the moving mirror of an FTS (Fourier Transform Spectrometer), it is applicable to any system requiring high performance linear motion. It is based on rigid double arm linkages connecting a base to a moving carriage through flexures. It is a monolithic design. The system is fabricated from one piece of material including the flexural elements, using high precision machining. The monolithic design has many advantages. There are no joints to slip or creep and there are no CTE (coefficient of thermal expansion) issues. This provides a stable, robust design, both mechanically and thermally and is expected to provide a wide operating temperature range, including cryogenic temperatures, and high tolerance to vibration and shock. Furthermore, it provides simplicity and ease of implementation, as there is no assembly or alignment of the mechanism. It comes out of the machining operation aligned and there are no adjustments. A prototype has been fabricated and tested, showing superb shear performance and very promising tilt performance. This makes it applicable to both cube corner and flat mirror FTS systems respectively.

10371-29, Session PWed

Mirrors design, analysis, and manufacturing of the 550mm Korsch telescope experimental model

Po-Hsuan Huang, Yi-Kai Huang, Jer Ling, National Space Organization (Taiwan)

In 2015, NSPO (National Space Organization) began to develop the sub-meter resolution optical remote sensing instrument of FORMOSAT-5 follow-on and next generation optical remote sensing satellite.

Upgraded from the RC-Cassegrain telescope optical system of FORMOSAT-5, the experimental optical system of advanced optical remote sensing instrument was enhanced to off-axis Korsch Telescope optical system which consisted of five mirrors. It contains: (1) M1: 550mm diameter aperture primary mirror, (2) M2: secondary mirror (M2), (3) M3: off-axis tertiary mirror, (4) two folding flat mirrors (FM1 & FM2), for purpose of overall volume limitation, mass reduction, long focal length and excellent optical performance.

By the end of 2015, we implemented several important techniques including optical system design, opto-mechanical design, FEM & multi-physics analysis and optimization system to do preliminary study and began to developed and design these large size lightweighting aspheric mirrors and flat mirrors.

The lightweighting mirror design and opto-mechanical interface design had been completed in August 2016, then we manufactured and polished these experimental model mirrors in Taiwan, all five mirrors ware completed as sphere surface by the end of 2016. Aspherize figuring, assembling tests and optical alignment verification of these mirrors will be tested with a Korsch telescope experimental structure model in 2017.

10371-30, Session PWed

Optimization of a sixteen-inch diameter primary mirror assembly of a ground-based telescope

Yi-Kai Huang, Po-Hsuan Huang, National Space Organization (Taiwan); Chien-Wen Shen, Guan Sheng Optical Co., Ltd. (Taiwan)

This article presents the opto-mechanical design of a primary mirror assembly of a ground-based telescope with optimization algorithm. The prototype of ground-based telescope - RC16 with 16 inches diameter blank primary mirror has been manufactured in 2016. However, a telescope with a blank primary mirror is too heavy to carry on for the stargazer. Besides, deformations caused by temperature difference and gravity will do significant effect to the large aperture mirrors with high-optical performance requirements. In order to reduce the weight and maintain

the stiffness simultaneously, the lightweight design and mounting interface design are critical and important. There are four types of system architectures in this project, including (1) two types of lightweight mirror designs - honeycomb type segments and sector type segments; (2) two types of mounting interface designs - retainer type support and CFRP type support. The optimization results showed that (1) the lightweight ratio of the primary mirrors are greater than 70%; and (2) the PV value of the mirrors supported by optimal mounting interfaces with gravity effect as a tilt of about 45 degrees and ±20? temperature difference effectively less than 1/4 ?.

10371-31, Session PWed

Development of an athermalized optomechanical system of large-aperture remote sensing instruments

Chia-Yen Chan, Shenq-Tsong Chang, Ting-Ming Huang, Instrument Technology Research Ctr. (Taiwan)

An integrated optimum athermalization design and analysis system will be developed in the study. The distance between the primary and secondary mirrors for a remote sensing instrument (RSI) will be taken as the objective function to improve the influence of the environment temperature variation on the optical images. Under a developing RSI model, the athermalization design to the secondary mirror based on the established system integrating a computer-aided design software, materials library, finite element analysis, Zernike polynomial fitting and optimization program will be executed. The design variables of the barrel, supporting structure and shims will be carried under high and low temperature changes respectively. The displacements of the secondary mirror with respect to primary mirror with the optimum athermalization design can be reduced to almost zero from -196 ?m and 131 ?m for two extreme thermal boundary conditions separately.

10371-32, Session PWed

Removal of diamond turning marks on an off-axis optics with magneto-rheological finishing

Sangwon Hyun, Korea Basic Science Institute (Korea, Republic of); Min-Woo Jeon, Korea Basic Science Institute (Korea, Republic of) and Chungnam National Univ. (Korea, Republic of); Byeong-Joon Jeong, I. Jong Kim, Geon-Hee Kim, Korea Basic Science Institute (Korea, Republic of)

This paper suggests a magneto-rheological finishing process for the post-treatment of diamond turning to remove the periodic micro structures and sub-surface damages with improvement of the original figure and surface roughness. A workpiece used in experiment is an off-axis aspherical mirror that has the electro-less nickel-phosphorus plated surface. The workpiece was processed by SPDT and MRF. Fast Fourier Transformation (FFT) and Power Spectrum Density (PSD) were performed for identifying the residual diamond turning marks on the turned and polished surfaces. The experimental results indicate that MRF can be suitable for remove the repeated micro patterns caused by diamond turning process with progress of the original figure and surface roughness. The off-axis aspherical mirror used has a surface of electro-less nickel-phosphorus and a body of aluminum alloy, Al6061-T6. The desired mirror has been machined by SPDTM directly using STS technique, and finished with magneto0rheological fluid. The machined surfaces were examined by a low-coherence interferometer, and frequency domain analysis was performed through FFT. For the results of above process, the turning marks, clearly visible in diamond turned surface, were absolutely removed after MR process. Surface roughness, evaluated by a mean of four times measurement in 50% position of ±x and ±y direction of aperture, was improved from 6 nm Sa and 7 nm Sq of the turned surfaces to 2 nm Sa and 3 nm Sq of the polished surface.

10371-33, Session PWed

Method validation of measurement of power flux of a flame with a thermopile for flame test of materials

José G. Suárez-Romero, Instituto Tecnológico de Querétaro (Mexico)

Flame test of materials are required in aero-space industry and astronomy due to extreme environmental conditions of operation and transport. Flame test standards require the measurement of temperature and power flux per unit area radiated by the flame in order to implement a reference flame and assure the reproducibility and repeatability of the test. Some authors have reported pour reproducibility when two different fuels are used. The size, homogeneity and spatial distribution of the flame are also important parameters which depend of the fuel and burner used. The above shows that more information are necessary to correctly manipulate the test. In this work it is shown a method validation of the measurement of the power flux with a thermopile. Validation permits demonstrate equivalence between methods and can help to improve reproducibility.

10371-18, Session 6

Analysis technique for controlling system wavefront error with active optics

Victor L. Genberg, Gregory J. Michels, Sigmadyne, Inc. (United States)

The integration of a linear optics model with general purpose finite element models allows active control of system wavefront error in an optical system. The source of WFE may be due to distortions from environmental loads or due to an incoming WFE from external effects. Inequality equations provide realistic actuator stroke limits. A genetic algorithm allows optimal placement of actuators. Examples are provided.

10371-19, Session 6

Using integrated models to minimize environmentally induced wavefront error in optomechanical design and analysis

Victor L. Genberg, Gregory J. Michels, Sigmadyne, Inc. (United States)

An effective method for the analysis and design of optomechanical systems is discussed. The integration of a linear optics model with general purpose finite element models allows mechanical design to be optimized using environmentally induced system wavefront error as a design response to be minimized or constrained. The general approach applies to static, dynamic, and thermal environments. Examples are provided.

10371-20, Session 6

Using multidisciplinary optimization For CCD shim design in the transiting exoplanet survey satellite

Gerhard P. Stoeckel IV, Keith B. Doyle, MIT Lincoln Lab. (United States)

The Transiting Exoplanet Survey Satellite (TESS) is an instrument consisting of four, wide field-of-view CCD cameras dedicated to the discovery of exoplanets around the brightest stars, and understanding the diversity of planets and planetary systems in our galaxy. Each camera utilizes a seven-element lens assembly with low-power and low-noise CCD electronics.

Advanced multivariable optimization capabilities accommodating arbitrarily complex objective functions have been added to internally developed integrated modeling and analysis software and used to assess system performance. Various optical phenomena are accounted for in these analyses including full dn/dT spatial distributions in lenses and charge diffusion in the CCD electronics. These capabilities are utilized to design CCD shims for thermal vacuum chamber testing and flight, and verify comparable performance in both environments across a range of wavelengths, field points and temperature distributions.

10371-21, Session 7

Adaptive optics mounting method for higher second harmonic generation efficiency of large aperture KDP crystal

Zheng Zhang, Hui Wang, Menjiya Tian, Tsinghua Univ. (China); Xusong Quan, China Academy of Engineering Physics (China); Yiming Rong, South Univ. of Science and Technology of China (China)

In virtue of the superior nonlinear optical properties, KDP (potassium dihydrogen phosphate) crystals have been employed as the harmonic generation optics since 1960s. In inertial confinement fusion (ICF) facilities like NIF in America and SG-? in China, there are hundreds of KDP crystals utilized to convert the infrared laser (?=1053nm) to ultraviolet laser (?=351nm) in order to improve the energy absorption efficiency at the target point. Due to the large aperture (430mm?430mm) and small thickness (12mm) character of the KDP crystals, gravity-induced and mount-induced surface distortion always lead to severe wavefront aberration and phase mismatching which would decrease the harmonic generation efficiency significantly. Hence, a novel mounting configuration based on adaptive optics method is proposed in this article. Moreover, mechanical model of the KDP module is established according to thin plate bending theory, subsequently, numerical calculation of the stress and deformation distribution induced by the gravity and mount force on the crystal plate are conducted with FEM. Further, optical calculations including the effect of surface stress and deformation on phase mismatching and SHG (second harmonic generation) efficiency are performed. Finally, surface modification effect of the adaptive optics mounting configuration is analyzed in comparison with the original mounting configuration. The results could demonstrate the powerful surface adjustment and SHG improvement capacity of this new method.

10371-22, Session 7

Pre-construction results of giant steerable science mirror for TMT

Fei Yang, Hongchao Zhao, Qichang An, Peng Guo, Haibo Jiang, Changchun Institute of Optics, Fine Mechanics and Physics (China)

The Changchun Institute of Optics, Fine Mechanics and Physics (CIOMP) team is developing the Giant Steerable Science Mirror (GSSM) for Thirty Meter Telescope (TMT) which has got into the preliminary design phase in 2017. To develop the passive support structure system for the largest elliptic-plan flat mirror and a smoothest tracking mechanism for the gravity-invariant condition, CIOMP has developed a 1/4 scale, functionally accurate version of the GSSM prototype as the pre-construction of GSSM. The prototype incorporates the same optical-mechanical system and servo control system as the GSSM. The size of the prototype mirror is 898.5mm?634mm?12.5 mm with elliptic-plan figure and is supported by 18 points whiffletree on axial and 12 points whiffletree on lateral. The main objective of the preconstruction includes validate the conceptual design of GSSM and increase more confidence when meet the challenge during the development of GSSM. The assembly, integration and verification of the prototype have been completed based on the results in 2016. CIOMP has get the sufficient test results during the pre-construction phase and got into the preliminary design for GSSM.

10371-23, Session 7

WFE Testing of a large mounted germanium plano optical beam splitter for cryogenic infrared application

Trent Newswander, Tyrel Rupp, Space Dynamics Lab. (United States)

Mounting large reflective-refractive optical elements for cryogenic space application requires careful engineering. Optical wavefront error performance is balanced with surviving launch environments and cryogenic temperatures. Mounting and ground testing of a 25 cm by 15 cm plano germanium optical beam splitter element was completed. Cryogenic WFE testing was performed down to 115K predicting compliance to operational environment performance requirements. This paper discusses the mount engineering including detailed analysis, testing and the results.

10371-24, Session 8

Optomechanical design of TMT NFIRAOS subsystems at INO

Frédéric Lamontagne, Nichola Desnoyers, Martin Grenier, Pierre Cottin, Mélanie Leclerc, Olivier Martin, Louis Buteau-Vaillancourt, INO (Canada); Marc-André Boucher, OMP inc. (Canada); Reston Nash, California Institute of Technology (United States); Olivier Lardière, David Andersen, Jenny Atwood, Alexis Hill, Peter W. G. Byrnes, Glen Herriot, Joeleff Fitzsimmons, Jean-Pierre Véran, National Research Council of Canada (Canada)

The adaptive optics system for the Thirty Meter Telescope (TMT) is the Narrow-Field InfraRed Adaptive Optics System (NFIRAOS). Recently, INO has been involved in the optomechanical design of several subsystems of NFIRAOS, including the instrument selection mirror (ISM), the beam splitter (NBS), and the source simulator system (NSS) comprising the focal plane mask (FPM), the laser guide star (LGS), and natural guide star (NGS) sources. This paper presents an overview of these subsystems and the optomechanical design approaches used to meet the optical performance requirements under environmental constraints.

10371-25, Session 8

Recent advancements in robotic micro-optical assembly at Lockheed Martin Optical Payload Center of Excellence

David Hwang, Lockheed Martin Coherent Technologies (United States)

Lockheed Martin Space Systems Company Optical Payloads Center of Excellence is in process of standing up the Robotic Optical Assembly System (ROAS) capability at Lockheed Martin Coherent Technologies in Colorado. Once fully realized, Robotic Optical Assembly will enable LM to create world-leading, ultra-low-SWAP photonic devices using a closed-loop control robot to precisely position and align multi-material micro-optics with a potential fill factor of >25 optics per square inch. This presentation will discuss the anticipated applications and optical capability when ROAS is fully operational, as well as challenge the audience to update their “rules of thumb” and best practices when designing low-SWAP optical-mechanical systems that take advantage of LMSSC’s ROAS capability. This presentation will reveal demonstrated optical pointing and stability performance achievable with ROAS, and why we believe these optical specifications are relevant for the majority of anticipated applications. After a high level overview of the ROAS current state, the discussion will focus in on recent results of the “Reworkable Micro-Optics Mounting IRAD”. These results from these IRADs will be correlated to the anticipated optical specifications

presented at the opening of the presentation. The presentation will end with a review of near term next steps, and if time allows, a discussion on unidentified applications as well as any questions or advice for the ROAS team from the audience.

10371-26, Session 8

The optomechanical design process: from vision to reality

E. Todd Kvamme, David M. Stubbs, Michael S. Jacoby, Isaac Weingrod, Lockheed Martin Space Systems Co. (United States)

The design process for an opto-mechanical sub-system is discussed from requirements development through test. The process begins with a proper mission understanding and the development of requirements for the system. Preliminary design activities are then discussed with iterative analysis and design work being shared between the design, thermal, and structural engineering personnel. Readiness for preliminary review and the path to a critical design review are considered, with special focus on determining appropriate margins against the system level requirements prior to committing dollars to a production order. The value of prototyping and risk mitigation testing is examined with a focus on when it makes sense to execute a prototype test program. System level margin is discussed in general terms, and the practice of trading margin in one area of performance to meet another area is reviewed. Requirements verification and validation is briefly considered. A discussion of test and its relationship to requirements verification concludes the design process.

10371-27, Session 8

The theory of acousto-optical correlator the radio signals and generalized superposition principle

Georgy I. Korol, Saint-Petersburg State Univ. of Aerospace Instrumentation (Russian Federation)

Acousto-optic modulator is an input device of dynamic signals in optical information processing systems, acousto-optical methods, where one of the basic operations of the processed radio signals, is to calculate the correlation functions, which is a non-linear operation on correlatable radio signals. This assumes a linear mapping of each of the input in optical computing device processes the radio signals. This assumes a linear mapping of each of input to the optical the computing device being processed radio signal. The most important characteristic acousto-optic modulator is its transmission function, which is its a non-linear mapping spreading in the environment the acousto-optical interaction acoustic waves excited processed radio signals. This situation requires a decision questions on the linearization of the transmission function acousto-optic modulator. The nonlinear mapping propagating in a medium acousto-optical interaction acoustic wave described in the the form of action is non-linear operator on an acoustic wave. This non-linear map represented by the formula of finite increments. The linear part of this formula is given by the first derivative of Frechet, which defines a linear operator, and consequently, the linear approximation is introduced into the system optical correlation processing information radio signals. Acousto-optical devices processing radio signals contain two acousto-optic modulators. In this case we are talking about the processing of radio signals in the form of their work. At the same time one of the main tasks is to establish transmission functions a pair of acousto-optic modulators provided linearization of transmission function of each.

10371-34, Session 8

Comparison of lenses' thermal expansion formulation in Zemax versus ANSYS with SigFit post processing

Joao Faria, José Alves, Eduardo Pereira, Univerity of Minho (Portugal)

This paper describes an objective to be implemented in a 3D scanner system whose principle of operation is based on a time of flight (TOF) sensor. The objective is constituted by four even aspheric lenses made of a polymeric material with an aperture of 25 mm @ f/# = 1,0. Due to the environment in which the objective is going to be installed, the working temperature ranges from -40°C to 110°C. To ensure a proper optical quality of the objective, several simulations were performed to evaluate its performance over a wide range of temperatures. Initially, only Zemax was used to evaluate the objective. Zemax considers a linear geometric expansion of every optical surface, which is here proved to not be the best approach to find a deformed geometry after a thermal load. The second approach is to create a 3D model and perform a finite element simulation in Ansys software. The input data is the thermal variation and the output is the deformed geometry of both lenses and barrel. Using SigFit software, it was possible to generate new mathematical equations of the deformed lenses and import this data into Zemax to start a new ray tracing. The evaluated properties for both approaches are: MTF, focal plane shift, spot radius and geometry, optical path difference, and transverse ray fan. The new shape and location of lenses differs for both scenarios, and the difference in the focal plane shift is around 12% between both.

Conference 10372: Material Technologies and Applications to Optics, Structures, Components, and Sub-Systems III

SPIE. OPTICS+ PHOTONICS OPTICAL ENGINEERING+ APPLICATIONS

Monday 7 –7 August 2017

Part of Proceedings of SPIE Vol. 10372 Material Technologies and Applications to Optics, Structures, Components, and Sub-Systems III

10372-1, Session 1

High stability and low thermal expansion alloy (Fe36Ni) reinforced with Si3N4

Timothy A. Stephenson, NASA Goddard Space Flight Ctr. (United States)

The development of materials with improved properties over conventional materials is critical to improve performance for demanding space applications. Iron Nickel Alloys materials are commonly used in thermal structures for high stability applications in optics, detectors, and electronics. Fe36Ni has a low CTE value, but suffers from a high density and low thermal stability. This paper presents a new class of material, Fe36Ni reinforced with silicon nitride particles ceramic to improve strength, thermal stability and reduce density. Mechanical and physical properties will be presented and manufacturing technology will be discussed for precision components.

10372-2, Session 1

Mechanical alloyed aluminum metal matrix composites (MMC)

Don H. Hashiguchi, Materion Brush Beryllium & Composites (United States); David Tricker, Andrew D. Tarrant, Materion Aerospace Metal Composites Ltd. (United Kingdom)

Aluminum alloys reinforced with ceramic particles produce a low density metal matrix composite (MMC) with enhanced mechanical and physical properties including relatively high modulus and vibration loss. This paper will outline the capability through Powder Metallurgy processing techniques made by mechanical alloying (MA). MA enables production of MMC's with micron to submicron mean particulate reinforcement size which increases mechanical properties in comparison to larger reinforcement particle size. Smaller reinforcement particles also result in a material that fits well within established value streams enabling conventional post consolidation metalworking and machining methods. The microstructure and properties of MMC's mechanical alloyed with base aluminum alloys 6061B and 2124A will be presented.

10372-3, Session 1

Enhanced aluminum reflecting and metal-dielectric solar blind filter coatings for the far-ultraviolet

Javier Del Hoyo, Manuel A. Quijada, NASA Goddard Space Flight Ctr. (United States)

The advancement of far-ultraviolet (FUV) coatings is essential to meet the specified throughput requirements of the Large UV/Optical/IR (LUVOIR) Surveyor Observatory which will cover wavelengths down to the 100 nm range. The biggest constraint in the optical thin film coating design is attenuation in the Lyman-Alpha Ultraviolet range of 100-130 nm in which conventionally deposited thin film materials used in this spectral region (e.g.aluminum protected with magnesium fluoride) often have high absorption and scatter properties degrading the throughput in an optical system. We investigate the use of optimally deposited Aluminum (Al) and Aluminum tri-fluoride (AlF_3) materials for reflecting and metal-dielectric solar blind bandpass filter coatings for use in the FUV. Optical characterization of the deposited designs has been performed using FUV spectrometry while the surface quality of the film is analyzed using optical profilometry. The optical thin film design and optimal deposition conditions to produce superior optical properties in the FUV using Al and AlF_3 are presented.

10372-4, Session 1

Characterization of PDMS samples varying its synthesis parameters for tunable optics applications

Josimar Marquez-Garcia, Jorge González García, Angel S. Cruz-Félix, Agustín Santiago Alvarado, Univ. Tecnológica de la Mixteca (Mexico)

Nowadays the elastomer known as polydimethylsiloxane (PDMS Sylgard 184), due to its physical properties, low cost and easy handle, have become a frequently used material for the elaboration of optical components such as: variable focal length liquid lenses, optical waveguides, solid elastic lenses, etc. In recent years, we have been working in the characterization of this material for potential applications in visual sciences, in this work we describe the elaboration of PDMS made samples, also, we present a physical and optical characterization of the samples by varying its synthesis parameters such as the proportion of base - curing agent, and both, curing time and temperature. In the case of mechanical properties, tensile and compression tests are carried out through a universal testing machine to obtain the respective stress-strain curves and in order to obtain information regarding its optical properties, UV-vis spectroscopy is applied to the samples to obtain transmittance and reflectance curves. Index of refraction of the samples elaborated with different synthesis parameters, is obtained through Abbe refractometer. Preliminary results from the characterization will determine the proper synthesis parameters for the elaboration of tunable refractive surfaces to be implemented in a opto-mechatronic system used to imitate the objective performance of the human eye for potential applications in robotics.

10372-18, Session 1

Visualization of diffusion mixing in a micro-mixer with flow paths fabricated by photolithography

Toshiyuki Horiuchi, Yuta Morizane, Tokyo Denki Univ. (Japan)

How two liquids were mixed was investigated by visualizing the mixing when they were simultaneously injected in a micro-mixer with lithographically fabricated Y-shape flow paths, and the mixing phenomena was analyzed in detail. To visualize the mixing, flows were observed by an optical microscope, and a clearly detectable chemical reaction was utilized. As the two liquids, a transparent aqueous solution of a strong alkali and a phenolphthalein ethanol solution were used. When they were simultaneously injected in Y-shape flow paths of a micro-mixer, they flowed at first in parallel along the joined path as laminar flows. This is because the Reynolds' number became very small caused by the narrow flow-path widths of 50-100 μm. However, because two liquids were always contacted at the boundary, they were gradually mixed by diffusion, and the color of the mixed parts changed to vivid red. For this reason, it was able to measure the diffusion distance from the flow path center. Because the flow speeds were much faster than the diffusion speeds, the area colored in red did not depend on the time but depended on the distance from the joint point. It was known that the distance from the joint point corresponded to the time

for mixing the liquids by the diffusion. It was clarified that the diffusion distance was proportional to the square root of the diffusion time or the distance from the joint point. The calculated diffusion coefficient of 1.2?10^-9 m^2/s was relevant.

10372-6, Session 2

Interfacial studies of a metallurgical bond between "activated" ultrasonically applied solder and high purity fused silica

Lawrence W. Shacklette, Harris Corp. (United States); Donna L. Gerrity, E&S Consulting, Inc. (United States); Michael R. Lange, James C. Beachboard, Harris Corp. (United States); Ronald Smith, S-Bond Technologies, LLC (United States)

Packaging of optical devices often requires the need for creating strong bonds between metal and silica. The most convenient and cost effective approach would be to directly solder to both silica and metal without requiring pre-metallization of the silica. Soldering to oxides and oxidized surfaces has been accomplished with various solders containing metals with strong affinity for oxygen. In this work we investigate solders based upon a tin-bismuth eutectic with potential activating additives of cerium, gallium, and titanium. Each of these metals are energetically capable of competing for the oxygen in silica, and are therefore capable of reducing or forming mixed oxides with silica under appropriate conditions. The bond between such an "activated" solder and high purity fused silica (HPFS) has been characterized by Time-of-Flight Secondary Ion Mass Spectrometry (TOF-SIMS). Two variations of solder produced by S-Bond Technologies, S-Bond 140 and S-Bond 140 M1 were bonded to silica using a fluxless ultrasonic technique. TOF-SIMS was then used to characterize the bond interface by measuring the distribution of elements as a function of depth through the interface. The results show that the presumed activating elements concentrate at the interface and that their oxides form the interfacial layer between the HPFS and the bulk solder. The efficacy of these additives was established by demonstrating that the block shear strength of the bond to HFPS was trebled by the addition of the aforementioned reactive metals to the base Sn-Bi solder.

10372-7, Session 2

Comparison of material properties between ultra low thermal expansion ceramics and conventional low thermal expansion glasses

Tomohiro Kamiya, Tadahito Mizutani, Japan Aerospace Exploration Agency (Japan)

Material properties of ceramics, which have extremely low thermal expansion coefficients, were studied for space-based telescope mirror application. Numbers of the key mechanical and thermal properties for the application were investigated, such as Young's modulus, Poisson's ratio, bulk density, 3-point bending strength, coefficient of thermal expansion (CTE), thermal conductivity and specific heat capacity. They were intensively investigated at a normal temperature range (0 to 50 °C) and compared with that of conventional low thermal expansion glasses under exactly the same testing configurations. In this study, we selected four ceramics; NEXCERA-N117B and NEXCERA-CD107 (KUROSAKI HARIMA), CO-720 (KYOCERA) and ZPF-N (NTK CERATEC). As a characteristic result, the Young's modulus of 140 GPa, bulk density of 2.58 g/cm3, CTE of less than 0.03 ppm/K at 23 °C and thermal conductivity of 4.7 W/m?K were obtained for NEXCERA-CD107. This means that the specific stiffness was 1.5 to 2 times higher and temperature uniformity was 3 times higher than conventional low thermal expansion glasses while dimensional thermal stability was ensured to be almost the same as the competitive glass materials. In the previous paper, the long term dimensional stability of NEXCERA was reported as 0.01 ± 0.01 ppm over 13 months. In addition, the excellent processability of NEXCERA for lightweight rib structures and excellent polishing characteristics using Magnetorheological Finishing (MRF) technology were also reported in another paper. It was therefore revealed that the low thermal expansion ceramics have appropriate and attractive material properties for future space telescope applications.

10372-8, Session 2

Inverse problem of Bragg's scattering for measuring the spectrum surface roughness in the optical gradient waveguide

Anatoly N. Osovitsky, Natalia Grishaeva, Peoples' Friendship Univ. of Russia (Russian Federation); Nikolai D. Espinosa Ortiz, Christian Vega, Univ. de las Fuerzas Armadas-ESPE (Ecuador)

A new method for measuring the spectrum of surface roughness based on Bragg scattering, is proposed. This method is characterized by its high precision of measurement of the spatial amplitudes and frequencies. Was determined the rang of spatial frequencies (periods) of harmonics in the roughness spectrum surfaces (0,PI). When the rotation's angle of grid is (0,PI/4) will be a forward scattering or Bragg's deflector. At rotation's angle of grid is (PI/2,PI/4) or (-3PI/4,-PI/2) will a Bragg's mirror.

The measurements are made in a gradient waveguide, obtained by ion exchange method.

10372-9, Session 2

Thermal and mechanical properties of tellurite glasses for mid-IR molded lens applications

Ju Choi, Linganna Kadathala, Eui S. Lee, Ganesh L. Agawane, Korea Photonics Technology Institute (Korea, Republic of)

Systematic series of ternary zinc lanthanum tellurite glasses with molar composition of (1-x) TeO2-La2O3-xZnO, where x = 10, 20, and 30, were prepared by a conventional melt quenching technique and their thermal and mechanical properties have been investigated via differential scanning calorimeter, dilatometer and autovick techniques for mid-IR lens applications. The compatibility of molding process for IR lens will be investigated. First of all, it was found that the glass transition temperature (Tg), softening temperature (Ts) and Knoop hardness (Hk) significantly increased when ZnO content increases from 10 to 30 mol%. Glass stability factor (?T), which is most important factor for molding process, decreased as the ZnO content increased from 10 to 30 mol% due to loose packing structure which is result of increase of non-bridging oxygens (NBOs) in the tellurite Te-O-Te network. The thermal expansion coefficient (CTE) decreased from 11.26 to 12.6 (10-6/K) when ZnO content increases from 10 to 30 mol%. These results clearly indicate that the investigated glasses are attractive for device applications.

10372-10, Session 3

A review on the advances in 3D printing and additive manufacturing of ceramics and ceramic matrix composites for optical applications *(Invited Paper)*

William A. Goodman, Goodman Technologies, LLC (United States)

This paper provides a review of advances in 3D printing and additive manufacturing of ceramic and ceramic matrix composites for optical

applications. Dr. Goodman has been pioneering additive manufacturing of ceramic matrix composites since 2008. He is the inventor of HoneySiC material, a zero-CTE additively manufactured carbon fiber reinforced silicon carbide ceramic matrix composite which is now made by Fantom Materials. HoneySiC is briefly discussed here. More recently Dr. Goodman has turned his attention to the direct printing of ceramics for optical applications via various techniques including slurry and laser sintering of silicon carbide and other ceramic materials.

10372-11, Session 3

Nano-diamond polishing of super hard materials

Rajiv Singh, Arul Chakkaravarthi Arjunan, Sinmat, Inc. (United States)

A new nano-diamond based mechanical polishing process has been developed and optimized for polishing super hard materials such as SiC, sapphire and diamond samples. The nano-diamond based process uses specially engineered nano-diamond particles that has ability to react with super hard materials when used for polishing. Such a reactive nano-diamond process leads to removal rates of about an order higher than the base particles and yields ultra-smooth surfaces (RMS <0.5nm) on the super hard materials along with very low sub-surface damage. The process yielded surface roughness less than 1 nm for silicon carbide, sapphire and diamond materials. The process has been studied for single crystalline, poly-crystalline and composite materials. The removal rates for different materials with the newly developed nano-diamond process compared to base nano-diamond particles and the surface finish obtained with the use of atomic force microscope, optical interferometer and tropel flat master will be presented. The mechanism of nano-diamond process will be explained in the conference.

10372-12, Session 3

Time scales of radiation damage decay in five optical materials

Frank U. Grupp, Univ.-Sternwarte München (Germany) and Max-Planck-Institut für extraterrestrische Physik (Germany); Norbert Geis, Reinhard Katterloher, Max-Planck-Institut für extraterrestrische Physik (Germany); Ralf Bender, Max-Planck-Institut für extraterrestrische Physik (Germany) and Univ.-Sternwarte München (Germany)

Radiation damage has been doe at Paiul Scherrer Cyclotron. Damage result was measured by a precise in situ photometric setup at 1/2 exposure and after the exposure. 1 minute 1 hour 1 day 1 week -.-- 1 year after exposure.

10372-13, Session 4

A rigid and thermally stable all-ceramic optical support bench assembly for the LSST Camera *(Invited Paper)*

Matthias Krödel, ECM Engineered Ceramic Materials GmbH (Germany); J. Brian Langton, SLAC National Accelerator Lab. (United States); Bill Wahl, Brookhaven National Lab. (United States)

This paper will presenting the ceramic design, fabrication and metrology results and assembly plan of the LSST camera optical bench structure which is using the unique manufacturing features of the HB-Cesic technology. The optical bench assembly consists of a rigid “Grid” fabrication supporting individual raft plates mounting sensor assemblies by way of a rigid kinematic support system to meet extreme stringent requirements for focal plane planarity and stability.

10372-14, Session 4

Quality evaluation of spaceborne SiC mirrors: the effects on mirror accuracy by variation in the thermal expansion property of the mirror surface

Masaki Kotani, Tadashi Imai, Haruyoshi Katayama, Japan Aerospace Exploration Agency (Japan); Hidehiro Kaneda, Nagoya Univ. (Japan); Takao Nakagawa, Keigo Enya, Japan Aerospace Exploration Agency (Japan)

We studied a large-scale lightweight mirror constructed of reaction-bonded silicon carbide (SiC)-based material as a key technology in future astronomical and earth observation missions. One of the most important technical issues for large-scale ceramic components is the uniformity of the material’s property, depending on part and processing. It might influence mirror accuracy due to uneven thermal deformation.

To correlate the material property of a mirror body and the mirror accuracy, the authors evaluated all over the mirror surface deviation of a prototype mirror by inputting actually measured coefficient of thermal expansion (CTE) data into a finite element analysis (FEA) model. The computationally simulated contour diagrams well reproduced the mirror accuracy profile that the actual mirror showed in cryogenic testing. Density data were also useful for evaluating the mirror surface deviation because they had a close relationship with the CTE.

Besides, systematic case studies for the conditions of CTE by FEA were also conducted to know the typical influence of material property nonuniformity on mirror accuracy and a comprehensive empirical equations for the series of CTE’s main factors were derived.

Through all these studies, wide-range practical computational evaluation technology of mirror accuracy was acquired.

10372-15, Session 4

Dimensional stability performance of a CFRP sandwich optical bench for microsatellite payload

Nichola Desnoyers, Philippe Goyette, Bruno Leduc, INO (Canada); Marc-André Boucher, OMP Inc. (Canada)

Microsatellite market requires high performance while minimizing mass, volume and cost. Telescopes are specifically targeted by these trade-offs. One of these is to use the optomechanical structure of the telescope to mount electronic devices that may dissipate heat. However, such approach may be problematic in terms of distortions due to the presence of high thermal gradients throughout the telescope structure.

To prevent thermal distortions, carbon fiber reinforced polymer (CFRP) technology can be used for the optomechanical telescope material structure. CFRP is about 100 times less sensitive to thermal gradients and its coefficient of thermal expansion (CTE) is between 200 to 600 times lower than typical aluminium alloys. Unfortunately, designing with CFRP material is not as straightforward as with metallic materials. There are many parameters to consider in order to reach the desired dimensional stability under thermal, moisture and vibration exposures. Designing optomechanical structures using CFRP involves many challenges such as interfacing with optics and sometimes dealing with high CTE mounting interface structures like spacecraft buses.

INO has designed a CFRP sandwich telescope structure to demonstrate the achievable performances of such technology. Critical parameters have been optimized to maximize the dimensional stability while meeting the stringent environmental requirements that microsatellite payloads have to comply with. The telescope structure has been tested in vacuum from -40°C to +50°C and has shown a good fit with finite element analysis predictions.

10372-16, Session 4

Challenges of designing and testing a highly stable sensor platform: HB-Cesic solves MTG star sensor bracket thermo-elastic requirements

Matthias Krödel, ECM Engineered Ceramic Materials GmbH (Germany); Christoph Zauner, KRP-Mechatec Engineering GbR (Germany)

The Meteosat Third Generation's extreme pointing requirements call for a highly stable bracket for mounting the Star Trackers. Within the early design phase, HB-Cesic®, a chopped fibre reinforced siliconcarbide, was selected as a base material for the sensor bracket. The high thermal conductivity and low thermal expansion of HB-Cesic® were the key properties to fulfil the demanding thermo-elastic pointing requirements of below 1?rad/K for the Star Trackers mounting interfaces. ECM (Engineered Ceramic Materials GmbH) and KRP-M (KRP-Mechatec Engineering GbR) were selected by OHB System GmbH in mid-2014 to design, manufacture, and test the Star Sensor Assembly Bracket (SAB).

This paper/poster concentrates on the design and main test activities to achieve and to verify the thermo-elastic, thermal, and structural requirements. Special attention is paid on the development and application of the thermoelastic distortion measurement system. Dominated by thermoelastic stability requirements, the design and analysis of the Bracket requires a multidisciplinary approach with the focus on thermal and thermo-elastic analyses. A major aspect of the thermal analysis was the optimisation of conductive and radiative heat fluxes to minimize the temperature gradient and thus subsequent thermoelastic deformations within the Bracket. Further, it was found that for achieving the necessary high accuracy level for thermoelastic deformation results within this project, a highly accurate presentation of temperature distribution and thus a fine geometrical resolution of the thermal model is required. Therefore, in addition to the ESATAN thermal analysis (~1000 nodes), a FEM (ANSYS) thermal analysis (40000 DOF) was performed and correlated with the test results.

A key challenge of the thermo-elastic analysis was the optimization of the interfaces between Bracket and Star Tracker as well as to the satellite platform in order to minimize interface loads and still maintain sufficient stiffness to meet eigenfrequency requirements. Morphological optimization techniques have been applied for this as well for a further lightweighting of the Bracket.

Experimental verification of such thermo-elastic stable systems is a challenging design task of its own. It requires test platforms having a thermo-elastic stability higher by a factor of 10 being exposed to the same temperature load as the item under test. Within this project, a thermo-elastic distortion measurement rig was developed with a stability of <0.1?rad/K in all three rotational degrees of freedom. This was achieved by combining capacitive displacement sensors and ultra low expansion (ULE) glass-ceramics. Already low drift yet still off-the-shelf sensors (by Micro-Epsilon Messtechnik) were further optimised by dedicated tests and design improvements to achieve a sensor

drift of <10nm/K within a 40K temperature range. Fifteen of these sensors were mounted to a Clearceram® ULE rig in a special spatial configuration for measuring the relative rotation of all three Star Tracker interfaces in all three axis.

In conclusion, the MTG Star Sensor Bracket shows excellent thermo-elastic stability and presents a significant building block to the overall accuracy of the satellite pointing system.

10372-17, Session 4

Trade-off studies on LiteBIRD reflectors

Hajime Sugai, Tomotake Matsumura, Kavli Institute for the Physics and Mathematics of the Universe (Japan); Junichi Suzuki, Muneyoshi Maki, Masashi Hazumi, High Energy Accelerator Research Organization, KEK (Japan); Nobuhiko Katayama, Shin Utsunomiya, Shingo Kashima, Yuki Sakurai, Kavli Institute for the Physics and Mathematics of the Universe (Japan); Hiroaki Imada, Japan Aerospace Exploration Agency (Japan); Hirokazu Ishino, Okayama Univ. (Japan); Takenori Fujii, Cryogenic Research Ctr., The Univ. of Tokyo (Japan)

The LiteBIRD satellite aims at detecting a signature imprinted on the cosmic microwave background (CMB) by the primordial gravitational wave predicted in inflation, which is an exponentially expanding era before the hot big bang. The extraction of such weak spiral polarization patterns requires the precise subtraction of our Galaxy's foreground emission such as the synchrotron and the dust emission. In order to separate them from the CMB by using their spectral shape differences, LiteBIRD covers a wide range of observing frequencies. The main telescope, Low Frequency Telescope (LFT), covers the CMB peak frequencies as well as the synchrotron emission. Based on the required sizes of optical elements in the LFT, an order of one meter, the telescope will consist of reflectors rather than lenses since the latter is limited in size availabilities of the corresponding materials. The image quality analysis provides the requirements of reflector surface shape errors within 30um rms. The requirement on surface roughness of 2um rms is determined from the reflectance requirement. Based on these requirements, we have carried out tradeoff studies on materials used for reflectors and their support structures. One possibility is to athermalize with aluminum, with the expected thermal contract of 0.4% from room temperature to 4-10 K. Another possibility is CFRP with cyanate resin, which is lighter and has negligibly small thermal contraction. For the reflector surface shape measurements including in low temperature, photogrammetry is a strong candidate with suitable accuracy and dynamic range of measurements.

10372-5, Session PMon

Manipulation of microbubbles through the phenomenon of thermocapillarity

Julio Aurelio Sarabia-Alonso Sr., Univ. Politécnica de Tulancingo (Mexico); Jose Gabriel Ortega-Mendoza, Univ. Tecnológica de Tulancingo (Mexico)

We present a theoretical-experimental study of the movement that undergoes a bubble that is immersed in an aqueous medium due to the phenomenon of thermocapillarity. This phenomenon has its origin in the force of Marangoni generated by the presence of a temperature gradient. The temperature gradient is produced by the incidence of photons on nano silver particles immobilized on the tip of an optical fiber. The results show that it is possible to manipulate a bubble through two optical fibers, controlling the incidence of photons in each of them.

Successful fabrication of GaN epitaxial layer on non-catalytically-grown graphene for smart packages

Sungwon Hwang, Kyung-Jin Yeum, Konkuk Univ. (Korea, Republic of)

Sapphire is widely used as a substrate for the growth of GaN epitaxial layer (EPI), but has several drawbacks such as high cost, large lattice mismatch, non-flexibility, and so on. Here, we first employ graphene directly grown on Si or sapphire substrate as a platform for the growth and lift-off of GaN-light-emitting-diode (LED) EPI, useful for not only recycling the substrate but also transferring the GaN-LED EPI to other flexible substrates. Sequential standard processes of nucleation/recrystallization of GaN seeds and deposition of undoped (u-) GaN/AlN buffer layer were done on graphene/substrate before the growth of GaN-LED EPI, accompanied by taping and lift-off of u-GaN/AlN or GaN-LED EPI. This approach can overcome the limitations by the catalytic growth and transfer of graphene, and make the oxygen-plasma treatment of graphene for the growth of GaN EPI unnecessary and smart packages.

10372-20, Session PMon

Characterization of ancient Chinese porcelains using optical coherence tomography

Song Liu, Qinghui Li, Shanghai Institute of Optics and Fine Mechanics (China); Yongqing Hu, Henan Provincial Institute of Cultural Relics and Archaeology (China)

Henan province is one of the few provinces which has many historical relics in China. Numerous clutural relics such as porcelains, bronzes, jades and so on have been excavated from the tombs and histortical sites of ancient times in Henan province. Porcelains with different kinds excavated from Baofeng county in Henan province and dated from Jin Dynasty to Yuan Dyansty have been analyzed by Optical Coherence Tomography (OCT). The phycial structures of glaze layer for different kinds of porcelains are obtained as 2D OCT images. The typical physical of glaze layer, such as glassy phase, heterogeneous phase, air bubbles and so on, are shown in OCT images. In order to distinguish the different types of glaze, the OCT images have been processed by Matlab software using image texture analysis technique. Parameters which are used to describe the OCT images are extracted based on image histogram and gray level co-occurrence matrix and appropriate parameters are determined to characterize and distinguish the glaze layer for different types of porcelains.

10372-21, Session PMon

Polishing aspheric mirrors of zero-thermal expansion cordierite ceramics (NEXCERA) for space telescopes

Jun Sugawara, Bumpei Mikashima, Krosaki Harima Corp. (Japan); Tomohiro Kamiya, Japan Aerospace Exploration Agency (Japan)

NEXCERA is an advanced cordierite ceramics with an extremely low thermal expansion coefficient of < 0.03 ppm/K at room temperature and superior mechanical properties. It has been used not only as structural components of LSI lithography, but also as optical reflecting mirrors in the precision metrology field requiring high accuracy and stability. Currently, it is regarded as a promising material essential for ultra-lightweight and thermally-stable optics for future optical missions that require extremely high observation performance because of its higher mechanical properties and higher stabilities compare to zero-thermal expansion glasses. To realize the high precision NEXCERA mirrors for space optics, it is important to develop a process for deterministic polishing of aspheric shape and a precise figure correction polishing for NEXCERA. This paper presents the results of mirror polishing for several shapes of NEXCERA such as plano, sphere, hyperbola and parabola. The plano mirror of 150 mm diameter was achieved a surface roughness of Ra around 0.3 nm. The convex hyperbolic mirror of 100 mm diameter was polished by MRF from a best-fit sphere and achieved a surface roughness of RMS 1 nm and a form accuracy of less than ?/10 in spite of an existence of sensitivity to sub-surface damage. The concave parabolic mirror of 250 mm diameter with 500 mm focal length was polished by computer-controlled asphere surface-finishing technology, and the results will be presented at the conference. Based on consequence of these work, it is expected that NEXCERA mirror will be applied to lightweight aspheric mirrors of space telescope.

Conference 10373: Applied Optical Metrology II

Tuesday - Wednesday 8 –9 August 2017

Part of Proceedings of SPIE Vol. 10373 Applied Optical Metrology II

10373-1, Session 1

Usefulness of orthogonal basis sets for predicting optical performance of wavefronts with mid-spatial frequency error *(Invited Paper)*

Zahra Hosseinimakarem, Angela Davies, Christopher J. Evans, The Univ. of North Carolina at Charlotte (United States)

Mid-spatial frequency texture on optical elements degrade their performance. Therefore, it is important to have a clear way of characterizing them and predicting the optical performance degradation. A Zernike polynomial representation of the wavefront can be used to predict the optical performance. The ability to generate very large orders of Zernike polynomials enables fitting and describing optical wavefronts all the way from low order form errors to mid-spatial frequencies. We will show decomposition of measured wavefronts into orthogonal bands of Zernike polynomials based on symmetry properties of these polynomials. Based on the filtering aspect of Zernike polynomials, we will present how different signatures affect optical performance differently. We will investigate the Strehl ratio as an optical performance metric for mid-spatial frequency and will see how the Strehl ratio of selected Zernike-filtered bands of a wavefront are related to the Strehl ratio of the entire wavefront. MTF is another useful metric for optical performance among optical designers. We will provide examples on how one can benefit from the linearity properties of MTF along with the orthogonality properties of Zernike polynomials to connect wavefront characterization representation to optical performance. We will present examples of both real and synthetic mid-spatial frequency textures to examine the approximation limitations of MTF when using linear systems formulation.

10373-3, Session 1

Improvement of accuracy in inner profile measurement of pipes and holes using an optical probe

Toru Yoshizawa, Tokyo Univ. of Agriculture and Technology (Japan) and NPO 3D Associates (Japan); Toshitaka Wakayama, Saitama Medical Univ. (Japan)

The requirements of inner profile measurement of pipes and tubes become recently larger and larger, and applications of inner profile measurement have rapidly expanded to various industrial fields such as mechanical engineering, automobile and heavy industries. We have proposed measurement method by incorporating a ring beam device that produces a circular beam and have developed various probe cameras for different inner profile measurement. In addition to measurement of mechanical components with inner diameter of 50 mm to 100 mm (typically such as car engine bores), in order to meet request of applying to smaller diameter pipes, we tried to improve the ring beam light source using a conical mirror and a laser diode. At the same time, we are trying to realize higher-sensitive probe on the basis of reducing noises due to speckles and others. One idea is proposed that is based on selective compliance applied method (SCAM). And the other is tried by checking the light source to get better result. Some examples are shown to verify availability of our trials in industrial applications.

10373-4, Session 1

Fusion of light-field and photogrammetric surface form data

Danny Sims-Waterhouse, Samanta Piano, Richard K. Leach, The Univ. of Nottingham (United Kingdom)

Photogrammetry based systems are able to produce 3D reconstructions of an object given a set of images taken from different orientations. In this paper, we implement a light-field camera within a photogrammetry system in order to capture additional depth information, as well as the photogrammetric point cloud. Compared to a traditional camera that only captures the intensity of the incident light, a light-field camera also provides angular information for each pixel. In principle, this additional information allows 2D images to be reconstructed at a given focal plane, and hence a depth map can be computed. Through the fusion of light-field and photogrammetric data, we show that it is possible to improve the measurement uncertainty of a millimetre scale 3D object, compared to that from the individual systems. By imaging a series of test artefacts from various positions, individual point clouds were produced from depth-map information and triangulation of corresponding features between images. Using both measurements, data fusion methods were implemented in order to provide a single point cloud with reduced measurement uncertainty.

10373-5, Session 1

Expansion of measurement area of three-dimensional deformation measurement speckle interferometry with same sensitivities in three directions under consideration of measurement sensitivity

Yasuhiko Arai, Kansai Univ. (Japan)

A novel in-plane and out-of-plane deformation simultaneous measurement method using only two speckle patterns grabbed before and after deformation of an object with rough surfaces has been proposed. In the new optical system, a phenomenon of the in-plane and the out-of-plane deformation can be simultaneously recorded by only one camera by using the multi-recording technology of speckle patterns. Furthermore, the same measurement sensitivities in three directions can be set in this system. Though the method can efficiently measure some deformation phenomena, the method has some area which cannot measure a deformation. The reason why there is such area is caused by the orthogonal laser beams as the coordinate system. In this paper, new optical system which is not based on the orthogonal laser beams is proposed in order to expand the measurement area of the method under consideration of measurement sensitivity. It is confirmed that the sensitivity of the deformation measurement system depends on the angles of vertices of coordinate system produced by laser beams. The sensitivity decreases sinusoidally as the angle decreases. In the experiments, the angle is defined as 80 degrees. At 80 degrees, it is also confirmed that the sensitivity is not changed drastically. The possibility of deformation measurement in the area where the deformation distribution cannot be measured by the conventional optical system is discussed. The situation of measurement accuracy in the extending of measurement area is investigated.

10373-6, Session 1

3D boundary extraction strategy using vector slices for the inspection of sheet parts

Liqun Ma, Changcheng Institute of Metrology & Measurement (China); Jingjing Fan, Yongqian Li, Northwestern Polytechnical Univ. (China); Zili Zhou, Changcheng Institute of Metrology & Measurement (China)

With the development of airplane manufacturing, too many bent sheet parts appear at the assembling segment. To improve the accuracy of the complete airplane assembling, many detecting methods of assembling accuracy have been employed. But the current methods aren't satisfied the requirement of rapid and accurate detection.

In this article, we put forward a project to extract the boundary of thin parts. The project is carried out after obtaining the discrete scanning points of sheet part, it can be divided into five parts: (1) constructing the complement relation of discrete points by methods of space division and K neighbor points searching, then triangle the discrete points based on the complement relation; (2) smoothing and simplifying the boundary points of scanning data of sheet part, fitting the simplified boundary points by B-spline, constructing the equal interval universal slices along the fitting boundary curve; (3) extracting the marginal data by solving the intersection between the surface of triangle and universal slices; (4) identifying the end points of arc chamfer and delete the linear segment, fitting the arc chamfer data by parabola and picking out the maximum curvature points, call these point ridge point; (5) obtaining the boundary points by fixed value compensation along the normal direction of ridge points. Comparing the extracted boundary points with measurement results of three coordinate measuring machine(CMM) and theoretical design line in SA software. In this article, we used a piece of 6mm thick board to compare with the results of CMM, used a piece of 2 mm thick board to compare with the theoretical design line, the comparing results show that the deviations of extracted points with reference data are in the range of 0.1mm, satisfying the required indicator.

10373-7, Session 2

Application of polarization in high-speed, high-contrast inspection

Matthew J. Novak, Technical Optics LLC (United States)

Industrial optical inspection requires high speed and high throughput of materials. Engineers use a variety of techniques to handle these inspection needs. Some examples include line scan cameras, high speed multi-spectral and laser-based systems.

High-volume manufacturing presents many challenges for inspection engineers. Often, manufacturers produce in quantities of millions per month, per week or even per day. Quality control of so many parts requires creativity to achieve the measurement needs. At times, traditional vision systems lack the contrast to provide the data required.

In this paper, we show how dynamic polarization imaging captures high contrast images. These images are useful for inspection tasks where optical contrast is low. We will cover basic theory of polarization. We show how to exploit polarization as a contrast enhancement technique. Finally, we show modeling for a polarization inspection application. The model shows how polarization can reveal low contrast materials such as adhesives on glass.

10373-8, Session 2

Deploying Mueller matrix polarimeter for characterizing diattenuation and retardation of subwavelength structure

Achyut Adhikari, Nanyang Technological Univ. (Singapore)

The essence of subwavelength structure measurement is in dire demand in advanced nanotechnology scenario. Mueller matrices for wire grid polarizer are measured experimentally using Mueller matrix polarimeter and validated with numerically simulated Lumerical Finite Difference Time Domain method. Wire grid polarizer are sub wavelength grating extensively used in display projection system attributable to its compact size; wide field of view and long term stability. Based on current state of art, where metrological equipment designed for nanometer level are quite expensive and complicated to use, this system and method has substantial scope. Experimentally calculated sub wavelength structure linewidth is validated with that of numerically simulated one by the aid of Mueller matrices. Further, intrinsic properties of the sample; diattenuation and retardance are experimentally calculated and verified by the numerical simulation.

10373-9, Session 2

Measurement of polarization state of light using in-plane spin splitting

Xiaodong Qiu, Zhaoxue Li, Zhiyou Zhang, Jinglei Du, Sichuan Univ. (China)

The measurement of polarization state of light, i.e., optical polarimetry, can provide essential information of the scattering objects. In this paper, we propose a precision method of polarization measurement using the in-plane spin splitting (IPSS). The IPSS, as a result of the spin-orbit interaction, manifests itself as the splitting in the incident plane of two circular polarized components of light beam reflected at an interface. By choosing a linear or elliptical incident polarization state, the IPPS can be observed in the coordinate or momentum spaces (i.e., spatial or angular IPSSs), respectively. Particularly, we find that the spatial (or angular) IPPS is extremely sensitive to the variation of the polarization direction (or ellipticity), when a horizontal polarized light beam is reflected at Brewster angle. Meanwhile, the spatial (or angular) IPPS is independent of the variation of the ellipticity (or polarization direction), when the polarization rotation angle and ellipticity are small. That is to say, the polarization direction and ellipticity of the light beam can be simultaneously estimated by measuring the spatial and angular IPSSs. In our experiment, we use a linear polarizer and a half-wave plate to produce the input polarization state. Then the light beam is reflected at the surface of a BK7 prism. Finally, the IPPSs are measured via the signal enhancement technique known from weak measurements with the built-in post-selection. Our results show that the input polarization state can be estimated with a high precision and may have applications in many fields, for example, magneto-optical effect and optical activity of chiral molecules.

10373-10, Session 2

The photonic spin Hall effect sensor

Linguo Xie, Zhiyou Zhang, Jinglei Du, Sichuan Univ. (China)

Refractive index sensing plays an important role in biological and chemical applications since a number of trace elements can be determined by measuring the refractive index. In this paper, we present an alternative refractive index sensing scheme based on the photonic spin Hall effect(PSEH). The PSHE manifests itself as opposite transverse displacements of left- and right-circular components when a linear polarized light beam is reflected or refracted at an interface between two media. We find that the spin splitting induced by the PSHE shows high sensitivity to the variation of the refractive index around the Brewster angle at a liquid-glass interface. Therefore, the refractive index sensing can be achieved by measuring the spin splitting. However, the spin splitting is of the order of several micrometers and it is difficult to detect using the conventional methods. In our case, the signal enhancement technique which is so-called weak measurement is employed to measure the spin splitting. We measure the amplified shift of spin splitting experimentally which can be several hundreds of micrometers. Our results show that the refractive index can be estimated with a precision of the order of 10-5 RIU. This method does not require the surface plasmon resonance structure based on noble metal films and the lock-in amplification technique, we believe that it is a robust, low-cost alternative to refractive index sensing.

10373-11, Session 3

Vibration-immune compact optical metrology to enable production-line quantification of fine scale features

Erik Novak, 4D Technology Corp. (United States)

Inspectors attempting to quantify defects and fine-scale features on precision machined surfaces such as turbine blades, drive train components, etc., are often limited by the capabilities and form factors of existing measurement techniques. For large components or to see features on complex geometries, inspectors most often rely on visual comparison tools or pin gauges to determine the geometry of surface features. These methods, however, are neither accurate nor precise, which can result in missed defects or rejection of good parts due to erring on the side of caution. Higher resolution metrology systems are are typically too expensive, slow and susceptible to environmental factors for use on the shop floor. Such instruments are also limited in their capability to measure defects on large components or in hard-to-reach areas. Inspectors must create plastic/rubber replicas of these surfaces, which can then be measured—a costly and time-consuming operation.

This talk will discuss a hand-held, video-rate, 3D optical metrology system for quantification of fine surface features for shop floor and in situ inspection and present critical performance tests including vertical and lateral resolution and gage capability.. With accurate, operator independent characterization, gage-capable measurements can be made on a variety of surfaces and geometries and proper determination of the severity of defects is possible. While the system cannot achieve the extremely high resolution of some optical systems, it bridges the gap between coarser coordinate measuring machines, stereoscopic imagers, and laser line projectors and such instruments. Various new applications will be discussed which are fundamentally enabled through access to a portable, vibration-immune, system that is both quantitative and easy-to-use.

10373-12, Session 3

Effective technique for evaluation of periodically-poled ferroelectric waveguide domains with nanoscale resolution based on frequency mixing

Pengda Hong, Yujie J. Ding, Lehigh Univ. (United States)

We have developed an effective technique for evaluating periodic domains of a ferroelectric waveguide including domain period, linear taper, and periodic domain depth. Such a technique is based on imaging of the surface-emitting second-harmonic beams generated generated by the waveguide. Using a periodically-poled lithium niobate domain waveguide, we have demonstrated that such a method has reached nanoscale spatial resolution.

10373-13, Session 3

Experimental investigation of natural convection in a rectangular cavity with two protruded half cylinders using a Mach-Zehnder interferometer

Akhil Krishnan Maliackal, Angarai R. Ganesan, Annamalai Mani, Indian Institute of Technology Madras (India)

Natural convection studies in an enclosure are very relevant since it spans a wide area of applications such as heat exchangers, chemical reactors, cooling of electronic equipment, etc. In the present study, an experimental investigation is performed in a rectangular cavity of dimension 46 mm x 23 mm with protruded copper half cylinders of diameter 15.8 mm (5/8 inch) each, placed in two different positions and two different configurations. Interferometry has always been a good technique for accurate measurements of temperature gradients. Mach-Zehnder interferometer is employed for visualising the isotherms and for quantitatively inferring the temperature gradient thereby local and average Nusselt number variation for the different configuration as well as the orientation of the test setup. The protruded half cylinders are maintained at constant temperature, ranging from 60 deg C to 120 deg C using an electric cartridge heater and associated temperature controller setup. A He-Ne laser with 24mm collimated beam size is used for experimental purposes. Further, it is planned to study the attributes associated with different aspect ratios along the length and breadth of the rectangular cavity for Rayleigh number varying from 10^3 to 10^4.

10373-14, Session 3

Authentication system using resonance evaluation spectroscopy (ASSURES)

Amit K. Lal, OMS Corp. (United States); James D. Trolinger, MetroLaser, Inc. (United States); Dave Dimas, Univ. of California, Irvine (United States)

This paper describes an ongoing instrument development project to distinguish genuine manufactured components from counterfeit components; we call the instrument ASSURES (Authentication System Using Resonance Evaluation Spectroscopy). The system combines Laser Doppler Vibrometry (LDV) with acoustical resonance spectroscopy (ARS) augmented with finite element analysis (FEA). Vibrational properties of components, such as resonant modes, damping, and spectral frequency response to various forcing functions, depend strongly upon the mechanical properties of the material, including its size, shape, internal hardness, tensile strength, alloy/composite compositions, flaws, defects, and other internal material properties. Although ARS has seen limited application, no one has fully exploited the information rich signals in the vibrational spectra of objects. Components with the same shape but made of different materials, different fatigue histories, damage, tampering, or heat treatment, will respond differently to high frequency stimulation. LDV offers high sensitivity and frequency bandwidth to measure the component's frequency spectrum, and overcomes many issues that limit conventional ARS, since the LDV beam can be aimed anywhere along the part as well as to multiple locations on a part. We have demonstrated ASSURES in a related application to detect manufacturing defects, specifications, and counterfeiting in similar parts. ASSURES is especially promising for use in added manufacturing technology AM because ASSURES signatures will act as digital codes that are unique to specific objects and even to specific locations on objects. We believe that such signatures can be employed to address many of the hypothetical and real vulnerability scenarios of importance to the manufacturing industry in general.

10373-15, Session 3

Optical mapping of surface roughnesses by implementation of a spatial light modulator

Laura M. Aulbach, Franziska Pöller, Min Lu, Shengjia Wang, Alexander W. Koch, Technische Univ. München (Germany)

It is well-known that the surface roughness of materials plays an important role in the operation and performance of technological systems. The roughness influences key parameters such as friction and wear and is directly connected to the quality and durability of the respective system. Tactile methods are widely used for the measurement of surface roughness, but a destructive measurement procedure or the lack of feasibility of online monitoring are crucial drawbacks. In the last decades, several non-contact, usually optical systems for surface roughness measurements have been developed, e.g., white light interferometry or speckle correlation. These techniques are in turn often unable to assign the roughness to a certain surface area or involve inappropriate adjustment procedures. One promising and straightforward optical measurement method is the surface roughness measurement by analyzing the fringe visibility of an interferometric fringe pattern. In our work, we employed a spatial light modulator in the interferometric setup to vary the fringe visibility and provide a stable and reliable measurement system. In previous research, the averaged fringe visibility or the fringe visibility along an observation profile have been analyzed. In this article, the analysis of the fringe visibility is extended to generate a complete roughness map of the measurement target. Thus, surface defects or areas of different roughnesses can be easily located.

10373-38, Session 3

Dimensional metrology of micro structure based on modulation depth in scanning broadband light interferometry

Yi Zhou, Yan Tang, Qinyuan Deng, Lixin Zhao, Song Hu, Institute of Optics and Electronics, Chinese Academy of Sciences (China)

Dimensional metrology for micro structure plays an important role in many science and industrial applications, such as integrated circuits (IC), medical cure, and chemistry. Broadband light interferometry is widely utilized in topography measurement due to its large measurement range, noncontact and high precision. In this paper, we propose a spatial modulation depth-based method to reshape the surface topography through analyzing the characteristics of both frequency and spatial domains in the interferogram. Due to the characteristics of spatial modulation depth, the method could effectively suppress the negative influences caused by light fluctuations and external disturbance. Both theory and experiments are elaborated to confirm that the proposed method can greatly improve the measurement stability and sensitivity with high precision. This technique can achieve a superior robustness with the potential to be applied in online topography measurement.

10373-16, Session 4

Phase measuring deflectometry for determining misalignment of segmented mirrors

Angela Davies, Trent Vann, Chris Evans, The Univ. of North Carolina at Charlotte (United States)

Alternative techniques for measurement of segment misalignment in a segmented mirror are of interest to the telescope community in the limit of large misalignment that precludes interferometric tracking. A variation of phase measuring deflectometry can be used to determine 5 degrees of freedom of the misalignment (DOF) with knowledge of the remaining 1 DOF. A camera and screen are positioned near the center of curvature, and the camera collects images of the screen pattern reflected from the mirror. In this application, the form of each segmented mirror is assumed known, so the misalignment contribution to the measurement can be separated. The approach is based on a Zernike analysis of distorted fringe patterns and their sensitivity to misalignment. We discuss simulation and experimental results in this paper.

10373-17, Session 4

Deflectometry for measuring mount-induced mirror surface deformations

Eric H. Frater, Ball Aerospace & Technologies Corp. (United States)

Deflectometry has been proven as a high precision and high dynamic range surface metrology technique. We report on the use of deflectometry to diagnose mount-induced optical surface deformations. A surrogate mirror from the OLI-2 earth-observing satellite mission is tested with deflectometry in a non-null configuration using only a CCD camera and an LCD computer monitor. Moments are mechanically induced at each flight-like mirror mount and the deformed surface is measured. Systematic errors in the surface measurements are significantly reduced by maintaining a consistent measurement geometry and evaluating moment-induced deformations differentially. The surface deformation modes from orthogonal moments at each mirror mount are compared to FEA predictions. The agility of this metrology sets the groundwork for in situ measurements of flight aspheric mirror surface deformations during component integration and prior to system testing.

10373-18, Session 4

General testing method for refractive surfaces based on reverse Hartmann test

Ping Xu, Daodang Wang, Zhidong Gong, China Jiliang Univ. (China); Rongguang Liang, College of Optical Sciences, The Univ. of Arizona (United States); Kong Ming, Jun Zhao, China Jiliang Univ. (China)

The testing of refractive wavefront enables the quantitative evaluation of refractive surfaces, such as the refractive lenses and glass bottles, and it plays a key role in the quality improvement of industrial products. The testing technique with high dynamic range is required to meet the measurement of refractive wavefront within large distortion range. In this paper, a general method based on reverse Hartmann test, a fringe-illumination deflectometry, is proposed to test the refractive surfaces. Ray tracing of the modeled test system is carried out to reconstruct the refractive wavefront from test refractive surface. To minimize the effect of geometrical error of test system, the computer-aided optimization of system geometry with iterative ray tracing is performed. According to the ray tracing result, the valid testing rays are obtained to reconstruct test wavefront, in which the TIR (total internal reflection) rays are removed from the acquired data to improve the measurement precision. Besides, the stitching method is applied to realize the full-aperture surface testing. To demonstrate the feasibility of the proposed method, experimental testing of glass bottles has been carried out and a good agreement is achieved, in which the RMS value of refractive wavefront is about 255 ?m and testing precision is better than 0.5 ?m. This testing method has preferable anti-interference ability, high dynamic range, low cost and character of suitable for field measurement. It is of great practicality for testing of transparent objects in industrial application.

10373-20, Session 4

Geometrical error calibration in reflective surface testing with reverse Hartmann test

Zhidong Gong, Daodang Wang, Ping Xu, China Jiliang Univ. (China); Rongguang Liang, College of Optical Sciences, The Univ. of Arizona (United States); Ming Kong, Jun Zhao, China Jiliang Univ. (China)

The development of deflectometry enables the high-precision testing of reflective surfaces with high dynamic range, such as the aspheric and freeform surfaces. In the fringe-illumination deflectometry based on reverse-Hartmann-test configuration, the reconstruction of test surface error is realized by ray tracing of the modeled test system. Careful calibration of system geometry is required to achieve high testing accuracy, and it is quite laborious and complicate. The calibration error of the geometrical relations among various components in the system, including the tilt angle deviations, lateral and longitudinal displacements, could introduce evident residual error in the testing result, even though the measurement accuracy of calibration device can reach the order of microns. For the convex surface with 2 inch aperture and 250 mm curvature radius, the RMS value of residual error corresponding to 1 ?m lateral displacement calibration error is about 0.080 ?m, and that for 0.01 degree tilt calibration error can reach 2.203 ?m. Thus, it places ultra-high requirement on the calibration devices.

To realize the high-precision reflective surface testing with reverse Hartmann test, a computer-aided geometrical error calibration method is proposed. The aberrations corresponding to various calibration errors of each component in test system are studied in detail. According to the aberration weights for various geometrical errors, the computer-aided optimization of system geometry with iterative ray tracing is carried out to calibrate the geometrical error. Both the numerical simulation and experiments have been performed to validate the proposed calibration method, and the accuracies in the order of sub-nanometer are achieved.

10373-21, Session 4

Study of annular sub-aperture stitching interferometry for aspheric surfaces

Zixin Zhao, Zhaoxian Xiao, Hangying Zhang, Xi'an Jiaotong Univ. (China)

Annular sub-aperture stitching interferometry (ASSI) has provided an alternative solution to measure rotationally symmetric aspheric surfaces with low cost and high flexibility. It is an effective way to test the aspheric surface with a larger aperture and larger relative aperture without null compensation. Currently, there are two main methods of full-aperture wavefront reconstruction. One is based non-overlapping sub-apertures and annular Zernike polynomial fitting, the full-aperture data is reconstructed by converting the fitting coefficients of sub-apertures into the fitting coefficients of full aperture. It is not suitable when there is a great local irregularity in some sub-aperture area, as the local irregular information may be missing. Another method is based on overlapping sub-apertures and the full-aperture data is obtained by minimizing the mismatch among all overlapping regions, which is more widely used. In this paper, two kinds of overlapping sub-aperture stitching algorithms, pairwise sequential stitching (PSS) and global synchronously stitching (GSS), were studied. The detailed mathematical expressions are shown in the form of matrix. Besides, the influence of the noise and number of sub-apertures to the two algorithms was also studied by simulation. At last, experimental results of a convex hyperboloid surface by using the two stitching algorithms are presented.

10373-22, Session 5

Development of an oxygen saturation measuring system using near-infrared spectroscopy

Kirara Kono, Doshisha Univ. (Japan)

Recently, the hypoxia imaging has been recognized as the advanced technique to detect cancers because hypoxia, which has a strong association to the biological features, is used for functional characterization of cancer. In previous studies, hypoxia imaging systems for endoscopic diagnosis have been developed. However, these imaging technologies can observe only blood vessels in mucous membrane in gastric because of visible light. Therefore, they could not detect scirrhous gastric cancer?which accounts for 10% of all gastric cancers and spreads rapidly into submucous membrane. To overcome this problem, we measured the blood oxygen saturation (SO2) in submucous membrane by using near-infrared (NIR) spectroscopy. NIR, which has high permeability for bio-tissues and high absorbency for hemoglobin, can image and observe blood vessel in submucous membrane. NIR system with LED lights and CCD camera module was developed to image blood vessel. We measured blood SO2 by optical density ratio (ODR) of two wavelengths, based on Lambert-Beer law. To image blood vessel clearly and measure blood SO2 accurately, we searched two optimum wavelengths by using a multilayer human gastric-like phantom which has same optical properties as human gastric one. By using Monte Carlo simulation of light propagation, we derived the relationship between ODR and blood SO2 and elucidated the influence of blood vessel depth on measuring blood SO2. These results were validated with experiments using our NIR system. Finally, it was confirmed that our system can detect SO2 in various depth blood vessels accurately.

10373-23, Session 5

Metrology of semiconductor structures using novel Fabry Perot fringe stretching system

Wojtek J. Walecki, Alexander Pravdivtsev, Frontier Semiconductor (United States)

Fabry-Perot (FP) fringes are widely used for measurement of thin optical films. Application of FP fringe method for very thick materials (such as silicon wafers) is limited since the spectral width of FP fringes decreases with thickness of a layer. Observation of thickness of wafers of silicon thicker than 50 mm is not possible using low resolution spectrometers.

We propose apparatus in which a reference etalon is introduced in the optical path of the beam between sample and spectrometer. In this arrangement, the low resolution spectrometer observes slow varying well separated fringes.

The frequency of these slow varying fringes corresponds to the difference of the FP fringes observed in the wafer alone and FP fringes observed in the etalon alone. Since thickness of the reference etalon is known, and since multiple etalons can be applied the thickness of the semiconductor wafer or other material can be established.

We present results of optical modelling, and characterization of the real life system. System is capable of measuring thicknesses of slabs of material having thicknesses from 0.5 to 10 mm. The reproducibility of the system is 0.01 um, and speed is limited by readout speed of 1D array detector and currently is about 10 ms (if thickness of the etalon is fixed).

In addition we present a simple solution transforming this system into Michelson interferometer and enabling slower phase sensitive measurements using this system, allowing easy identification of different layers and their optical properties in multilayer samples. The phase sensitive solution is used for easy generation of recipies in semiconductor metrology tool.

10373-24, Session 5

Rapid, automated, quality control of diffraction grating efficiency

Mark R. Fisher, Agilent Technologies, Inc. (United States)

A diffraction grating is found at the heart of every modern spectrophotometer and yet, despite being used for over 60 years, a practical and efficient characterization tool has proven to be elusive. Part of the challenge can be attributed to the unique angular dependent geometry (dispersion) of gratings. Here we demonstrate automated grating efficiency measurements of four reflection gratings (300, 1200, 1800 and 3600 grooves per mm). Total measurement time was less than 2 hrs at a maximum of 161 wavelengths per grating. This approach can reduce quality assurance, or design verification, test time from days to hours when compared to equivalent manually operated systems.

Multi-angle Photometric Spectroscopy (MPS) was used to measure the reflectance of gratings across a range of wavelengths and angles. A recent development by Agilent Technologies, the Cary 7000 Universal Measurement Spectrophotometer (UMS) combines both reflection and transmission measurements from the same patch of a sample's surface in a single automated platform. Angles of incidence range 5 deg ≤ |?i| ≤ 85 deg (i.e. angles on either side of beam normal noted as +/-) under s or p polarized light.

We describe the use of MPS on the Cary 7000 UMS by changing grating angle with respect to the incident beam (?i), from 20 deg to 80 deg and the fixed detector position (?d), user defined. This optical geometry replicates a typical monochromator design configuration where the entrance aperture represents the entrance slit of the monochromator and the detector the exit slit. Both s and p polarization efficiency profiles were collected within the range 250 nm to 2500 nm automatically without the need for user intervention.

This spectroscopic approach provides useful input into to quality assurance programs while simultaneously reducing test costs and enhancing part throughput.

10373-25, Session 5

Spatially and temporally resolved diagnostics of dense sprays using gated femtosecond digital holography

James D. Trolinger, MetroLaser, Inc. (United States); Derek Dunn-Rankin, Ali Ziaee, Univ. of California, Irvine (United States); Andrei K. Dioumaev, MetroLaser, Inc. (United States); Marco Minniti, Univ. of California, Irvine (United States)

This paper describes research that demonstrated that gated, femtosecond, digital holography enables 3D microscopic viewing inside dense, almost opaque sprays and can provide a new and powerful diagnostics capability for combustion researchers that enables seeing fuel atomization processes never seen before. The method works by exploiting the extremely short coherence and pulse length (approximately 30 micrometers in this implementation) provided by a femtosecond laser combined with digital holography to eliminate multiple and wide angle scattered light from particles surrounding the injection region, which normally obscures the image of interest. Photons that follow a path that differs in length by more than 30 micrometers from a straight path through the field to the sensor cannot contribute to the holographic recording of photons that travel in a near straight path (ballistic and "snake" photons). To further enhance the method, off-axis digital holography was incorporated to enhance signal to noise ratio an image processing capability in reconstructed images by separating the conjugate images, which overlap and interfere in conventional in-line holography. Because this is ground-breaking research, fundamental relationships and limitations were also examined in addition to demonstrating capabilities. The project is a continuing collaboration between MetroLaser and the University of California, Irvine.

10373-26, Session 6

Focusing schlieren systems using digitally projected grids

Drew L'Esperance, Benjamin D. Buckner, Spectabit Optics, LLC (United States)

Schlieren imaging has been an essential method for studying aerodynamic effects, particularly thermal convection, shock waves, and turbulent flows. This paper describes a compact portable digital focusing schlieren system that can be used to visualize relatively large fields for applications in ventilation design and aerodynamics research. Visualizing large fields is difficult using classical schlieren systems that employ collimated light because their field of view is limited by the size of the mirrors or lenses. Background-oriented schlieren systems are well-suited for visualizing large fields, but their sensitivity is limited by the need to simultaneously maintain focus on the background pattern and the test area. Lens and grid-based focusing schlieren systems are essentially hybrids between classical and background-oriented systems. They can visualize fields that are much larger than possible with comparably priced classical schlieren systems, while providing more sensitivity than background-oriented schlieren systems. Using commercially available camera lenses and optics, fields up to several square meters can be visualized. A key innovation in the system presented here is that digital display devices are used to display the background pattern, which simplifies the optical system and reduces its size. To calibrate the system, proprietary software is used to analyze images acquired by the system's digital camera, and then a background pattern is computed that is complementary to the cutoff grid. The calibration software also provides real-time background subtraction and contrast enhancement. The schlieren system is portable enough that it can be set up quickly in industrial facilities.

10373-27, Session 6

Application of the instrument transfer function to a fringe projection system for measuring rough surfaces

Bin Zhang, Angela Davies, John Ziegert, Christopher J. Evans, The Univ. of North Carolina at Charlotte (United States)

The fringe projection is a novel technique for surface inspection of the layered metal additive manufacturing (AM) process [1], [2]. When used as a surface texture/roughness measuring tool, this technology offers several benefits over the state-of-the-art interferometry methods. First, the instrument can be placed far from the measured object such that the measurements can be made in situ. Second, the fabrication cost is relatively lower than the interferometers because of the less rigid optical fabrication and alignment tolerances. However, fringe projection as a surface texture/roughness measuring technique is still immature. The spatial measurement performance is seldom mentioned by the commercial system vendors or in the literature. The instrument transfer function (ITF) has been proposed as a spatial resolution metric for topography measuring instruments [3], [4]. In this paper, we will investigate the application of ITF to a custom fringe projection system designed for measuring metal AM surfaces. We have found that the linear condition that is required for a meaningful use of ITF is approximately the case when the surface deviation is much smaller than (less than 1/10) the effective wavelength. These conclusions are supported by an analysis of the mathematical model of fringe projection and by extensive simulation. The relationships between ITF, the approximate validity, and optical diffraction will be discussed.

10373-28, Session 6

A three-dimensional scanning apparatus based on structured illumination method and its application in dental scanning

Jae Sung Ahn, Anjin Park, Korea Photonics Technology Institute (Korea, Republic of); Ju Wan Kim, Byeong Ha Lee, Gwangju Institute of Science and Technology (Korea, Republic of); Joo Beom Eom, Korea Photonics Technology Institute (Korea, Republic of)

We demonstrated a three-dimensional (3D) dental scanning apparatus based on structured illumination. A liquid lens was used for tuning focus of the 3D scanning apparatus and a piezomotor stage was used for shift of structured light. By incorporating the liquid tunable lens and the piezomotor stage into the 3D scanning apparatus, we fabricated a compact apparatus and reduced mechanical movement of optical parts inside the apparatus. A simple algorithm, which only detects intensity modulation, was used to perform optical sectioning with structured illumination. As an application in dental scanning, we reconstructed the 3D point cloud models of a dental gypsum cast by piling up sectioned images of the dental cast along the focal axis of the 3D scanning apparatus. We also performed 3D registration of the 3D point cloud models to exhibit a 3D model of the entire dental cast.

10373-29, Session 6

A calibration method immune to the projector errors in fringe projection profilometry

Ruihua Zhang, Shanghai Univ. (China); Yulin Shang, Xi'an Polytechnic Univ. (China)

Fringe projection profilometry is a typical three-dimensional (3D) shape measurement method, and has been extensively applied to many fields. In it, system calibration is a tedious task to establish the mapping relationship

between the object depths and the fringe phases. This paper presents an efficient calibration method based on cross-ratio invariance in the system geometry. In this procedure, we measure the phase maps corresponding to the reference board perpendicularly to three positions with known depths as the reference phase maps. And then calculating the cross-ratio of points along each incident light ray to determine the phase-to-depth relations. When measuring an object, the depth map is calculated from the reference and object phases by employing the pixel shifts on the image plane of the camera. This method is immune to the errors sourced from the projector, including the distortions in the geometric shapes and in the intensity profiles of the projected fringe patterns. Experimental results demonstrate the proposed method is feasible and valid.

10373-39, Session 6

Multimodal and synthetic aperture approach to full-field 3D shape and displacement measurements *(Invited Paper)*

Malgorzata Kujawi?ska, Robert Sitnik, Warsaw Univ. of Technology (Poland)

Recently most of the measurement tasks in industry, civil engineering, security and culture heritage applications require characterization and monitoring of 3D objects and structures and their performance under changing conditions. These requirements can be met if multimodal measurement (MM) strategy is applied. It rely on effective combining structured light method and 3D digital image correlation with laser scanning/ToF, thermal imaging, multispectral imaging and BDRF measurements. In the case of big size and/or complicated objects MMS have to be combined with hierarchical or synthetic aperture (SA) measurements. Both: MM and SA strategies are presented and their applicability is shown at interesting civil engineering and cultural heritage applications.

10373-30, Session PWed

Collimator focus check with interferometer

Ho-Lin Tsay, Yu-Chuan Lin, Sheng-Tsong Chang, Ting-Ming Huang, Instrument Technology Research Ctr. (Taiwan)

Collimator is popular used in optical testing in laboratory to simulate target in a distance. Glass plate or metal plate with pattern is fundamental constitute of collimator focal plane, which should be placed precisely with respect to its optics. For focal plane of collimator being in open space, collimating test is straightforward with a flat mirror. Reflection of the projected beam forms an image identical to focal plane pattern. Comparing pattern and its re-entrance image claims a simple way to check collimator's collimating properties.

However, most focal plane of collimator are surrounding by opto-mechanical structure. It is not possible to observe the pattern and its image simultaneously. A method mentioned in ISO-13485 standard using a penta-prism and theodolite can be used to check the collimating properties. This method measures relative angle in different aperture part of collimator to derive angle deviation of the collimating beam. This method is quantitative and suitable for large aperture collimator but time-consuming.

For small aperture collimator which focal plane is surrounding by opto-mechanical structure. We develop a method to check collimating properties with a Fizeau interferometer involving non-common path interferometry. Power element of interferometric analysis was used as an indicator for focus adjustment. As a result, a fast method to check focal plane position is developed.

Results derived from this method are compared with that derived from angle deviation measurement method.

10373-31, Session PWed

Characterizing the surface fluctuation of an epitaxial wafer by using the Shack-Hartmann wave-front sensor

Pao-Keng Yang, Yao-Kai Zhuang, Minghsin Univ. of Science and Technology (Taiwan)

By using a light-emitting diode as the probing light source and a Shack-Hartmann wave-front sensor to execute a relative measurement, we present a simple and sensitive method for characterizing the surface fluctuation of a nominally flat sample. We used an epitaxial wafer for test. The measured reflected wave front from the surface of the sample was first calibrated to be a planar surface. The surface fluctuation of the test sample could be estimated from the increment on the variance of the wave-front surface to its regression plane after the sample had been shifted by a small distance by using the Bienaymé formula.

10373-32, Session PWed

Fabrication and testing of a long-scale physically stitched diffraction grating using a compact laser interference lithography system with a blu-ray laser diode

Xinghui Li, Xiangwen Zhu, Qian Zhou, Graduate School at Shenzhen, Tsinghua Univ. (China); Haiou Lu, Tsinghua Univ. (China) and Graduate School at Shenzhen, Tsinghua Univ. (China); Kai Ni, Xiaohao Wang, Graduate School at Shenzhen, Tsinghua Univ. (China)

In this research, a technology enabling long-scale (>1000mm) sub-micron periodic diffraction gratings was investigated. Differing from the conventional metal belt type diffraction gratings fabricated by ruling engine, the long-scale grating presented here is formed by physically stitching multiple interference lithographied 20 mm order short-scale gratings, which dramatically simplifies the fabrication systems. Five such kinds of gratings are mounted on a plane substrate to form a 100 grating unit and multiple units are further connected. An interference lithography system for fabrication of these short-scale gratings was constructed by using a compact and cost-effective 405 nm blu-ray laser diode. Four-axis alignment errors that influence the uniformity of grating periods are thoroughly analyzed and a testing platform was established for calibration. Fabricated short-scale gratings were precisely evaluated and grating uniformity was verified to be higher than 95%. A 100 mm grating unit was assembled and tested. Alignment errors were controlled within comparable levels with the flatness of commercial optical glass. These performances proved that this unit is able to be connected for a 1000 mm order scale grating, which will greatly benefits precision positioning of linear motion stages based production engineering.

10373-33, Session PWed

Combined subminiature infrared particulate matter sensors with humidity sensors for reliable mass concentration outputs

Dong-Ik Kim, Han-Jung Kim, Taejoong Lee, Ctr. for Integrated Smart Sensors (Korea, Republic of)

In this paper, we propose a combined subminiature infrared particulate matter (PM) sensor with a capacitance type humidity sensor. In general, PM sensors show number or mass concentration of suspended PM2.5/PM10 in the air, but relative humidity can affect optical type PM sensors. In result,

the concentration of PM is a need for correction depending on the relative humidity. To correct PM concentration, a subminiature humidity sensor was installed inside the PM sensor and several correction factors were applied to a calibration process. Owing to the humidity sensor scale, there is a margin to reduce the PM sensor size also. Furthermore, we applied a specially designed aspheric lens pair with an effective focal length of 2.97 mm to the PM sensor for a subminiature dimension.

10373-34, Session PWed

Advanced polarization sensitive analysis in optical coherence tomography

Aleksandra Wieloszy?ska, Marcin R. Strakowski, Gdansk Univ. of Technology (Poland)

The optical coherence tomography (OCT) is an optical imaging method, which is widely applied in variety applications. This technology is used to cross-sectional or surface imaging with high resolution in non-contact and non-destructive way. OCT is very useful in medical applications like ophthalmology, dermatology or dentistry, as well as beyond biomedical fields like stress mapping in polymers or protective coatings defects detection. Standard OCT imaging is based on intensity images which can visualize the inner structure of scattering devices. However, there is a number of extensions improving the OCT measurement abilities. The main of them are the polarization sensitive OCT (PS-OCT), Doppler enable OCT (D-OCT) or spectroscopic OCT (S-OCT). Our research activities have been focused on PS-OCT systems. The polarization sensitive analysis delivers an useful information about optical anisotropic properties of the evaluated sample. This kind of measurements is very important for inner stress monitoring or e.g. tissue recognition. Based on our research results and knowledge the standard PS-OCT provide only data about birefringence of the measured sample. However, based on the OCT measurements more information including depolarization and diattenuation might be obtained. In our work, the method based on Jones formalism are going to be presented. It is used to determine birefringence, dichroism and optic axis orientation of the tested sample. In this contribution the setup of the optical system, as well as tests results verifying the measurements abilities of the system are going to be presented. The brief discussion about the effectiveness and usefulness of this approach will be carried out

Optical stabilisation for time transfer infrastructure

Josef Vojtech, Ondrej Havlis, Pavel Skoda, Vladimír Smotlacha, Petr Munster, Michal Altman, Tomas Horvath, Jan Radil, Martin Slapak, Radek Velc, Lada Altmannova, CESNET z.s.p.o. (Czech Republic)

Transfer and distribution of precise time and stable frequency becomes an attractive alternative to satellite based methods for distances up to units of thousands of kilometers. We present developed of infrastructure for transfer of these precise quantities. Actually infrastructure over spans more than 1500 km reaches three countries. Infrastructure utilizes DWDM layer or creates overlay over this layer in optical network, using the available resources, i.e. reserved optical bandwidth in DWDM (Dense wavelength division multiplexing) CESNET network. Inside the Prague capital area, we also use a CWDM (Coarse wavelength division multiplexing) channel. These resources allow us to setup permanent bidirectional single fiber path between any two points of presence deployed in involved institutes. Now there are actively connected seven organizations in the Czech Republic and also one foreign institute – the Austrian national time and frequency laboratory BEV in Vienna. The infrastructure shares fibers with data channels at 10 or 100 Gbps without any measurable interactions. As transport delay significantly fluctuates (annul changes about 350ns for the longest link) mainly due to temperature influenced changes of fiber refractive index and length and also by vibrations it is important to stabilize the delay. We present practical issues of variety of optical methods for delay stabilization, ranging from different delay lines (free space tuned by distance change or fiber based tuned by temperature change) to change of transmission wavelength or chromatic dispersion of optical path.

Demodulation of single carrier-frequency interferogram by pixel-level Lissajous figure and ellipse fitting

Fengwei Liu, Yongqian Wu, Fan Wu, Institute of Optics and Electronics (China)

In this paper, we present a novel method to demodulate the phase from single carrier frequency interferogram. It is based on pixel-level Lissajous figure and ellipse fitting (PLEF). Compared with FT method which is a global operation in frequency domain, the local demodulation in spatial domain mechanism makes it more flexible and accurate. The variation of phase distribution over a few pixels, i.e., local phase shifts , are considered with a more adaptable assumption. The mathematic model of demodulation is of interest. The correctness of the mathematic model is firstly demonstrated by simulations and the corresponding theoretical error of the phase demodulation is as less as 1e-4 rad level, followed by a comprehensively discussion on different influence factors. The experiments finally validate the effectiveness of proposed method.

10373-37, Session PWed

Robust phase unwrapping algorithm for 3D profile measurement applications

Meiqi Fang, Hong Zhao, Yueyang Ma, Xi'an Jiaotong Univ. (China)

Phase unwrapping is a significant procedure that has raised a great interest in many coherent imaging systems. What we believe to be a new phase unwrapping algorithm, is described and tested. The method starts from the fact that 2-D wrapped phase distribution can be regarded as a response to two orthogonal 1-D direction excitation signals. This suggests a cepstrum analysis to be implemented in the phase unwrapping problem. The simulated and real experimental results performed on fringe projection profilometry confirm the validity of our approach. In fact, this proposed method is possible to attain a fast and practical phase unwrapping solution with enhanced noise robustness.

10373-40, Session PWed

Measurement of vibration using phase-only correlation technique

Settu Balachandar, Vipin Karthikeyan, SRI Krishna College of Engineering & Technology (India)

A novel method for the measurement of vibration is proposed and demonstrated based on laser triangulation. Experiment involves, launching a Line-laser probe beam perpendicular to the axis of vibrating object. The reflected probe beam is recorded by high speed camera. The dynamic position of the line laser in image plane is governed by magnitude and frequency of vibrating test-object. Using phase correlation technique the maximum distance travelled by the probe beam in CCD plane is measured in-terms of sub-pixels using Matlab. The preliminary result of the proposed method is reported for the acceleration from 1g to 3 g, and the frequency from 6Hz to 26Hz.

Conference 10374: Optical Modeling and Performance Predictions IX

Measurements of the optical anisotropy parameter of Tb:CaF2 crystal

Alexey Yakovlev, Ilya L. Snetkov, Oleg V. Palashov, Institute of Applied Physics of the Russian Academy of Sciences (Russian Federation)

CaF2 crystals with Tb ions could be used as the magnetooptical material in Faraday isolators and rotators [1]. In such devices it is important to minimize of thermal depolarization that appears in magnetooptical element. One of the method of minimizing of thermal depolarization is based on its dependence on crystallographic axes [2]. Depolarization takes the minimum value in the optimal orientation of crystallographic axes, that is determined by the optical anisotropy parameter [3]. Because of weak absorption at 1070 nm, the depolarization in Tb:CaF2 (10at.% Tb) crystal does not show the dependence on laser power up to 1.5 kW [1] and it is not possible to apply the existing method of heating of the crystal to determine the optical anisotropy parameter [4].

In the experiment we used another method that is based on heating of the side surface of the cylindrical optical element. Obtained values for Tb:CaF2 were compared with data for CaF2 measured by both methods of heating of crystal. Using the obtained value of the optical anisotropy parameter at 1070 nm the optimal orientation of crystallographic axes for Tb:CaF2 was determined. Obtained value of the optical anisotropy parameter is necessary for numerical simulations and for minimizing of the thermal effects in such crystals.

Aqueous ethanol detection using a fiber-optic sensor based on Fresnel reflection

Umesh Sampath, Dae-gil Kim, Minho Song, Chonbuk National Univ. (Korea, Republic of)

The measurement of ethanol concentrations in liquid environments is of vital importance for a variety of purposes such as food industry, ethanol production, chemical processing, fuel processing, and to use in forensic science and physiological research. Most common and commercial ethanol measurement techniques utilize semiconductor, electronic, and fuel cells. However, these systems are designed exclusively for vapor-phase measurements. Thus, they are usually bulky, and limited in range and selectivity. Also, the functionality is more limited than the required number of applications. These creates a demand for sensors to measure the ethanol concentrations in aqueous solutions with simple design and good accuracy.

Optical fiber sensors have a great potential for various biological and chemical solute concentration measurement applications. In recent years, optical sensors have also been studied to measure the ethanol concentration. Various configurations, which include U-bent multimode fiber and tapered optical fiber with Graphene Oxide (GO) coating, have provided successful results to measure wide range of ethanol concentration in aqueous solutions. In addition to these, we propose a novel fiber-optic ethanol sensor based on Fresnel reflections. The proposed sensor system is functionalized with a thin-layer of ethanol-sensitive graphene oxide (GO) coating on a single mode optical fiber end. The trace of ethanol concentration was measured by the variations in Fresnel reflection intensity and the optical properties of graphene oxide. Aqueous ethanol concentration from 10% to 100% was measured successfully with the sensor system. The proposed fiber end with GO film exhibited real-time, remote measurements of ethanol concentration with high precision.

The optical schemes of head-mounted displays

Galina E. Romanova, Alexey V. Bakholdin, Vladimir N. Vasilyev, ITMO Univ. (Russian Federation)

Recently there is a growing interest to the head up and head mounted systems. There are many variants of implementation of the head-mounted display system for various purposes with different characteristics. The configuration of the system is highly affected by both type of the image generator and the type of the used combiner.

In many cases we need to design many variants of the scheme and even design new type to compare the characteristics and make a decision to manufacture and realize the system. We have considered several variants of the layout of the systems and compare their characteristics including the packaging and image quality. The systems were designed for operating with the same image generator.

10374-20, Session PMon

Optical system for UV-laser technological equipment

Yuri V. Fedosov, Galina E. Romanova, Maxim Y. Afanasiev, ITMO Univ. (Russian Federation)

Recently there is an intensive developing of intelligent industrial equipment. It can be rapidly adjusted for manufacturing and processing of certain details. This equipment can be robotic systems, automatic wrappers and markers, CNC machines and 3D printers.

The equipment considered in the work is the system for selective curing of the photopolymer using the UV-laser, and using the UV-radiation in such equipment leads to additional technical difficulties.

In many cases for transporting the radiation from the laser to the point processed multi-mirror system is used, but such systems are usually difficult to adjust. Additionally such multi-mirror systems are usually used as a part of equipment for laser cutting of metals using high-power IR-lasers. For the UV-lasers using many mirrors leads to crucial radiation losses because of many reflections .

So, during the development of the optical system for technological equipment using UV-laser, we need to solve two main tasks: to transfer the radiation for working point with minimum losses and to include the system for managing the radiation spot position.

We introduce the system for working with UV-laser with 1 W power and wavelength 423 nm based on fiber system.

The modeling has shown that the optical system gives the sizes of the light spot of about 300 ?m, the designed optical and mechanical systems (prototypes) were manufactured and assembled. In the paper we present the layout of the technological unit, the results of the theoretical modeling of the parts of the system and some experimental results.

Optical modeling of light scattering for refractive-index detection of liquids in a microcapillary with low-coherence rainbow diffractometry

Grzegorz Swirniak, Wroclaw Univ. of Science and Technology (Poland)

Capillary electrophoresis (CE) is a technique that employs narrow capillary tubes (internal diameters from 2 μm up to approx. 700 μm) for the analysis of high-efficiency separations of large and small chemical compounds. Detection in CE is a challenge due to small dimensions of a measurement volume. Through the years, a variety of measurement techniques have been used to identify analytes of interest. CE detectors based on refractive index (RI) measurements allow to characterize micro-domain systems on-line with potentially high sensitivity of the measurement data to changes in RI. Importantly, RI detection allows to characterize samples with no deed of a chemical derivatization, so no pre-column workup is involved. Most of RI optical detectors for CE use a form of interferometric imaging and measure time-dependent concentration of separated ions. Common interferometric techniques include: amplitude splitting interferometry, holographic RI sensing, backscattering interferometry, whispering-gallery modes, and surface plasmon resonances sensing. The use of a lasers as measurement tools for this purpose is common due to both spatial and temporal coherence of laser light.

The aim of this manuscript is to present a different approach to RI sensing for CE which bases on the study of a rainbow phenomenon arising from light scattering by an unmodified glass capillary containing an analyte. Unlike most state-of-the-art interferometric techniques for RI detection, it uses a beam of light having low temporal coherence, which (i) reduces the detrimental sensitivity of the rainbow pattern to small changes in RI of the analyte, (ii) improves the stability of the inverse problem allowing to determine the RI of an analyte without the classical RI ambiguity problem related to morphology dependent resonances (MDRs), and (iii) offers a wide-range RI detection. A constant progress in developing light sources producing a high-intensity, polychromatic radiation (e.g. LED, SLD, etc.) as well as some optical elements capable of converting such light beams with minimal aberrations, makes a practical implementation of the described method feasible.

The main part of the work will be devoted to a numerical prediction of the sensitivity of the measurement data to changes of the refractive index with relative issues. However, as a qualitative understanding of the scattering mechanisms is necessary to extract the desired information, a detailed information about the scattering process will be also provided.

10374-22, Session PMon

Density of states of Cs3Sb calculated using density-functional theory for modeling photoemission

Daniel Finkenstadt, U.S. Naval Academy (United States); Samuel G. Lambrakos, Kevin L. Jensen, Andrew Shabaev, U.S. Naval Research Lab. (United States); Nathan A. Moody, Los Alamos National Lab. (United States)

An analysis is presented that provides a density of states (DOS or D(E)) factor for Cs3Sb in the calculation of its quantum efficiency QE and emittance using a Moments Approach. The analysis is based on density functional theory (DFT) adapted for the practical application of treating photoemission from bulk metal and semiconductor materials, and the interfaces between them. The Moments approach treats the processes of absorption, transmission and emission separately, for which DFT affects parameters and processes associated with each step, of which D(E), the optical constants n and k, and materials parameters such as effective mass m and band gap Eg are paramount. Such factors are required to provide the components of an evaluation similar to the Tsu-Esaki formula for calculating current density over and through and over barriers, and will become more important when a proper quantum mechanical treatment of the emission barrier is considered beyond the simplistic thermal model (transmission probability is unity only for energy levels in excess of the barrier height and zero otherwise). Such features are expected to be far more consequential if the barrier supports resonant levels, e.g., heterostructures.

The effect of laser ablation parameters on optical limiting properties of silver nanoparticles

Irmak Gürsoy, Roketsan A.S. (Turkey); Halime Gul Yaglioglu, Ankara Üniv. (Turkey)

This paper presents the effect of laser ablation parameters on optical limiting properties of silver nanoparticles. The current applications of lasers like range finding, guidance, detection, illumination and designation have increased the potential for temporary or permanent damage on imaging systems or eyes. The ability of laser detection introduces the risks of sensors or eyes get harmed when laser power above the systems damage threshold level. There are some ways to protect these systems like neutral density (nd) filters, shutters, etc. But these limiters are reduced the total amount of light that gets into the system, response time may not be fast enough to prevent damage and caused precipitation in performance due to deprivation of transmission or contrast. In the present case, optical limiting filters are needed that is transparent for low laser intensities and limit or block the high laser intensities. We used silver nanoparticles for laser ablation and silver solutions were synthesized by Nd:YAG nanosecond laser at 532 nm of a high purity silver target immersed in pure water. UV-Vis spectrophotometer was employed to characterize the absorbance of silver nanoparticles. Laser power and ablation time was changed. The effect of altering these parameters on laser ablation efficiency of nanoparticles was investigated experimentally and optimum values were specified. These results are more useful indications for characterization of silver nanoparticles solutions for obtaining high performance optical limiters.

10374-24, Session PMon

Impact of the necking phenomenon on the spectral behavior of WO3 aggregates

Krzysztof Skorupski, Wroclaw Univ. of Technology (Poland)

Fractal-like aggregates are usually modelled as monodisperse particles positioned in point contact. However, this is a rough approximation which may lead to many inaccuracies in light scattering simulations. In reality, much more advanced connections between primary particles exist. Brasil studied the impact of the necking phenomenon on the morphological parameters of these geometries. He proposed a parameter for measuring the particle intersection level. It gives accurate results providing that investigated aggregates are composed of monodisperse, spherical particles. In this work, new parameters for measuring both the intersection level and the neck level were introduced. In contrast to the study be Brasil, they can be used regardless of the particle size and shape. Additionally, the impact of the connection type on the spectral behavior of WO3 aggregates was studied. Two cases were investigated: when the volume of the aggregate (or two connected primary particles) was constant regardless of the connection type, and when it was dependant on the connection size and shape. For light scattering simulations, the ADDA algorithm was used. The wavelength varied from 400nm to 800nm. The number of dipoles per wavelength was never smaller than 200. The refractive index for WO3 was adapted from the paper by Vourdas et al. The results prove that necks have strong impact on the spectral behavior of WO3 aggregates. For example, in some cases, the relative cross section error can be even larger than 50%. They also prove that connections, which exist between primary particles, should not be excluded from aggregate models.

Dynamic/jitter assessment of multiple potential HabEx structural designs

Joseph B. Knight, H. Philip Stahl, NASA Marshall Space Flight Ctr. (United States)

Dynamic analyses of multiple configurations of a proposed Habitable Exo-Planet (HabEx) 4 m off-axis telescope structure were performed to predict effects of jitter on primary mirror wave front error and primary/secondary mirror alignment. The dynamic disturbance used as the forcing function was the James Webb Space Telescope reaction wheel assembly vibration emission specification level. The objective of these analyses was to predict "order-of-magnitude" performance for various structural configurations which will roll into efforts to define the HabEx structural design's global architecture. Structural design parameters varied included structural vs. non-structural tube and secondary mirror (SM) to science instrument enclosure. Primary Mirror (PM) wave front error, PM/SM alignment, and overall mass of each configuration are reported.

Challenges in coronagraph optical design

Russell A. Chipman, James Breckinridge, College of Optical Sciences, The Univ. of Arizona (United States)

To accurately predict the performance of space-based terrestrial exoplanet coronagraphs, we have integrated several analysis methods: geometric ray tracing, polarized vector wave propagation and diffraction theory, and statistical optics. The space-based exoplanet coronagraph performance requires an accurate end-to-end (object to mask to detector) optical system model to guide science decisions, technology development to direct the optical system engineering needed to balance subsystem requirements and to define system ground & space calibration methodologies.

Due to the extreme specifications for exoplanet coronagraphs, such as the goal of resolving planets with a brightness less than 10^-9 of their star located within 3 Airy disk radii, geometric ray-tracing alone provides insufficient information to estimate contrast & SNR for exoplanet characterization. Using the Polaris-M polarization analysis program, we have analyzed how uncorrected coating polarization aberrations couple light around 10^-5 of the incident light into crossed polarized diffraction patterns about twice the size of the Airy disk. Since these orthogonal polarized components exiting with wavefront aberrations different from the principal uncoupled beams, their wavefronts not corrected by the deformable optics systems. Polarization aberrations expansions have shown how these polarization aberrations scale with mirror coatings, fold mirror angles, and numerical aperture. Form birefringence of the telescope mirrors is also analyzed to tolerance this poorly understood, but potentially damaging effect.

10374-3, Session 1

Improving wavefront estimation and control in high-contrast coronagraphy using a polarization compensation algorithm

Jessica Gersh-Range, N. Jeremy Kasdin, Princeton Univ. (United States)

Instrumental polarization is a concern for high-contrast coronagraphs because it introduces errors that cannot be corrected simultaneously with the current two-deformable-mirror wavefront estimation and control scheme, thereby degrading the final contrast. This problem cannot be solved by imaging in a single polarization because light that is initially in one polarization leaks into the orthogonal polarization as it propagates through the optical system; polarizers would be needed before and after the optical system, and this solution is impractical for a large telescope. Current mitigation schemes are hardware-oriented, seeking to cancel the instrumental polarization or minimize its sources. We have developed a complementary, algorithmic approach that compensates for instrumental polarization by subdividing the measured intensity based on the initial polarization and isolating the portion affected by wavefront control.

Our algorithm uses knowledge of the optical system and a set of final intensity measurements to estimate the composition of the incident light, then propagates the result through the optical system to estimate how each polarization component of the incident light contributes to the measured intensity. The estimates of these final intensity contributions are incorporated into a wavefront estimation and control scheme that considers only the estimates of the portions of the wavefront it can correct, and estimates of uncorrectable portions can be subtracted from the final image during postprocessing. In this paper, we present simulations that demonstrate the potential performance improvements that our approach provides, and we provide a preliminary discussion of the impact of model errors and uncertainties.

10374-4, Session 1

Optical performance prediction of space instruments using ray-tracing-based Earth system model

Dongok Ryu, Sug-Whan Kim, Yonsei Univ. (Korea, Republic of); Robert P. Breault, Breault Research Organization, Inc. (United States)

We report a new end-to-end computation model for performance evaluation of space optical instrument. The model combines the observing instrument, the global earth as an observation target and the sun as a light source in non-sequential ray tracing environment. Simultaneous imaging and spectroscopic results are provided using this model with fully resolved spatial, spectral, and temporal coverage of sub-models of Earth. Especially, the global earth system model is defined with a set of optical characteristics representing its 16 types of lands, a ocean and 3D atmosphere components. The incident sun-light interacts with the earth components in terms of reflection, refraction, transmission, absorption and scattering before it enters into the instrument aperture. This new model is capable of evaluating spectroscopic performance as well as imaging and radiometric performances of the optical instrument almost simultaneously from integrated ray tracing computation. We applied this technique to HRI-VIS instrument in EPOXI mission. A hypothetical two-mirror Cassegrain imager is designed with a 300 mm diameter aperture and 21.504 mm ? 21.504 mm focal plane. The simulation images are compared with observations from HRI-VIS meaurement for a day from UTC Mar.18, 2008. The surface scales are 55.0km/pixel for simulation and 54.9km/pixel for observation. Then we measured the defocus aberration of the instrument using a defocus mapping tool and edge spread function with six gradually defocused simulation images. The measuring result shows that optical path between primary and secondary mirror increases by 55.498 ?m from the diffraction-limited condition. This study shows the global Earth system model that includes an instrument model is new and powerful tool for evaluating the performance of an earth observing instrument when used in design, manufacturing and integration phases.

10374-5, Session 2

Augmented method to improve thermal data for the figure drift thermal distortion predictions during the JWST OTIS cryogenic vacuum test

Sang C. Park, Smithsonian Astrophysical Observatory (United States); Timothy M. Carnahan, NASA Goddard Space Flight Ctr. (United States); Lester Cohen, Smithsonian Astrophysical Observatory (United States); Cherie B. Congedo, SGT, Inc. (United States); Michael

J. Eisenhower, Smithsonian Astrophysical Observatory (United States); Wes Ousley, Genesis Engineering Solutions LLC (United States); Andrew Weaver, ATA Aerospace (United States); Kan Yang, NASA Goddard Space Flight Ctr. (United States)

The JWST Optical Telescope Element (OTE) assembly is the largest optically stable infrared-optimized telescope currently being manufactured and assembled, and is scheduled for launch in 2018. The JWST OTE, including the 18 primary mirrors, secondary mirror, and the Aft Optics Subsystems (AOS) are designed to be passively cooled and operate at near 45K. These optical elements are supported by a complex composite backplane structure. As a part of the structural distortion model validation efforts, a series of tests are planned during the cryogenic vacuum test of the fully integrated flight hardware at NASA JSC Chamber A. The successful ends to the thermal-distortion phases are heavily dependent on the accurate temperature knowledge of the OTE structural members. However, the current temperature sensor allocations during the cryo-vac test may not have sufficient fidelity to provide accurate knowledge of the temperature distributions within the composite structure. A method based on an inverse distance relationship among the sensors and thermal model nodes was developed to improve the thermal data provided for the nanometer scale WaveFront Error (WFE) predictions. The Linear Distance Weighted Interpolation (LDWI) method was developed to augment the thermal model predictions based on the sparse sensor information. This paper will encompass the development of the LDWI method using the test data from the earlier 'pathfinder' cryo-vac tests, and the results of the notional and as tested WFE predictions from the structural finite element model cases to characterize the accuracies of this LDWI method.

10374-6, Session 2

Propagation of polarization domain walls in standard optical fibers: beyond the Manakov model

Massimiliano Guasoni, Optoelectronics Research Ctr., Univ. of Southampton (United Kingdom) and Lab. Interdisciplinaire Carnot de Bourgogne, Univ. de Bourgogne (France); Pierre Yves Bony, Marin Gilles, Lab. Interdisciplinaire Carnot de Bourgogne, Univ. de Bourgogne (France); Josselin C. Garnier, Lab. de Probabilités et Modèles Aléatoires, Univ. Paris 7 (France); Antonio Picozzi, Julien Fatome, Lab. Interdisciplinaire Carnot de Bourgogne, Univ. de Bourgogne (France)

An optical polarization domain wall (PDW) is a localized structure of the kink type connecting two regions of space with different polarizations. Here we report a direct observation of PDW propagating within a standard optical fiber commonly used in optical communications. Furthermore, we exploit the topological properties of PDWs for optical data transmission beyond the Kerr limit of normally dispersive fibers. In order to generate a periodic train of PDWs, a 1555-nm continuous-wave is first intensity modulated by 30-ps square-shape pulses at a repetition rate of 14 GHz. This pulse train is then split in 2 out-of-phase, delayed and polarization multiplexed replica so as to obtain a pure orthogonal polarization flip-flopping at 28-GHz. After amplification, these PDWs are injected into a 10-km long normally dispersive fiber. When only one polarization component is injected into the fiber the output signal is strongly impaired by chromatic dispersion and self-phase modulation. In contrast, when both orthogonally polarized components propagate along the fiber the strong binding force imposed by cross-phase modulation compensate for the classical defocusing regime , leading to an undistorted propagation of PDWs. It is worth noting that the propagation of PDWs in km-long fibers question the validity of the Manakov model commonly accepted to describe light propagation in standard telecom fibers. In conclusion, these outcomes constitute the first experimental observation of kink–antikink solitary wave propagation in nonlinear fiber optics and open the way to new physical models describing light propagation in modern telecom fibers.

10374-7, Session 2

Coupled-fiber Bragg grating sensor structure for cryogenic conditions

Umesh Sampath, Dae-gil Kim, Minho Song, Chonbuk National Univ. (Korea, Republic of)

Fiber Bragg grating sensors have numerous advantages over other electro-mechanical sensors, such as zero electromagnetic interference, multiplexing capability, and can be embedded with less detrimental effects. Major drawback of the FBG sensors relies on cross sensitivity towards the applied temperature and the strain. Moreover, the low thermal sensitivity of silica at low temperatures creates additional difficulties in implementing FBG sensors at cryogenic conditions.

In this work, we present the possibilities of simultaneous sensing of the strain and the temperature by measuring the reflected wavelengths from coupled fiber Bragg gratings in cryogenic temperatures. We aimed to overcome the cross-sensitivity problem of FBG as well as improving the temperature sensitivity of gratings at cryogenic temperatures. For the purposes, we used polymer resin as a coating material for a FBG sensor. The polymer coated FBGs (PCFBGs) show high sensitivities to cryogenic temperatures because of the thermal expansion of polymer resin. The average temperature sensitivity of 42 pm °C-1 was obtained for a range -195 °C to 25 °C. To obtain strain free PCFBG, one PCFBG is encapsulated inside a glass capillary tube. Analogously, to eliminate the thermal expansion of capillary material at the one end, FBG is cleaved free and the other end is fixed with temperature resistant epoxy resin. The optical system readout simultaneously the applied strain and the temperatures successfully at cryogenic conditions.

10374-8, Session 3

Improved ray tracing simulation for aero-optical effect of a hypersonic projectile in wind tunnel using multiple gradient-index layer method

Seul Ki Yang, Yonsei Univ. (Korea, Republic of); Sehyun Seong, Dongok Ryu, Yonsei Univ. (Korea, Republic of) and SphereDyne Co., Ltd. (Korea, Republic of); Sug-Whan Kim, Yonsei Univ. (Korea, Republic of) and Ctr. for Galaxy Evolution Research (Korea, Republic of) and Yonsei Univ. Observatory (Korea, Republic of); Sang-Hun Jin, LIG Nex1 Co., Ltd (Korea, Republic of); Ho Jeong, Hyun Bae Kong, LIG Nex1 Co., Ltd. (Korea, Republic of)

We propose improved the simulation method of the aero-optical effect for a hypersonic projectile using multiple gradient-index (GRIN) layer method. The method discretizes anisotropic inhomogeneous media into multiple refractive index layers. Each layer constructs the refractive index distribution function derived from the flow field by Computational Fluid Dynamics (CFD) analysis. In this study, the target used the flow field in the hypersonic wind tunnel corresponds to Mach 7 in speed, 16km in altitude for density. The wedge shaped projectile has semi-vertex angle 12° and fused silica seeker window. The observation instrument inside the wind tunnel consists of a He-Ne fiber laser, a beam expander, a folding mirror, a beam reducer and a Shack-Hartmann sensor. The light source generated 2828 rays and numerical aperture (NA) is 0.12 with beam incident angle variation from 60° to 78°. The Shack-Hartmann sensor has 68?68 pixels and each pixel diameter is 0.108 mm. The simulation results show that the 2D optical path length (OPD) map was estimated in the real optical test measurement, the OPD change value was calculated by the difference OPD map between with and without the flow field. The RMS OPD had a tendency to decrease linearly as the beam incident angle increases and is 0.0141 ? at 78° in beam incident angle. For comparison with other method, we simulated ray equation methods and obtained comparable results.

10374-9, Session 3

The fluid field flow and optical system performance analysis

Ming-Ying Hsu, Ting-Ming Huang, Instrument Technology Research Ctr. (Taiwan)

Optical system performance is easily affected by variable surrounding conditions, including the precision optical system, as its performance is changed with flow field in the air or surrounding water. The air content of water vapor, carbon dioxide concentration, and dry air has a ratio that will affect the air refractive index. Water is another material of general optical systems, affected by surrounding conditions as well. Lithography and the microscope lens are commonly used for contact with water, with their refractive nature, changed by the pressure and density in the flow field. In addition, temperature and light wavelength are two important parameters of the air and water refractive index. This study calculates fluid field pressure and velocity distribution, and then transfers it to air and water refractive index differences in the optical system. We also evaluate optical performance variations with fluid field changes, which can improve optical design and system alignment progress by avoiding surrounding condition changes.

10374-10, Session 3

A fiber-optic ice detection system for large-scale wind turbine blades

Dae-gil Kim, Sampath Umesh, Minho Song, Chonbuk National Univ. (Korea, Republic of)

Recently, because of environmental issues, the demand for wind energy has rapidly increased world widely including colder and higher altitude regions. The cold weather operation of wind turbines, however, lead to problems, such as the ice accretion on surfaces and the impacts of low temperature on the materials of wind turbine blades. Due to imbalance, disrupted aerodynamics, or damages, icing can cause substantial problems in the reliability of large-scale wind turbines.

In this paper, for the purpose of detecting the ice growth, a fiber-optic sensor system is proposed. The system is based on the measurement of Fresnel-reflection intensities from the ends of single mode fibers, and it consists of a broadband light source, an AWG (arrayed waveguide grating), an optical circulator, and a spectrometer. The input broadband light illuminates the AWG via the optical circulator. After de-multiplexing by the AWG with different central wavelengths, the Fresnel-reflection signals from all channels are multiplexed again, detected, and analyzed by a spectrometer which consists of a volume phase grating and a photo-detector array. The intensity variation of each channel corresponds to the ambient refractive index variation of the measurement point. The transition in Fresnel-reflection intensity can identify the status of ambient medium, such as the ice, the water, and the air. Experimental results show that the proposed system can clearly detect the growth of ice in real time.

10374-11, Session 4

Balancing diffraction efficiency and laser damage in diffractive optics

Steven T. Glass, Thomas J. Suleski, The Univ. of North Carolina at Charlotte (United States)

Diffractive optics serve as an enabling technology for a host of applications requiring high power laser focusing and beam shaping, ranging from materials processing to military applications, among others. The ability of such components to resist damage under intense irradiation is of mounting importance as lasers attain ever higher power levels. Diffractive optics inherently contain sharp discontinuities that can enhance electric field distributions within the component, which can lead to increased laser damage. In many cases, diffractive optics are realized as multi- level step-wise approximations to an ideal shape. The increased number of phase levels increases the operating efficiency of the component, but also introduces additional surface discontinuities. As a consequence, it is useful to consider both diffraction efficiency as well as susceptibility to laser damage as performance criteria for diffractive optics in high-power laser systems. Researchers have previously analyzed subwavelength, AR gratings for geometrical field enhancement effects, but conventional diffractive elements with discontinuities have not received as much attention. In this paper, we apply FDTD simulations to determine a general relationship connecting field enhancement to basic grating parameters: period, depth, number of phase levels, step width, and step height. We discuss the results of these simulations, connecting them to diffraction efficiency, fabrication complexity, and laser damage thresholds in different optical materials.

10374-12, Session 4

Mounting and environmental effects on stress birefringence in silicon and zinc selenide windows

Kevin W. Peters, Thomas Yurovchak, Benjamin Dwyer, David E. Thompson, Robert T. Carlson, BAE Systems (United States)

Stress birefringence in an output window affects the performance of polarization dependent remote sensing instruments, such as polarimeter based systems and certain lidar systems. In such instruments, stress birefringence results in reduced signal to noise ratios. Understanding the impact of window stress birefringence is crucial to understanding system performance. This paper utilizes a finite element model (FEM) to analyze the stress in Silicon and Zinc Selenide Windows induced by mounting and environmental conditions. Specifically, the impact of mounting induced twisting modes due to over tightened screws from the window mount to the platform are investigated. Additionally, the impact of environmental pressure differentials across the window are analyzed. The nodal results of the FEM model are interpolated to a uniform grid inside the window in order to simplify a polarization ray trace. Using these interpolated stresses in the window, the stress induced index ellipsoid matrix is calculated. Using this matrix, a Jones calculus based propagation is performed for an arbitrarily polarized input beam passing through the window. Since the accuracy of this method depends on the sampling in the window, a nodal analysis is performed to determine the minimum number of analysis layers that are necessary to achieve an accurate prediction of the stress birefringence. Using the method outlined, the impact of mounting and environmental effects on window performance is predicted and presented for both Silicon and Zinc Selenide windows. This paper also presents experimental results which validate the analysis method and its predictions.

10374-14, Session 4

Modeling the extremely lightweight Zerodur mirror (ELZM) thermal soak test

Thomas Brooks, NASA Marshall Space Flight Ctr. (United States); Tony B. Hull, The Univ. of New Mexico (United States); Ron Eng, H. Philip Stahl, NASA Marshall Space Flight Ctr. (United States)

Schott's Extremely Lightweight Zerodur Mirror (ELZM) has been tested in the X-ray & Cryogenic Facility (XRCF) at Marshall Space Flight Center (MSFC). The mirror's surface was measured interferometrically at room temperature and at three soak temperatures (275K, 250K and 230K). The change in the mirror's figure caused by the change in the mirrors temperature is determined. A thermoelastic model was built and the change in the mirror's optical surface is estimated for thermal gradients, mount effects, and coefficient of thermal expansion (CTE) inhomogeneity. The predictions of this model are compared to the test results, and the model is correlated to the test results by adjusting the mirror's spatial CTE distribution. The surface figure change per mirror depth caused by changing the temperature of a Zerodur mirror is estimated.

10374-15, Session 4

Calculation of density of states for modeling photoemission using method of moments

Daniel Finkenstadt, U.S. Naval Academy (United States); Samuel G. Lambrakos, Kevin L. Jensen, Andrew Shabaev, U.S. Naval Research Lab. (United States); Nathan A. Moody, Los Alamos National Lab. (United States)

Modeling photoemission using the Moments Approach (akin to Spicer's "Three Step Model") is often presumed to follow simple models for the prediction of two critical properties of photocathodes: the yield or "Quantum Efficiency" (QE), and the intrinsic spreading of the beam or "emittance". The simple models, however, tend to obscure properties of electrons in materials, the understanding of which is necessary for a proper prediction of a semiconductor or metal's QE and emittance. This structure is characterized by localized resonance features as well as a universal trend at high energy. Presented in this study is a prototype analysis concerning the density of states (DOS) factor D(E) for Copper in bulk to replace the simple three-dimensional form currently used in the Moments approach. This analysis demonstrates that excited state spectra of atoms, molecules and solids based on density-functional theory can be adapted as useful information for practical applications, as well as providing theoretical interpretation of density-of-states structure, e.g., qualitatively good descriptions of optical transitions in matter, in addition to DFT's utility in providing the optical constants and material parameters also required in the Moments Approach.

10375-1, Session 1

New tools for the design of freeform mirrors

Donald C. Dilworth, Optical Systems Design, Inc. (United States)

Free-form mirrors offer design possibilities not possible with centered shapes, and are becoming more practical as manufacturing techniques improve. New design methods and algorithms are presented that can quickly lay out and optimize systems of mirrors, correcting image quality and distortion. Of special importance is the requirement that a given mirror must not block the beam between two others. This too can be managed automatically with these new methods.

10375-2, Session 1

Design of light guide sleeve on hyperspectral imaging system for skin diagnosis

Yung-Jhe Yan, Chao-Hsin Chang, Hou-Chi Chiang, Mang Ou-Yang, National Chiao Tung Univ. (Taiwan)

A hyperspectral imaging system is proposed for early study of skin diagnosis. A stable and high hyperspectral image quality is important for analysis. Therefore, a light guide sleeve (LGS) was designed for the embedded on a hyperspectral imaging system. It provides a uniform light source on the object plane with the determined distance. Furthermore, it can shield the ambient light from entering the system and increasing noise. For the purpose of producing a uniform light source, the LGS device was designed in the symmetrical double-layered structure. It has light cut structures to adjust distribution of rays between two layers and has the Lambertian surface in the front-end to promote output uniformity. In the simulation of the design, the uniformity of illuminance is about 92%. In the measurement of the actual light guide sleeve, the uniformity of illuminance is about 91%.

10375-3, Session 1

Imaging spectrometer design for high data fidelity *(Invited Paper)*

Pantazis Mouroulis, Jet Propulsion Lab. (United States)

This talk will review the design principles and techniques behind imaging spectrometer design leading to high spectroscopic data fidelity. These involve optical design, tolerancing and alignment, stray light, as well as methods of assessment and verification. Examples from deployed systems illustrate the methods. Some recent results on the use of freeform surfaces will also be shown.

10375-4, Session 1

Achieving linearity with an optical quadrant detector tracking system

Victor J. Doherty, Dina Aouani, EIDOLON Optical, LLC (United States); Michael S. Costello, Franklin W. Olin College of Engineering (United States)

Conventional round spot quadrant detector trackers are inherently non-linear. This non-linearity requires multiple iterations to converge onto perfect alignment with the object tracked. We created a system that generates a square spot. When convolved with a quadrant detector, this spot achieves perfect alignment in one iteration. This invention is thus essential to any system which requires speed and accuracy. In this paper, we introduce the theory behind the square spot as well as the design of our linear optical quadrant detector tracking technology.

10375-5, Session 2

Multi-band filter design with less total film thickness for short-wave infrared application

Yung-Jhe Yan, I-Pen Chien, National Chiao Tung Univ. (Taiwan); Po-Han Chen, National Central Univ. (Taiwan); Sheng-Hui Chen, Yi-Chun Tsai, Mang Ou-Yang, National Chiao Tung Univ. (Taiwan)

A multi-band pass filter array was proposed and designed for short wave infrared applications. The central wavelengths of the multi-band pass filters are located about 905 nm, 950 nm, 1055 nm and 1550 nm. By theory of the optical interference band pass based on H-L structure, the spectrum performance relies on the refractive index difference between the chosen high and low refractive indexes materials, and the repeated periods with the high and low refractive index thin film layers. When determining high and low refractive index materials, spectrum performance was improved by increasing repeated periods. Consequently, the total film thickness increases rapidly. In some cases, a thick total film thickness is difficult to process in practice, especially when incorporating photolithography liftoff. Actually the maximal thickness of the photoresist being able to liftoff will bound the total film thickness of the band pass filter. For the application of the short wave infrared with the wavelength range from 900nm to 1700nm, silicone was chosen as a high refractive index material. Different from other dielectric materials used in the visible range, silicone has a higher absorptance in the visible range opposite to higher transmittance in the short wave infrared. In other words, designing band pass filters based on silicone as a high refractive index material film could not obtain a better spectrum performance than conventional high index materials like TiO_2 or Ta_2O_5, but also its material cost would reduce about half compared to the total film thickness with the conventional material TiO_2. Through the simulation and several experimental trials, the total film thickness below 4 um was practicable and reasonable.

10375-6, Session 2

Multilayer interference coatings with the Gaussian profile for Nd:YAG lasers

Evgeni V. Kuznetsov, Vladimir V. Novopashin, Alexsandr V. Shestakov, JSC “Research Institute” POLYUS “them. M.F. Stelmaha” (Russian Federation)

The development of laser technologies defined the novel quality demands to optical interference coatings. For many technological applications is very important to use lasers with equal distribution of laser intensity across the beam. . These mirrors are used as output coupler in the laser cavity to form radiation close to the Gaussian distribution which using radially varying thickness that have been proved the most practical. Multilayer dielectric mirrors with a smooth changing reflection are used in various types of laser resonators. So, application of such mirrors, permit realize the selection of transverse modes in which the minimal losses possess the transverse mode with amplitude distribution close to distribution of mirror reflection. If mirror has Gaussian distribution, laser radiation generate arise on one or several limited transverse modes. Volumes mode in active media and output power decrease, however, brightness along axis, increase. Using such mirrors is

expedient inner unstable resonator of high power laser in this case we can provide the optimum correlation of the output signal functions. Uniform beams can be obtained by placing some optical elements such as refractive components, binary filters, and holographic systems outside a laser cavity. Intra-cavity optical elements have been demonstrated to be an approach to reducing the impact of edge diffraction in unstable resonators. Diffraction optical elements, a graded-phase mirror, two prisms and the Gaussian mirror are considered as intra-cavity modification accessories [1]. The dielectric graded reflectivity mirrors also minimizes losses, because its filtering action on the cavity field translates into useful output. Besides, optical coatings for laser components must have different requirements depending on the laser system. A common performance requirement is high laser-induced damage resistance, which depends on a number of factors involving optical, mechanical, thermal, and structural properties of the coating. Most of these characteristics are affected by the deposition properties. To maximize the damage threshold, the absorption within the layers has to be low and intensity of the electric field should be minimized. The damage occurs in the local electric field strength reaches its critical value at a weak point of the multilayer system. The electric field in the films must be as low as possible to avoid the film damage caused by the Joule effect and/or ionization process [2]. Since the absorbance is proportional to n?E?2, the high index layer will absorb more energy at the same electric field amplitude [3, 4]. So, the materials with high index must have the low absorption during deposition. In this work the ability of producing multilayer graded interference mirrors with smooth changing profile based on ZrO2 – SiO2 are considered. The processes are made by electron-beam evaporation with ion-beam source to assisted deposition and minimized absorption. In the multilayer dielectric graded mirror the thickness if only alternate layer must smooth varied along the cross section. The method of fixed mask are used which was remove at fixed definite distance. Masks that introduced between deposited material and substrate had various diameters and thickness, and distance to sample surface was varied too. The results of design analysis show that the height of the high reflection zone increases with the number of layers. Although, the main principal points of deposition multilayers graded mirrors had earlier publications, this paper show the ability simple method of obtaining such mirrors on a common vacuum set-up. Thus, in present paper, the design and fabrication of a dielectric graded reflectivity mirror for Nd:YAG laser were reported. The obtained results show that the fabrication graded mirror has maximum reflectance in the 1050 – 1270 nm wavelength range and can be used in the Nd:YAG laser applications, especially those requiring the uniform illumination.

Introducing the quantum efficiency of fluorescence of SCHOTT optical glasses

Ralf Jedamzik, Frank Elsmann, Axel Engel, Uwe Petzold, Jana Pleitz, SCHOTT AG (Germany)

The fluorescence of optical glasses is a property that needs to be taken into account in optical designs for life science applications. Many optical glasses from SCHOTT have very low intrinsic fluorescence values. Usually this fluorescence depends on the excitation wavelength and the optical glass type. The fluorescence of optical glasses is usually defined as the quotient of the integral of the emission spectrum with the integral of the emission spectrum of a reference glass (e.g. SF1). This definition does not give any information about the actual quantum efficiency of the fluorescence. In this presentation recent data on the integral fluorescence of SCHOTT optical glasses are presented. Additionally, first measurements of the quantum efficiency of SCHOTT optical glasses are presented and compared to the standard method.

10375-8, Session 2

Cryogenic refractive index of Heraeus homosil glass

Kevin H. Miller, Manuel A. Quijada, NASA Goddard Space Flight Ctr. (United States); Douglas B. Leviton, Leviton Metrology Solutions, Inc. (United States)

This paper reports measurements of the refractive index of Homosil (Heraeus) over the wavelength range of 0.34—1.10 um and temperature range of 120—335 K. These measurements were performed by using the Cryogenic High Accuracy Refraction Measuring System (CHARMS) facility at the NASA's Goddard Space Flight Center. These measurements were in support of an integrated Structural-Thermal-Optical-Performance (STOP) model that was developed for a field-widened Michelson interferometer that is being built and tested for the High Spectral Resolution Lidar (HSRL) project at the NASA Langley Research Center (LaRC). The cryogenic refractive index measurements were required in order to account for the highly sensitivity performance of the HSRL instrument to changes in refractive index with temperature, temperature gradients, thermal expansion, and deformation due to mounting stresses. A dense coverage of the absolute refractive index over the aforementioned wavelength and temperature ranges was used to determine the thermo-optic coefficient (dn/dT) and dispersion relation (dn/d?) as a function of wavelength and temperature. Our measurements of Homosil will be compared with measurements of other glasses from the fused silica family studied in CHARMS as well as measurements reported elsewhere in literature.

10375-9, Session 3

Camera system MTF: combining optic with detector

Torben B. Andersen, Zachary A. Granger, Lockheed Martin Space Systems Co. (United States)

MTF is one of the most common metrics used to quantify the resolving power of an optical component. Extensive literature is dedicated to describing methods to calculate the Modulation Transfer Function (MTF) for stand-alone optical components such as a camera lens or telescope, and some literature addresses approaches to determine an MTF for combination of an optic with a detector. The formulations pertaining to a combined electro-optical system MTF are mostly based on theory, and assumptions that detector MTF is described only by the pixel pitch which does not account for wavelength dependencies. When working with real hardware, detectors are often characterized by testing MTF at discrete wavelengths. This paper presents a method to define a polychromatic detector MTF based on MTF measurements that are made at multiple discrete wavelengths within a defined passband. Additionally, it is shown how this assigned polychromatic detector MTF may be combined with a polychromatic optic MTF to describe the system MTF. This approach is compared to MTF predictions based solely on the monochromatic detector MTFs.

10375-10, Session 3

Diffraction and geometrical optical transfer function calculation time comparison

José Antonio Díaz, Univ. de Granada (Spain); Virendra N. Mahajan, College of Optical Sciences, The Univ. of Arizona (United States)

In a recent paper, we compared the diffraction and geometrical optical transfer functions (OTFs) of an optical imaging system, and showed that the GOTF approximates the DOTF within 10% when a primary aberration is about two waves or larger [Appl. Opt., 55 (12), 3241–3250 (2016)]. In this paper, we determine and compare the times to calculate the DOTF

by autocorrelation of the pupil function (that reduces to an integration of a complex exponential of the aberration difference function), 2D digital autocorrelation of the pupil function, and by a Fourier transform (FT) of the point-spread function (PSF); and the GOTF by a FT of the geometrical PSF (that reduces to an integration over the pupil plane of a complex exponential of the scalar product of the spatial frequency and transverse ray aberration vectors), and by a FT of the spot diagram. Our starting point for calculating the OTFs is the wave aberrations of the system in its pupil plane, and the ray aberrations in the image plane. Numerical results for primary aberrations and some typical imaging systems show that the direct integrations are slow, but the calculation of the DOTF by a FT of the PSF is as fast as the GOTF calculation by a FT of the spot diagram.

10375-11, Session 3

Polarisation effect on wide angle lens relative illumination

Simon Thibault, Zhengeng Zhuang, Univ. Laval (Canada); Jocelyn Parent, ImmerVision (Canada)

The consumer devices of tomorrow are evolving beyond capturing classic pictures and videos. The lenses of yesterday are narrow and restrictive. New generation of super wide angle lenses capture our surroundings in full 360°, allowing our friends and families to step inside our universe and experience it, live.

However, for such wide angle lens coverage, the relative illumination of the lens must take it account the vectorial nature of the light. Consequently, the light polarisation becomes a very important parameters. Custom coating exist to avoid light transmission polarisation fall off. But for consumer applications, complex coating is not a solution because it raises the cost.

In this talk, we will dicuss how to take care of the polarisation during the design and analysis of the lens design. We will also provide design tips to limit the polarisation impact.

10375-12, Session 3

Linear decomposition of the optical transfer function for annular pupils

Jim Schwiegerling, College of Optical Sciences, The Univ. of Arizona (United States)

A technique for decomposing the Optical Transfer Function (OTF) into a novel set of basis functions has been developed. The decomposition provides insight into the performance of optical systems containing both wavefront error and apodization, as well as the interactions between the various components of the pupil function. Previously, this technique has been applied to systems with circular pupils with both uniform illumination and Gaussian apodization. Here, systems with annular pupils are explored. In cases of annular pupil with simple defocus, analytic expressions for the OTF decomposition coefficients can be calculated. The annular case is not only applicable to optical systems with central obscurations, but the technique can be extended to systems with multiple ring structures. The ring structures can have constant area as is often found in zone plates and diffractive lenses or the rings can have arbitrary areas. Analytic expressions for the OTF decomposition coefficients again can be determined for ring structures with constant and quadratic phase variations. The OTF decomposition provides a general tool to analyze and compare a diverse set of optical systems.

10375-13, Session 3

Assembly of a micro-optical resonator based on silicon micro mirrors for use in gyroscopes

Ingmar Leber, Thalke Niesel, Technische Univ. Braunschweig (Germany); Christian Werner, Yu Liang, Physikalisch-Technische Bundesanstalt (Germany); Andreas H. Dietzel, Technische Univ. Braunschweig (Germany); Jens Flügge, Physikalisch-Technische Bundesanstalt (Germany)

For realization of a miniaturized optical gyroscope the precise assembly of optical micro optical components is crucial [1].To detect the rotation rate with such an optical gyroscopes the laser beam must circulate many times and not leave the resonator due to small misalignments. A passive free space triangular ring resonator shall be assembled in which the light is circulating by reflections at three mirrors. The beam path encloses an area of about 100 mm?. An external light source at 1550nm will be used to activate the resonator, because silicon is translucent at this wavelength and the light can couple into the resonator through the silicon mirrors. To achieve an inherent alignment two of the mirrors are fabricated with a micro technology manufacturing process within the same crystal by wet etching resulting in very perfect {111} facets. The etching solution was optimized with respect to process time and smoothness of the mirror surfaces. To further increase the reflectivity of the mirrors different kinds of coatings are tested. With these two well positioned mirrors the assembly challenge reduces to 3DOF alignment of the third {001} mirror for which a well-designed adjustable spacer is developed. In first tests resonance in a linear cavity test setup has been demonstrated already.

10375-43, Session 3

Wavefront analysis from its slope data

Virendra N. Mahajan, College of Optical Sciences, The Univ. of Arizona (United States); Eva Acosta, Univ. de Santiago de Compostela (Spain)

In the aberration analysis of a wavefront over a certain domain, the polynomials that are orthogonal over and represent balanced wave aberrations for this domain are used. For example, Zernike circle polynomials are used for analysis of a circular wavefront. When the data available for analysis are the slopes of a wavefront, as, for example, in a Shack-Hartmann sensor, the polynomials used are those that are orthogonal to the gradient of Zernike polynomials. Similarly, annular polynomials are used to analyze the annular wavefronts for systems with annular pupils, as in a rotationally symmetric two-mirror system such as the Hubble space telescope. In this paper we discuss the vector functions that are orthogonal to the gradient of aberration polynomials. Instead of integrating the wavefront slope data and then obtain the wavefront aberration coefficients, these vector functions can be used directly to obtain such coefficients.

10375-14, Session 4

Fabrication of multi-focal microlens array on curved surface for wide-angle camera module

Guig-Gu Pan, Guo Dung J. Su, National Taiwan Univ. (Taiwan)

In this paper, we presented a compact camera that consists of microlens arrays with different focal lengths. The design integrates the principle of an insect's compound eye and the human eye. It contains a curved hexagonal microlens array and a hemispherical lens. Compared with normal mobile phone cameras which usually need no less than four lenses, the proposed system use only two lenses. Furthermore, the diameter of our microlens is 400 um and the radius of curvature of curved surface is 2 mm. To make the critical microlens arrays, we used the inkjet printing to control the focal lengths of each microlens and use replication method to form a different curvature hexagonal microlens array.

10375-15, Session 4

The effect of optical system design for laser micro-hole drilling process

Chien-Fang Ding, Yin-Te Lan, Yu-Lun Chien, Hong-Tsu Young, National Taiwan Univ. (Taiwan)

Lasers are a promising high accuracy tool to make small holes in composite or hard material. They offer advantages over the conventional machining process, which is time consuming and has scaling limitations. However, the major downfall in laser material processing is the relatively large heat affect zone or amount of molten burrs it generates, even when using nanosecond lasers over high-cost ultrafast lasers. In this paper, we constructed a nanosecond laser processing system with a 532 nm wavelength laser source. In order to enhance precision and minimize the effect of heat generation with the laser drilling process, we investigated the geometric shape of optical elements and analyzed the images using the modulation transfer function (MTF) and encircled energy (EE) by using optical software Zemax. We discuss commercial spherical lenses, including plano-convex lenses, bi-convex lenses, plano-concave lenses, bi-concave lenses, best-form lenses, and meniscus lenses. Furthermore, we determined the best lens configuration by image evaluation, and then verified the results experimentally by carrying out the laser drilling process on multilayer flexible copper clad laminate (FCCL). The paper presents the drilling results obtained with different lens configurations and found the best configuration had a small heat affect zone and a clean edge along laser-drilled holes.

10375-16, Session 4

Focal tunable liquid crystal lens with floating ring electrode

Chi-Yen Huang, Che-Ju Hsu, National Changhua Univ. of Education (Taiwan); Jyun-Jia Jhang, National Changhua Univ of Education (Taiwan); Jia-Cih Jhang, National Changhua Univ. of Education (Taiwan)

Liquid crystal (LC) lenses have attracted much attention, owing to the light weight and an adjustable focal length without mechanically moving parts. Among the developed LC lenses, the hole-patterned LC lens has a convenient fabrication process, a simple addressing scheme, and widely tunable focal range. Nonetheless, a thick dielectric layer (TDL) has to be inserted between the hole-patterned electrode and the LC layer to distribute the fringing electric field throughout the center of the aperture hole (AH). However, the inserted TDL significantly increases the operation voltage of the LC lens. In this paper, we propose a hole-patterned LC lens with a wide diameter of 6 mm. In our design, a floating ring electrode (FRE) is embedded into the interface between the dielectric layer and the LC layer. This structure confines the electric field in the hole patterned area, therefore assists in distributing the fringing electric field throughout the LC layer and thus assists in tilting the LCs in the AH center of the lens. Therefore, the dielectric layer used in the conventional hole-patterned LC lens can be effectively decreased. The decreased thickness of the dielectric layer provides the FRE LC lens with the advantages of lower operation voltage and large tunable focal range. With a voltage of 40 V, the introduced floating ring electrode modulates the phase retardation of the LC lens in a nearly perfect quadratic form with wavefront error approaching 0.07 ?. The design principle, simulation and fabrication of the LC lens are demonstrated in this paper.

10375-17, Session 4

Zoom system without moving element by using two liquid crystal lenses with spherical electrode

Ren-Kai Yang, Guo Dung J. Su, Chia-Ping Lin, National Taiwan Univ. (Taiwan)

A traditional zoom system is composed of several elements moving relatively toward other components to achieve zooming. Unlike tradition system, an electrically control zoom system with liquid crystal (LC) lenses is demonstrated in this paper. To achieve zooming, we apply two LC lenses whose optical power is controlled by voltage to replace two lenses in traditional zoom system. The mechanism of zoom system is to use two LC lenses to form a simple zoom system. We found that with such spherical electrode, we could operate LC lens at low voltage range from 31V to 53 V for wide tunability in optical power. For each LC lens, we use concave spherical electrode which provide lower operating voltage and great tunability in optical power respectively. For such low operating voltage and compact size, this zoom system with zoom ratio approximate 3:1 could be applied to mobile phone, camera and other applications.

10375-18, Session 4

Tunable refractive power by mutual rotation of helical lens parts

Ingo Sieber, Thomas Martin, Peter Stiller, Karlsruher Institut für Technologie (Germany)

This paper describes a refractive optics consisting of two lens parts with helical surface structures which allows for tuning of the optical refraction power by means of a mutual rotation of the conjugated lens parts around the optical axis. Thus the refraction power can be tuned continuously in a designated range. The shape of the helical surfaces is formed by changing the radius of curvature subject to the polar angle. Combination of such two surfaces results in an optics with tunable refraction power by a mutual rotation. This optics is multifocal with at least two sectors with different individually tunable refraction power. To obtain a monofocal rotation optics, obscuration of the lens sector providing the unwanted refraction power is necessary.

Conventional lens systems providing tunable refraction power do so by mutual axial or lateral shift of the lenses or the lens parts. Hence additional space for lens movement is needed in the design. Since the rotational optics allows adjustment of the refraction power by a mutual rotation of the lens parts no displacement of lenses is needed allowing for a more compact design.

Optics with tunable refraction power by a mutual rotation of two or more diffractive optical elements have been examined and published appropriately. To our knowledge this is the first scientific publication of a varifocal optics with a continuously adjustable refraction power by means of mutual rotation of two refractive lens parts consisting of conjugated helical surface structures.

10375-27, Session PMon

A lazy way to design infrared lens

RongSheng Qiu, Jian Dong Wu, Long Jiang Chen, Kun Yu, Hao Jun Pang, Bai Zhen Hu, Shanghai Aerospace Control Technology Institute (China)

Optical system design in infrared band often brings more challenges than that in visible band. This is because: first, the quantity of the infrared lens design examples is much less than its visible counterpart; Second, infrared optical systems are often installed on UAV or other military electro–optical system, they are usually under a strictly limited space; Third, optical materials with useful transmission in the infrared region exhibit larger changes in refractive index with temperature (dN/dT) than optical glass used in visible band. This in turn introduces larger changes in focus or image quality over temperature for infrared systems compared to comparable focal length visual systems. Athermalization must be taken into account; Forth, compared to the cost-effective visible measurement instrument, infrared centration measurement instrument is too expensive to afford. As a result, each step in the alignment plan needs to pay enough attention; Fifth, stray light in infrared optical system is more complicated in such a way that stray light not only comes from outside but also inside of lens itself.

This essay proposed a stepwise design method of infrared optical system

guided by the qualitative approach. The method fully utilize the powerful global optimization ability, with a little effort to write code snippet in optical design software, frees optical engineer from tedious calculation of the original structure. An easy-to-assemble athermalized MWIR lens was designed based on this method. Because of its compactness, the lens has enough space for filter wheel installation, has the multispectral sensing ability.

10375-28, Session PMon

Design two-dimensional (crossed) diffraction grating in Czerny-Turner spectrometer using freeform mirrors

Yuri Bazhanov, Elena Demura, Rasima Chercashina, Precision Systems and Instruments Corp. (Russian Federation); Vadim Vlakhko, DynaOptics (Singapore)

The possibility of building a spectrometer based on a flat two-dimensional (crossed) grating is being considered. High-order spectres diffracted by such grating are located on the receiver sequentially in the form of horizontal lines, although there is no additional dispersive element. The most suitable layout for this is the Czerny - Turner, in which flat grating is located between the two concave mirrors. We selected one embodiment of this layout, when grating is located in parallel beams, and the distance from the grating to the second mirror was 0.85f, where f is focal length of the second mirror. In this case a spectral image lies in the plane and, with transverse aberrations minimization, can be recorded on receiver with high quality.

In this paper an attempt to compensate for the transverse aberrations is made by using a diffraction grating with variable spacing grooves in both sections and aspheric mirror elements of layout, including ones having a free-form surface.

Using crossed grating greatly simplifies the device layout and may be particularly effective when used in the ultraviolet and infrared regions of the spectrum, due to a small choice of transmissive materials for manufacturing spectral prisms. This paper gives examples of such case.

10375-29, Session PMon

Off-axial Gregory telescope design with freeform mirror corrector

Yuri Bazhanov, Precision Systems and Instruments Corp. (Russian Federation); Vadim Vlakhko, DynaOptics (Singapore)

In this paper a well-known approach is used for calculation of off-axis three-mirror telescope. It includes usage of conic cross-sections properties, each of the sections forming a stigmatic image. To create a compact optical system, a flat mirror aberration corrector is introduced, which is at later stage transformed into a free-form surface in order to compensate field aberrations. Similarly, one can introduce such a corrector in finalized layout for its further optimization and getting a suitable form, including the conversion of multimirrors axial optical system into decentered one.

As an example, off-axial Gregory telescope embodiment is used for infrared waveband region, due to the fact that, unlike the Cassegrain telescope, it provides a real exit pupil, and usage of the mirror corrector brings several advantages. Firstly, this feature may be used to include cold stop or adaptive mirror in the exit pupil, wherein corrector is introduced into a converging beam before the focus of the first mirror. Secondly, when placing corrector in the exit pupil of the optical system it is possible to eliminate high and low order aberrations of center point, which in turn improves optical system f-number, and minimize field aberrations. As another example, off-axial Ritchey-Chretien telescope embodiment is used as a good fit for visible region systems. Analysis and calculation results of optical systems with free-form correctors with surfaces, defined by Power polynomial series are presented in this paper. Advantages of different free-form surfaces usage depends on optical system layouts specifics.

10375-30, Session PMon

Comparative analysis of characterization techniques for SLM-LC using Jones matrices

Juan-Miguel Olvera-Angeles, Alfonso Padilla-Vivanco, Univ. Politécnica de Tulancingo (Mexico)

A comparative analysis between the Saleh and Yamauchi model is presented also a variation of the Yamauchi model for the characterization of SLM-LC (light space modulation - liquid crystal) is realized. The Jones matrices are used for these models. Broad phase modulation and linear transmission are obtained in comparison with the Yamauchi model. A high contrast is obtained from the variation of the transmission and phase modulation than in the Yamauchi model. The results presented are for SLM-LC LC 2012 Holoeye brand. The Mach-Zehnder interferometer is used for phase measurement. We present a more extensive phase modulation obtained using the Saleh method or the Yamahuchi method. Experimental results are presented.

10375-31, Session PMon

Optimization of wavefront coding imaging system using Heuristic algorithms

Enrique Gonzalez Amador, Alfonso Padilla Vivanco, Carina Toxqui Quitl, Univ. Politécnica de Tulancingo (Mexico)

An optimization process of a wavefront coding (WFC) imaging system is presented. This allows us to obtain high resolution images. This optimization is achieved by seeking the most appropriate linear superposition of Zernike polynomials. Heuristic algorithms are used to search for optimal parameters such as phase mask intensity and parameters of restoration filter to get the best restored image. This process is performed using a Wiener filter. Numerical and experimental results of the proposed system show invariance to defocus and astigmatism aberrations.

10375-32, Session PMon

Optical schemes for compact space objectives

Kseniia D. Butylkina, Galina E. Romanova, Alexey V. Bakholdin, ITMO Univ. (Russian Federation)

During last decades the number of space apparatus for the distant Earth monitoring is dramatically growing. The optical-electronic devices are comprised of the modern space units as the equipment on board and usually contain the optical system (objective) and the photodetector module. The most widely used objectives are the mirror systems and catadioptric systems because they can provide compact sizes together with the high image quality. The most widely used are the Ritchey-Chretien telescopes (with and without additional lens correctors) and Korsch systems.

The objectives for the space apparatus should have extremely small sizes (less than 0,4 of focal length) and wide angular field (more than 1 degree), high image quality to provide the resolution 1,5 – 4 meters (on the Earth surface) with the altitude 350 – 400 km and 600 – 700 km and work with wide spectral range.

The research of the schemes which can be used for the space apparatus for the Earth surveillance is carried out based on the third-order aberration theory. The derived equations can help for preliminary designing and researching of the three-mirror schemes of the Korsch-type and the systems without an intermediate image and also for the analysis of the two-mirror systems with lens correctors placed after the secondary mirror in the converging beam of rays.

In the work, we have considered several scheme types and compare them from the point of view of the future application as a part of the space equipment. The image quality and baffle configuration are also presented.

Infrared simulation and performance validation of pinhole and 4-bar collimator targets for static performance evaluation of thermal imaging systems

Doruk Kucukcelebi, Roketsan A.S. (Turkey)

The minimum resolvable temperature difference (MRTD) and minimum detectable temperature difference (MDTD) are widely accepted static performance test parameters that best describe the field performance of thermal imaging systems. MRTD test is measured by determining the minimum temperature difference between the 4-bar target and the background required to resolve the thermal image of the bars by an observer. On the other hand, MDTD test is measured by determining the minimum temperature difference between the target and the background, which is required to detect the target from the thermal image. Different temperature differences between the target and the background and different target spatial dimensions were used while conducting both MRTD and MDTD measurements using collimator test systems. In this study, to evaluate the field performance of various thermal imaging systems, MRTD and MDTD tests were applied. Then, infrared simulations of pinhole and 4-bar collimator static test system targets were described based on the electro-optical parameters of unit under test (UUT) including detector resolution, system SiTF (Signal Transfer Function) and total optical transmission. With these inputs, the infrared simulation images of pinhole and 4-bar targets, which have adjustable temperature difference and different spatial frequency, were obtained in MATLAB environment. Then, the infrared simulations of pinhole and 4-bar target images were verified with various thermal imaging systems. Lastly, field performance results of the thermal imaging systems with respect to MRTD and MDTD static performance test parameters were provided.

10375-34, Session PMon

Mask in thickness uniformity for three coating materials

Cheng-Chung Jaing, Kai-Lun Wu, Jing-Han Xie, Jian-Wei Chen, Minghsin Univ. of Science and Technology (Taiwan); Yeuh-Yeong Liou, Chienkuo Technology Univ. (Taiwan); Pang-Shiu Chen, Minghsin Univ. of Science and Technology (Taiwan)

Uniform coatings are necessary for mass production. Masks are commonly adopted to obtain uniform coatings in e-beam evaporation chambers. The mask, located between the e-gun and the substrate inside the chamber, can correct the thickness distribution of thin films in the e-beam deposition. One mask is generally applicable to one material. However, there are few studies on the application of a mask to more than one material evaporated from one single e-beam source. In this study, a mask suitable for three materials evaporated from one single e-beam source is developed to obtain uniform thickness distribution on a substrate holder. The three coating materials are SiO_2, TiO_2 and Ag respectively. The design method is based on film thickness theory and the assumption that a substrate holder rotates about its central axis during the deposition of films. The emissive characteristics, which modify the cosine law of the surface source, of the three materials are characterized by thickness distributions of films deposited without a mask in an e-beam evaporation chamber. The form of a mask is decided by an optimized emissive characteristic which causes its thickness distribution to be closest to the three film thickness distributions described above. The uniform thickness distributions of the SiO_2, TiO_2 and Ag films deposited with the designed mask are achieved in an e-beam evaporation chamber. The design of a mask in thickness uniformity for three coating materials cuts the development time and requires less trial and error than traditionally experimental correction loops.

Using the afocal compensator of the catadioptric systems for removal the thermal defocus

Galina E. Romanova, Alexey V. Bakholdin, ITMO Univ. (Russian Federation); Stepan E. Ivanov, ITMO Univ (Russian Federation)

The work associates with the ground-based catadioptric systems with two-component afocal achromatic compensator. The most catadioptric systems with afocal compensator have the power mirror part and the correctional lens part. The correctional lens part can be in parallel, in convergent beam or in both. One of the problems of this kind systems design is the thermal defocus by reason of the thermal aberration and the housing thermal expansion.

It is introduced the technique of thermal defocus compensation by choosing the optical material of the afocal compensator components. The components should be made from the optical materials with thermo-optical characteristics so after temperature changing the compensator should become non-afocal with the optical power enough to compensate the image plane thermal shift.

There is the requirement to Abbe coefficients of the components in view of achromatical properties of the compensator that reduces essentially the applicable optical materials quantity.

The catalogues of the most vendors of optical materials in visible spectral range are studied for the purpose of finding the suitable couples for the technique. In the result, it is shown the advantage of the plastic materials application.

The thermo-chromatical aberration is not considered in view of smallness.

The examples of the optical design are given.

10375-36, Session PMon

The improved optical setup for Abbe-Porter experiment

Volodymyr N. Borovytsky, Oleksii Hudz, Vytaliy Antonenko, National Technical Univ. of Ukraine (Ukraine)

The interesting experiments which have confirmed Abbe theory of image formation have been done by E. Abbe, A. Porter and L. Mandelshtam. These experiments have become the classical ones and they are widely used for explanation of Fourier optics. The principal disadvantage of them is difference in optical schemes for observation of an output images and observation of their spatial spectrums. The proposed optical setup makes possible demonstration of two stages of image formation – obtaining a spatial spectrum (Fourier analysis) and composing an output image (Fourier synthesis) – together. This setup contains two imaging channels that are separated by a beam splitter after a microscope objective. The first one forms a magnified image of a spatial spectrum, the second one – a magnified output image. These images can be observed on a screen, or via eyepieces or using image sensors. Any occluding of spectrum zones becomes visible and it leads to the corresponded changes in an output image. All technical details of the setup are described including calculations of a field of view and irradiance in an image plane. The images and their spatial spectrums registered using this setup are presented and discussed. This optical setup would be useful for optical education and conduction optical research.

10375-37, Session PMon

Development of surgical binoculars on the basis of polymeric lenses

Anna O. Voznesenskaya, ITMO Univ (Russian Federation); Alisa Ekimenkova, Artem Muratov, Lev Andreev, ITMO Univ. (Russian Federation)

In the modern world to carry out medical operations on the thin blood vessels, as well as in the manufacture of microelectronic circuits and manufacture of jewelry special optical systems (surgical binoculars) of a relatively small magnification are used. For the additional accommodation of the eye during the transition from observation with and without glasses an optical system which locates object and image in the same plane is necessary.

It can be a specially developed system that allows to change the base of the eye and the angle of convergence. At low magnifications one can use an ordinary spectacle frame, which is mounted on the ordinary glasses system.

The Galileo system is used for the binoculars design of relatively small magnification. Binoculars with prismatic system provide higher magnification. That allows the operator to see all of the items within the surgical field. Binoculars are manufactured strictly in accordance with the individual characteristics.

Key features of this systems are superior indicators of image clarity, lack of distortion and excessive fatigue of the eye. It could be achieved by application of high quality optics. Meantime the systems should have low weight and size. Lenses made of glass are much heavier construction.

The basis of this work is a modification of the modern design of surgical binoculars and the replacement of mineral glass with polymer lenses.

Specific weight of plastic is two times less than glass, so the glasses with polymer lenses are much lightweight. In addition, lightweight of plastic allows to use spectacle frame without rims or semi-rimless. Also in today's world strengthening coatings for polymeric lenses were developed to make them as scratch resistant as mineral. At the moment, glass has almost no advantages over plastic: plastic is lighter, more stable to impact and traumatic safe. Besides, polymers are better materials from an economic point of view.

In this article is presented the analysis of polymeric materials for the manufacture of lenses, and comparison of their optical properties. Using Zemax software and commercial catalogue of optical polymers and plastics optical systems of binoculars according to the Galileo scheme with polymeric materials for different magnifications were designed. To reduce aberrations and achieve high quality of the optical systems, mutual arrangement of materials is performed, and optical system optimization is realized.

Replace the minerals lens with the plastic ones helps to make binoculars convenient to use and makes easy the work of the operator as well as reduces the cost of the surgical bicnoculars and increases their availability on the world market without loss of image quality.

Optical spherometer for measuring large curvature radii of convex surfaces

Jorge Alvarado-Martínez, Univ. Politécnica de Tulancingo (Mexico); Sergio Vazquez y Montiel, Univ. Tecnológica de la Huasteca Hidalguense (Mexico); César Joel Camacho Bello, Univ. Politécnica de Tulancingo (Mexico)

Measuring large curvature radii of convex surfaces with high precision is a challenge because the spherometer's focus must be positioned at the apex of the surface and at the center of curvature of the surface by moving the surface or the spherometer. If the center of curvature is greater than the distance from the focus to the spherometer, then measurement is not possible. In this work we propose to use the FOCOIVA system [1] to move the focus of the spherometer in longitudinal way without modifying the f number by moving two lenses inside it, with this mechanism it is possible to measure radii of curvature of several meters in length. The curves of movement of the lenses and the optical parameters of the lenses that compose the spherometer are presented.

Optimization of corneal topography maps by bio-inspired algorithms

Gerardo Diaz-Gonzalez, José Alfredo Jiménez-Hernández, Univ. Tecnológica de la Mixteca (Mexico); Marcelo David Iturbe-Castillo, Instituto Nacional de Astrofísica, Óptica y Electrónica (Mexico); Rigoberto Juarez-Salazar, Ctr. de Investigación y Desarrollo de Tecnología Digital (Mexico); Agustín Santiago-Alvarado, Univ. Tecnológica de la Mixteca (Mexico)

Nowadays, corneal topography mapping is a technique to detect and measure irregularities that appear in the human cornea surface. This technique is very useful for laser surgery planning or design of ophthalmic lenses. In this work, we propose a computational algorithm based on biological processes for refractive power optimization of corneal topography maps. The geometrical parameters of the cornea and other optical elements of the human eye are computationally optimized and analyzed by an intuitive graphic user interface.

Ray tracing for inhomogeneous media applied to the human eye

Gerardo Diaz-Gonzalez, José Alfredo Jiménez-Hernández, Univ. Tecnológica de la Mixteca (Mexico); Marcelo David Iturbe-Castillo, Instituto Nacional de Astrofísica, Óptica y Electrónica (Mexico); Rigoberto Juarez-Salazar, Ctr. de Investigación y Desarrollo de Tecnología Digital (Mexico)

Inhomogeneous or gradient index media exhibit a refractive index varying with the position. This kind of media are very interesting because they can be found in both synthetic as well as real life optical devices such as the human lens. In this work, we present the development of a computational tool for ray tracing in refractive optical systems. Particularly, the human eye is used as the optical system under study. An inhomogeneous medium with similar characteristics to the human lens is introduced and modeled by the so-called slices method. The usefulness of our proposal is illustrated by several graphical results.

Iterative paraxial design method based on an analytic calculation and its application to a three-group inner-focus zoom system

Euisam S. Lee, Juhyeon Choi, Yeon Hwang, Youngbok Kim, Korea Photonics Technology Institute (Korea, Republic of)

A paraxial design method based on an analytic calculation has been presented to overcome the problems of the conventional method for the design of initial zoom lens. We have theoretically derived the set of available zoom equations for three-group inner-focus zoom systems with infinite object distance, by using the matrix representation for paraxial ray tracing. Also we have made the program tool to calculate the first orders of lens

groups and zooming locus from the zoom equations using Matlab. The various constraints of three-group inner-focus zoom system could simply be described since the paraxial ray tracing equations are expressed in Gaussian brackets. The first orders of each group are used to calculate the zooming locus and then they are evaluated if the constraints are satisfied. If not, the first orders of each lens group should be changed to meet the constraints. The stability of this iterative paraxial design method has been confirmed and applied to the initial design for a three-group inner-focus zoom system having short total track of 12 mm and zoom ratio of 3x at all zoom positions.

Optical modeling of bullet-shaped LED for use in self-luminous traffic signs

Ted Liang-tai L. Lee, Yi-Chun Chen, Ming-Siou Tsai, Ching-Cherng Sun, National Central Univ. (Taiwan)

Bullet-shaped LEDs are commonly used in self-luminous traffic signs as LED dotted matrices due to their low cost, simplicity, robustness and ease of installation. This study aims to design a lens module on the bullet-shaped LEDs to reduce glare sensation by creating a desirable amount of backscatter onto the retroreflective sheets of traffic signs. Unfortunately, due to the high tolerance of the manufacturing process, the midfield modeling of bullet-shaped LEDs is a difficult task. In this paper, we use a proven modeling algorithm and expand its capabilities to model bullet-shaped LEDs, aiding us in designing beam-shaping lens in the midfield region.

A simple low-cost method that creates a model suitable for the high tolerance found in bullet-shaped LEDs is proposed, based on first measuring multiple one-dimensional intensity patterns at interested distances from multiple LEDs to form a database, including distances at 10, 14, 19, 24, 34, 49, and 100 mm. Their normalized cross correlations are then calculated to find the batch that has the most similarity and base our model off that batch. Finally, we validate the model via Monte Carlo simulations in comparison to the original one-dimensional intensity patterns in the database. Current work is mainly focused on building a fast and reliable measuring platform, and acquiring abundant data for the database.

The platform has been demonstrated to obtain an average of 97% in normalized cross correlation between different batches of the same model LED, and a model of that LED is currently under development. Future work will be focused on improving our model for the high tolerance bullet-shaped LEDs with the main goal to apply our model in designing a lens that directly covers the LED to provide a reasonable amount of backscatter for use in highway traffic signs.

10375-20, Session 5

Visual ergonomic evaluations on four different designs of LED traffic signs

Yi-Chun Chen, Ting-Yuan Huang, National Central Univ. (Taiwan); Tsung-Xian Lee, National Taiwan Univ. of Science and Technology (Taiwan); Ching-Cherng Sun, National Central Univ. (Taiwan)

Traffic signs are an indispensable part of our daily lives. However, traditional signs with retroreflective sheets and external lighting are almost invisible in severe weather such as heavy rains or fogs. Making traffic signs self-luminous with LEDs is a promising solution for longer legible viewing distance. To investigate the legibility and visual comfort of LED traffic signs, an ergonomic experiment is designed and performed.

Four different LED highway traffic signs are custom made, including three self-luminous ones as LED lightbox, LED backlight and regional LED backlight, and one non-self-luminous sign with external LED lighting. In our previous study, the luminance operating range of white texts on the self-luminous traffic signs has been identified to provide satisfactory legibility and visual comfort. The self-luminous signs in the present study are lit to the same luminance within that range. The illuminance of the external-lit one complies with the traffic-sign regulations. The four signs are hanged side-by-side and evaluated by observers through questionnaires. Four left-to-right hanging orders arranged by a Latin square are employed to compensate the possible viewing-order effect. Preliminary results from eight participants and four rounds show that the four designs have statistically significant differences in their legibility, visual comfort and user preference. The most preferred design is regional LED backlight, probably owing to its high contrast between the white texts and green background. Further evaluations with more observers are underway to verify the findings in the pilot study. The research outcome shall offer practical directions in designing LED traffic signs.

10375-21, Session 5

Smart lighting using a liquid crystal modulator

Alexandre Baril, Simon Thibault, Tigran Glastian, Univ. Laval (Canada)

Since the massive invasion of LED lighting over the illumination market, a clear trend of need appeared for a more effcient and targeted lighting. The project leads this trend by developing an evaluation board to test smart lighting applications with a new liquid crystal light modulator recently developed for broadening LED light beams. These modulator are controlled by electricals signals and they are characterised by a very linear working zone.

This feature allows the implementation of a closed loop control with a sensor feedback. We show that the use of computer vision is a promising opportunity for closed loop control. The developed evaluation board integrates the liquid crystal modulator, a camera, a LED light source and all the required electronics to implement a closed loop control with a computer vision algorithm.

10375-22, Session 5

High-efficiency zoom spotlight based on solid-state lighting

Shih-Kang Lin, Xuan-Hao Lee, Mao-Teng Ho, Tsung-Hsun Yang, Ching-Cherng Sun, National Central Univ. (Taiwan)

In this study, we propose an optical design for a high- efficiency zoom spotlight. The zoom spotlight has a reflector, a solid-state light source and a fixed lens. The solid-state light source of the zoom spotlight can be moved longitudinally so that the zoom spotlight can output a broad beam,

a collimated beam, or a beam ranging between the broad beam and the collimated beam. We also discuss the structure design for the solid-state light source to increase the output luminous flux. The simulation analysis and the corresponding experiment results are demonstrated.

10375-23, Session 5

Combining the transformation and the integration methods to design a refractive lens-array for signal lighting applications

Mahmoud Essameldin, Friedrich Fleischmann, Thomas Henning, Hochschule Bremen Univ. of Applied Sciences (Germany); Walter Lang, Univ. Bremen (Germany)

The design of a secondary optical lens for light beam shaping using the transformation method is performed by transforming the light source energy distribution using the concepts of energy conservation and light energy mapping. Using these concepts creates a dependency relation between the output optical performance and the luminous intensity distribution of the light source. This relation leads to errors on the optical performance due to the fabrication misalignment between the light source and the secondary optical lens. On the other hand, in the illumination applications, the integration method has been proved to be an efficient method for achieving a high degree of homogenized luminous intensity distribution by integrating and superimposing the light source energy over the illuminated objects.

In signal lighting applications, the luminous intensity distribution must meet the requirements regarding the brightness perception of users over the spatial angular distribution, not the illumination of objects. In this paper, the integration method is combined with the transformation method to design a refractive lens-array for signal lighting applications. The difference between the two methods is described, presenting the advantages of the combination process. Design procedures are explained in detail including the lens-array modeling. The optical performance is investigated using an optical ray tracing. Finally, the influence of the misalignment between the light source and the refractive lens-array is measured.

10375-24, Session 6

Development of the infrared instrument for gas detection

Ching-Wei Chen, Chia-Ray Chen, National Space Organization (Taiwan)

MWIR (Mid-Wave Infrared) spectroscopy shows a large potential in the current IR devices market, due to its multiple applications, such as gas detection, chemical analysis, industrial monitoring, combustion and flame characterization. It opens this technique to the fields of application, such as industrial monitoring and control, agriculture and environmental monitoring. However, a major barrier, which is the lack of affordable specific key elements such a MWIR light sources and low cost uncooled detectors, have held it back from its widespread use. In this paper an uncooled MWIR detector combined with image enhancement technique is reported. This investigation shows good results in gas leakage detection test. It also verify the functions of self-developed MWIR lens and optics. A good agreement in theoretical design and experiment give us the lessons learned for the potential application in infrared satellite technology. A brief discussions will also be presented in this paper.

10375-25, Session 6

Optical design of an athermalised dual field-of-view step zoom optical system in MWIR

Doruk Kucukcelebi, Roketsan A.S. (Turkey)

In this paper, the optical design of an athermalised dual field of view step zoom optical system in MWIR (3.7μm – 4.8μm) is described. The dual field of view infrared optical system is designed based on the principle of mechanical passive athermalization method not only to achieve athermal optical system but also to keep the high image quality within the working temperature between -40 ºC and +60 ºC. The infrared optical system used in this study had a 320 pixel x 256 pixel resolution, 30μm pixel pitch size cooled MWIR focal plane array detector. In this study, the step zoom mechanism, which has the axial motion due to consisting of a lens group, is considered to simplify mechanical structure. The optical design was based on moving a single lens along the optical axis for changing the optical system's field of view not only to reduce the number of moving parts but also to athermalize for the optical system. The optical design began with an optimization process using paraxial optics when first-order optics parameters are determined. During the optimization process, in order to reduce aberrations, such as coma, astigmatism, spherical and chromatic aberrations, aspherical surfaces were used. As a result, athermalised dual field of view step zoom optical design is proposed and the performance of the design using proposed method was verified by providing the focus shifts, spot diagrams and MTF analyzes' plots.

10375-26, Session 6

Contact lens design with slope-constrained Q-type aspheres for myopia correction

Wei-Jei Peng, Yuan-Chieh Cheng, Wei-Yao Hsu, Zong-Ru Yu, Cheng-Fang Ho, Instrument Technology Research Ctr. (Taiwan); Khaled Abou-El-Hossein, Nelson Mandela Metropolitan Univ. (South Africa)

The design of the rigid contact lens with slope-constrained Q-type aspheres for myopia correction is presented in this paper. The spherical contact lens is the most common type for myopia correction, however the spherical aberration (SA) caused from the pupil dilation in dark leads to the degradation of visual acuity which can't be corrected by spherical surface. The spherical and aspheric contact lenses are designed respectively based on Liou's schematic eye model, and the criterion is the normal vision on optical axis, that is defined as the resolution of one arc-minute. After optimization, the aspheric design is superior to the spherical design, and the aspheric surface corrects the SA for improving the visual acuity on retina. For avoiding the scratch caused from the contact profilometer, the aspheric surface is designed to match the measurability of the interferometer. The Q-type aspheric surface is employed to constrain the root-mean-square (rms) slope of the departure from a best-fit sphere directly, because the fringe density is limited by the interferometer. The maximum departure from a best-fit sphere is also controlled according to the measurability of the aspheric stitching interferometer (ASI). The inflection point is also removed in optimization for measurability and appearance. Therefore, the aspheric contact lens is successfully designed with Q-type aspheres for measurability of the interferometer. It not only corrects the myopia but also eliminates the spherical aberration for improving the visual acuity in dark based on the schematic eye model.

10376-1, Session 1

Curved sensors for compact high-resolution wide field designs *(Invited Paper)*

Christophe Gaschet, CEA-LETI (France); Emmanuel Hugot, Lab. d'Astrophysique de Marseille (France); Bertrand Chambion, Stéphane Gétin, Gaid Moulin, Stéphane Caplet, Aurélie Vandeneynde, CEA-LETI (France); David Henry, Commissariat à l'Énergie Atomique (France); Wilfried Jahn, Lab. d'Astrophysique de Marseille (France)

Over the recent years, a huge interest has grown for curved electronics, particularly for opto-electronics systems. Indeed, an optical system always has some aberrations, specifically for off-axis rays with Petzval Field curvature and astigmatism aberrations, which bend the focal plane. Usually, these aberrations are corrected with additional lenses, with the aim of coinciding the focal plane with a flat sensor. For more compact systems, this addition is impossible and corrections are made at the expense of the resolution. As the consequence, the main challenge is to obtain a compact system with a high resolution. In this paper, we proposed a new design architecture which has been developed specifically for a mechanically compatible curved image sensor. This type of optical design permits high performances and compactness without aspheric lenses, and has been evaluated in comparison with a benchmark system. For example, the gain of compactness is more than 50% compared to an equivalent system. Moreover, the role of different aberrations will be detailed, particularly for the Petzval curvature and astigmatism. We will also discuss trade-offs of several characteristics, such as stop shift, field of view of the system and chief ray angle at the edges of the sensors. Besides, curved sensors has also been studied, with results of its mechanical limits and electro-optical tests. All these experiments and results demonstrate the feasibility and the high performances at the entire optical system level.

10376-2, Session 1

Focus-induced photoresponse: a fundamentally novel approach to optical distance measurements

Christoph Lungenschmied, TrinamiX GmbH (Germany); Oili Pekkola, TrinamiX GmbH (Germany); Christian Lennartz, TrinamiX GmbH (Germany); Ingmar Bruder, TrinamiX GmbH (Germany)

Focus-Induced Photoresponse (FIP) is a patented monocular technology for optical distance measurements [1]. It relies on physical phenomena which are fundamentally different from established technologies such as time-of-flight, stereo vision, structured light or systems based on image processing. In this presentation, the underlying principles of the technology as well as application examples are introduced.

FIP exploits the nonlinear transient photoresponse of various organic as well as inorganic semiconductors when exposed to optical radiation. When a light-emitting (or reflecting) object moves in and out of focus, the size of the image that it creates on a sensor surface determines the magnitude of the photoresponse. As the focal point shifts with the distance between the collecting lens and the object, the sensor response yields a unique signature for every distance.

The device layout can hence be simple: the main components are modulated light sources, a lens and a non-pixelated sensor. Due to the unstructured sensor, resolution is not restricted by pixel size. FIP does not require large computational power as neither image processing nor stereo vision is required. By proper choice of optics and sensor type, the system can be adapted to any measuring task. We have successfully demonstrated functionality for wavelengths from visible light to IR and for distances up to 100 m.

[1] Bruder et al. (US 9,001,029 B2) DETECTOR FOR OPTICALLY DETECTING AT LEAST ONE OBJECT.

10376-3, Session 1

Ideal-lens stars

Jakub Bělín, Univ. of Glasgow (United Kingdom); Tomás Tyc, Masaryk Univ. (Czech Republic); Stephen Oxburgh, Johannes Courtial, Univ. of Glasgow (United Kingdom)

We recently showed how structures of ideal (thin) lenses can act as (ray-optical) transformation-optics devices. This was done by breaking the structure down into all sets of ideal lenses in the structure that share a common edge, and showing that these sets have very specific imaging properties.

In order to start the development of a general understanding of the imaging properties of sets of ideal lenses that share a common edge, we investigate here particularly simple and symmetric examples of combinations of ideal lenses that share a common edge. We call these combinations ideal-lens stars. An ideal-lens star is formed by N identical ideal lenses, each placed such that they share a principal point (which lies on the common edge) and such that the angles between all neighbouring lenses are the same.

We find that that passage through every single ideal lens in the ideal-lens star images any point to itself. Furthermore, light-ray trajectories in ideal-lens stars are piecewise linear approximations to conic sections. (In the limit of N approaching infinity, they are conic sections.) Finally, we show that light-ray trajectories in ideal-lens stars are closely related to the family of trajectories of particles with the same ratio of angular momentum and mass in the Kepler problem.

10376-4, Session 1

High-speed video analysis of ballistic trials to investigate the crack propagation in glass laminates

Arash Ramezani, Hendrik Rothe, Helmut-Schmidt Univ. (Germany)

In the security sector the partly insufficient safety of people and equipment due to failure of industrial components are ongoing problems that cause great concern. Since computers and software have spread into all fields of industry, extensive efforts are currently made in order to improve the safety by applying certain numerical solutions.

This work will focus on transparent armor consisting of several layers of soda lime float glass bonded to a layer of polycarbonate to produce a glass laminate. Details of ballistic trials on transparent armor systems are presented. Several targets of different laminate configurations were tested to assess the ballistic limit and the crack propagation for each design. Here, even the crack formation must precisely match later simulations. The crack propagation is analyzed using image processing software for highly accurate measuring functions. The goal is to evaluate the effects of ballistic glass with numerical simulations, promoting an effective development process. Due to the fact that all engineering simulation is based on geometry to represent the design, the target and all its components are simulated as CAD models. Using a CAD-neutral environment that supports direct, bidirectional and associative interfaces with CAD systems, the geometry can be optimized successively. The work will also provide a brief overview of ballistic tests to offer some basic knowledge of the subject, serving as a basis for the comparison of the simulation results. The objective of this work is to improve the safety of ballistic glasses. Instead of running expensive trials, numerical simulations should identify vulnerabilities of

structures. Contrary to the experimental result, numerical methods allow easy and comprehensive studying of all mechanical parameters. Modeling will also help to understand how the transparent armor schemes behave during impact and how the failure processes can be controlled to our advantage. By progressively changing the composition of several layers and the material thickness, the transparent armor will be optimized. There is every reason to expect possible weight savings and a significant increase in protection, through the use of numerical techniques combined with a small number of physical experiments.

10376-5, Session 1

Imaging with pairs of skew lenses

Jakub Bělín, Stephen Oxburgh, Univ. of Glasgow (United Kingdom); Tomáš Tyc, Masaryk Univ. (Czech Republic); Johannes Courtial, Univ. of Glasgow (United Kingdom)

Many of the properties of thick lenses can be understood by considering these as a combination of parallel ideal thin lenses that share a common optical axis. A similar analysis can also be applied to many other optical systems. Consequently, combinations of ideal lenses that share a common optical axis, or at least optical-axis direction, are very well understood. Such combinations can be described as a single lens with principal planes that do not coincide. However, in recent proposals for lens-based transformation-optics devices the lenses do not share an optical-axis direction. To understand such lens-based transformation-optics devices, combinations of lenses with skew optical axes must be understood.

In complete analogy to the description of combinations of pairs of ideal lenses that share an optical axis, we describe here pairs of ideal lenses with skew optical axes as a single ideal lens with sheared object and image spaces. The transverse planes are no longer perpendicular to the optical axis. We construct the optical axis, the direction of the transverse planes on both sides, and all cardinal points. We believe that this construction has the potential to become a powerful tool for understanding and designing novel optical devices.

10376-7, Session 2

Temporal focal plane filter arrays

Israel J. Vaughn, The Univ. of New South Wales (Australia); Andrey S. Alenin, Scott Tyo, UNSW Canberra (Australia)

We recently defined a new formalism for engineering spatial information channels for focal plane filter arrays (FPFAs) in a general way for any physical light property measured via irradiance including spectral bands, polarimetric bands, and general coherence. The formalism encompasses color filter arrays, micropolarizer arrays, and microantenna arrays over a pixelated irradiance sensor. The formalism derives the physical channels available from the parameters of the unit cell used to tile the focal plane array: the unit cell geometry, the filter transmission functions, the number of unit cells, and the unit cell filter weights. We also recently showed that switching the polarization measuring properties in time over a fixed micropolarizer array would perform well compared with snapshot systems, even given increased noise due to doubling the temporal framerate. We present preliminary results on the extension of our FPFA framework to include temporal effects. Instead of a 2D unit cell which completely defines the system channels, a 3D unit cell consisting of 3D attenuation functions on a 3D rectangular lattice in (x,y,t) is defined, and specific examples are shown for micropolarizer array systems with a ferroelectric variable retarder; and a color filter array system utilizing tunable etalons for color filter modulation.

10376-8, Session 2

Aberrations of temporally modulated optical wavefronts in dispersive optical systems *(Invited Paper)*

David H. Parker, Parker Intellectual Property Enterprises, LLC (United States)

Classical time-invariant lens aberrations, and methods for correcting them, are well known in the art. However, the design, analysis, and construction of optical components and systems for temporally modulated optical wavefronts--and in particular, wavefronts in optical time-of-flight or phase measurement instruments, such as laser trackers, heterodyne laser interferometers, and spherical retroreflectors, require additional considerations to correct for what will be called Optical Amplitude Modulation (OAM) aberrations. Ray tracing analysis is time-invariant and thus insensitive to temporal modulation of the rays. Secondary considerations must be given to the wavefront of the modulated envelope which is focused on a detector, i.e., while the rays converge to a focus, the phase of the modulated envelope will in general depend on the path of the rays. Elements from communications theory, including amplitude modulation (AM) and analysis in the Fourier transform frequency domain are unified with classical optics, where the optical wavelength of a laser is treated as a carrier signal and the AM produces two slightly offset sidebands. The sidebands produce the OAM aberration due to dispersion and different paths through the optical elements. Suggestions are made for methods for correcting OAM aberrations, such as lens designs that are achromatic at the two sidebands, the use of specific materials matched to the carrier wavelength, the use of corrector plates, and computer modeling tools. A review of relevant patent literature is included.

10376-10, Session 2

A novel surface plasmon-coupled tunable wavelength filter for hyperspectral imaging

John F. Turner II, Ajaykumar H. Zalavadia, Cleveland State Univ. (United States)

The development of ultra-compact handheld hyperspectral imagers has been impeded by the scarcity of small widefield tunable wavelength filters. The widefield modality is preferred for handheld imaging applications in which image registration can be performed to counter scene shift caused by irregular user motions that would thwart scanning approaches. Conventional widefield tunable filters like the liquid crystal tunable filter and acousto-optic tunable filter achieve narrow passbands across a wide spectral range by utilizing large interaction lengths, thereby increasing the thickness of the device along the optical path. In addition, these technologies rely on rather bulky external control circuitry and, in the case of acousto-optic filters, high power requirements. In the work presented here, we introduce a novel widefield tunable filter for visible and near infrared imaging based on surface plasmon coupling that can be miniaturized without sacrificing performance. The surface plasmon coupled tunable filter (SPCTF) provides diffraction limited spatial resolution with a ~10nm nominal passband and a spurious free spectral range of more than 300nm. Acting on the p-polarized component, the device is limited to transmitting 50 percent of unpolarized incident light. This is higher than the throughput of comparable Lyot-based liquid crystal tunable filters that employ a series of linear polarizers. The design of the SPTF is presented along with a comparison of its performance to calculated estimates of transmittance, spectral resolution, and spectral range.

10376-11, Session 3

Thermally tunable III-V photonic crystals for coherent nonlinear optical circuits

Ranojoy Bose, Hewlett-Packard Labs. (United States); Marina Radulaski, Hewlett Packard Labs. (United States); Tho Tran, Ray Beausoleil, Hewlett-Packard Labs. (United States)

We have developed a platform for low-energy, fast, nonlinear optical gates that can be coherently connected using low-index waveguides, with the idea of eventually scaling up to large nonlinear optical networks for applications in computation and sensing. The individual gates comprise of gallium arsenide photonic crystals designed at the edge of the photonic bandgap of the bulk material, thereby enhancing nonlinear effects, and allowing for switching using only a few femto Joules of energy. For scaling to multiple photonic crystal gates that are coherently connected, we surrounded the photonic crystal using glass cladding and designed bus waveguides running in a vertically displaced layer of low-index material. This design potentially allows us to connect multiple gates without the large lithographic constraints of photonic crystal waveguides that may be alternatively used. Any large network of optical gates also requires precise tuning of optical resonances. Some applications may require tuning of all gates to a single frequency, while others require tuning to precise known frequencies (DWDM is one example). We have achieved this by designing highly efficient chrome heaters on chip that can tune our photonic crystal resonances to nearly 6 nm, with a tuning efficiency of 1.5 nm/mW. This is well within our fabrication discrepancy of 5 nm in devices patterned with the same lithographic dose. With these capabilities, we have built photonic circuits comprising of 5 photonic crystal cavities connected to microheaters, and have characterized the linear performance of such a circuit pre-tuning.

10376-12, Session 3

Short range, >100Kbits/s, visible light communication protocol design for high-gamma smartphones

Jaime R. Ek-Ek, Ctr. de Investigación e Innovación Tecnológica (Mexico); Ponciano J. Escamilla-Ambrosio, Ctr. de Investigación en Computación (Mexico); Abraham Sierra-Calderon, Ctr. de Investigación e Innovación Tecnológica (Mexico); Abel Sanchez-Nieves, Escuela Superior de Ingenieria Mecanica y Electrica (Mexico); Abraham Rodriguez-Mota, Escuela Superior de Ingenieria Mecanica y Electrica, Unidad Zacatenco (Mexico)

High gamma smartphones based on Android operating system support the development of third-party applications. This kind of devices include subsystems such as sensors and actuators which can be used for diverse purposes. One example is the implementation of short range visible light communication (VLC) channels where the built-in light-emitting diode (LED) is the transmitter, and the complementary metal-oxide semiconductor (CMOS) camera works as the receiver. A major challenge for this communication channel is the modulation bandwidth of the light source which is limited to a few MHz, and the availability of a line-of-sight. The camera shutter is limited to a few frames per second (30 or 60 fps) for a few bits per second transmission, but the Rolling Shutter effect could allow the enhancement of the bit rate. In this work, we propose a VLC protocol design for the use of the built-in camera and the flash LED in order to implement a short range VLC channel, for high gamma mobile-to-mobile devices based on Android. The design is based on On-Off Keying (OOK) modulation for initially transmitting a few bits. Based on the rolling shutter effect in the CMOS image sensor, bright and dark fringes can be observed within each received frame, and the data can then be retrieved. Furthermore, two thresholding schemes for high fluctuation and large extinction ratio (ER) variations in each frame, are explored. Full protocol design and short range (5cm), >100Kbits/s, VLC demonstration and image processing results will be included in the presentation.

10376-13, Session 3

Experimental realisability of lens cloaks

Stephen Oxburgh, Jakub B?lín, Euan Cowie, Johannes Courtial, Univ. of Glasgow (United Kingdom)

We recently showed how to construct omni-directional ray-optical transformation-optics devices out of ideal thin lenses. These devices can be seen as theoretical generalisations of the paraxial, four-lens, “Rochester cloak”.

Here we investigate the practical realisability of such devices. We use ray-tracing simulations to compare real-lens cloaks in which the ideal lenses are replaced by glass lenses, by phase holograms of lenses, and by generalised confocal lenslet arrays (GCLAs, also known as telescope windows). We show that such devices can only work over a limited field of view.

10376-14, Session 3

Design and implementation of a large depth-of-field and large aperture optical system

Xiaohu Guo, China North Vehicle Research Institute (China); Lingqin Kong, Yijian Wu, Yuejin Zhao, Liquan Dong, Ming Liu, Beijing Institute of Technology (China)

In this paper, it presents a new imaging technology that could realize to extent the depth of field and contribute to receive the large iris aperture optical system. The new technology combines lenses assistance and the aberration modulation. Based on the method, we establish a new optical system. Simulation results indicate that the modulation transfer function (MTF) curves of this optical system have consistency feature during different object distances. According to the feature, we can restore ambiguous images to unambiguous ones. Compared with another normal optical system, the experimental results indicate that the new optical system has the large depth of field and large iris aperture features.

10376-15, Session 3

Dip-and-bake low-cost high-performance lenses for smartphone-based microscopy

Bhuvaneshwari Karunakaran, Joseph Tharion, Debjani Paul, Soumyo Mukherji, Indian Institute of Technology Bombay (India)

Low cost miniature lenses can transform smartphones into quality microscopes for use in low resource and low infrastructure settings. Such handheld microscopes can have potential applications in healthcare, forensics, surveillance, environmental monitoring and so on. The existing low cost techniques of fabricating miniature lenses require dispensing of polydimethylsiloxane (PDMS) in known quantity, which is challenging due to its high viscosity[1,2]. In this paper, we present a mould-free approach to fabricate high performance elastomer lenses reproducibly. A hanging drop of PDMS was formed by dipping a highly curved substrate (in our case, a 5mm diameter PDMS lens) in liquid PDMS and curing it. The resultant lens profile resembled a parabola and has improved light collecting ability[1]. The need for dispensing known quantities of PDMS was overcome, thus, resulting in reproducible lens fabrication. This action was repeated to obtain higher lens curvatures (radius of curvature down to 1.42±0.02mm). The focal length was measured to be 4.6±0.5mm, respectively, across three lenses fabricated. Further, we place a lens at the smartphone camera and transform it into a portable pocket microscope with ~80X magnification (without smartphone digital zoom) and ~2μm resolution (fringe visibility=0.07). We imaged various biological samples and compared the images to a conventional microscope. Also, we show that the micro-features on the Indian currency notes can be imaged using these microscopes in ambient light. This has potential impact in addressing the fake currency

determination.

10376-16, Session 4

Gait motion analysis using optical and inertial sensor fusion to design human kinetic energy harvesting systems *(Invited Paper)*

Oliver Kröning, Hendrik Rothe, Helmut-Schmidt Univ. (Germany)

Biomechanical energy harvesting converting kinetic energy from human motion into electrical energy appeared as a promising technology for powering mobile devices.

The optimization of these energy harvesting systems requires knowledge about human gait as an energy source to maximize the power output. Therefore, motions during walking and running have to be evaluated to determine the amount of available and convertible energy in several body parts. The efficiency of vibration energy harvesting systems is also dependent on the adjustment of the systems' dimensions and frequency characteristics to the driving force.

Thus, this paper presents a solution fusing optical sensors and inertial measurement units (IMU) to analyze human locomotion. High-speed cameras are used to track the positions and angles of the synchronized inertial body sensors in an earth frame while the IMUs acquire gyroscope, accelerometer and magnetometer data. This data is used to calculate linear acceleration and actual orientation represented in quaternions by applying an algorithm by Madgwick. The orientation gives major information about the effect of the driving force on moving masses of the system as energy harvesting devices are often designed as single-axis generators. Frequency responses of acceleration data from different body positions while gait cycles are analysed as well. Furthermore, prospects and issues converting acceleration into velocity and position data and vice versa are discussed.

10376-17, Session 4

Design, manufacture, and evaluation of prototype telescope windows for use in low-vision aids

Euan Cowie, Univ. of Glasgow (United Kingdom); Cyril Bourgenot, Durham Univ. (United Kingdom); Johannes Courtial, Univ. of Glasgow (United Kingdom); John Girkin, Gordon Love, David Robertson, Laura Young, Durham Univ. (United Kingdom)

Pixellated optics, a class of optical devices which preserve phase front continuity only over small sub areas of the device, allow for properties that would not be possible without this discretized phase continuity. One set of such devices are telescope windows (TWs), also known as generalised confocal lenslet arrays, where two arrays of lenslets are positioned confocally such that they are miniature telescopes. TWs allow for very general mappings between object space and image space and can be designed for a range of potential uses.

One such potential use is as low-vision aids (LVAs), where they are hoped to combine the function and performance of existing devices with the size and comfort of lower power eyewear. For these devices the TWs are designed to magnify objects, recreating the effect of traditional refracting telescope within a thin, planar device. Such devices can, therefore, be made significantly lighter than existing LVAs, increasing the comfort of the wearer.

We have developed a series of prototype TW devices to examine their real-world performance, focussing on the resolution, magnification and clarity attainable through the devices. It is hoped that these will form the basis for a future LVA devices. This development has required novel manufacturing techniques and a phased development approach centred on maximising performance. Presented here will be an overview of the development so far, alongside the performance of the latest devices.

10376-18, Session 4

Design of a three-view cooperative scanning handheld OCT probe for intraoperative microvascular imaging

Shizhao Peng, Yong Huang, Shaoyan Xia, Yuanzhen Jiang, Yanfeng Wu, Xiaodi Tan, Beijing Institute of Technology (China)

To meet the needs of real-time imaging in intraoperative microsurgical vessel anastomosis and to break through the bottleneck of limited penetration depth caused by absorption and scattering from blood, we present a novel design of three-view cooperative scanning handheld OCT probe. It is based on a low coherence source with 1.3?m central wavelength for extra-vascular imaging. Traditional OCT probe always scan from one direction and suffers from the problem of incomplete cross-sectional view of the vessel under investigation. We've designed an MEMS mirror based OCT handheld probe, which can be used to generate cross-sectional images from 3 view directions to increase the field of view in the depth direction. In addition, to adapt to vessels of different sizes, we've also designed a micro-stage to be used together with the handheld probe to solve the hand-trembling problem. The rectangle scanning range is about 3 * 3mm in three-view, which can meet the imaging demands of most vessels. We believe that application of the probe will greatly improve the quality of micro-vascular anastomosis success rate.

10376-19, Session 4

Research of the optical scheme for an endoscopic optical coherent tomography

Helen A. Tsyganok, Alina Dubrovskaya, ITMO Univ. (Russian Federation)

The method of the endoscopic optical coherent tomography (EOCT) allows carrying out noncontact diagnostics of organs in the scanning mode, to research a structure of an integumentary epithelium of a mucous membrane at a depth up to 2 mm, revealing its damages, to differentiate preinvazivny and microinvasive early cancer.

The EOKT method is based on the Michelson interferometer: illumination is generated by the superluminescent diode, passes through a lens, and gets on a beam splitter. In an object branch of the interferometer illumination going to optical fiber at the end of biological tissue is located. Illumination passes back on a beam splitter and gets on the receiver after reflection from the last.

In the reference branch illumination after a beam splitter passes through a lens, is reflected from system of mirrors, returns, getting to a lens, and then on the receiver. For safe and effective diagnostics the optimum wavelength of the radiation of 1300 nanometers based on a reversal spectrum of biological tissue was selected.

The optical probe represents the microscope objective consisting of two lenses and the swung mirror and protective plate made from leucosapphire. Scanning of tissue is carried out by rolling of a mirror by one degree from the basic provision. For the purpose of determination of complete physical losses in optical fiber theoretical calculation was made.

10376-35, Session 4

Thin head-mounted display utilizing reflective optics design

Chia-Ping Lin, Guo Dung J. Su, National Taiwan Univ. (Taiwan)

For wearable device, the most importance point for image system is miniaturization. In this paper, we present a head-mount display that reduce the distance between the eyeball to the lens and its thickness. In traditional, the thickness of head-mount display is not thin enough because of it is designed that the light source transmit a series of lenses. It make a large volume of head-mounted display. The system consists of three curve mirrors and a free-form lens. Mirrors and lens can form a reflective design. The image source is placed be next to the eyeball. We expect the image to go through the mirrors to the eyeball so that make the volume of head-mount display be thinner. The system is 60 mm thick and 140 mm wide. The field of view is designed to be 140 degree (V) and 110 degree (H).

10376-20, Session 5

Glasses-free 2D/3D switchable display using an integrated single lightguide plate (LGP) with a trapezoidal light-extraction (TLE) film

Jin-Ho Lee, Yoonsun Choi, Samsung Advanced Institute of Technology (Korea, Republic of); Igor Yanusik, Alexander Morozov, SAMSUNG R&D Institute Rus. (Russian Federation); Hyoseok Hwang, Samsung Advanced Institute of Technology (Korea, Republic of); Dongkyung Nam, SAMSUNG Electronics Co., Ltd. (Korea, Republic of); Du Sik Park, Samsung Advanced Institute of Technology (Korea, Republic of)

We present a 10.1-inch 2D-3D switchable display using an integrated single light guide plate (LGP) with a trapezoidal light-extraction (TLE) film. The integral single LGP is composed of inverted trapezoidal line patterns made by adding a TLE film on its top surface and straight lenticular lens patterns on its bottom surface. The TLE film is also bonded to the bottom surface of LCD panel to maintain the 3D image quality, which can be seriously deteriorated by the gap variations between the LCD panel and LGP. The inverted trapezoidal line patterns act as slit apertures of parallax barriers for 3D mode. Light beams from LED light sources placed along the left and right edges of LGP bounce between the top and bottom surfaces of the LGP, and when they hit the side edges of the inverted trapezoidal patterns, they are emitted toward the LCD panel. The lenticular lens patterns arranged along the horizontal direction scatter the light beams from LED light sources arranged on the top and bottom edges of LGP uniformly, together with a reflective film disposed under the LGP for 2D mode. Applying the integrated single LGP with a TLE film, we realized a 2D-3D switchable display prototype with a 10.1-inch tablet panel of WUXGA resolution (1,200x1,920). Consequently, we showed light-field 3D display and 2D display images without interference artifacts between both modes, and also achieved the brightness uniformity over 80%. This display easily generates both 2D and 3D images without increasing the thickness and power consumption.

10376-21, Session 5

Combining three wavelength illumination and parallel phase shift interferometry for high-speed high-resolution and real-time motion tracking and 3D imaging

Michael Ney, Ibrahim Abdulhalim, Ben-Gurion Univ. of the Negev (Israel)

Phase based imaging and sensing have been for decades effective optical methodologies for high resolution surface profiling. Several techniques for acquiring the phase information encoding the surface topography have been developed; the most prominent is phase shift interferometry (PSI) in which several phase shifted interference images are usually acquired in a sequence and are algebraically combined to extract the phase information. However, phase imaging is limited both by the 2ϖ phase modulo limiting the ability to map structures with heights only up to half the source's wavelength i.e. several hundreds of nm, and also by error induced by the movements of the sample between the acquisitions of phase shifted interference images. Several approached for dealing with these limitations have been developed that provided only a limited solution, e.g. using a beat wavelength interferogram by a two wavelength illumination but that is more sensitive to phase noise and thus less accurate and parallel PSI in which all phase shifted images are acquired simultaneously but that does not resolve the height limitation. We have developed a combined and improved technique for parallel PSI and three wavelength illumination enabling overcoming both limitations without elevating phase noise sensitivity and have set up two prototypes: the first allowing video rate 3D imaging of moving samples such as biological live samples or high throughput scanning of metrology samples with nm scale resolution, and the second allowing single point very high speed axial motion tracking and vibrometry with sub-nm scale resolution and max step height of 30μm.

10376-22, Session 6

Development of quadruplet-camera system for pipe thread measurement

Shudo Takenaka, Toshifumi Kodama, Takahiro Yamasaki, JFE Steel Corp. (Japan); Kingo Sawada, JFE Tubic Corp. (Japan)

Optical measurement of pipe thread has the problem of uncertainty below 1?m(?) at manufacturing plant level where object position and shape is not all same. The authors propose a measurement method by designing optical specification to suppress diffraction effect and adopting optical shading/aberration correction and sub-pixel edge-detection processing.

In this method, 4 CCD line Cameras are opposite to 4 Parallel light sources (Quadruplet-Camera system) in order to measure by four points of circumference on pipe. By moving those Quadruplet-Camera system in an axial direction of pipe, thread images are acquired.

In optical usual approach, Numerical Aperture(NA) of the lens is increased to acquire high optical resolution, however the diffracted rays which form a diffraction pattern is found in the edge area of the cylindrical object with increase of the NA, so that it causes measurement uncertainty. And increase of the NA which leads narrow depth of field (D.O.F.), causes instability on measurement results at manufacturing plant.

The authors design compatible optical specification, and result that stability on measurement which means eliminating diffraction effect and wide D.O.F. is taken precedence over high optical resolution for application at manufacturing plant, and adopt optical shading/aberration correction and sub-pixel edge-detection processing in order to supplement the image of low optical resolution.

In this manuscript, first, we explain the proposed method and confirmation experiments in the laboratory. We also explain a new optical measurement system based on the concept described above in a manufacturing plant to prove the effectiveness of the method. We concluded that the measurement system has sufficient performance which repeatability below 1?m (?) for use as a practical system.

10376-23, Session 6

Robust shearography system for inspection of defects in composite material using diffractive optics

Fabio A. da Silva, Mauro E Benedet, Analucia V. Fantin, Daniel P. Willemann, Armando A. Gonçalves Jr., Univ. Federal de Santa Catarina (Brazil)

The most commonly optical configuration used to produce the lateral shifted images, in a Shearography system, is the Modified Michelson interferometer, because of its simple configuration. Tests carried out in recent years have shown that the modified interferometer of Michelson is a device that presents good results in laboratory environment, but still presents difficulties in field. These difficulties were the main motivation

for the development of a more robust system, able to operate in unstable environments. The proposed configuration presents a diffractive optical element (DOE) positioned between the image sensor and the objective lens, producing a lateral displacement of the specimen image. The design using a DOE to generate the lateral shifted images is an attractive alternative compared to the Michelson interferometer. Besides the diffractive optical configuration to be more compact, the high efficiency, around 80%, allows a better utilization of the incident light. Another great advantage of the DOE configuration is the same intensity average from the two interference patterns, since the light intensity distributions in the +1 and -1 orders are very similar, resulting in high contrast fringes.

Since the pitch of a diffractive grid, which produces an acceptable lateral displacement for the measurement, is about 60 times greater than the wavelength of a green laser, the DOE configuration becomes much more robust to external influences compared to the Michelson Interferometer configuration.

This work describes the shearography system with DOE configuration, and presents phase maps results of specimens produced and coated with composite material.

10376-24, Session 6

540nm pulsed laser design for particle image velocimetry applications

Abraham Sierra-Calderon, Jaime R. Ek-Ek, Ctr. de Investigación e Innovación Tecnológica (Mexico); Abel Sanchez Nieves, Escuela Superior de Ingeniería Mecánica y Eléctrica (Mexico); Gabriel Plascencia-Barrera, Jose A. Alvarez Chavez, Ctr. de Investigación e Innovación Tecnológica (Mexico)

Different types of mechanical and digital devices for measuring the velocity of fluids such as rotameters, annubar tubes, orifice plates, are suitable options. A limitation of such devices is that the direct interaction with the flux causes unwanted perturbations affecting their results. In this work, the design of a 540nm pulsed fiber laser system for measuring the velocity of water as a fluid via the Particle Image Velocimetry (PIV) technique is proposed. In particle image velocimetry, the fluid motion is made visible by adding small tracer particles and from the position of these particles, at two instances of time, it is possible to determine the flow velocity. The proposed, made in-house, non-commercial PIV system consists of: a second harmonic generation Q-switched Yb-doped fiber laser emitting 540nm pulses, a CCD camera, a pair of cylindrical diverging lenses, reference beads, and the fluid under test. The Yb3+-doped fiber laser itself is capable of producing 540nm, 5 – 15ns, 400mJ pulses at 500Hz – 15kHz repetition rates, suitable for PIV flow field studies. Full fiber laser design, in-house PIV system integration and flow field measurement results will be included in the presentation.

10376-25, Session 6

A confocal microscope with programmable aperture arrays by polymer-dispersed liquid crystal

Ting-Jui Chang, Guo Dung Su, National Taiwan Univ. (Taiwan)

A programmable array microscope (PAM) is one kind of confocal microscopes which uses the spatial light modulator (SLM) to serve both the source and detection aperture as the scanning apertures. Usually, PAM uses the digital micromirror device (DMD) or liquid crystal based optical components (like LCOS) as the spatial light modulator. The latter one has no mechanical movement part in the system, but it needs polarizer in, and it will reduce the light utilization rate. We present a programmable array microscope (PAM) which uses the polymer-dispersed liquid crystal (PDLC) chip as the spatial light modulator. PDLC is a polarization-free material, so we can improve the light utilization rate twice as other liquid crystal based PAMs. Furthermore, in our system, the incident light is perpendicular to the PDLC chip, while others can't or need more SLMs. Therefore, our system will make the whole system more compact. Also, it can increase the dynamic range compare to other liquid crystal based PAMs.

Imaging application based on an electrically tunable polarization-independent liquid crystal microlens array

Zhaowei Xin, Qing Tong, Yu Lei, Dong Wei, Xinyu Zhang, Haiwei Wang, Changsheng Xie, Huazhong Univ. of Science and Technology (China)

In this study, a polarization-independent liquid crystal microlens array (P-LCMLA) for imaging application is proposed and demonstrated. This device is composed of double layered nematic liquid crystal with orthogonal alignment, two aluminum deposited silica substrates and a double-sided indium-tin oxide (ITO) silica. The double-sided ITO glass is sandwiched between the two hole-patterned aluminum electrodes to separate the orthogonal liquid crystal (LC) layers. The experiment results show that a high beam utilization efficiency and a compound point spread function are obtained by this novel configuration with low applied voltages. The normalized focusing intensity is polarization-insensitive to the incident light under certain driving voltages applied on both LC layers. The cascaded microstructure provides a wide operation range in the manipulation of incident beams and also emerges multiple operation modes for imaging applications, such as conventional planar imaging with adaptive beam adjustment, polarization imaging mode, and polarization-independent imaging mode. Therefore, a big advantage of the device proposed by us is that it cannot only be used to obtain two orthogonal polarization images but also in conventional planar or 2-dimensional (2D) intensity imaging, dual-mode wavefront imaging, and 3-dimensinoal (3D) information measurement. Since the polarization-independent microlens array demonstrates high optical efficiency, low power consumption, multiple imaging modes and simple manufacture, this kind of microlens array has a potential to be used in imaging application and many other optical systems.

Fast sub-wavelength imaging using scattering medium and computational phase mask

Shenghang Zhou, Nanjing Univ. of Science and Technology (China)

Recent studies have shown that the phase-modulated light (by SLM) can be focused perfectly by feedback process. Under the SLM made, sub-100nm scanning can be performed in a certain range surrounding the focus by the memory effect. But scanning other areas would be time-consuming for the repetition of focusing process that based on feedback. In this paper, we proposed a time-saving method to realize the whole process by a single feedback-based focusing process and computational phase mask.

Focus-induced photoresponse: Insights into the microscopic mechanisms and optical features behind the novel technique for optical distance measurements

Oili Pekkola, TrinamiX GmbH (Germany); Christoph Lungenschmied, TrinamiX GmbH (Germany); Christian Lennartz, Ingmar Bruder, TrinamiX GmbH (Germany)

Focus-Induced Photoresponse (FIP) is a patented monocular technology for optical distance measurements [1]. It relies on physical phenomena which are fundamentally different from established technologies such as time-of-flight, stereo vision, structured light or systems based on image processing. This presentation gives insights into the microscopic mechanisms and optical features leading to the FIP effect.

FIP exploits the nonlinear transient photoresponse of various organic as well as inorganic semiconductors when exposed to optical radiation. When a light-emitting (or reflecting) object moves in and out of focus, the size of the image that it creates on a sensor surface determines the magnitude of the photoresponse. As the focal point shifts with the distance between the collecting lens and the object, the sensor response yields a unique signature for every distance.

The functional principle of FIP is illustrated with experimental results as well as optical and electrical simulations. The microscopic mechanisms leading to the nonlinear photoresponse under modulated excitation are illustrated. The essential role of the optics used in the system is demonstrated. Examples of sensors based on various semiconductors are introduced in order to show the broad applicability of the FIP technology. We have successfully demonstrated functionality for wavelengths from visible light to IR and for distances up to 100 m.

An optical chip aggregometer based on laser transmission to detect alterations in the aggregation of glycosylated RBC

Martín A. Toderi, CONICET-UNR (Argentina) and Univ. Nacional de Rosario (Argentina); Natalia Lerda, Patricia Buszniez, Univ. Nacional de Rosario (Argentina); Bibiana D. Riquelme, Univ. Nacional de Rosario (Argentina) and CONICET-UNR (Argentina)

The study of erythrocyte (RBC) aggregation is of great interest because of its implications on human health, alterations are observed in vascular pathologies such as hypertension and diabetes, as a consequence of a decrease in the erythrocyte surface electric charge. It is of great importance to develop techniques and equipment, which allows evaluation and characterization of the erythrocyte aggregation phenomenon. Human RBC tend to form aggregates which initially consist of face-to-face linear structures that resemble a stack of coins which are generally called rouleaux. RBC aggregation can be analyzed by recording the intensity of transmitted light through a blood sample in real time. The graphic of the variation of light intensity as a function of time is called syllectogram. Several syllectograms of altered blood samples were obtained with a low cost disposable-chip aggregometer based on laser transmission. Complementary parameters were assessed by an Erythrocyte Rheometer based on laser difractometry. Studies were carried out varying the erythrocyte surface electric charge by enzymatic and non-enzymatic glycosylation. A minimum sample volume of 15μL was used and the parameters, Parameters Amp_100 (the normalized light intensity at 100 s,) and t_12 (the time required to reach the 50% of the total amplitude of transmitted light) show sensibility to this alteration. Viscoelastic parameters DI (deformability index), μ (elastic module) and (surface viscosity of the membrane) are lower than control tests. These light-based devices are of interest for further applications in Clinical Medicine related to vasculopathies.

Optical design of optical synthetic aperture telescope

Chenghao Zhou, Zhile Wang, Harbin Institute of Technology (China)

Optical synthetic aperture (OSA) is a promising solution for very high-resolution imaging while reducing its volume and mass. In this paper, first, the configuration of OSA systems are analyzed and the design methods of two types (Fizeau and Michelson) of OSA systems are summarized and researched. Second, Fizeau and Michelson OSA prototype systems are designed in detail. In the Michelson configuration, the instrument is made of sub-telescopes distributed in entrance pupil and combined by a common telescope via folding periscopes. The design of Michelson configuration is more difficult than that of Fizeau configuration.

In the design of Fizeau configuration, according to the third aberration theory two-reflective system is deigned. Then the primary mirror of the two mirror system is replaced by the synthetic aperture. The whole system was simulated by Zemax software to obtain the Modulation transform function (MTF).

In the design of Michelson configuration, the system is first divided into three parts: the afocal interferometric telescopes, beam combiner system and folding periscopes. The three parts are designed respective and then combined in Zemax software to obtain the MTF.

Method for synthesis of high-accuracy dynamic non-linear control systems

Vladimir L. Kodkin, South Ural State Univ. (Russian Federation)

Optical Engineering + Application conference in 2016 had only few reports dedicated to high-accuracy position control systems for optical complexes. However, at SPIE Optics + Photonics Exhibition 2016 dozens of companies offered such projects. In that respect, this report may be of interest for academic community.

The main method for assessment of performance of automatic control systems is assessment of stability of a system as it allows the evaluation of dynamics and accuracy as well as the method for additional adjustment and technological capacity of the whole complex comprising the system. As a rule, complex systems do not reduce to linear systems or other known variants, so their analysis is normally based on modeling or simplified calculation. In the suggested paper the known criterion of stability for non-linear systems by Popov involves not frequency locus of linear part, but logarithmic frequency characteristics of the system, including non-linear frequency characteristics. It allows the development of conditions of stability and methods of adjustment for such complex systems as servo drives with non-rigid mechanics and alternating-current systems which cannot be analyzed with the help of known methods. In the systems where the stated methods are used accuracy and speed performance are increased fivefold at an average. All theoretical calculations are confirmed by experiments and modeling.

10376-32, Session PWed

Common-path holographic objective for conventional photographic camera

Vira R. Besaga, Nils C. Gerhardt, Ruhr-Univ. Bochum (Germany); Peter P. Maksimyak, Yuriy Fedkovych Chernivtsi National Univ. (Ukraine); Martin R. Hofmann, Ruhr-Univ. Bochum (Germany)

In this paper, we introduce a direct-view digital holographic camera objective for off-axis external white-light illumination, which is based on a standard photographic objective as the main component. The direct view operation is provided via a modified common-path point diffraction interferometer on a transmission diffraction grating (92 grooves/mm) basis. The spatial separation of the interacting beams is realized with a self-fabricated copper mask (465±5 ?m apertures) with a back-reflection suppressing coating. This ensures self-interference between the 0th and the 1st diffraction orders at the smallest possible overlapping angle. The objective system is matched for a conventional CMOS sensor, where a hologram is written. Due to the used photographic objective in the current system configuration, a compensation lens module is applied for reshaping the beam entering the interferometric module. The proposed system operates under external illumination with two standard photographic flashes synchronized between each other and providing homogeneous sample illumination from opposite directions. The system operability was proven as well for coherent (He-Ne laser, 632 nm) as for low-coherent (SLD, 850 nm) and several broadband (white LED, halogen lamp) sources. For the self-reference mode the copper mask has to be replaced by a pinhole based two-aperture spatial filter. Although, the initial design has been proposed for self-emitting and reflecting samples, the system independence on the illumination part enables operation in transmission mode as well. Modular assemblage ensures easy system scalability and up-grade possibilities. As a proof of system operability, reconstructed amplitude and phase information of test samples is presented.

Computer tool for achromatic and aplanatic cemented doublet design and analysis

Tatiana Ivanova, Galina Romanova, Tatiana Zhukova, Olga Kalinkina, ITMO Univ. (Russian Federation)

Algorithm and computer tool for cemented doublet synthesis by Slusarev's methodology are presented. Slusarev's methodology is based on lookup tables that allow calculating doublet radii by given value of third-order coma, spherical aberration and chromatic aberration using specific algorithm. The most time consuming part of cemented doublet synthesis by Slusarev's methodology is selection needed parameters from lookup tables. This part is automated and presented in this paper.

The input parameters for tool are desired values of third-order coma, spherical aberration and chromatic aberration of cemented doublet. The tool looks up several appropriate pairs of optical glasses corresponding to specified value of chromatic aberration and then calculates radii of surfaces for each pair of glasses corresponding to specified third-order coma and spherical aberration. The resulted third-order aberrations and real aberrations (transverse, longitudinal, axial color and coma) are calculated for obtained system. Several doublets can be analyzed in result table and the chosen one can be imported into Zemax. The calculated cemented doublet parameters can be analyzed and optimized in optical system design software.

The tool allows making the first step of optical system design fast and simple. It allows to design not only the system which is free of the third-order spherical aberration, coma and axial color, but obtain necessary value of aberration for compensation of aberrations in another part of optical system. Possibility to automatically choose optical glasses and compare the real aberration of the preliminary designed system is especially important features of the developed software.

Offset pixel aperture technique for extracting depth information

Byoung-Soo Choi, Myunghan Bae, Sang-Hwan Kim, Jimin Lee, Chang-Woo Oh, Kyungpook National Univ. (Korea, Republic of); Seunghyuk Chang, Jongho Park, Sang-Jin Lee, Ctr. for Integrated Smart Sensors (Korea, Republic of); Jang-Kyoo Shin, Kyungpook National Univ. (Korea, Republic of)

The 3-dimensional (3D) imaging is an important area which can be applied to face detection, gesture recognition, and 3D reconstruction. Many techniques have been reported for 3D imaging using various methods such as time of fight (TOF), stereo, and structured light. These methods have limitations such as use of light source, multi-camera, or complex camera system. In this paper, we propose the offset pixel aperture (OPA) technique which is implemented on a single chip so that the depth can be obtained without increasing hardware cost and adding extra light sources. 3 types of pixels including Red (R), Blue (B), and White (W) pixels were used for OPA technique. The aperture is located on the W pixel, which does not have a color filter. Depth performance can be increased with a higher sensitivity because we use white (W) pixels for OPA with Red (R) and Blue (B) pixels for imaging. The RB pixels produce a defocused image with blur, while W pixels produce a focused image. The focused image is used as a reference image to extract the depth information for 3D imaging. This image can be compared with the defocused image from RB pixels. Therefore, depth information can be extracted by comparing defocused image with focused image using the depth from defocus (DFD) method. Previously, we proposed the pixel aperture (PA) technique based on the depth from defocus (DFD). The OPA technique is expected to enable a higher depth resolution and range compared to the PA technique. The pixels with a right OPA and a left OPA are used to generate stereo image with a single chip. The pixel structure was designed, simulated and fabricated using 0.11 μm CMOS image sensor (CIS) process. Optical performances of various offset pixel aperture structures were evaluated using optical simulation with finite-difference time-domain (FDTD) method.

Conference 10377: Optical System Alignment, Tolerancing, and Verification XI

Sub-cell turning to accomplish micron-level alignment of precision assemblies

Jay Kumler, JENOPTIK Optical Systems, LLC (United States); Christian Buß, TRIOPTICS GmbH (Germany)

Higher performance expectations for complex optical systems demand tighter alignment requirements for lens assembly alignment. In order to meet diffraction limited imaging performance over wide spectral bands across the UV and visible wavebands, new manufacturing approaches and tools must be developed if the produces will be produced consistently in volume production.

This is especially applicable in the field of precision microscope objectives for life science, semiconductor inspection and laser material processing systems. We observe a rising need for the improvement in the optical imaging performance of objective lenses. The key challenge lies in the micron-level decentration and tilt of each lens element.

One solution for the production of high quality lens systems is sub-cell assembly with alignment turning. This process relies on an automatic alignment chuck to align the optical axis of a mounted lens to the spindle axis of the machine. Subsequently, the mount is cut with diamond tools on a lathe with respect to the optical axis of the mount. Software controlled integrated measurement technology ensures highest precision. In addition to traditional production processes, further dimensions can be controlled in a very precise manner, e.g. the air gaps between the lenses. Using alignment turning simplifies further alignment steps and reduces the risk for errors.

This paper describes new challenges in microscope objective design and manufacturing, and addresses difficulties with standard production processes. A new measurement and alignment technique is described, and strengths and limitations are outlined.

10377-3, Session 1

Photonic Doppler velocimetry probe used to measure grain boundaries of dynamic shocked materials *(Invited Paper)*

Robert M. Malone, Morris I. Kaufman, Daniel K. Frayer, Kevin D. McGillivray, National Security Technologies, LLC (United States); Steven A. Clarke, Saryu J. Fensin, David R. Jones, Los Alamos National Lab. (United States)

Material scientists have developed computational modeling to predict the dynamic response of materials undergoing stress, but there is still a need to make precision measurements of surfaces undergoing shock compression. Miniature Photonic Doppler velocimetry (PDV) probes have been developed to measure the velocity distribution from a moving surface traveling tens of kilometers per second. These probes use hundreds of optical fibers imaged by optical relays onto different regions of this moving surface.

While previous work examined large surface areas, we have now developed a PDV microscope that can interrogate 37 different spots within a field of view of <1 mm, with a standoff distance of 17 mm, to analyze the motion differences across grain boundaries of the material undergoing dynamic stress. Each PDV fiber interrogates a 10 μm spot size on the moving surface. A separate imaging system using a coherent bundle records the location of the PDV spots relative to the grain boundaries prior to the dynamic event. Designing the mounting structures for the lenses, fibers, and coherent bundle was a challenge. To minimize back reflections, the fibers are index matched onto the first relay lens, which is made of fused silica. The PDV fibers are aligned normal to the moving surface. The imaging probe views the surface at an 18° angle. The coherent bundle is tilted 11° to its optical relay. All components are assembled into a single probe head assembly. The coherent bundle is removed from the probe head to be used for the next dynamic event. Alignment issues will also be discussed.

10377-4, Session 1

Slope-based precision optical testing using portable laser coordinate measuring instruments

Manal Khreishi, NASA Goddard Space Flight Ctr. (United States) and The Univ. of Arizona (United States); Raymond G. Ohl, Theodore J. Hadjimichael, NASA Goddard Space Flight Ctr. (United States); Joseph E. Hayden, Sigma Space Corp. (United States)

High precision, portable coordinate measuring instruments such as laser radars (LR) and laser trackers (LT) have been used for optical system alignment and integration. The LR's ability to perform a non-contact scan of surfaces was previously utilized to characterize large spherical and aspheric mirrors. In this paper, we explore the use of an LR/LT as an accurate, fast, robust, and non-contact tool for prescription characterization of optical surfaces. Using Nikon's MV-224/350 LR and Leica's Absolute Tracker AT401/402 instruments, proof of concept measurements were performed to characterize a variety of optical components using "direct and through" measurements of calibrated metrology targets. The results were compared to the nominal parameters and were cross-checked using an LR scan and other approaches. Custom macros in metrology software and other data reduction code were developed to calculate the surface slopes from the "direct and through" target measurements. As with a typical slope-based technique, the slopes were integrated to obtain the optical surfaces being tested. We discuss potential applications across the fields of optical component fabrication and system alignment and testing.

10377-5, Session 1

Integrated confocal Raman probe combined with a freeform reflector-based lab-on-chip

Qing Liu, Vrije Univ. Brussel (Belgium); Giancarlo Barbieri, Univ. degli Studi di Pavia (Italy); Hugo Thienpont, Vrije Univ. Brussel (Belgium); Heidi Ottevaere, Univ. degli Studi di Pavia (Belgium) and Vrije Univ. Brussel (Belgium)

Traditionally, Raman spectroscopic analyses are done in a specialized lab, with considerable requirements in terms of equipment, time and manual sampling of substances of interest. In this paper we take a step from bulky, laboratory analyses towards lab-on-chip (LOC) analyses. We miniaturize the Raman spectroscopic analyses by combining a free-form reflector based polymer lab-on-chip (LOC) with a Raman probe. By using the confocal detection principle we aim to enhance the detection of Raman signals from the substance of interest due to the suppression of the background Raman signal from the polymer of the chip.

In a first step, we present the design of the free-form reflector and the optical simulation of the Raman excitation, scattering and collection system by means of non-sequential ray-tracing software (ASAP) combined with a mathematical code. In these simulations, the excitation laser emits at a wavelength of 785nm. A free-form reflector with a diameter of 1.6 mm and based on a parabolic mirror is optimized to ensure that all incident light is focused into a common focal point, especially for rays that are strongly bent which is the case due to the high NA of the reflector. Next, the Raman scattering is captured by a multimode fiber and sent to a spectrometer. Our simulations demonstrate that our system allows confocal measurements and that small physical displacements of the lab-on-chip result in a small collection loss. We can conclude that the polymer background signal is suppressed when collecting Raman signals from solutions under test in the fluidic channel resulting in a higher sensitivity.

In a next step, we miniaturized the external optical components, surrounding

the reflector embedding optofluidic chip, and assembled these in a Raman probe. Finally we demonstrated the proof-of-concept by measuring the Raman signature of urea solutions with different concentrations in pure water. The alignment errors between the Raman probe and lab-on-chip were measured and evaluated. We believe these confocal Raman based spectroscopic devices pave the way for the development of portable and robust lab-on-a-chip systems which can be mass-deployed for use in the field and for point-of-care diagnostic applications.

Tolerancing a lens for LED uniform illumination

Jieun Ryu, The Univ. of Arizona (United States); Jose Sasian, College of Optical Sciences, The Univ. of Arizona (United States)

We use a closed form surface used to produce LED uniform illumination to determine alignment and fabrication tolerances.

The effects of wavelength, lateral displacement, tilt, and surface errors are analyzed and tolerances are determined.

10377-7, Session 2

Understanding product cost vs performance through an in-depth system Monte Carlo analysis *(Invited Paper)*

Mark C. Sanson, Corning Incorporated (United States)

The manner in which an optical system is toleranced and compensated will greatly affect the cost to build it. By having a detailed understanding of different tolerance and compensation methods the end user can decide what criteria is most important to them cost or performance. A detailed phased approach Monte Carlo analysis can be used to demonstrate the tradeoffs between cost and performance. In complex high performance optical systems, performance is fine-tuned by making adjustments to the optical systems after they are initially built. This process allows one to achieve the overall best system performance without needing to fabricate components to stringent tolerance levels that can often be outside of a fabricator's manufacturing capabilities. A good performance simulation of as built performance can interrogate different steps of the fabrication and build process. This can help to determine if the measured parameters are within the acceptable range of the system build at that stage. Finding errors before an optical system progresses further into the build process saves both time and money. Having the appropriate tolerances and compensation strategy tied to a specific performance level will optimize the overall product cost.

10377-8, Session 2

Specifying tilts, decenters, and beam deviations using the new edition of ISO 10110-6

Ray Williamson, Ray Williamson Consulting (United States)

ISO 10110-6 is the international standard for specifying centration of optical components and systems. The original version addressed only surface tilt angles of individual spherical and rotationally-invariant aspheric components. Because the intent of ISO Standards is to facilitate commerce, additional expressions and situations were included in the update: 1) Axial and circular runout, beam deviation, and lateral decenter may more directly reflect the measurement technique of the inspector, the primary interest of the designer, or the concerns of the optomechanical engineer. 2) The relation of components within a system to each other and to their mechanical reference points must have a clear description. 3) The industry's capabilities now include previously unattainable forms, which must be clearly toleranced.

As a result of international collaboration over a decade, the 2016 edition now includes surface tilts, axial and circular runout, beam deviation, and decenter of components and systems, including aspheres, circular and non-circular cylinders, and general surface forms. This expansion necessitates a more detailed notation system, which this presentation describes.

10377-9, Session 2

Specification and tolerancing of bulk glass material imperfections with ISO standards

Allen Krisiloff, Triptar Lens Co., Inc. (United States)

Standards for the specification of tolerances for glass material imperfections have been evolving over the past 40 years. Today, several individual ISO Standards for drawings and drawing notation -- ISO 10110-2, ISO-10110-3, and ISO-10110-4, which were last revised in 1993 -- are being merged and re-written to incorporate technical improvements and enhance the clarity of presentation. The new standard, tentatively numbered ISO 10110-18, is on schedule for release in 2018. It will also provide notation to directly utilize concepts and quality classes defined in ISO 12123, the newly revised standard for raw glass material. New ways to specify striae and a way to specify raw material specifications on a finished part drawing are two additional highlights of the revised versions of this set of ISO standards. This paper will discuss the old shortcomings, their corrections, and the new features incorporated into the set of standards currently under final development and whose publication is expected next year.

10377-10, Session 2

Generalized surface contributions for misalignment sensitivity analysis

Mateusz Oleszko, Herbert Gross, Friedrich-Schiller-Univ. Jena (Germany)

In order to perform a misalignment sensitivity analysis of an optical system it is helpful to know what are the contributions of individual surfaces to the total wavefront aberrations. The expansion of wavefront aberration function is an analytic method used for that purpose.

An alternative numerical approach to describe wavefront aberrations of symmetry free optical systems is proposed. Data from the trace of multiple ray sets are used to determine surface contributions. Surface contributions are defined as modules bounded by reference spheres located at the successive surfaces. Further contributions are divided due to their origin into intrinsic, induced and transfer components. Each component is determined from the separate set of rays. Intrinsic part results from refraction of an ideal wavefront on the surface. It is therefore independent on the rest of the system. Induced and transfer parts are both the effect of incoming aberrations and error in mapping of intersection coordinate grids on reference spheres. Hence they both describe dependencies between individual surfaces and potential misalignments. Induced part is acquired by subtracting the intrinsic part from the complete refraction effect. Transfer term results from distortion of coordinates arising upon propagation of the aberrated wavefront between successive surfaces.

The method is combined with Zernike fringe decomposition approach, which allows to perform detailed analysis of system aberrations in respect to individual surfaces and their misalignments in a well known classification. Results are presented for single field point or in the form of full field displays.

10377-2, Session 3

SFR test fixture for hemispherical and hyperhemispherical camera systems

John M. Tamkin, Imaging Insights, LLC (United States)

Traditional methods for testing wide field lenses and cameras have either

used expensive projection systems, use targets on rotation stages, or have placed pre-distorted targets within box-like test fixtures. With all these methods, it is important to recognize that factory floor space is premium. For many applications, hemispherical camera lenses have short focal lengths (less than 3 mm), but still require reasonably small F-numbers to collect sufficient light and accomodate small pixel size (< 2.4 micron) sensors. This creates a hyperfocal distance that is reasonably short: 600 to 700mm. In this work, we fabricated a box from low cost and lightweight alumicore the box contains internal "leaves" with 600mm radius cutouts along vertical, horizontal and diagonal axes consistent with 16:9 camera formats. We then fabricated 24 2" backlit targets from PVC pipe, plastic fresnel lenses, low-cost sheet diffusers and 3D printed parts. which were attached to the leaves. along the edge of each leaf, we secured LED strip lights to provide "Almost point sources", which are accurately located in angle space. In this paper, we describe the design space where "reasonably" sized boxes with rear projection targets can be used, and where the design can be adapted to use low-cost projectors fabricated using the same techniques, thus achieving low cost and small factory footprint.

10377-11, Session 3

Optical alignment using a CGH and an autostigmatic microscope

Robert E. Parks, Optical Perspectives Group, LLC (United States); Chunyu Zhao, Arizona Optical Metrology LLC (United States)

It is often necessary to locate an optical or mechanical component precisely relative to another as in cementing a doublet or in aligning an off-axis parabola to a mount. We show that one way of making a fixture to do this is to make a computer generated hologram (CGH) that will produce foci or axes in space when illuminated with a point source of quasi-monochromatic light. An ideal instrument to use is an autostigmatic microscope (ASM) because it serves as a means of illuminating the CGH with a point source as well as viewing the reflected focused spot or line.

Once the reflected stigmatic image is located with um precision, the center of curvature of an optical surface or ball, or focus of an off-axis parabola, can be aligned to the image, again using the ASM with the same sort of precision.

We use this scheme to show how one would go about cementing a double or aligning an off-axis parabola to a mount using only the custom CGH and an ASM. It will become obvious from these examples that the same methodology can be used to create fixtures for a variety of alignment cases such as aligning balls to a CGH used for null testing to see that the CGH is precisely and repeatably located relative to a transmission sphere. The method makes full use of the flexible nature of patterning CGHs and of kinematic principles.

10377-12, Session 3

Measurement of low-order aberrations with an autostigmatic microscope

William P. Kuhn, Opt-E (United States)

Autostigmatic alignment tools are in common use for alignment and metrology of optical and mechanical systems. The autocollimator is the classical tool for alignment tasks at infinite conjugates involving flat optics or a collimated wavefront. The autocollimator is the common name for an autostigmatic telescope. Autocollimators in conjunction with auxiliary optics can be used for a variety of tasks including alignment of linear stage axes or finding the axis of rotation of a bearing. The autostigmatic microscope is a finite conjugate autostigmatic alignment tool and is sometimes referred to as a point source microscope (PSM). Autostigmatic microscopes are useful for locating optics via their center-of-curvature, while autocollimators locate the surface normal of flat optics.

The addition of a piezo-electric focusing stage and phase retrieval algorithms to a compact, adaptable autostigmatic microscope provides a means to introduce a precise amount of phase diversity (defocus) allowing one to collect in-focus and out-of-focus images. The images can be used in conjunction with phase retrieval algorithms to estimate the wavefront and low-order aberrations of the system being aligned. Since alignment errors introduce low-order aberrations, the emphasis is on low-order aberrations, to guide and ultimately qualify an optical system. A description of the instrument and initial results are reported.

10377-13, Session 3

Review of Zernike polynomials and their use in describing the impact of misalignment in optical systems *(Invited Paper)*

Jim Schwiegerling, College of Optical Sciences, The Univ. of Arizona (United States)

Zernike polynomials provide a generalized framework for analyzing the aberrations of non-rotationally symmetric optical systems with circular pupils. Even when systems are designed to be rotationally symmetric, fabrication and alignment errors will lead to non-rotationally symmetric aberrations. The properties of the Zernike polynomials are reviewed to illustrate their properties. Different indexing and ordering schemes are compared to demonstrate some of the potential pitfalls and limitations of using these functions. An example system with common misalignments such as tilt and decenter is analyzed to illustrate the changes in Zernike terms and how this information can provide feedback to the alignment process.

10377-25, Session 3

Ground to on-orbit alignment study of the WFIRST and resulting architecture changes in the telescope architecture

John G. Hagopian, Lambda Consulting (United States); Lisa Bartusek, NASA Goddard Space Flight Ctr. (United States); Thomas M. Casey, Sigma Space Corp. (United States); David A. Content, NASA Goddard Space Flight Ctr. (United States); Guangjun Gao, Sigma Space Corp. (United States); Alden S. Jurling, Catherine T. Marx, Bert A. Pasquale, Qian Gong, NASA Goddard Space Flight Ctr. (United States); Arthur L. Whipple, Conceptual Analytics, LLC (United States)

The Wide-Field Infrared Survey Telescope (WFIRST) mission is the top-ranked large space mission in the New Worlds, New Horizon (NWNH) Decadal Survey of Astronomy and Astrophysics. WFIRST will settle essential questions in both exoplanet and dark energy research and will advance topics ranging from galaxy evolution to the study of objects within the galaxy. The WFIRST mission uses a repurposed 2.4-m forward optical telescope assembly (FOA), which, when completed with new aft optics will be an optical telescope assembly (OTA). WFIRST is equipped with a Wide Field Instrument (WFI) and a Coronagraph Instrument (CGI). An Instrument Carrier (IC) meters these payload elements together and to the spacecraft bus (S/C). A distributed ground system receives the data, uploads commands and software updates, and processes the data.

A significant change to the OTA includes moving the tertiary mirror from the instrument package to a more conventional three-mirror anastigmat (TMA) telescope design that provides a wide 0.28-sq° instrumented field of view to the Wide Field Instrument (WFI). In addition, separate relays from the primary and secondary mirror feed the Wide Field Instrument (WFI) and CoronaGraph Instrument (CGI). During commissioning the telescope is aligned using wavefront sensing with the WFI. A parametric and Monte-Carlo analysis was performed, which determined that alignment compensation with the secondary mirror alone degraded performance in the other instruments. This led to the addition of a second compensator in the WFI optical train to alleviate this concern. This paper discusses the

trades and analyses that were performed and resulting changes to the WFIRST telescope architecture.

10377-16, Session 4

Simultaneous angular alignment of segment mirrors using sinusoidal pattern analysis

Heejoo Choi, Isaac Trumper, Dae Wook Kim, College of Optical Sciences, The Univ. of Arizona (United States)

We present a simultaneous angular alignment method for segmented mirrors, which are often utilized for advanced telescopes to achieve a large combined optical surface. Tip and tilt angles of the mirrors are measured with less than 10 ?rad resolution by monitoring the reflection of a displayed sinusoidal pattern off the mirrors under test. Because a single instrument concurrently covers multiple mirrors, all measured angles are with respect to a common origin, which enables precise angular control of each mirror.

10377-17, Session 4

Alignment and testing of the James Webb Space Telescope observatory vibration fixture and handling and integration fixture

Kyle McLean, NASA Goddard Space Flight Ctr. (United States); Paul Bagdanove, SGT, Inc. (United States); Joshua A. Berrier, Tech Innovations (United States); Emmanuel Cofie, SGT, Inc. (United States); Tiffany M. Glassman, Northrop Grumman Aerospace Systems (United States); Theodore J. Hadjimichael, Eric L. Johnson, NASA Goddard Space Flight Ctr. (United States); Joshua Levi, Amy Lo, Northrop Grumman Aerospace Systems (United States); Joseph C. McMann, Sierra Lobo, Inc. (United States); Raymond G. Ohl, NASA Goddard Space Flight Ctr. (United States); Dean Osgood, Sierra Lobo, Inc. (United States); James E. Parker, NASA Goddard Space Flight Ctr. (United States); Kevin W. Redman, Vicki Roberts, Sierra Lobo, Inc. (United States); Matthew Stephens, Genesis Engineering Solutions, Inc. (United States); Adam Sutton, Northrop Grumman Aerospace Systems (United States); Gregory W. Wenzel, Sierra Lobo, Inc. (United States); Jerrod L. Young, NASA Goddard Space Flight Ctr. (United States)

NASA's James Webb Space Telescope (JWST) is a 6.6m diameter, segmented, deployable telescope for cryogenic IR space astronomy. The JWST Observatory architecture includes the Primary Mirror Backplane Support Structure (PMBSS) and Integrated Science Instrument Module (ISIM) Electronics Compartment (IEC) which is designed to integrate to the spacecraft bus via six cup/cone interfaces. Prior to integration to the spacecraft bus the JWST observatory must undergo environmental testing, handling, and transportation. Multiple fixtures were developed to support these tasks including the vibration fixture and handling and integration fixture (HIF). This work reports on the development of the nominal alignment of the six interfaces and metrology operations performed for the JWST observatory to safely integrate them for successful environmental testing.

10377-18, Session 4

Metrology for trending alignment of the James Webb Space Telescope before and after ambient environmental testing

Theodore J. Hadjimichael, NASA Goddard Space Flight Ctr. (United States); Joshua A. Berrier, IntellecTechs (United States); Jeffery S. Gum, NASA Goddard Space Flight Ctr. (United States); Joseph E. Hayden, Sigma Space Corp. (United States); Manal Khreishi, Kyle McLean, Raymond G. Ohl, NASA Goddard Space Flight Ctr. (United States); Kevin W. Redman, Sierra Lobo, Inc. (United States); Joseph F. Sullivan, Ball Aerospace & Technologies Corp. (United States); Gregory W. Wenzel, Sierra Lobo, Inc. (United States); Jerrod L. Young, NASA Goddard Space Flight Ctr. (United States)

NASA's James Webb Space Telescope (JWST) is a 6.6m diameter, segmented, deployable telescope for cryogenic IR space astronomy. The JWST Observatory architecture includes the Optical Telescope Element (OTE) and the Integrated Science Instrument Module (ISIM) element which contains four science instruments (SIs). Prior to integration with the spacecraft, the JWST optical assembly is put through rigorous launch condition environmental testing. This work reports on the metrology operations conducted to determine any changes in subassembly alignment, including primary mirror segments with respect to each other, the secondary mirror to its support structure, the tertiary mirror assembly to the backplane of the telescope and ultimately to the Integrated Science Instrument Module (ISIM).

10377-19, Session 4

Assembly, alignment, and test of the Transiting Exoplanet Survey Satellite (TESS) flight optical assemblies

Gregory Balonek, Michael P. Chrisp, Kristin E. Clark, Christian D. Chesbrough, James E. Andre, Joshua J. Brown, Benjamin C. Richards, Michael Dalpiaz, Joseph Lennon, MIT Lincoln Lab. (United States)

The Transiting Exoplanet Survey Satellite (TESS) will carry four visible waveband, seven-element, refractive F/1.4 lenses, each with a 34 degree diagonal field of view. This paper describes the methods used for the assembly, alignment and test of the four flight optical assemblies. Prior to commencing the build of the four flight optical assemblies, a Risk Reduction Unit (RRU) was successfully assembled and tested. The lessons learned from the RRU were applied to the build of the flight assemblies. The main modifications to the flight assemblies include the inking of lens element number three for stray light mitigation, tighter alignment tolerances and making use of diamond turning for critical surfaces. Each one of the optical assemblies was tested interferometrically and measured with a non-contact profilometer to predict the optimal shim between the lens assembly and detector before -75C environmental testing. In addition to individual test data, environmental test results from prior assemblies allows for the exploration of marginal differences between each of the optical assemblies.

10377-20, Session 4

High-precision laser microcutting and laser microdrilling using diffractive beam-splitting and high-precision flexible beam alignment

Frank Zibner, Fraunhofer-Institut für Lasertechnik (Germany); Jens Holtkamp, Pulsar Photonics GmbH (Germany); Clemens Hönninger, Amplitude Systèmes (France); Arnold Gillner, Fraunhofer-Institut für Lasertechnik (Germany)

High-precision laser micro machining gains more importance in industrial applications every month. Optical systems like the helical optic offer highest quality together with controllable and adjustable drilling geometry, such as taper angle, aspect ratio and heat effected zone. The helical optic is based on a rotating Dove-prism which is mounted in a hollow shaft engine together with other optical elements like wedge prisms and plane plates. Although the achieved quality can be interpreted as extremely high the low process efficiency is a main reason that this manufacturing technology has only limited demand within the industry. The objective of the research studies presented in this paper is to dramatically increase process efficiency as well as process flexibility. Multi beam processing is used to parallelize the fabrication of periodic structures as most application only require a partial amount of the emitted ultra-short pulsed laser power. In order to achieve highest flexibility using multi beam processing the single beams are diverted and re-guided in a way that enables the option to process on different probes or semimanufactures with each single beam. Experiments are carried out using high power ultra-short pulsed laser sources such as a Trumpf TruMicro 5270 and a modified Amphos 400 system with an output power of almost 700W and a pulse duration of 2ps.

10377-21, Session PMon

Calculation of lens alignment errors using the ray transfer matrices for the lens assembly system with an autocollimator and a rotation stage

Jiyoung Chu, Sungwhi Cho, Won Don Joo, Sangdon Jang, SAMSUNG Electronics Co., Ltd. (Korea, Republic of)

One of the most popular methods for high precision lens assembly of an optical system is to use an autocollimator and a rotation stage. Some companies provide software calculating lens states along with their lens assembly systems, but calculation algorithms are unknown. In this paper, we suggest a calculation method for lens alignment errors using the ray transfer matrices. Alignment errors like decenter and tilt of a lens element can be calculated from tilts of front and back surfaces of the lens. Tilt of each surface can be obtained from a position of the reticle image on a CCD camera of the autocollimator. Rays from a reticle of the autocollimator are reflected from the target surface of the lens rotating with the rotation stage along an optical axis and imaged on the CCD camera. To get the clear image, a distance between the autocollimator and the first lens surface should be adjusted according to a focusing lens of the autocollimator and lens surfaces of the first to the target surface. Ray propagations for the autocollimator and the lens surfaces with tilts can be expressed effectively by using ray transfer matrices, so that lens alignment errors can be derived from them. This method is compared with Zemax simulation for various lenses with spherical or flat surfaces and its error is less than a few percent.

10377-22, Session PMon

Self-compensation for trefoil aberration of symmetric dioptric microlithographic lens

Wei-Jei Peng, Cheng-Fang Ho, Wei-Yao Hsu, Instrument Technology Research Ctr. (Taiwan)

The i-line microlithographic lens with unity magnification can be applied for the 3D integrated circuit steppers. The configuration of the microlithographic lens can be divided into three types: the dioptric type, the catoptric type, and both the catoptric and dioptric type mixed together. The dioptric type with unity magnification is typically designed as symmetry on both image and object sides to counterbalance aberrations on each side of the pupil effectively. The lens mounting is very critical for the diffraction-limit microlithographic lens because the mounting stress degrades image quality seriously. The three-point mounting is a semi-kinematic mounting without over constrain to decrease surface deformation obviously instead of the ring mounting, however, the disadvantage is significant trefoil aberration of the large-aperture lens due to gravity. The kinematic mounting is a method to make the surface deformation almost zero, but it's complicated and too expensive for the i-line microlithographic lens. Clocking of lens is a practical method of compensating the surface figure error for optimum wavefront error during pre-assembly phase, and then the yield rate of post-assembly for fine alignment increases. The three-point mounting of two pairs of symmetric lenses on both sides which crosses 60 degree is beneficial to compensate the trefoil aberration effectively, and it is a cost-effective method to approach the wavefront error close to the design nominal. In this study, the compensation method for the trefoil of the large-aperture lens employed in the symmetric dioptric microlithographic lens is verified in simulation.

10377-23, Session PMon

Research methodologies and justification of technical means of determining the accuracy characteristics of alignment control optical-electronic system

Maksim A. Kleshchenok, Valery V. Korotaev, Ivan S. Nekrylov, ITMO Univ. (Russian Federation)

Reconciliation of alignment - one of the most complex and demanding operations carried out during the maintenance of turbine unit and other mechanisms. Alignment largely determines the duration and complexity of major repairs. On the quality of these works depends largely on the duration of start-up, as well as the reliability and efficiency of turbine repaired.

Misalignment of shafts in a machine can cause following negative effects:

1) Emergence of moment causes generation forces reaction in the bearings of the machine

2) Overload of bearing shafts which leads to increase of distortions by 20% reduces bearing life estimated by 50%

3) Wear of seals, which in turn increases bearing damage risk due to penetration of dirt and grease leakage

4) Overload and vibration, those cause damage of couplings (overheating, weakened or broken bolts) and shafts

5) Power consumption engine may rise up to 20%, as a result of machine shafts warps.

For proper work of complex technological equipment its components need to be spatially positioned relative to assembly axis with high accuracy. As a result, the problem of contactless control of the position of objects relative to the extended linear base is relevant in many areas of technology. The task of object positioning is offer performed by means of optical – electronic measuring systems (OEMS), because of its high accuracy, remoteness and high level of automatization. OEMS determine the offset of basic parts of cylinders relative to the stage of turbine rotor axis with accuracy of 0.05 mm in the vertical and horizontal planes. The axis of the engine defined in the base bores (BB) during the measurement. OEMS allows recalculating

measurements relative to its own sighting line (SL) to given rotor axis, whereby there is no need "align" SL at predetermined coordinates, which is significantly automated of the measurement process.

In OEMS task of spatial positioning is implemented using the autoreflection and autocollimation techniques convergent beams, which allows for highly accurate measurement of linear offsets without determining the distance to the controlling element and provide power to the test object.

In this paper, we consider the influence of various factors and the noise on the invariant transformation of measurement information in autoreflection alignment control schemes. Theoretical and experimental research carried out for basic errors on bidiods and biprizms schemes.It is shown that the main influencing factors are non-linear transformations in optical systems and the impact of air path. Experimental studies were carried out on the basis of two opto-electronic control systems alignment, in which the control element is in the form of one or two corner-cube prisms.

10377-24, Session PMon

Raman laser spectrometer optical head: qualification model assembly and integration verification

Gonzalo Ramos Zapata, Miguel Sanz-Palomino, Andoni Moral Inza, Carlos Pérez, Tomás Belenguer-Dávila, Maria del Rosario Canchal, INTA Instituto Nacional de Técnica Aeroespacial (Spain); Jose Antonio Rodriguez Prieto, Amaia Santiago, Cecilia Gordillo, Ingeniería de Sistemas para la Defensa de España (Spain); David Escribano, INTA Instituto Nacional de Técnica Aeroespacial (Spain); Guillermo López-Reyes, Fernando Rull, Univ. de Valladolid (Spain)

Raman Laser Spectrometer (RLS) is the Pasteur Payload instrument of the ExoMars mission, within the ESA's Aurora Exploration Programme, that will perform for the first time in an out planetary mission Raman spectroscopy. RLS is composed by SPU (Spectrometer Unit), iOH (Internal Optical Head), and ICEU (Instrument Control and Excitation Unit). iOH focuses the excitation laser on the samples (excitation path), and collects the Raman emission from the sample (collection path, composed on collimation system and filtering system). Its original design presented a high laser trace reaching to the detector, and although a certain level of laser trace was required for calibration purposes, the high level degrades the Signal to Noise Ratio confounding some Raman peaks. So, after the bread board campaign, some light design modifications were implemented in order to fix the desired amount of laser trace, and after the fabrication and the commitment of the commercial elements, the assembly and integration verification process was carried out.

A brief description of the iOH design update for the qualification model (iOH EQM) as well as the assembly process are briefly described in this papers. In addition, the integration verification and the first functional tests, carried out with the RLS calibration target (CT), results are reported on.

Conference 10378: Sixteenth International Conference on Solid State Lighting and LED-based Illumination Systems

Tuesday - Wednesday 8 –9 August 2017

Part of Proceedings of SPIE Vol. 10378 Sixteenth International Conference on Solid State Lighting and LED-based Illumination Systems

10378-1, Session 1

Efficiency droop mitigation progress in blue and green III-nitride LEDs *(Invited Paper)*

Hee Jin Kim, Robert Armitage, Tsutomu Ishikawa, Isaac Wildeson, Parijat Deb, Lumileds, LLC (United States); Andrew M. Armstrong, Sandia National Labs. (United States); Zhibo Zhao, Akshay Singh, Silvija Gradecak, Massachusetts Institute of Technology (United States); Eric A. Stach, Brookhaven National Lab. (United States)

10378-2, Session 1

Challenges and new developments for conversion in solid state lighting *(Invited Paper)*

David O'Brien, JeKaterina Jurkova, Rainer Butendeich, Marcus Adam, Robert Schulz, Benjamin Gruber, Ralph Bertram, OSRAM Opto Semiconductors GmbH (Germany); Maria J. Anc, OSRAM SYLVANIA Inc. (United States); Britta Göötz, OSRAM Opto Semiconductors GmbH (Germany)

The careful control of LED spectral output is critical for a broad range of LED application areas. Optical down converters are the key technology in defining this spectral response and a number of recent advances in narrow band phosphors and quantum dot converters have the potential to improve existing applications as well as enabling new ones. Ultra-narrower spectral widths and finely tunable peak wavelengths have the potential to significantly improve current LED performance. Particularly in the area of solid state lighting these technologies have the potential to yield higher color rendering as well as higher overall efficiency.

10378-4, Session 1

Cryogenic characterization of LEDs for space application

Jerome Carron, Ctr. National d'Études Spatiales (France); Anne Philippon, Institut d'Astrophysique Spatiale (France); Lip Sun How, Audrey Delbergue, David Cillierre, AdvEOTec (France); Sahar Hassanzadeh, Institut d'Astrophysique Spatiale (France); Mathieu Boutillier, Pascale Danto, Ctr. National d'Études Spatiales (France)

In the frame of EUCLID project, the Calibration Unit of the VIS (VISible Imager) instrument must provide an accurate and well characterized light source for in-flight instrument calibration without noise when it is switched off. The Calibration Unit consists of a set of LEDs emitting at various wavelengths in the visible towards an integrating sphere. The sphere's output provides a uniform illumination over the entire focal plane. Some results about the radiation effects on LED properties are available in the litterature [1], but Light Emitting Diodes (LEDs) are not yet Space qualified at present. Therefore, a mission oriented full screening, qualification and EMC tests of some potential candidates Commercial Off The Shelf (COTS) LEDs has been carried out.

The calibration Unit will work at cryogenic temperature (136 K) for 6.25 years and uses a total of six different wavelengths. A total of 9 reference LEDs, coming from three different manufacturers (EPIGAP, EPITEX and OPTRANS), were selected, screened and submitted to a custom qualification plan in order to cover the needs of the mission.

The screening sequence includes thermal cycles between 323K and 136K under vacuum and Burn-in under atmospheric pressure. Based on screening results, a statistical method has been used to classify the LEDs into three subgroups per reference: Flight Models (25), Qualification Models (46) and Spares.

The qualification tests aimed to fulfill all the mission requirements : . The endurance subgroupat hot and cold temperatures simulated the thermal stress situations to which components will be subjected and took into account the number of LED ON/OFF operations. The environmental subgroup tested LEDs hardness versus on-ground and in-flight environments. Radiation subgroup using proton radiations has been performed at cryogenic temperatures. . Mechanical subgroup (destructive testing) aimed to construction defects, solderability and Electrostatic Discharge (ESD) sensitivity.

All the electrical and optical parameters of the LED have been monitored and recorded at ambient and cryogenic temperatures. These results have been compiled in order to show the total deviation of the LED electrical and electro-optical properties in the whole mission and to select the best suitable LED references for the mission.

The results of this complete qualification demonstrate the good reliability of most of the tested LEDs to withstand space environment and extreme conditions.

Then 6 wavelengths were selected and submitted to an EMC sensitivity test at room and cold temperature by counting the number of photons when LEDs drivers are OFF. Characterizations were conducted in the full frequency spectrum in order to implement solutions at system level to suppress the emission of photons when the LED drivers are OFF. LEDs impedance was also characterized at room temperature and cold temperature and no major difference has been detected.

10378-5, Session 1

Analysis of spectral power distributions for multi-channel platforms in a patient room application

James J. Kim, Tony Esposito, Patricia Rizzo, Dorene Maniccia, Philips Research Americas (United States)

A prototype innovative lighting system for a patient room application that integrates multi-channel luminaire platforms into indoor general area luminaires has been demonstrated. This system has spectrally tunable capabilities, and satisfies the visual and nonvisual needs of occupant, while providing an energy-efficient solution. We evaluated the performance of two different multichannel platforms in different luminaire types using a unique color processing algorithm. The LED modeling and simulations enabled optimization of spectral power distributions, color, light output, and efficacy. This paper discusses the complicated results of SPDs developed for the patient room application, especially how they are effective for positively impacting the visual and human circadian systems.

10378-35, Session 1

Opportunities and challenges for 3D printing of solid-state lighting systems *(Invited Paper)*

Nadarajah Narendran, Indika U. Perera, Xi Mou, Dinusha R. Thotagamuwa, Rensselaer Polytechnic Institute (United States)

Low energy use and reduced maintenance have made the light-emitting diode (LED), a solid-state light (SSL) source, the preferred technology for many lighting applications. With the explosion of LED products in the marketplace and subsequent price erosion, market transformation is expected to move quickly in the next few years. Manufacturers, therefore, are looking for lower cost materials and manufacturing methods to keep up with low price requirements. 3-D printing, also known as additive manufacturing, could be a potential solution to this need. During the past few years manufacturers in the automotive, aerospace, and medical industries have embraced 3-D printing for manufacturing parts and systems for their applications. This revolution could also pave the way for the lighting industry to step into the 3-D printing era for the production of lower cost, custom lighting systems that can be printed on-site to achieve on-time and on-demand manufacturing. One unique aspect of LED fixture manufacturing is that it requires thermo-mechanical, electrical, and optical components. This presentation will cover the current status of affordable 3-D printers capable of making mechanical, electrical, and optical components for the creation of lighting fixtures. Examples of printed components explored in our laboratory and their performance will be shown. Finally, this presentation will include a discussion of the improvements needed in the printer and materials technologies to enable 3-D printing to become a mainstream manufacturing tool for SSL fixtures.

10378-6, Session 2

A comparison of color fidelity metrics for light sources using simulation of color samples under lighting conditions *(Invited Paper)*

Hyeokjun Kwon, Yoojin Kang, Junwoo Jang, LG Display (Korea, Republic of)

Color fidelity has been used as one of indices to evaluate the performance of light sources. Since the Color Rendering Index (CRI) was proposed at the CIE, many color fidelity metrics have been proposed to increase the accuracy of the color fidelity. This paper focuses on a comparison of the color fidelity metrics in an aspect of accuracy with human visual assessments. To visually evaluate the color fidelity of light sources, we made a simulator that can make the color samples under lighting conditions. In this paper, eighteen color samples of the Macbeth color checker under test light sources and reference illuminants for each of them are simulated and displayed on monitor. With only a spectrum set of the test light source and reference illuminant, color samples under any lighting condition can be simulated. In this paper, the spectrums of the two LED and two OLED light sources that have similar values of CRI are used for the visual assessment. In addition, the results of the visual assessment are compared with the two color fidelity metrics that include the CRI and IES TM-30 (Rf), proposed by the Illuminating Engineering Society (IES) in 2015. Experimental results indicate that Rf is outperform CRI in terms of correlation with visual assessment.

10378-7, Session 2

Comparison of methods for measurement of HP-LEDs based on the junction temperature *(Invited Paper)*

Yuqin Zong, Noe V. Medina, National Institute of Standards and Technology (United States)

High power LEDs (HP-LEDs) are key building blocks of solid-state lighting products, therefore, it is important for LED manufacturers, lamp/luminaire manufactures, and testing/calibration laboratories to measure their optical and electrical properties with high accuracy. Measuring HP-LEDs has been difficult because they are highly sensitive to their junction temperatures, which rise rapidly when they are turned on. Various methods have been proposed and used to measure HP-LEDs, but most of them are only useful for particular applications and unable to produce accurate and reproducible measurement results. To address the measurement need, the Illuminating Engineering Society (IES) recently approved three methods that can be used for the measurement of HP-LEDs, which are the DC method, single-pulse method, and continuous-pulse method [1]. All three measurement methods refer to the junction temperature of an HP-LED as the thermal condition and thus, the measured results are considered to be equivalent as long as the junction temperature is set to be the same. However, our recent study shows that the difference in the measurement results of the three different methods can be significant (e.g., 5 % in total luminous flux) due to significant heating of the junction and/or phosphor material of the HP-LED during the period of a measurement. In this paper, we will describe the measurement of HP-LEDs using the three different methods, compare the measurement results, and discuss the cause that results in the significant difference.

Low-NEP pyroelectric detector for calibration of UV and IR sources and detectors

George P. Eppeldauer, Vyacheslav B. Podobedov, Leonard M. Hanssen, Catherine C. Cooksey, National Institute of Standards and Technology (United States)

Pyroelectric radiometers with spectrally constant response have been developed in the last few years at NIST with the cooperation of several detector manufacturers. The new devices have noise-equivalent-power (NEP) values less than 1 nW/Hz^1/2 sufficiently low for use at the output of regular monochromators. Their response flatness is an order of magnitude better than that of filtered detectors and can be used to extend the reference responsivity scales of silicon-trap-detectors to both the UV and IR wavelength ranges. For the first time, the irradiance responsivity of a pyroelectric detector has been determined. Based on spectral reflectance measurements of the black coating of the pyroelectric detector, the relative spectral response was determined between 0.25 and 30 micrometers. This relative function was then converted into absolute spectral responsivity using absolute tie points from a silicon-trap-detector in the VIS range. Similarly, the flat response between 1.6 and 2.5 micrometers can also be utilized and a close to constant irradiance responsivity can be realized. This irradiance responsivity will be used as a reference scale for the NIST SIRCUS facility where tunable laser sources are used for the spectral responsivity calibration of detectors, instead of using a monochromator. The spectral power responsivity of the pyroelectric detector is the internal standard of the NIST VIS-IR detector calibration facility for the 0.6 to 24 micrometers wavelength range. The pyroelectric standard can be used to calibrate other types of detectors for spectral power responsivity using detector substitution. The flat pyroelectric standard calibrated for the spectral irradiance responsivity, was used to calibrate other irradiance measuring detectors and also to measure the broadband (integrated) irradiance from UV and blue LEDs without using any source standard. All the pyroelectric

detector based calibrations described here were performed in AC measurement mode with expanded uncertainties of about 2 % (k=2).

10378-10, Session 3

Ultra-high power semiconductor devices: heat-sinking using GaN-on-diamond *(Invited Paper)*

Martin Kuball, Univ of Bristol (United Kingdom)

GaN devices when operated at high powers are limited by excessive temperature rise in the device critical regions. Traditionally SiC, Si or sapphire substrates or homoepitaxy on GaN substrates is used, however the substrate thermal conductivity is rather limited. We review the use of diamond substrates with their ultra-high thermal conductivity for GaN devices, and the opportunities (and challenges) this offers.

10378-11, Session 3

Growth and characterization of GaN/InN/GaN heterostructures on GaN substrate templates using migration-enhanced, plasma-assisted MOCVD

Daniel Seidlitz, Brendan Cross, Viktoriia E. Babicheva, Yohannes Abate, Georgia State Univ. (United States); Axel Hoffmann, Technische Univ. München (Germany); Nikolaus Dietz, Georgia State Univ. (United States)

This contribution will present the structural and optoelectronic properties of GaN/InN heterostructures grown by Migration Enhanced Plasma-assisted Metal Organic Chemical Vapor Deposition (MEPA-MOCVD) on GaN/sapphire templates.

In comparison to conventional MOCVD, MEPA-MOCVD utilizes as nitrogen precursor plasma-activated nitrogen species (N*/NH*/NHx*) in the after-glow regime above the growth surface. The plasma-activated nitrogen species can generated by a hollow cathode plasma source (13.56 MHz, 50 – 600 W) at lower temperatures compared to the ammonia decomposition. The kinetic energies of the excited species stabilize the growth surface and reduce the partial pressure difference between InN and GaN binaries, enabling to potential stabilization of both binaries in the same temperature regime. Tailoring the kinetic energies and plasma activated nitrogen species are specific processing parameter, in addition to nitrogen flux through the plasma source, MO flows, and reactor pressure explored.

We will present characterization results (using Atomic Force Microscopy (AFM) and Raman) and optoelectronic (Fourier Transform Infrared - FTIR) studies on the formation of InN/GaN and GaN/InN/GaN heterostructures and interfaces by deposition of a thin InN/InGaN quantum well (QW) and GaN/InN/GaN layers in the same temperature range. High-resolution s-SNIN (scattering type scanning near-field infrared nanoscopy) studies will be presented on spontaneous polarization induced charge accumulations in GaN/InN/GaN interfaces as function of process parameters.

The influence of growth parameters such as growth temperature, plasma power, reactor pressure and pulsed supply of Metalorganic (MO) and plasma activated nitrogen precursors are examined by AFM, Raman and FTIR spectroscopy. A correlated analysis of the macro/microscopic/nanoscopic investigations on the structural properties, crystal quality, surface morphology, film thickness, and optoelectronic characteristics (free carrier concentration and high-frequency dielectric function) will be presented.

10378-12, Session 3

High-resolution spectroscopy and imaging of interfacial strain fields in InN/GaN and GaN/InN/GaN heterostructures

Yohannes Abate, Alireza Fali, Viktoriia E. Babicheva, Nikolaus Dietz, Georgia State Univ. (United States)

We investigate nanoscale interfacial properties of GaN/InN heterostructures grown on GaN/sapphire templates, using Migration Enhanced Plasma-assisted Metal Organic Chemical Vapor Deposition (MEPA-MOCVD). High-resolution s-SNIN (scattering type scanning near-field infrared nanoscopy) studies are utilized to study spontaneous polarization induced charge accumulations at GaN/InN/GaN interfaces. s-SNIN optical and infrared spectroscopic images are correlated with the process parameters and optimum values for maximum local charge accumulation are reported. An advanced theoretical model that uses realistic growth and imaging parameters is developed to guide the experimental results and interpret results.

10378-13, Session 3

Growth and characterization of GaN/GaAlN heterostructures on GaN substrate templates

Lance Hubbard, Pacific Northwest National Lab. (United States); Viktorriia E. Babicheva, Yohannes Abate, Georgia State Univ. (United States); Vincent T. Woods, Pacific Northwest National Lab. (United States); Nikolaus Dietz, Georgia State Univ. (United States)

This contribution will present the structural and optoelectronic properties of GaN/GaAlN heterostructures grown by Metal Organic Chemical Vapor Deposition (MOCVD) on GaN/sapphire templates. The target parameters for the materials heterostructures have been modeled for utilization in Avalanche Photodiode Detector Structures (APD) operating in the near UV region. Optical modeling has improved absorption within the heterojunction as well as maximized light trapping within the device. Electronic modeling has determined the optimal dopant concentrations for maximum impact ionization rate, as well as tolerance to defects and unintentional doping. This application will require advances in the defect densities, surface morphology, and interfaces. Surface morphological and structural properties of the GaN/GaAlN heterostructures are analyzed by Atomic Force Microscopy (AFM), Raman spectroscopy. The optoelectronic properties (phonon structures, free carrier concentrations, and carrier mobility) as well as layer thickness information, are determined by Fourier Transform Infrared Reflectance (FTIR) spectroscopy. High-resolution s-SNIN (scattering-type scanning near-field infrared nanoscopy) studies are utilized to study spontaneous polarization induced charge accumulations at GaN/GaAlN/GaN interfaces and how these impact the point- and extended defect formation and their evolution with layer thickness. A correlation of such interfacial defects (type and concentration) with microscopic/nanoscopic structural properties, surface morphology, and optoelectronic properties (free carrier concentration and high-frequency dielectric function) is attempted

10378-14, Session 3

The optical properties of phosphor converted white LED with adding Zirconium dioxide particles *(Invited Paper)*

Quang-Khoi Nguyen, Yu-Yu Chang, National Central Univ. (Taiwan); Benoit Glorieux, Institut de Chimie de la Matière Condensée de Bordeaux (France); Tsung-Hsun Yang, Ching-Cherng Sun, Chien-Hung Hsu, National Central Univ. (Taiwan)

Return to Contents

We performed the simulation and experiment to investigate the influence of Zirconium dioxide (Zirconia, ZrO_2) particles on the optical properties of phosphor converted white LED (pcW-LED). An efficient optical model was developed and applied to the incorporation diffuse particle of ZrO_2 into a hemisphere package containing YAG phosphors. The optical properties (chromaticity, packaging efficiency) were estimated as a function of phosphor and ZrO_2 particles, through the calculation of effective radius, refractive index, and absorption and conversion efficiency, in a range of correlated color temperature 4500 K to 6500 K. In the same way, the amount of phosphor and ZrO_2 can be calculated accurately to obtain a targeted optical property in a hemisphere LED design. Especially, the angular distribution of CCT was also diminished, and even almost inexistent for low CCT design. In addition, the adding of ZrO_2 particles allows clearly decreasing the amount of phosphor for an identical target CCT. It is really suitable in the context of decreasing the amount of phosphor or in some applications where the color uniformity is an important parameter, like indoor down-lighting.

Spectra control of RE doped calcium silicate through topochemical reduction strategy for white LED application

Jingshan Hou, Yongzheng Fang, Shanghai Institute of Technology (China)

In this work, europium-doped calcium silicate (abbreviated as C2S:Eu) was prepared by a topochemical reduction strategy with aluminum as a solid-state reducing agent at the calcination temperature from 300°C to 1000°C. The emission intensity ratio of Eu^{2+}/Eu^{3+} started to increase at 400°C, indicating the occurrence of the reduction of Eu^{3+}. Such prepared samples showed stronger emission intensity from Eu^{2+} centers than the ones prepared by traditional CO reduction. Especially, the Al-reduced C2S:Eu^{2+} calcinated at 1000°C exhibited PL intensity as 300% high as the CO-reduced C2S:Eu^{2+} prepared at the same temperature. This phenomenon is further explained from the standpoint of the different reduction reaction kinetics of solid state Al and vapor phase CO at the same temperature. This result suggested that this strategy can be used as an effective tool for the spectra control of the rare earth doped luminescent systems, thus opening up new avenues to develop novel optical materials for the white light emitting diodes applications.

10378-16, Session 3

Strong coupling between ordered Ag nanosphere and a-SiNx:O induced highly efficient blue LED

Zhongyuan Ma, Nanjing Univ. (China)

Developing a highly efficient blue light emission source has long been a major focus of Si-based optoelectronic integration as a sustainable solution of IC industry. In recent years, localized surface plasmon resonance (LSPR) from metal nanostructures has attracted great interest due to its unique application in increasing the luminescence efficiency of silicon light source. The energy match between LSPs from metal NPs and excitons in luminescent material is the key factor to achieve the enhancement of spontaneous radiations. As the wavelength of LSPR is highly dependent on the size and shape of metal nanostructures, a nanofabrication technique to produce metal nanostructures with controllable size and shape is vital important.

In this work we demonstrate ordered and controllable Ag nanosphere arrays with higher surface coverage in large region can be realized by laser annealing combined with self-assembled process of nanosphere lithography. Sharply enhancement of blue electroluminescence intensity can be obtained through strong coupling with the excitons of a-SiNx:O by tuning the size of Ag nanosphere from 170 to 300 nm. Finite-difference time-domain solution (FDTD) calculation confirms that the quadrupolar mode of the plasmon for Ag-sphere arrays play the dominant role in the coupling of Ag-sphere arrays with a-SiNx:O films. The successful fabrication of the Ag nanosphere arrays ensures the strongly localized character of quadrupolar mode, which prominently enhances the blue emission from a-SiNx:O via the effective energy coupling between the LSPs and the excitons. Our method supplies a new way for a-SiNx:O as a highly efficient blue LED in the future.

Improving the thermal stability of $K_2SiF_6:Mn^{4+}$ red phosphor using atomic layer deposition in a fluidized bed reactor

Otmar M. Ten Kate, Technische Univ. Delft (Netherlands); Y. Zhao, Technische Univ. Delft (Netherlands) and Xiamen Univ. (China); H. T. Hintzen, J. R. van Ommen, Technische Univ. Delft (Netherlands)

In recent years, the Mn^{4+} doped K_2SiF_6 (KSF) phosphor has gained a lot of attention due to its efficient and narrow red line emission after blue light excitation, which makes it a very promising phosphor for phosphor converted white light emitting diodes (pc-wLEDs).[1,2] In pc-wLEDs a blue LED chip is combined with red and green-emitting phosphors to obtain warm-white light. However, the KSF:Mn^{4+} phosphor suffers from thermal degradation as a result of oxidation, severely limiting its lifetime and applicability. Recently, we demonstrated that YAG:Ce^{3+} phosphor particles can be protected against thermal degradation, by coating them with a thin Al_2O_3 layer using atomic layer deposition in a fluidized bed reactor (ALD-FBR).[3] ALD-FBR is a technique to deposit thin (several nm) closed layers on powder particles in a controlled way via sequential deposition of the reactants. Here we will report on the deposition of Al_2O_3 on KSF:Mn^{4+} phosphor particles using ALD-FBR with trimethylaluminium (TMA) and ozone as reactants. We will discuss the influence of water on the fluidization of KSF powders and its role in the deposition processes. In addition, the influence of thickness of the Al_2O_3 coating on the optical properties and thermal stability of the KSF:Mn^{4+} phosphor will be discussed.

New phosphors Eu^{2+} and Ce^{3+} doped $Sr_{4-x}(Si,Al)_{19+x}(N,O)_{29+x}$ for white LED applications

Chunyun Wang, Takashi Takeda, Hokkaido Univ. (Japan) and National Institute for Materials Science (Japan); Shiro Funahashi, Rong-Jun Xie, Naoto Hirosaki, National Institute for Materials Science (Japan)

Light-emitting diodes (LEDs) have been steadily consolidating their share in the lighting and display market. Phosphor-converted (pc) white LED becomes the preferred way to generate white light especially for general lighting, as it is much cheaper and simpler than RGB system. Phosphors are essential to high color quality and luminous efficacy. However, the number of commercially available phosphors is very limited. Therefore, developing

new phosphors suitable for various white LED applications is very important.

Recently, our group developed the single-particle-diagnosis approach [1-2] to discover new phosphors, with which a tiny luminescent microcrystalline particle down to 5-10 ?m can be selected from powder mixtures. In this work, we report a new green emitting Sr-sialon:Eu phosphor discovered by this approach. The crystal structure was solved and refined from single crystal X-ray diffraction data. Sr-sialon:Eu crystallizes in the trigonal space group P3m1 (no. 156) with a = b = 12.1054 Å, c = 4.8805 Å and Z = 1, and consists of a network of corner sharing (Si,Al)(N,O)4 tetrahedra. Upon doping with Eu2+, the emission band can be tuned from 487 nm to 541 nm with fwhm = 96-124 nm. Ce3+ doped Sr-sialon phosphor shows strong blue emission around 435 nm with a fwhm ≈ 90 nm after 355 nm light excitation. The blue luminescence exhibits a small thermal quenching behavior at high temperature. These performances show that the new Eu2+ and Ce3+ doped Sr-sialon phosphors are promising for white LED applications.

Selecting the optimal synthesis parameters of InP/Cd[x]Zn[1-x]Se quantum dots when combined with different broad band phosphors to optimize color rendering and efficiency of a remote phosphor white LED

Jana Ryckaert, António Correia, Kevin Smet, KU Leuven (Belgium); Mickaël D. Tessier, Dorian Dupont, Zeger Hens, Univ. Gent (Belgium); Peter Hanselaer, Youri Meuret, KU Leuven (Belgium)

Combining traditional phosphors with a broad emission spectrum and non-scattering quantum dots with a narrower emission spectrum can have multiple advantages for white LEDs. It allows to reduce the amount of scattering in the color conversion element (CCE), increasing the efficiency of the complete system. Furthermore, the unique possibility to tune the emission spectrum of quantum dots allows to optimize the resulting LED spectrum in order to achieve optimal color rendering properties for the light source. However, finding the optimal quantum dot properties to achieve the desired efficiency and color rendering is a non-trivial task. Instead of simply summing up the emission spectra of the blue LED, phosphor and quantum dots, we propose a complete simulation tool that allows an accurate analysis of the final performance for a continuous range of different quantum dot properties. A model is included that generates the absorption and emission spectrum of the considered InP/Cd[x]Zn[1-x]Se quantum dots as a function of certain quantum dot parameters that can be controlled during the synthesis, namely core size, shell size and cadmium fraction. The recycling of the reflected light from the CCE by the LED package is taken into account, as well as the reabsorption and the associated red-shift. This simulation tool is used to scan through these synthesis parameters and we find the ideal quantum dot for two specific broad band phosphors, in each case providing the optimal efficiency and color rendering for the white LED with a specific pumping LED, phosphor and recycling cavity, with the desired CCT.

10378-21, Session 4

Fabrication of CuInS2/ZnS quantum dots-based white light-emitting diodes with high color rendering index

Chih-Chun Hsiao, Shu-Ru Chung, Yu-Sheng Su, National Formosa Univ. (Taiwan)

Among solid-state lighting technology, phosphor-converted white light-emitting diodes (pc-WLEDs) are excellent candidates to replace incandescent lamps for their merit of high energy conservation, long lifetime, high luminous efficiency as well as polarized emissions. Semiconductor quantum dots (QDs) are emerging color tunable emissive light converters. They have shown significant promise as light emitters, as solar cells, and in biological imaging. It has been demonstrated that the pc-WLED devices integrated with red emissive ZnCdSe QDs show improved color rendering index of device. However, cadmium-based QDs have limited future owing to the well-known toxicity. Recently, non-cadmium luminescence materials, i.e. CuInS2-based QDs, are investigated as desirable low toxic alternatives. Particularly, CuInS2-based QDs exhibit very broad emissions spectra with full width at half maximum (FWHM) of 100-120 nm, large Stokes shifts of 200~300 meV and finely-tunable emissions. In order to adjust emission wavelengths and improved quantum yield (QY), CuInS2/ZnS (CIS/ZnS) core/shell structure was introduced. Therefore, CIS/ZnS QDs have been extensively investigated and be used as colour converter in solid-state lighting. Synthesis and application of CuInS2/ZnS core/shell QDs are conducted using a hot injection route. CIS/ZnS core/shell QDs with molar ratio of Cu:In equal to 1:4 are prepared. For WLED fabrication, the CIS/ZnS QD is dispersed in toluene first, and then it is blended with transparent acrylic-based UV resin. Subsequently, the commercial green-emitting Lu3Al5O12:Ce3+ (LuAG) phosphors are mixed with QD-resin mixture. After that, the QDs-phosphors-resin mixtures are put in the oven at 140 °C for 1 h to evaporate the toluene. Subsequently, the homogeneous QDs-phosphors-resin mixture is dropped on the top of a blue LED chip (InGaN). Then, the device is cured by 400 W UV light to form WLED. The emission wavelength of CIS/ZnS QD exhibits yellow region of 552 nm with QY of 76 %, and with relatively broad bandwidth of 86 nm. The structure of CIS/ZnS belongs to chalcopyrite phase and its average particle size is 3.2 nm. The luminous efficacy, color rendering index (CRI), correlated color temperature (CCT), and CIE chromaticity coordinate of WLED is 47.3 lm/W, 89, 5661 K, and (0.33, 0.29), respectively.

10378-22, Session 5

High lumen density sources based on LED-pumped phosphor rods: opportunities for performance improvement *(Invited Paper)*

Dick K. G. de Boer, Philips Research (Netherlands)

Recently, LED-based sources with high brightness (up to 10^9 lm/(m2 sr) have been developed [1,2,3,4]. These sources can be applied in projection systems, as well as in other applications requiring high brightness. The technology makes use of a transparent phosphor rod that is pumped by a multitude of blue LEDs. Most of the converted light is guided in the rod towards one of its small sides, where it is extracted using suitable extraction optics.

In this paper, the requirements for the optical materials for phosphors and extraction optics will be discussed. Because of the high lumen density inside these materials, special attention should be given to non-linear processes that limit the performance. Possibilities to overcome these limitations will be discussed.

Progress in extremely high brightness LED-based light sources *(Invited Paper)*

Christoph G. A. Hoelen, Philips Lighting B.V. (Netherlands)

Although the maximum brightness of LEDs has been increasing continuously during the past decade, their luminance is still far from what is required for multiple applications that now still rely on the high brightness of discharge lamps. In particular for high luminous flux applications with limited étendue, like in front projection systems, only very modest luminance values in the beam can be achieved with LEDs compared to systems based on discharge lamps or lasers. With dedicated LED architectures, phosphor converted green light emitters for projection may achieve luminance values up to ca 200 Mnit (108 lm/m2sr). In this paper we report on the progress made in the development of light engines based on a light converter rod pumped with blue LEDs. This concept, named ColorSpark High Lumen Density LED technology, has recently been introduced. These sources outperform the étendue and brightness limits of LEDs by multiple factors. In LED front projection systems, green LEDs are the main limiting factor. With our green modules, we now have achieved peak luminance values in excess of 1.5 Gnit, enabling LED-based projection systems with over 3500 ANSI lm. The green light source efficiency has been increased considerably, reaching 45-60 lm/W under application conditions. The module architecture as well as module and system performance characteristics are reviewed, and compared against alternative projection systems. Finally an extension of this concept to yellow light sources is presented, enabling a further breakthrough in the performance of LED-based projection systems and a wide variety of other high brightness applications.

10378-24, Session 5

The impact of the driving frequency on the output flux of high-power InGaAlP-LEDs during high-current pulsed operation

Benjamin Schulz, Stefan Morgott, OSRAM Opto Semiconductors GmbH (Germany)

Direct red light-emitting diodes based on InGaAlP comprise a strong temperature sensitivity regarding their output flux. In Étendue limited applications, like digital projectors, these LEDs are usually driven at current densities exceeding 3 A/mm? in pulsed mode. The losses inside the semiconductor lead to a large amount of heat, which has to be removed most efficiently by a heatsink to keep the junction temperature as low as possible and therefore to obtain the maximum output flux. One important performance parameter is the thermal resistance Rth of the LED, which has been improved during the last few years, e.g. by the development of new high-power chips and packages.

In our present approach, we investigated the influence of the driving frequency – which is closely related to the thermal impedance Zth – on the luminous and the radiant flux of red LEDs. A simulation model based on the electro-thermal analogies was implemented in SPICE and the optical and electrical characteristics of one LED type (OSRAM OSTAR Projection Power LE A P1W) were measured under application-related driving conditions while varying the parameters frequency, duty cycle, forward current, and heatsink temperature.

The experimental results show clearly that the luminous and the radiant flux go up when the driving frequency is increased while the other parameters are maintained. Moreover, it can be noticed that the degree of this effect depends on the other parameters. The largest impact can be observed at the lowest tested duty cycle (30 %) and the highest tested current density (4 A/mm?) and heatsink temperature (80 °C). At this operating point, the luminous and the radiant flux increase by 20 % and 14 % respectively when raising the frequency from 240 Hz to 1920 Hz.

10378-25, Session 5

Opto-thermal design of a white light point source based on high power blue laser diodes

António Correia, Peter Hanselaer, Youri Meuret, KU Leuven (Belgium)

When designing white light systems, using laser diodes allows for an accurate control of the intensity pattern when combined with optical components, but also imposes severe challenges regarding the thermal packaging of colour conversion element (CCE) used for the blue laser diode(s). Accounting for both optical and thermal effects is critical to correctly assess the performance of white light systems based on laser diodes. We propose an opto-thermal design that produces white light with a very small spatial extent, approaching a point source. We optimize this system’s performance with an opto-thermal simulation tool that adjusts its optical and thermal properties and allows estimating the maximum incident optical power that still results in a thermally stable white light system. We show that even when using high power laser diodes to excite a millimetre scale CCE, it is still possible to have a thermally stable white light system.

10378-8, Session PWed

Dome diagnostics system of optical parameters and characteristics of LEDs

Vladimir S. Peretyagin, Nikita A. Pavlenko, ITMO Univ. (Russian Federation)

The intensive development of LED technologies resulted in the creation of new, more efficient and high-power LEDs. Such LEDs are usually used in devices of the street lighting, industrial (decorative and accent) and domestic lighting. It was possible by the rapid increase their energy, spatial (viewing angle of LEDs ranges from 10 to 160 deg), spectral (colorimetric) and electrical characteristics as well as reliability and durability of quasi-monochromatic light sources.

Opportunities of using LEDs in these fields are connected with combination of a powerful LED light with practically any form of its spatial distribution as well as a wide variety of color shades. However, development and production (especially mass production) of LED lighting devices are impossible without a thorough analysis of its parameters and characteristics. So, design methods for developed lighting device, its structure, size and reliability, all of this depends on the results of analysis. The development of equipment for quality analysis of LED (assessment of parameters and characteristics of LEDs proposed by manufacturers) is an important problem for a variety of areas where LEDs are used today.

This work presents a diagnostic system of optical parameters and characteristics of LEDs. The main feature of this system is the presence of 55 RGB photodiodes. These photodiodes from a hemispherical structure (in the hemispherical frame). This structure allows analysis of spatial (angular) and energy parameters and characteristics of LEDs on all upper hemisphere of its radiation. Also the uses of RGB photodiodes will enable measure the color parameters of LEDs radiation. Such device allows us to analyze parameters of LEDs in three-dimensional space and to assess the quality of LED products.

10378-26, Session PWed

Universal fixture design for body mounted LED lights

Debdyut Hajra, B.P. Poddar Institute of Management & Technology (India)

Today LED headlamps, armbands and ankle-bands, shoe-lights etc. have become very popular. These find extensive use in search and rescue operations, mining, carving, etc. and are also used by individuals during

hiking, trekking, running, etc. during dark hours. They serve two main purposes: they provide sufficient illumination in low light conditions and they are used to indicate the presence of a person after dark. These have the same basic requirements. They must produce sufficient light, have high durability, long battery life, must be light weight and energy efficient. This paper discusses possibilities of designing a universal LED fixture can be designed so that it meets the respective needs of everyone irrespective of their background and industry. It discusses the materials to be used for its different body parts, innovative clip design for attachment with support structures like head and armbands, helmets, shoes, etc. It also discusses the energy efficiency that can be achieved and alternatives for charging like fast-USB charging and also integration of solar charger in the fixture. Discussions have also been made on controlling intensity level of illumination using ambient sensors and manually through integrated buttons. IOT integration with the fixture also been discussed. Using IOT allows remote control, data collection, measuring performance and efficiency of the device. It also emphasizes the importance of having a universal design. Effort has been made to standardize the fixture design in reference to methods specified by renowned bodies such as DOE, IES, BIS, etc.

10378-27, Session PWed

Self CCT stabilization for white LEDs from turn-on stage to thermal equilibrium

Tsung-Hsun Yang, Shin-Mei Wu, National Central Univ. (Taiwan); Benoit Glorieux, Institut de Chimie de la Matière Condensée de Bordeaux (France); Xuan-Hao Lee, Ching-Yi Chen, Yu-Yu Chang, Yeh-Wei Yu, Ching-Cherng Sun, National Central Univ. (Taiwan)

In this paper, a self-balancing method of the phosphor efficiency for pcW-LEDs from the initial turn-on state to thermal equilibrium is proposed and demonstrated. For the obtainment of a pcW-LED with stabilized CCT, we proposed a novel scheme about the selection of the suitable peak wavelength of the blue LED under normal operation condition during the defined life time. According to experiment results, expect an observation of the turning pint for CCT variation upon rising temperature, the self-balance group was obtained as small as 7K and 83K when the initial CCT of the pcW-LEDs was around 4700K and 6300K, respectively. Besides, we also proposed a new factor, guide number, to figure out the design and choose the matching blue LED die and phosphor pair for self-balancing.

10378-28, Session PWed

Modeling and simulation of a solar simulator with multi-wavelength high-power LEDs

Yoon Kim, Reuben T. Lewis, Calvin College (United States)

This paper presents the modeling and simulation of a solar simulator that is comprised of multiple- wavelength high-power LEDs.

A solar simulator is a light source which can provide optical power to measure the characteristics of solar panels indoors. For this application, the light source requires an optical spectrum and irradiance that is similar to solar rays. A high-power LED-based light source is considered to provide a light-weight design, higher luminous efficacy, and longer operating life. To match the solar spectrum, the light source in the form of an LED array needs various types of LEDs whose wavelengths and intensities are different from one another.

The proposed solar simulator includes a high-density LED fixture containing a 10 by 10 array of high-intensity LEDs. The square fixture measures 5 inches (127 mm) per side. Additional fixtures can be added seamlessly to provide optical power over an area of any desired size.

The goal of this work is to find the optimum layout for an array of high-power LEDs in order to generate an optical spectrum similar to solar rays with uniform irradiance. The fixture has 100 LEDs of 13 different types. Each LED in the fixture has a specific wavelength and intensity set by a 3D optical modeling tool.

This work presents the parameters that affect spectral match and uniformity of irradiance. The parameters are the number of different LEDs used, their intensities, spacing, and arrangement.

The number of LEDs and their intensities for a spectral match were computed by a developed algorithm. Modeling and simulation for uniformity of irradiance were carried out by a 3D optical modeling tool.

The results include the spectral and irradiance distributions of the light fixture.

The color enhancement and collimation features of the multi-colored LEDs with different periodic microstructure on the top surface of TIR lens

Shang-Ping Ying, Minghsin Univ. of Science and Technology (Taiwan); Han-Kuei Fu, Industrial Technology Research Institute (Taiwan)

Due to the advantages, such as high efficiency, power consumption reduction, no mercury, pure saturated color, high reliability and long lifetime, the solid-state lighting based on light-emitting diodes (LEDs) has become very popular at this stage. In the lighting applications such as spot lighting, downlighting, architectural and show lighting, the color-tunable properties with collimating beam of LEDs are highly demanded. The color–tunable lighting is easily achieved using multi-colored LEDs instead of inefficient color filters. However, the applications of multi-colored LEDs usually appear the undesirable light patterns such as color separation or color fringes. At the meantime, the use of TIR (total internal reflection) lens for multi-colored LEDs to collimate the light from the LEDs with different color will introduce seriously undesirable artifacts. Thus, a periodic microstructure surface on the top surface of the TIR lens would be used to reshape the light from the different colored LED chips in the multi-colored LEDs, and then decrease the color separation and color nonuniformity. In this study, the TIR lens with periodic microstructure surface on the top surface would be used to collimate the light from multi-colored LEDs with low color separation or color fringes. The analysis of color enhancement and collimation features of the multi-colored LEDs with different periodic microstructure on the top surface of the TIR lens is presented.

Analysis of stereo depth for 3D LED autostereoscopic displays based on physiological limitations

Shu An, Graduate School at Shenzhen, Tsinghua Univ. (China); Ping Su, Graduate School at Shenzhen Tsinghua Univ (China); Zehao He, Jianshe Ma, Graduate School at Shenzhen, Tsinghua Univ. (China)

Stereo depth is the most important factor for the 3D experience when viewing an autostereoscopic display. In this paper, we investigate the influence of viewing distance and viewing angle to the stereo depth . First, we build the ideal stereo depth model based on the physiological limitation. Second, we establish a wave aberration model based on diffraction theory. The simulation and experimental results agree with the theoretical analyses. The model is of significant importance for giving a guidance on display system designing.

10378-31, Session PWed

The fabrication and performance of laser light engine used in next-generation laser projector system

Yung-Peng Chang, National Chung Hsing Univ. (Taiwan) and Taiwan Color Optics, Inc. (Taiwan); Jin-Kai Chang, National Sun Yat-Sen Univ. (Taiwan); Wei-Chih Cheng, Taiwan Color Optics, Inc. (Taiwan); Chun-Nien Liu, Wood-Hi Cheng, National Chung Hsing Univ. (Taiwan)

A laser projector system usually includes a laser light engine (LLE) module The LLE module consists of optical mirrors, diffuser glasses, blue laser diode, and color phosphor. The color phosphor is a key component in the LLE module which consists of a micro motor and two glass-based yellow and green phosphor-converted layers. The conversion layers of the yellow Ce:YAG and green Ce:LuAG phosphors are bonded on an aluminum substrate. A blue laser array source is used to excite the color phosphpr and then release yellow and green lights. Then, the combinations of blue, yellow, and green lights become white-laser light for use in the LLE module. In this study, the fabrication of LLE with two glass-based yellow and green phosphor-converted layers is presented. The optical performance of the LLE including lumen, lumen efficiency, chromaticity, and transmission is detailed discussion. This study demonstrates the adapting glass as a phosphor-converted color phosphor in the LLE modules that provide high-reliability and better performance for use in the next-generation laser projector system.

10378-32, Session PWed

Light box for investigation of characteristics of optoelectronics detectors

Agnieszka Szreder, Gdansk Univ. of Technology (Poland)

In this paper, a light box for investigation of characteristics of optoelectronic detectors is described. The light box consists of an illumination device, an optical power sensor and a mechanical enclosure.

The illumination device is based on four types of high-power light emitting diodes (LED): white light, red, green and blue. The illumination level can be varied for each LED independently by the driver and is measured by optical power sensor. The mechanical enclosure provides stable mounting points for the illumination device, sensor and the examined detector and protects the system from external light, which would otherwise strongly influence the measurement results. Uniformity of illumination distribution provided by the light box for all colors is good, making the measurement results less dependent on the position of the examined detector.

The response of optoelectronic detectors can be investigated using the developed light box for each LED separately or for any combination of up to four LED types. As the red, green and blue LEDs are rather narrow bandwidth sources, spectral response of different detectors can be examined for these wavelength ranges.

The described light box can be used for different applications. Its primary use is in a student laboratory setup for investigation of characteristics of optoelectronic detectors. Moreover, it can also be used in various colorimetric or photographic applications. Finally, it will be used as a part of demonstrations from the fields of vision and color, performed during science fairs and outreach activities increasing awareness of optics and photonics.

Smart street lighting solution for remote rural areas of India

Debdyut Hajra, B.P. Poddar Institute of Management & Technology (India)

Though many smart street lighting solutions are available for urban areas, comparatively fewer solutions exist for rural areas. In the recent times, village streets have been illuminated with artificial lights as a part of rural development drive undertaken by the governments of respective countries. But, vehicle and pedestrian traffic is quite low through village roads. Hence, if light remains on all night long on such roads, then there is a huge wastage of energy. This calls for solutions to reduce this energy loss in an efficient manner. There are a lot of factors which must be kept in mind while designing solutions. Many villages lack the proper infrastructure to support new technologies. Communication facilities are limited, lack of local technically skilled labor, lack of security, etc. After evaluating these opportunities and challenges, an attempt has been made to devise a smart street lighting solution tailored for remote rural areas in India. One part of the solution discusses how intensity of the LED street lights can varied according to the ambient lighting conditions using sensors and LED switching in LED matrix. An artificial intelligence (AI) has also been modelled to identify traffic conditions using PIR sensors and object identification through image processing and independently control the lights. It also tracks the performance and status of each light. It would send this data and necessary notifications to a distant control center for human evaluation. This solution is also applicable for other rural areas throughout the world.

High-speed modulation of GaN-based light-emitting diode with embedded photonic crystals

Zi-Xuan You, Tung-Ching Lin, Jian-Jang Huang, National Taiwan University (Taiwan)

Using GaN-based light-emitting diodes (LEDs) as a radio source for visible light communication (VLC) is one of alternative choice in a high-speed data system. However, the spontaneous radiative recombination lifetime in the multiple quantum wells (MQWs) usually restrict the modulation bandwidth of LEDs. For LEDs accompanied photonic crystal (PhC) structure, the guided photonic modes can be extracted with a shorter radiative recombination lifetime; therefore improve the performance of the devices for VLC. In this paper, we compare various PhC structures with corresponding dynamic behaviors in both small- and large-signal modulation. Faster transient responses and higher efficiency of the out-coupled modes were obtained in the room-temperature time-resolved photoluminescence (TRPL) and Raman scattering measurement. Here, sub-GHz modulation of GaN-based PhCLED is demonstrated, and the PhCLED exhibits a higher bandwidth than the conventional LED structure. Our study also indicates that we can not just keep scaling down the masa size of LEDs to increase the operation frequency owing to the light output power may become dull and reduce the performance of VLC system.

Conference 10379: Nonimaging Optics: Efficient Design for Illumination and Solar Concentration XIV

Sunday - Monday 6 –7 August 2017

Part of Proceedings of SPIE Vol. 10379 Nonimaging Optics: Efficient Design for Illumination and Solar Concentration XIV

10379-3, Session 1

Étendue and angular acceptance of the asymmetric compound parabolic concentrator

Melissa N. Ricketts, Roland Winston, Jonathan Ferry, Univ. of California, Merced (United States)

While the use of the asymmetric compound parabolic concentrator (ACPC) for solar concentration has been addressed, documentation regarding the étendue and angular acceptance of the ACPC is absent from the literature. This paper delves into the 2D design of the ACPC and discusses its étendue and angular acceptance, offering a new design tool regarding such instances when symmetry is broken. It is found that unlike the compound parabolic concentrator (CPC) whose angular acceptance fills a symmetric ellipse, the ACPC's angular acceptance fills an asymmetric ellipse in some cases, and a folded ellipse in others. Both cases are dependent on the maximum acceptance angles of the design. Ray tracing is utilized to confirm both the angular acceptance ellipses and étendue, as well as to offer a visual representation of the intensity distribution for asymmetric designs in both angular and phase space.

10379-4, Session 1

How the Hilbert integral theorem inspired flowlines

Roland Winston, Lun Jiang, Univ. of California, Merced (United States)

The connection of the Hilbert integral theorem to nonimaging optics appears in the first book on the subject. (Welford and Winston, The optics of the nonimaging concentrators). The flowline design method in nonimaging optics came much later. We discuss in this talk the over arching connection between the two.

10379-2, Session 2

Why do we still care about CPV?

Marco Stefancich, Dubai Electricity and Water Authority (United Arab Emirates); Matteo Chiesa, Harry N. Apostoleris, Masdar Institute of Science & Technology (United Arab Emirates)

With PV module prices low and flat-plate technology dominating the market, the industry has taken a hard turn away from concentrator systems. This is unsurprising as CPV involves higher up-front costs and large balance of system, including dual-axis tracking and in some cases active cooling, and on-site output is compromised by factors including optical losses, spectral effects and soiling to a greater extent that flat-plate systems. Despite this, we believe that concentrators still have a role to play in the long-term sustainability of the PV sector, but these advantages are best realized by aggressively rethinking the way we design PV concentrators. Here we argue, based on an analysis of manufacturing, material supply and end-of-life issues, that CPV can mitigate the negative environmental affects associated with PV manufacturing and disposal. This will likely be the primary justification for concentrators going forward, and it addresses a major challenge which has not yet been fully confronted by the industry, as the amount of PV in production and use has been quite small until recently, and large-scale module retirement is still some years away. We propose a number of module solutions utilizing low-concentration optics, tracking integration and light splitting which can remove the cost barriers to CPV while retaining its positive sustainability impact.

10379-5, Session 2

Optical performance effects of the misalignment of nonimaging optics solar collectors

Jonathan Ferry, Melissa N. Ricketts, Roland Winston, Univ. of California, Merced (United States)

The use of nonimaging optics in the application of high temperature solar thermal collectors can be extremely advantageous in eliminating the need to track the sun. The stationary nature of nonimaging optics collectors, commonly called external compound parabolic concentrators (XCPC's), present a unique design challenge when orienting them to collect sunlight. Many facilities throughout the world that adopt XCPC's are not situated to orient the collectors in the ideal angle facing the sun. This North-South misalignment can adversely affect the optical and power performance of the XCPC collector. To characterize how this misalignment effects XCPC's, raytracing simulations are conducted for varying offset angles of the collectors from the North-South plane. Optical performance is analyzed for multiple nonimaging optics designs accounting for the daily and seasonal movement of the sun in the sky. These results are compared to an ideal compound parabolic concentrator (CPC) with no angular misalignment from the North-South plane. Using the CPC as a baseline, a correlation between angular misalignment and seasonal optical performance is determined.

10379-6, Session 2

Optimization of photovoltaic V-Trough concentrators through genetic algorithms based on the interactions with beam radiation

Andrés Arias-Rosales, Ricardo Mejía-Gutiérrez, Univ. EAFIT (Colombia)

V-Trough concentrators use simple and low-cost non-imaging optics, namely flat mirrors, to boost the performance of regular solar cells. To improve their collecting power, the geometrical parameters can be explored for specific radiation and tracking conditions. Given the amount of possible configurations, and the interdependence of the parameters involved, genetic algorithms are a suitable approach to navigate the space of possible solutions. This work performs a V-trough study through such algorithms with unprecedented design flexibility, since the parameters, such as lengths and tilting angles, can be individually defined as static or as dynamic in function of the solar elevation. This allows the assessment of novel V-trough configurations, such as asymmetric mirrors with tracking tilting or sliding. The genetic algorithms, based on an analytical beam radiation model, were designed with several modalities: Maximization of the effective optical concentration or the cost-effectiveness; minimization of the cost or the space needed to fulfill a given energy need; or multi-objective. The capacities of these algorithms are explored in a case study and different heuristics within the genetic functions are assessed. For the same case study, the set-ups obtained with the convergence of the algorithms are then compared against set-ups designed through an interactive software. This comparison suggests that genetic algorithms, such as the ones developed in this work, are effective tools for defining the V-Trough geometrical parameters under personalized conditions. The genetic solutions can be as competitive as the ones achieved by a qualified engineer with an interactive simulation software.

10379-7, Session 2

Broadband angular selectivity in solar concentrators

Harry N. Apostoleris, Masdar Institute of Science & Technology (United Arab Emirates); Yichen Shen, Duncan C. Wheeler, Thomas A. Cooper, Massachusetts Institute of Technology (United States); Matteo Chiesa, Masdar Institute of Science & Technology (United Arab Emirates); Marin Soljacic, Massachusetts Institute of Technology (United States)

In designing solar concentrator optics there are many parameters that must be optimized in order to create a useful system, such as compactness, number of elements or interfaces, and acceptance angle, among others. Using geometric optics, tradeoffs between these parameters become inevitable. For example, a lens, trough or dish may be compact but has low tolerance of angular misalignment; angular tolerance can be improved by adding secondary and tertiary optics, but this increases complexity and reduces optical throughput; nonimaging optics such as the CPC offer wide acceptance angles from as single element, but are too long to be practical, in most applications, above low concentrations. These tradeoffs can be avoided by using angle-selective photonic materials to exploit the equivalence between angular restriction and concentration. Recently, broadband angular selectivity in optical films has been demonstrated by the Soljacic group in MIT. In this collaborative work we use this material to experimentally demonstrate two visible-spectrum optical concentrators. We demonstrate that these concentrators are thermodynamically ideal when the material properties are ideal, and describe the material improvements most essential for improving device performance, and discuss how commercial solar concentrator systems could be improved by the use of angular-selective optics

10379-8, Session 3

Testing light concentrators prototypes for the Cherenkov Telescope Array

François B. Hénault, Pierre-Olivier Petrucci, Laurent Jocou, Institut de Planétologie et d'Astrophysique de Grenoble (France)

The Cherenkov Telescope Array (CTA) shall be the largest cosmic gamma ray detector ever built. Each MST focal plane consists in an array of 2000 photomultipliers equipped with their own light concentrating optics. Within the CTA Consortium, IPAG is in charge of designing, subcontracting the realization to industry, and testing CTA light concentrators. Prototypes were manufactured by different industrial companies and tested in our laboratory on a test bench specifically built for the project. Each type of concentrator has been submitted to extensive performance measurements, including radiometric efficiency at different wavelengths and rejection curves. The final selected concentrator is the CPC, although non-imaging lenses exhibit interesting radiometric performance

10379-9, Session 3

Synthesis of freeform refractive surfaces forming various radiation patterns using interpolation

Iana Mazur, Anna O. Voznesenskaya, Pavel Krizskiy, ITMO Univ. (Russian Federation)

Optical freeform surfaces are very popular today in such fields as lighting systems, sensors, photovoltaic concentrators, and others. The application of such surfaces allows to obtain systems with a new quality with a reduced number of optical components to ensure high consumer characteristics: small size, weight, high optical transmittance. This article presents the methods of synthesis of refractive surface for a given source and the radiation pattern of various shapes. The light beams of rays coming from the source passes through the optical element and form the radiation pattern of the necessary shape. Calculation of the refractive surface is reduced to solving the integrated differential equation, which uses a refractive index, the function describes of a given radiation pattern, the direction vector of the beam and the function characterizing the distance from the refracting plane to the origin. This algorithm is implemented for the refracting optical free-form element, using the Matlab program. The outcome is a set of points, which belong to the free-form surface, approximating them, we will get the necessary element. This was done with the help of a computer simulation of a freeform surface a cubic spline interpolation. Interpolation algorithm was implemented in C ++. The result is a 3-D profile of the required optical component.

10379-10, Session 3

Designing freeform reflectors using new source-target mapping method

Egor V. Byzov, Leonid L. Doskolovich, Evgeniy S. Andreev, Nikolay L. Kazanskiy, Image Processing Systems Institute, Russian Academy of Sciences (Russian Federation) and Samara Univ. (Russian Federation)

In this paper a new kind of source-target map for design mirrors generating prescribed two-dimensional line-shaped intensity distributions is presented. Line-shaped means that distribution is defined in region with a high aspect ratio, obtained from the line by direct replacement for each point on the segment perpendicular to the reference. This map is a generalization of the mapping, used in the well-known problem of reflective optical elements design generating one-parameter intensity distributions. Design examples show high performance of the proposed method, including for areas with a small aspect ratio. For rectangular and elliptical intensity distributions with

angular dimensions from 80°x20° to 40°x20° the relative standard error does not exceed 8.5%

10379-11, Session 3

Efficiency of geometric designs of non-tracing flexible solar panels: Mathematical simulation

Malgorzata Marciniak, Yasser Y. Hassebo, LaGuardia Community College (United States); Delfino Enriquez, Maria-Ignacia Serey-Roman, LaGuardia Community College, The City Univ. of New York (United States)

The purpose of this study is to analyze various surfaces of flexible solar panels and compare them to the traditional flat panels mathematically. We evaluated the efficiency based on the integral formulas that involve flux. We performed calculations for flat panels with different positions, a cylindrical panel, conical panels with various opening angles and segments of a spherical panel. Our results indicate that the best efficiency per unit area belongs to particular segments of spherically-shaped panels. In addition, we calculated the optimal opening angle of a cone-shaped panel that maximizes the annual accumulation of the sun radiation per unit area.

10379-12, Session 4

Shaping and homogenization of LED white light using aperiodic scattering cell arrays

Daniel Asoubar, Roberto Knoth, Hagen Schweitzer, LightTrans International UG (Germany); Frank Wyrowski, Huiying Zhong, Friedrich-Schiller-Univ. Jena (Germany)

Shaping of LED white light is of increasing interest for several industrial applications. There are several known design concepts available. However these concepts suffer from high uniformity errors, low efficiencies, chromatic aberrations and/or high tolerance sensitivity. To overcome these limitations we present a novel design concept which is based on the design of aperiodic scattering cell arrays. In a first design step, a unit scattering cell is designed. Afterwards this cell is periodically replicated. Finally the periodicity of the array is broken using parametric optimization. Obtained design results are compared with experimental data.

10379-13, Session 4

Compact collimators designed with a modified point approximation for light-emitting diodes

Tao Luo, Gang Wang, Sun Yat-Sen Univ. (China)

The refraction-internal reflection-reflection-refraction (RIXR) type lens which has been designed by SMS method is an ultra-compact collimator very close to ideal concentrator. However, the shapes of the lens are also sensitive to design conditions and all the curves designed are formed automatically and can't be pre-determined.

We present a novel freeform lens design method for an application to LED collimating illumination. A modified compact collimating lens design with point source approximation is presented to form compact air-gap RIXR type collimators. Two freeform surface of the lens are constructed simultaneously, with the point source approximation to get uniform luminous exitance at the exit surface. The method is derived from a basic geometric-optics analysis and construction approach. By using this method, a compact collimated lenses with Aspect Ratio = 0.219 is presented. With optimization of initial parameters, a highly collimating lens with Cree XP-E LED and optical simulation efficiency of 83.06% under a view angle of ± 1.5 deg is constructed. Moreover, the utility efficiency (UE) inside the angle defined by ideal concentrator hypothesis with different lens-to-LED size ratios for both the lens in this paper and Total-internal-reflection (TIR) lenses are presented that the UE of the lens in this paper has improved to more than 90% with lens-to-LED size ratio larger than 16:1 and the "size effect" is restrained compared with traditional TIR lenses. A prototype of the collimator lens is also made to verify the practical performance of the lens, which has light distribution very compatible with the simulation results.

10379-14, Session 4

Control of ray deflection angles in the design of secondary optics with multiple surfaces

Sergey V. Kravchenko, Kseniya V. Andreeva, Samara Univ. (Russian Federation) and Image Processing Systems Institute, Russian Academy of Sciences (Russian Federation); Mikhail A. Moiseev, Image Processing Systems Institute, Russian Academy of Sciences (Russian Federation) and Samara Univ. (Russian Federation); Leonid L. Doskolovich, Image Processing Systems Institute (Russian Federation) and Samara Univ. (Russian Federation)

The use of LEDs in the modern lighting devices makes the problem of designing secondary optics quite relevant. For the purpose of street, industrial and emergency lighting optical elements with two free-form surfaces are usually used. In this study the method for computation of such LED optics is proposed. In this approach the optical element surfaces are designed sequentially: firstly the inner surface is computed and then the outer one. At the beginning of each surface computation a piecewise smooth solution should be designed. Such a surface generates discrete intensity distribution that approximates the continuous one. In order to compute piecewise smooth solution we propose to utilize the supporting quadric method. After we have had piecewise smooth surface the smooth one is obtained by fitting NURBS-spline on it. Such a method allows controlling the balance of deflection angles between the inner and outer surfaces. It has been proven that in the case of point source, the maximal efficiency is obtained when each surface performs the half of the required ray deflection. As an example, the optical element with equal ray deflection part in each surface generating intensity distribution for ME1 class roadway lighting is designed. The simulation results of the luminance and illuminance distribution confirm good quality of the proposed method.

10379-1, Session 5

Thermodynamic foundation of nonimaging optics

Lun Jiang, Roland Winston, Univ. of California, Merced (United States)

Nonimaging Optics is the theory of thermodynamically efficient optics and as such depends more on thermodynamics than on optics. Hence in this paper a condition for the "best" design is proposed based on purely thermodynamic arguments, which we believe has profound consequences for the designs of thermal and even photovoltaic systems. This new way of looking at the problem of efficient concentration depends on probabilities, the ingredients of entropy and information theory while "optics" in the conventional sense recedes into the background. Much of the paper is pedagogical and retrospective. Some of the new development of flowline designs will be introduced at the end and the connection between the thermodynamics and flowline design will be graphically presented. We will conclude with some speculative directions of where the new ideas might lead.

10379-16, Session 5

Thermodynamic investigation of segmented CPC

Bennett K. Widyolar, Univ. of California, Merced (United States)

A new parameter Flux Efficiency (FE), which combines concentration ratio and optical efficiency, is introduced which directly relates to the maximum achievable flux on the absorber and allows comparison between ideal and non-ideal concentrators. The effect of approximating curved CPC profiles by a finite number of flat segments on the Incident Angle Modifier (IAM), optical efficiency, and newly defined Flux Efficiency is presented, providing new considerations for designing geometric concentrators under real world constraints.

10379-28, Session 5

Advances on geometric flux optical design method *(Invited Paper)*

Ángel García-Botella, Univ. Politécnica de Madrid (Spain); Antonio A. Fernandez-Balbuena, Daniel Vázquez-Moliní, Univ. Complutense de Madrid (Spain)

Nonimaging optics is focused on the study of methods to design concentrators or illuminators systems. It can be included in the area of photometry and radiometry and it is governed by the laws of geometrical optics. The field vector method, which starts with the definition of the irradiance vector E, is one of the techniques used in nonimaging optics. Called “Geometrical flux vector” it has provide ideal designs. The main property of this model is, its ability to estimate how radiant energy is transferred by the optical system, from the concepts of field line, flux tube and pseudopotential surface, overcoming traditional raytrace methods. Nevertheless this model has been developed only at an academic level, where characteristic optical parameters are ideal not real and the studied geometries are simple. The main objective of the present paper is the application of the vector field method to the analysis and design of real concentration and illumination systems. We propose the development of a calculation tool for optical simulations by vector field, using algorithms based on Fermat`s principle, as an alternative to traditional tools for optical simulations by raytrace, based on reflection and refraction law. This new tool provides, first, traditional simulations results – efficiency, illuminance/irradiance calculations, angular distribution of light- with lower computation time, photometrical information needs about a few tens of field lines, in comparison with million rays needed nowadays. On the other hand the tool will provides new information as vector field maps produced by the system, composed by field lines and quasipotential surfaces. We show our first results with the vector field simulation tool.

10379-29, Session 5

Point to point multispectral light projection applied to cultural heritage

Daniel Vázquez-Moliní, Antonio A. Fernandez-Balbuena, Univ. Complutense de Madrid (Spain); Ángel García-Botella, Univ. Politécnica de Madrid (Spain)

Regarding cultural heritage preservation and exhibition of art goods it is necessary to take into account social, cultural and economic needs that show opposing requirement. The use of new of light sources based on LED technology should allow the develop of systems that combine both requirements and allow to make these art goods available to the next generations according to sustainability principles. The goal of this work is to develop light systems and sources with an optimized spectral distribution for each specific point of the art piece. This optimization process implies to maximize the color fidelity reproduction and the same time to minimize the photochemical damage. Perceived color under these sources will be similar (metameric) to technical requirements given by the restoration team uncharged of the conservation and exhibition of the goods of art. Depending of the fragility of the exposed art objects (i.e. spectral responsivity of the material) the irradiance must be kept under a critical level. Therefore, it is necessary to develop a mathematical model that simulates with enough accuracy both the visual effect of the illumination and the photochemical impact of the radiation. Spectral reflectance of a reference painting The mathematical model is based on a merit function that optimized the individual intensity of the LED-light sources taking into account the damage function of the material and color space coordinates. Moreover the algorithm used weights for damage and color fidelity in order to adapt the model to a specific museal application. In this work we show a sample of this technology applied to a picture of Sorolla (1863-1923) a important Spanish painter title “woman walking at the beach”.

10379-17, Session 5

The error tolerance of nonimaging optic systems

Ali Hassanzadeh, Bennett K. Widyolar, Lun Jiang, Roland Winston, Univ. of California, Merced (United States)

In real world applications the nonimaging optics has the advantage of high error tolerance compared to conventional imaging optics. In this paper we present the result of a solar collector constructed with the nonimaging optics principles and the effect of off-positioning its absorbers on its optical efficiency. Thermal analysis of such effects are also presented.

10379-18, Session 5

Tracking and shape errors measurement of concentrating heliostats

Mathieu Coquand, Institut de Planétologie et d’Astrophysique de Grenoble (France) and PROMES-CNRS (France); Cyril Caliot, PROMES-CNRS (France); François B. Hénault, Institut de Planétologie et d’Astrophysique de Grenoble (France)

In solar tower power plants, the tracking accuracy, facets misalignment and surface shape errors of concentrating heliostats are of prime importance on the efficiency of the system. Methods enabling quick adjustment of a field with a huge number of heliostats are essential for the rise of solar tower technology. In this communication is described a new method for heliostat characterization that makes use of four cameras located near the solar receiver and simultaneously recording images of the sun reflected by the optical surfaces. Data processing then allows reconstructing the shape errors of the heliostats, including tracking and canting errors. The mathematical basis of the process is explained. Numerical simulations demonstrate that the measurement accuracy of this method is compliant with the requirements of solar concentrating optics. Finally, we present our first experimental results obtained on the THEMIS experimental solar tower plant.

10379-19, Session 5

Optimizing luminescent solar concentrators *(Invited Paper)*

Boaz Ilan, Univ. of California, Merced (United States)

This talk will review some of the challenges in making efficient luminescent solar concentrators, the modeling efforts, and how to optimize the performance of these devices.

10379-20, Session 5

Enhancing the light conversion efficiency in a luminescent solar concentrator by using a prism film

Pao-Keng Yang, Hua-Yu Tseng, Chia-Wei Lin, Min-Hsiu Chung, Tsung-Wei Huang, Minghsin Univ. of Science and Technology (Taiwan)

We present a method for enhancing the light conversion efficiency of a luminescent solar concentrator by putting a prism film on the upper surface for receiving the incoming light. The luminescent solar concentrator under study was composed of a thick glass with a luminescent film deposited on the top surface and a solar cell attached to the lateral surface. The prism film will deflect the incident light into two different directions. Dependence of the conversion efficiency on the incident angle of the sunlight and influence of the rotation of the prism film on the conversion efficiency were also investigated. Experimental results show that the prism film will increase the light falling on the solar cell in our luminescent solar concentrator.

10379-21, Session 5

The characteristics of luminescent solar concentrators (LSCs) using inorganic phosphors

Shang-Ping Ying, Bing-Mau Chen, An-Ting Li, Minghsin Univ. of Science and Technology (Taiwan)

The Luminescent Solar Concentrator (LSC) consists of a transparent plate with solar cells on one or more sides. The incoming sunlight is absorbed by the luminescent dyes or particles, which are embedded in the transparent plate or applied in a film on the top or bottom of the transparent plate. The absorbed light is re-emitted at a longer wavelength, and part of the re-emitting light is trapped in the transparent plate by total internal reflection (TIR). Then the solar cells attached to the edges of the transparent plate would collect the light and convert it to electricity. However, the luminescent dyes or particles used in the conventional LSC still suffer from reduced efficiencies and lifetimes, then the inorganic phosphors with relatively high quantum yields, good absorption properties and longer lifetime could be alternative materials used in the structure. In this study, the ray-tracing simulation is used to investigate the optical characteristics of the LSC with the inorganic phosphors embedded film on the top or bottom of the transparent plate. The simulation results will also be used to study the loss mechanisms in the LSC with inorganic phosphors embedded film.

10379-22, Session PMon

Optimization design of nonimaging Fresnel lens using total internal reflection prisms for light concentration

Perla M. Viera-González, Guillermo E. Sánchez-Guerrero, Edgar Martínez-Guerra, Univ. Autónoma de Nuevo León (Mexico); Daniel Enrique Ceballos-Herrera, Univ. Nacional Autónoma de México (Mexico)

The efficiency in Fresnel lenses is affected by three principal sources: energy lost due to material absorption; geometric losses such as chromatic dispersion or surface roughness; and reflectance losses at refracting surfaces. On this subject, the design of nonimaging Fresnel lenses integrated by refractive and total internal reflection (TIR) prisms is presented. This design method uses iterative calculations for design every prism and it selects the best option to avoid reflectance losses. An example of a Fresnel lens design and characterization is shown, including its spatial and angular distribution, and a comparison with a nonimaging Fresnel lens composed only by refraction prisms is performed, having as result the analysis of the cases when the TIR increases the efficiency of the Fresnel lenses. In addition, the study about how acceptance angle of the lens affects the iteration method in the selection of the prism with the minimal lost is included.

10379-23, Session PMon

Numerical analysis of lateral illumination lightpipes using elliptical grooves

Guillermo E. Sánchez-Guerrero, Perla M. Viera-González, Edgar Martínez-Guerra, Univ. Autónoma de Nuevo León (Mexico); Daniel Enrique Ceballos Herrera, Univ. Nacional Autónoma de México (Mexico)

Lightpipes are used for illumination in applications such back-lighting or solar cell concentrators due to the high irradiance uniformity, but its design requires several parameters. This work presents a procedure to design a square lightpipe that control the area of emission on its lateral face using commercial LEDs placed symmetrically in the lightpipe frontal face. We propose the use of grooves using total internal reflection placed successively in the same face of extraction to control the area of emission. The LED area of emission is small compared with the illuminated area, and, as expected, the lateral face total power is attenuated. These grooves reduce the optical elements in the system and can control areas of illumination. A numerical analysis is presented to show how the selected parameters affect in the area to illuminate.

10379-24, Session PMon

Design and manufacturing of cascaded DCG based holograms for spectrum-splitting PV systems

Yuechen Wu, Benjamin D. Chrysler, Silvana Ayala Pelaez, Raymond K. Kostuk, The Univ. of Arizona (United States)

In this work the technique of designing and manufacturing broad band volume transmission holograms using dichromate gelatin (DCG) is summarized for solar spectrum-splitting application. Spectrum splitting photovoltaic system uses a series of single bandgap PV cells that have different spectral conversion efficiency properties to more fully utilize the solar spectrum. In such a system, one or more high performance optical filters are usually required to split the solar spectrum and efficiently send them to the corresponding PV cells. An ideal spectral filter should have a rectangular shape with sharp transition wavelengths. DCG is a near ideal holographic material for solar applications as it can achieve high refractive index modulation, low absorption and scattering properties, and long term stability to solar exposure after sealing. In this research, a methodology of designing and modeling a transmission DCG hologram using RCWA for different PV bandgap combinations is described. To achieve a broad diffraction bandwidth and sharp cut-off wavelength, a cascaded structure of multiple thick holograms are used. Material and processing factors that are taken into consideration for the optimization process include: the grating variation during the wet development process, the film thickness, the grating vector, the index modulation, and the average and differential swelling. A set of experiments are also described to verify the design principles and optimization model.

10379-25, Session PMon

Impact of internal forced air cooling on radiative absorption of a gas-particle medium in a small particle solar receiver

James O'Hara, San Diego State Univ. (United States)

A high output solar receiver utilizing a specifically developed infrared-absorbing, air-particle mixture as the working fluid is being developed for a power plant. Solar radiation, redirected and focused by a heliostat field is concentrated into the receiver and absorbed by a "black" air particle mixture with flows through the receiver. The exiting mixture, now superheated, serves as the input to a gas turbine in a Brayton power cycle. Current efforts pertain to cooling of the receiver window as high levels of incident radiation heat the window directly through absorption within the glass and indirectly as the participating air-particle gas mixture serves to heat the internal face of the window beyond the material limits. The solution to lowering the operating temperature of the receiver window without sacrificing power level and system performance is to internally cool the internal surface of the window with jets of air. The cooling air mixes with the gas-particle mixture and has the effect of changing the optical path through the receiver by temporarily displacing, and impacting the density uniformity of the absorbing medium in the receiver, thus lowering the total mass of "black" particles that are exposed to incident radiation. This has a direct impact on the absorption of the working fluid for a given mass flow and therefore impacts system efficiency. Computational fluid dynamics coupled with a radiation simulation is employed to predict the impact of the forced-air convection on different aspects: effectiveness of window cooling, change in optical path length within the absorbing air-particle medium, and overall receiver efficiency. Transient effects are also studied.

Optical coatings for luminescent solar concentrators

Cheng-Chung Jaing, Po-Chun Lu, Jian-Wei Chen, Wei-Gwo Yu, Jing-Han Xie, Pao-Keng Yang, Bing-Mau Chen, Minghsin Univ. of Science and Technology (Taiwan)

In this paper, the luminescent solar concentrator comprises a thick glass with a spectrally-selective optical coating deposited on the bottom surface and an inorganic phosphor layer stacked on the coating surface. A solar cell is attached to the lateral surface of the thick glass. Spectrally-selective coatings are applied to reflect and redirect the invisible solar radiation to the edges of luminescent solar concentrators. These coatings also transmit the visible solar light and the emission light of the inorganic phosphor. The short-circuit current of the solar cell is measured in a solar simulator with metal-dielectric heat mirrors and dielectric edge filters coated on the thick glass of the luminescent solar concentrators respectively. Experimental results show that the dielectric edge filter will increase the short-circuit current and the invisible light falling on the solar cell in our luminescent solar concentrator. The metal-dielectric coatings, silver-based transparent heat mirrors, will not increase the short-circuit current in our luminescent solar concentrator due to absorption of metal films.

10379-30, Session PMon

Real time 3D photometry

Antonio A. Fernandez-Balbuena, Daniel Vázquez-Moliní, Univ. Complutense de Madrid (Spain); Ángel García-Botella, Univ. Politécnica de Madrid (Spain); Jesus Romo, Valeo (Spain)

The photometry and radiometry measurement is a well-developed field. The necessity of measuring designed systems involve the use of several techniques like gonio-photometry. Actual goniophotometer are a precise measurement tool that is used in the lighting area like head car lighting, concentrator and collimator measurement and all the designed and fabricated optical systems that works with light.

There is one disadvantage in this kind of measurements that try to obtain the intensity polar curves and the total flux of the optical system. In the industry, there are good goniophotometers that are precise and reliable but they are very expensive and the measurement time is long. In industry the cost can be of minor importance but measuring time that is around 30 minutes is of major importance due to trained staff cost.

We have designed a system to measure photometry in real time, it consists in a curved screen to get a huge measurement angle and a CCD. The system to be measured projects light onto the screen and the CCD records a video of the screen obtaining an image of the projected profile.

A complex calibration permits to trace screen data (x,y,z) to intensity polar curve (I,??). This intensity is obtained in candels (cd) with an image + processing time below one second.

Conference 10380: Ultrafast Nonlinear Imaging and Spectroscopy V

Sunday - Monday 6 –7 August 2017

Part of Proceedings of SPIE Vol. 10380 Ultrafast Nonlinear Imaging and Spectroscopy V

10380-1, Session 1

Effects of cations and cholesterol with sphingomyelin membranes Investigated by high-resolution broadband sum frequency vibrational spectroscopy *(Invited Paper)*

Zhen Zhang, Yi-Yi Li, Rong-Juan Feng, Li-Li Lu, Yuan Guo, Institute of Chemistry, Chinese Academy of Sciences (China)

Sphingomyelin(SM) is specifically enriched in the plasma membrane of mammalian cells. Its molecular structure is compose by N-acyl-Derythro-sphingosylphosphorylcholine. The function of the SM related to membrane signaling and protein trafficking are relied on the interactions of the SM, cations, cholesterol and proteins. Therefore, the new techniques has to be applied to probe the detailed interactions of the molecules. In this report, the interaction of three different nature SMs, cations and cholesterol at air/aqueous interfaces are investigated by high-resolution broadband sum frequency vibrational spectroscopy(HR-BB-SFG), respectively. The Effects on the hydration of the headgroup and ordering of the alky chain of the SMs influenced by cations and cholesterol are studied systematically. Firstly, we focused on the sphingomyelin in the presence and absence of Ca2+, Na+ and K+ to characterize the specificity of cation binding to the headgroup of the sphingomyelin membranes in terms of molecular structure and the hydration. Secondly, we studied the sphingomyelin structural change in the present of different ratio of cholesterol, which reveals the role of hydrogen bonding in cholesterol's association with SM. Overall, the results demonstrate the importance of using HR-BB-SFG that can probe the nanoscale molecular interaction mechanism of SMs and cations and cholesterol are discussed in this report. Our results shed lights on understanding the relationship on the interactions of complex molecules at surfaces and interfaces.

10380-2, Session 1

High resolution vibrational sum frequency generation spectroscopy revealing new properties of the complex interfacial molecular systems: Spectral splitting, molecular symmetry, and supramolecular chirality *(Invited Paper)*

Zhou Lu, Yi-Yi Li, Rongjuan Feng, Jian Hou, Yingxue Ma, Zhen Zhang, Yuan Guo, Minghua Liu, Institute of Chemistry, Chinese Academy of Sciences (China)

The vibrational sum frequency generation spectroscopy (VSFG) has recently become a versatile characterization tool for the molecular interfaces owing to its unique surface selectivity and submonolayer sensitivity. In the past years, the applications of the VSFG technique have expanded into various research fields including biological sciences, environmental chemistry, heterogeneous catalysis, electrochemistry, and etc. However, the limited spectral resolution in the traditional VSFG techniques has hampered its further efforts to reveal the molecular details of the complex interfacial molecular systems. In this presentation, we will discuss the most recent progresses of our newly developed high resolution VSFG (HR-VSFG) spectrometer. With a 50-picosecond visible laser pulse synchronized and phase-locked with a ~35 femtosecond broadband infrared pulse, we can ultimately achieve a spectral resolution of <0.5 wavenumber using this HR-VSFG setup. The unprecedented high resolution, together with the powerful VSFG polarization dependent analysis, has enabled us to resolve the unpredicted spectral splitting for the commonly studied interfacial molecules. Assisted with the proper theoretical modeling, we can further infer the new molecular symmetry models used to describe the interfacial vibrational modes. These new spectroscopic data has helped bring new insights about the interfacial properties of the complex molecular systems such as the phospholipid membranes and macromolecular interfaces. The examples of new HR-VSFG studies on the interfacial supramolecular chirality will also be discussed.

10380-3, Session 1

Second-harmonic generation in semiconductor nanostructures and applications *(Invited Paper)*

Kai Wang, Huazhong Univ. of Science and Technology (China)

Second-harmonic generation (SHG) is a fundamental second-order nonlinear optical process, and it is quite sensitive to the polarization angle of the pumping light with respect to the crystallographic orientation of materials. In our works, we systematically studied SHG in single ZnS nanowires (NWs). The results indicate that the SHG response is quite sensitive to the orientations of c-axis as well as the (100) and (010) crystal-axis of ZnS NWs, thus all the three crystal-axis orientations of ZnS NWs are precisely determined by the SHG method. Secondly, we demonstrate a highly sensitive detection of the lattice distortion in single bent ZnO nanowires (NWs) by SHG microscopy. A high detection sensitivity of 10-3 nm on the bending distortion is obtained in our experiment. Thus, SHG microscopy provides a sensitive all-optical and non-invasive method for in situ detecting the lattice distortion under various circumstances. Thirdly, we studied the enhanced SHG in the hybrid nanostructures that a single ZnS nanobelt was half covered with aluminum (Al) film, which is an ideal platform for studying the SHG enhancement effects of the Al coating. The results indicate that the Al coating in the hybrid nanostructures not only confines the pumping laser in the ZnS effectively, but also concentrates the emitted SHG signal greatly, increasing the signal collection efficiency. The Al-based hybrid nanostructures open up new possibilities for low-cost, highly efficient and directional coherent nano-light sources at short wavelength.

10380-4, Session 1

Observation of polar domains in metallic layered oxides *(Invited Paper)*

Gregory A. Stone, Shiming Lei, Ke Wang, The Pennsylvania State Univ. (United States); Danilo Puggioni, Northwestern Univ. (United States); Zhiqiang Mao, Tulane Univ. (United States); James M. Rondinelli, Northwestern Univ. (United States); Venkatraman Gopalan, The Pennsylvania State Univ. (United States)

Recent studies of the systems Ca3B2O7 (B = Ti, Mn), have experimentally confirmed hybrid improper ferroelectricity, a geometrically induced displacement route to inversion symmetry breaking, in layered oxides. This approach does not require B-sites with a d0 configuration opening up the possibility phase coexistence within a single material, such as polarity and metallicity in a single material system as proposed by Anderson and Blount over fifty years ago and recently observed in LiOsO3. Despite the large amount of literature available on ferroelectric domains and domain walls in insulating materials, there have been no such reports for a polar metal system. Using a combination of nonlinear optical second harmonic generation (SHG) microscopy and atomic scale imaging we report for the first time direct observation of polar domains and walls the metallic system Ca3Ru2O7. SHG maps show the existence of 180o walls and 90o degree walls (simultaneously ferroelastic) which meander throughout the system

giving rise to both charged and neutral walls. Atomic-scale transmission electron microscopy confirms hybrid improper ferroelectricity the mechanism responsible for the polar behavior in this material. TEM images also show the presence of unique domain wall interactions that transform uncharged walls into energetically unfavorable charged walls and the role defects have on the domain structure.

10380-5, Session 1

Nonlinear characterization of two dimensional materials

Alexander S. Cocking, William Murray, Kazunori Fujisawa, Pennsylvania State Univ. (United States); Anna Laura-Elias, The Pennsylvania State Univ. (United States); Mauricio Terrones, Zhiwen Liu, Pennsylvania State Univ. (United States)

Two-dimensional materials have attracted significant interest recently for their unique optical properties compared to their bulk counterparts. Specifically, the family of transition metal dichalcogenides (TMD), such as MoS2 and WS2, have large second order nonlinear susceptibility. Extraordinary second harmonic generation and sum frequency generation have been observed. Here we investigate the second order nonlinearity of 2D materials, including TMD layered materials with dopants and defects. Experimental results and preliminary theoretical analysis will be discussed.

10380-6, Session 2

Supercontinuum generation using longitudinal z-polarized vectorial beam *(Invited Paper)*

Wenkai Zhang, Beijing Normal Univ. (China)

Broadband laser sources based on supercontinuum generation in femtosecond laser have been widely used for time-resolved absorption spectroscopy, material characterization, pulse compression, signal processing, three-dimensional imaging, ranging, atmospheric remote sensing, and medical diagnosis. Supercontinuum is generally generated by the strong non-linear effect when the narrow spectrum light pulse propagates in the nonlinear medium. Supercontinuum was first found in glass, followed by the generation of supercontinuum in solids, liquids, gases, and waveguides. The spectral broadening caused by self-phase modulation is related to many factors such as peak power, polarization, pulse shape and initial chirp of the input pulse. Researchers have put a lot of effort to extend the applicability of the supercontinuum. Here, we report the supercontinuum generation using the longitudinal z-polarized vectorial beam. Unconventional polarization states, also known as "vector beams," have become increasingly compelling in recent years. As we know, the conventional polarization states, such as linear, circular or elliptical polarizations, can be uniquely described by a specific point on the surface of the Poincaré sphere. However, the vector beams have a spatial inhomogeneous polarization state, and therefore cannot be described by a point, but rather by a number of points on the Poincaré sphere. In this article, the effect of the different polarization states on supercontinuum generation is studied.

10380-7, Session 2

Tunable optical source based on divided pulse soliton self-frequency shift

Chenji Zhang, Pennsylvania State Univ. (United States); Victor Bucklew, Perry S. Edwards, Atoptix, LLC (United States); Corey Janisch, The Pennsylvania State Univ. (United States); Zhiwen Liu, Pennsylvania State Univ. (United States)

We presented a broadly tunable, power scalable, multi-line, ultrafast source. The source is based on combining principles of pulse division with the phenomenon of the soliton self-frequency shift. By using this system, interferometric pulse recombination is demonstrated showing that the source can decouple the generally limiting relationship between output power and center wavelength in soliton self-frequency shift based optical sources. Broadly tunable multi-color soliton self-frequency shifted pulses are experimentally demonstrated. Simultaneous dual-polarization second harmonic generation was performed with the source, demonstrating one novel imaging methodology that the source can enable.

10380-8, Session 2

Iteratively-seeded mode-locking for high performance ultrashort pulsed lasers *(Invited Paper)*

Victor Bucklew, Atoptix, LLC (United States); William Renninger, Yale Univ. (United States); Perry S. Edwards, Atoptix, LLC (United States); Zhiwen Liu, Pennsylvania State Univ. (United States)

Ultrashort pulsed mode-locked lasers with exceptional performance qualities (e.g. short temporal widths or high peak powers) are desired for applications ranging from biomedical imaging to materials processing. Despite rapid progress in source development, evidence suggests that performance limits anticipated theoretically have not yet been reached. In this talk, we review recent progress and help resolve the discrepancy by presenting a limit to mode-locked laser performance based on the route taken to reach the desired steady-state pulse solution instead of on the pulse solution itself. Furthermore, we introduce an iteratively seeded method of mode-locking that allows this limit to be surmounted.

10380-9, Session 2

High power fiber laser pumped femtosecond optical parametric resources *(Invited Paper)*

Jintao Fan, Minglie Hu, Tianjin Univ. (China)

Wavelength tunable femtosecond laser sources are of great importance in many applications. Series examples of such a source used optical parametric generator, optical parametric oscillator and optical parametric amplifier are presented in this report.

10380-10, Session 3

Ultrafast MeV electron diffraction/ microscopy at SLAC *(Invited Paper)*

Xiaozhe Shen, Renkai Li, Jie Yang, Stephen P. Weatherspy, Xijie Wang, SLAC National Accelerator Lab. (United States)

SLAC recently launched the ultrafast electron diffraction and microscopy (UED/UEM) Initiative, with the goal to develop the world's leading ultrafast electron scattering instruments, which are complementary with x-ray free-electron lasers such as LCLS and LCLS-II. The first step of the Initiative is a MeV UED system which is now actively supporting an ultrafast science program, and at the same time serving as a testbed for instrumentation development.

In this talk, design of the SLAC MeV UED system will be briefly introduced. Key machine performance parameters will be reviewed, including machine stability and reproducibility, as well as reciprocal-space and temporal resolution. Ultrafast dynamics from a variety of samples, including 2D materials, thin nanofilms, nanoparticles, and gas-phase molecules have

been studied using this machine. Selected ultrafast science experiment results will be presented. In the meantime, much R&D efforts have been devoted for novel machine capabilities to enable new science opportunities. For example, we have experimentally demonstrated a femtosecond MeV electron microdiffraction, which is capable to resolve local structure from single crystal of ?m lateral size with 100 fs root-mean-square temporal resolution. Future developments include 10-fs temporal resolution UED, THz pumping capability, etc. We will also discuss R&D towards the next step of the Initiative, which is to develop key technologies for future UEM with unprecedented combined spatial-temporal resolution. This R&D will focus on a superconducting radio-frequency photocathode gun, which features high accelerating field hence high beam brightness, excellent energy stability, and outstanding flexibility in bunch length from picosecond to a hundred picoseconds.

10380-11, Session 3

Ultrafast imaging of molecular dynamics with electron diffraction *(Invited Paper)*

Martin Centurion, Univ. of Nebraska-Lincoln (United States); Jie Yang, SLAC National Accelerator Lab. (United States); Markus Guehr, Univ. Potsdam (Germany); Xiaozhe Shen, Renkai Li, SLAC National Accelerator Lab. (United States); Omid Zandi, Kyle J. Wilkin, Univ. of Nebraska-Lincoln (United States); Theodore Vecchione, Ryan N. Coffee, Jeff Corbett, Alan R. Fry, Nick Hartmann, Carsten Hast, Kareem Hegazy, Keith R. Jobe, Igor V. Makasyuk, Joseph S. Robinson, SLAC National Accelerator Lab. (United States); Matthew S. Robinson, Univ. of Nebraska-Lincoln (United States); Sharon Vetter, Stephen P. Weathersby, Chales Yoneda, Xijie Wang, SLAC National Accelerator Lab. (United States)

Ultrafast electron diffraction (UED) has the potential to capture changes in the structure of isolated molecules on the natural spatial and temporal scale of chemical reactions, that is, sub-Angstrom changes in the atomic positions that happen on femtosecond time scales. UED has the advantage that electron sources can easily reach sub-Angstrom spatial resolution, but so far femtosecond resolution had not been available for gas phase experiments due to the challenges in delivering short enough electron pulses on a gas target and the velocity mismatch between laser and electron pulses. Recently, we have used relativistic electron pulses at MeV energy to solve these challenges and reach femtosecond resolution. We have, for the first time, imaged coherent nuclear motion in a molecule with UED. In a proof-of-principle experiment, we captured the motion of a laser-excited vibrational wavepacket in iodine molecules. We are currently performing experiments in more complex molecules to capture laser-induced dissociation and conformational changes. We have also developed a table top 100 keV source that relies on a pulse compressor to deliver femtosecond electron pulses on a target and uses a tilted laser pulse to compensate for the velocity mismatch between the laser and the electrons. This source has a high repetition rate that will complement the high temporal resolution of the relativistic source.

10380-12, Session 3

Imaging electronic motions by ultrafast electron diffraction *(Invited Paper)*

Hua-Chieh Shao, Univ. of Nebraska-Lincoln (United States); Anthony F. Starace, Univ. of Nebraska-Lincoln (United States)

Recently ultrafast electron diffraction and microscopy have reached unprecedented temporal resolution, and transient structures with atomic precision have been observed in various reactions. It is anticipated that these extraordinary advances will soon allow direct observation of electronic motions during chemical reactions. We therefore performed a series of theoretical investigations and simulations to investigate the imaging of electronic motions in atoms and molecules by ultrafast electron diffraction. Two prototypical electronic motions were considered for hydrogen atoms. For the case of a breathing mode, the electron density expands and contracts periodically, and we show that the time-resolved scattering intensities reflect such changes of the charge radius. For the case of a wiggling mode, the electron oscillates from one side of the nucleus to the other, and we show that the diffraction images exhibit asymmetric angular distributions. If the energies of scattered electrons are resolved, our simulations show that additional details of the electronic motions can be obtained, enabling proper interpretations of electronic motions from energy-resolved diffraction images. Owing to the demonstrated abilities of ultrafast electrons to image these motions, we have proposed to image a coherent population transfer in lithium atoms using currently available femtosecond electron pulses. A frequency-swept laser pulse adiabatically drives the valence electron of lithium atoms from the 2s to 2p orbitals, and a time-delayed electron pulse maps such motion. Our simulations show that the diffraction images reflect this motion both in the scattering intensities and the angular distributions. This work is supported by NSF Grant No. PHYS-1505492.

10380-13, Session 3

Charge carrier dynamics in semiconductors studied by scanning ultrafast electron microscopy

Ebrahim Najafi, California Institute of Technology (United States)

With the continuous miniaturization of semiconductor devices, interfacial carrier dynamics have become essential to the device performance and efficiency. The disruption of the translational symmetry at the surfaces and interfaces makes the formation of interfacial barriers and defect states often inevitable. Despite such profound deviations from the bulk, there is only limited experimental evidence about how carriers behave at these boundaries, primarily due to the lack of a microscopy technique that can provide sufficient resolutions in both space and time. Scanning ultrafast electron microscopy (SUEM) is a recently developed technique that allows high resolution imaging of the electronic and structural dynamics at the femtosecond, picosecond and nanosecond timescales. In this work, we investigated the spatial dynamics of charge carriers in silicon by SUEM; specifically, we explored the initial super-diffusion of carriers after optical excitation which lasted tens of picoseconds and ultimately transitioned into the steady-state surface diffusion. Interestingly, at large excitation densities, electrons and holes showed non-linear transport behavior, resulting in the emission of plasma waves. Finally, we studied charge carrier dynamics at the silicon p-n junction which showed that charge separation was an ultrafast process which was not limited to the junction and began tens of micrometers away; in addition, the separated carriers remained localized in both space and time across the junction for tens of nanoseconds before they recombined to recover the ground state.

10380-14, Session 4

Serial single molecule electron diffraction imaging: A possible solution to the crystallization problem *(Invited Paper)*

Wei Kong, Oregon State Univ. (United States)

Serial single molecule electron diffraction imaging (ss-EDI) relies on signal accumulation of molecules oriented in the same direction to solve the problem of crystallization in atomic structure determination of molecules and nanoclusters. A critical issue in this approach is substrate free molecular orientation. Electric field induced alignment and/or orientation relies on effective suppression of thermal rotation, thus superfluid helium droplets with an equilibrium temperature of 0.4 K offer the desired cooling effect. However, the droplet matrix also introduces a diffraction background. Here

we demonstrate the practicality of electron diffraction of single molecules inside superfluid helium droplets. By taking advantage of velocity slip of a pulsed droplet beam, selective diffraction from monomers, dimers and even larger clusters can be obtained. To further extend this approach to macromolecular ions and nanoclusters, we also demonstrate doping of ions from electrospray ionization into superfluid helium droplets. Although the ultimate demonstration of ss-EDI is still steps away, steady efforts are being made toward the final goal.

10380-15, Session 4

Momentum-space imaging of ultrafast electron-phonon coupling in functional materials *(Invited Paper)*

Hermann A. Dürr, SLAC National Accelerator Lab. (United States)

The functional properties of materials often depend on the detailed interplay of electronic, spin and lattice degrees of freedom. The complexity of this interplay leads to some of the most technologically useful behavior. Effects from anomalous thermal expansion, through optical switching of magnetization, to superconductivity emerge from this complexity. However, understanding the details of this electron–spin –lattice interplay is perhaps the most challenging scientific problem in condensed matter physics. The availability of femtosecond lasers allowed the detailed study of electronic & spin scattering, thermalization, and electron-phonon energy transfer in real time. Ultrafast electron diffraction is a unique tool to probe the excitation of phonons on equal footing. In this talk I will give an overview of recent results for the momentum resolved detection of transient phonon populations in ultrathin films and nanoructures.

10380-16, Session 4

Spatiotemporal visualization of molecular rotational dynamics in femtosecond laser fields *(Invited Paper)*

Hui Li, Jian Wu, Heping Zeng, Peifen Lu, Kang Lin, Junyang Ma, Xiaochun Gong, Qinying Ji, Qiying Song, Wenbin Zhang, East China Normal Univ. (China)

A rotational wave packet (RWP) can be created when a molecule is nonresonantly excited by laser pulses with durations much shorter than the molecular rotational periods. More interestingly, a unidirectional molecular rotation at THz frequency can be initiated by optical kicking. Such phenomenon has attracted many interests in the fields of molecular deflection, generation of molecular vortices, and etc. However, a comprehensive physical picture of the spatiotemporal evolution of the impulsively excited molecular unidirectional rotation has lacked for more than 10 years since its first observation. Here, we directly visualize the spatiotemporal evolution of an impulsively created unidirectional spinning molecular RWP using the coincidence Coulomb explosion imaging technique (CCEIT) in an intense ultrafast laser field for the first time [1]. Both the experimental results and the numerical simulations show rich dynamical information. Depending on the timing or polarization of the pump pulses, the well-confined cigar- or disk-shaped RWP can be impulsively kicked to rotate clockwise or counterclockwise which afterwards disperses and exhibits field-free revivals owing to the time-dependent beating of the coherently populated rotational states. Very recently, the rotational echo of an impulsively excited RWP has been visualized using the CCEIT [2]. The quantum and classical dynamics of the echo phenomena will be discussed. These results will improve the understanding in other fields of physics and trigger the developments in many applications.

Smartphone chloridometer for point-of-care diagnosis of cystic fibrosis

Chenji Zhang, Jimin Kim, Jian Yang, Zhiwen Liu, Pennsylvania State Univ. (United States)

Chloride is an essential electrolyte that maintains homeostasis within the body, thus evidence of various conditions and diseases can be presented in the chloride levels of biological fluids, such as in sweat chloride which is the primary diagnostic criteria for cystic fibrosis (CF). Yet the transition of chloride sensors from laboratories to the point-of-care has been hindered by prohibitive costs, such that analytical methods for sweat chloride is predominated by manual titration in almost 70% of clinical laboratories. Thus our primary objective in this work is the development of a low cost, point-of-care sweat diagnostics system for cystic fibrosis. We recently established a citrate-derived synthesis platform for the versatile design of new fluorescence chloride sensors with improved sensing properties. As a next step, we herein designed a smartphone operated fluorometer equipped with a citrate-derived chloride sensor such that chloride levels correspond to measurable changes in fluorescence emission. To evaluate clinical performance, we implemented clinical validation with sweat from individuals with or without CF. To our knowledge, this is the first clinical demonstration of a fluorescence-based chloridometer. Such advances in performance and cost-reduction may meet the clinical needs of a reliable point-of-care diagnostic system for CF, and may significantly improve diagnostic accuracy by reducing technical complexity in fast-paced clinical settings.

10380-18, Session 5

Step-index optical fiber based on citrate-based synthetic polymers

Chenji Zhang, Dingying Shan, Jian Yang, Zhiwen Liu, Pennsylvania State Univ. (United States)

The turbidity of biological tissue due to fundamental light-tissue interactions has been a long-standing challenge in biomedical optical technologies. Implanting fibrous optical waveguide into tissue and organ for light delivery and collection is one of the most effective way for alleviate this problem. In this manuscript, by taking advantage of the favorable designability and processibility of citrate-based synthetic polymers, two bio-elastomers with distinct optical properties but matched mechanical properties and similar biodegradation profiles were developed. Combining with an efficient two-step fabrication method, we created a new biodegradable and biocompatible step-index optical fiber. Benefited from this step-index structure and high tunability of citrate-based bio-elastomers, our optical fiber not only demonstrated outstanding optical performance (0.4dB/cm loss), but also had favorable mechanical and biodegradable properties. Apart from the fabrication and characterization of our optical fiber, we successfully demonstrated the functionalities of multimode fiber imaging, deep tissue light delivery and in vivo fluorescence detection of our newly designed optical fiber. We believe the flexible, biodegradable and low loss optical fiber designed in our work offers a valuable tool for optical applications including imaging, detecting, sensing, optogenetic stimulation, and treatment to target regions underneath deep tissue.

10380-19, Session 5

Measure the spatial distribution of corneal elasticity by combining femtosecond laser induced breakdown spectroscopy and acoustic radiation force elasticity microscope

Hui Sun, Xin Li, Zhongwei Fan, Academy of Opto-Electronics, CAS (China); Mingyong Hu, Hefei Univ. of Technology (China)

Purpose: The nonhomogeneous structure of the cornea suggests a unique spatial distribution of corneal elasticity. Non-invasive measurement of this distribution is critical to understanding how biomechanics control corneal stability and refraction. We show that the anterior cornea is more rigid than the underlying posterior stromal bed without disturbing the overall corneal structure.

Methods: Corneas from fresh porcine eyes (Sierra Medical, Whittier, CA) were excised from the globe leaving a 2 mm scleral rim intact. The corneal samples were suspended in collagen gelatin (10% w/w) within a water tank filled with deionized, degassed water. The water tank was attached to a 3-D mechanical stage allowing for precise control of cavitation bubble placement within the cornea. Femtosecond laser pulses induced optical breakdown and produced cavitation in the anterior and posterior cornea. A confocal ultrasonic transducer applied 6.5 ms acoustic radiation force-chirp bursts to the bubble at 1.5 MHz while monitoring bubble position using pulse-echoes at 20 MHz. A cross-correlation method was used to calculate bubble displacements. Maximum bubble displacements are inversely proportional to the Young's modulus. The laser induced breakdown spectroscopy (LIBS) were measured in the anterior and posterior cornea with the same femtosecond laser pulses to see whether the laser induced plasmas signals will show relationship to Young's modulus.

Results: Bubble displacement was 18-25% greater in the posterior cornea relative to the anterior cornea. This indicates a larger Young's modulus in the anterior cornea in the direction orthogonal to the corneal surface. But the laser induced breakdown spectroscopy from the same femtosecond laser source gave the similar results for different locations of cornea.

Conclusions: Our results show that the anterior cornea is stiffer than the posterior cornea and that ARFEM is capable of non-invasively measuring the distribution of corneal elasticity while the LIBS does not have such ability.

10380-20, Session 6

Infrared fingerprint spectroscopy of nanoscale molecules with graphene plasmons *(Invited Paper)*

Qing Dai, National Ctr. for Nanoscience and Technology of China (China)

Infrared (IR) spectroscopy is widely used for chemical identification in such as chemical detection, food safety and biosensing, due to its fast and noninvasive measurement of molecular vibrational fingerprints. In particular, in the molecular fingerprint region from 600 to 1500 wavenumber (corresponds to the wavelength range of 6-16 micrometer), complex vibrational characteristics of molecules in bulk materials can be effectively distinguished to enable unambiguous identification of molecular structures and species. However, molecular fingerprinting at the nanoscale level still remains a significant challenge, due to weak light–matter interaction between micron-wavelengthed infrared light and nano-sized molecules. We demonstrate molecular fingerprinting at the nanoscale level using our specially designed graphene plasmonic structure on 300 nm CaF2 nanofilm supported on doped silicon. This structure not only avoids the plasmon–phonon hybridization, but also provides in situ electrically-tunable graphene plasmon covering the entire molecular fingerprint region, which was previously unattainable. We enhance about 8-nm PEO film vibrational signatures up to larger than 20-fold. In addition, undisturbed and highly confined graphene plasmon offers simultaneous detection of in-plane and out-of-plane vibrational modes with ultrahigh detection sensitivity down to the sub-monolayer level, significantly pushing the current detection limit of far-field mid-infrared spectroscopy. Our results provide a platform, fulfilling the long-awaited expectation of high sensitivity and selectivity far-field fingerprint detection of nano-scale molecules for numerous applications.

10380-22, Session 6

Ultrafast optical spectroscopy of individual nano-materials *(Invited Paper)*

Kaihui Liu, Peking Univ. (China)

When the characteristic length of a material shrink to 1 nm scale, many distinct physical phenomena, such as quantum confinement, enhanced many-body interactions, strong van der Waals inter-material couplings and ultrafast charge separation, will appear. To investigate the related fascinating low-dimensional physics, we need a tool to quantitatively link the atomic structures to the physical properties of these very small nano-materials. In this talk, I will introduce our recently developed in-situ TEM + high-sensitive ultrafast nano-optical spectroscopy technique, which combines capability of structural characterization in TEM and property characterization in ultrafast nano-optical spectroscopy on the same individual nano-materials. Several examples of using this technique to study the 1D carbon nanotube and 2D atomic layered systems will be demonstrated.

10380-23, Session 6

Ultrafast imaging of microstructures and coherent transients in hybrid perovskite materials *(Invited Paper)*

Jigang Wang, Ames Lab., Iowa State Univ. (United States)

The most compelling principle beyond conventional wisdom is that a coherent photoexcitation and hot state delocalization on ultrafast time scales are responsible for a photocarrier generation and quasi-instantaneous probability of energy migration in highly efficient photovoltaic materials. Until now the origin is unclear in the new organic-inorganic perovskite systems despite they have emerged as new revolutionary materials for light-harvesting and electron-transporting applications. In this talk, I will discuss our measurements to image local carrier/exciton population, electronic coherence and charge transport across different grains and grain boundaries (~10-1000 nm). Our results demonstrate a quantitative, ultrafast microscopy spectroscopy tools and elucidate the impact of microstructure on coherent/incoherent charge transport in the hybrid perovskites.

10380-24, Session 6

Ultrafast pump-probe and Raman experiments of individual plasmonic junctions *(Invited Paper)*

Eric O. Potma, Alexander Fast, Kevin T. Crampton, Vartkess A. Apkarian, Univ. of California, Irvine (United States)

We present pump-probe and Raman measurements on individual plasmonic nano-junctions. The time-resolved measurements reveal differences between capacitive and conductive junctions, and paint a detailed picture of the ultrafast electrodynamics of the nano-junction. The insights gleaned from these measurements help interpret the ultrafast response of single molecules placed in the junction.

10380-25, Session 6

Efficient triplet exciton generation in hybrid perovskites *(Invited Paper)*

Kenan Gundogdu, North Carolina State Univ. (United States)

Triplet excitons (TE), bound electron-hole pairs with unity spin and long lifetime, form the basis for exploitation in applications including singlet oxygen generation, photodynamic therapy, and photochemical

Return to Contents

upconversion. As a result, an emerging theme in the realm of nanostructured inorganic semiconductors is the extraction of their transiently stored potential in the form of molecular triplet excited states. In some instances, the efficiency of the triplet energy transfer process approaches unity, leading to generation of surface-bound triplets with lifetimes on the millisecond time scale. These observations are mostly limited to molecular or reduced-dimensional structures, and most typically are pursued in solution phase. While organic-inorganic perovskites have attracted substantial attention for application to optoelectronics, the generation of TEs from the broad perovskite family (i.e., both 3D and lower-dimensional frameworks) remains largely unexplored. In the present work, efficient TE generation on picosecond time scales in a 2D perovskite $(CH_3NH_3)_2Pb(SCN)_2I_2$ is demonstrated using static and transient spectroscopic techniques.

10380-26, Session 7

Redox-sensitive heme imaging with transient absorption microscopy *(Invited Paper)*

Jesse W. Wilson, Erkang Wang, Colorado State Univ. (United States)

Ultrafast pump-probe microscopy enables visualization of non-fluorescent materials in biological tissue, such as melanin and hemoglobin. Whereas transient absorption has been primarily a physical chemistry technique, used to gain insight into molecular and electronic structure, pump-probe microscopy represents a paradigm shift in translating transient absorption into an analytical technique, which can clearly resolve pigments with nearly indistinguishable linear absorption spectra. Extending this technique to other important targets, such as mitochondrial respiratory chain hemes, will require new laser sources and strategies for selecting pump and probe wavelengths to optimize contrast. We will present recent developments on both of these fronts. The laser system we have developed to elicit a pump probe response of respiratory chain hemes is based on an amplified Yb:fiber ultrafast laser that uses modest spectral broadening followed by sum frequency generation to produce a tunable pulse pair in the visible region. Wavelength tuning is accomplished by changing quasi-phase matching conditions. We will present preliminary imaging data in addition to discussing how to manage sample heating problems that arise from performing transient absorption measurements at the high repetition rates needed for imaging microscopy. In the second part of the talk, we will present the use of a subset selection algorithm to choose pump-probe wavelength combinations to optimally measure redox in mixtures of heme proteins.

10380-27, Session 7

Simultaneous two-photon photoactivation and readout of brain activity in 3D with single neuron resolution *(Invited Paper)*

Nicolas C. Pegard, Alan Mardinly, Hillel Adesnik, Laura Waller, Univ. of California, Berkeley (United States)

Understanding how the brain processes information requires the ability to monitor and control neural activity with minimally invasive methods. Optogenetics offers a viable avenue towards large-scale neural control with photosensitive opsins and functional fluorescence markers that externally indicate or trigger action potentials with light.

Fast readout of neural activity in large volumes of brain tissue is made possible by 3D point scanning two photon holography. However, the limiting factor for two-way communication with the brain is photoactivation. Current techniques either suffer from poor spatial resolution, temporal resolution or only operate in small volumes. Precise photo-activation of large custom subsets of neurons such as those involved in a particular brain function remains impossible.

Our technique, 3D Scanless Holographic Optogenetics with Temporal focusing (3D-SHOT), combines temporal focusing, for single neuron spatial resolution, and 3D computer generated holography, for custom targeting within a large volume and with adequate temporal resolution. Temporal focusing and 3D holography are made compatible by giving up the ability to generate custom shapes. For this, we rely on a Custom-made Temporally-Focused Pattern (CTFP) adjusted to the characteristic dimensions of a neuron soma. We then implement point cloud holography, with an SLM in the Fourier domain to replicate the CTFP the desired locations in the volume of interest by all-optical convolution.

Here, by digitally aligning functional imaging and photostimulation, our technology is able to establish all-optical two-way communication with many neurons spatially distributed across a large volume of brain tissue.

10380-28, Session 7

Molecular spectroscopy and dynamics of novel FRET Sensors in crowded environments *(Invited Paper)*

Hannah Leopold, Jacob Schwarz, Megan Currie, Erin D. Sheets, Ahmed A. Heikal, Univ. of Minnesota Duluth (United States)

Macromolecular crowding affects numerous cellular processes including protein folding, biochemical reaction kinetics and transport. As a result, there is a need for new crowding probes, as well as integrated, noninvasive, and quantitative approaches to investigate those processes in heterogeneous, crowded environments, both in vivo and in vitro. In this contribution, we will highlight our recent findings on novel FRET probes (mCerulean—linkers—mCitrine), which can be genetically encoded in living cells with site specificity. Time-resolved fluorescence and anisotropy measurements were employed to characterize the spectroscopy and molecular dynamics of these probes as a function of biomimetic crowding (Ficoll-70 and glycerol at variable concentrations in PBS buffer). At the single molecule level, fluorescence fluctuation analyses were also used to quantify the translational diffusion coefficient of the probes in crowded environments as a means to quantify the hydrodynamic radii while elucidating the underlying diffusion mechanism. Our comprehensive studies of these FRET probes on multiple time scales would help understand the length/time scales associated with macromolecular crowding. Importantly, these results represent a first step towards quantitative, non-invasive studies of in vivo crowding.

10380-29, Session 7

Second harmonic generation chiral imaging in biological tissues *(Invited Paper)*

Shi-Wei Chu, National Taiwan Univ. (Taiwan)

Chirality plays a fundamental role in biomedical fields; many drugs, enzymes, and biomolecules cannot function unless their chiralities are correct. Since the conformation of a molecule, as well as the chirality, is very sensitive to the local microenvironment, it is vital to characterize molecular chirality without altering the surrounding conditions. To determine the chirality in materials, optical activity is the most common way. In linear optics, optical rotatory dispersion and circular-dichroism are the two well-developed methods for probing chirality. However, their weak contrast, poor optical sectioning, and low penetration depth constrain its application to study chirality in tissues and real bio-samples. Therefore, previous research has been mostly limited to surfaces or solutions.

In contrast to linear optics, there are several nonlinear optical activity effects in chiral materials, such as vibrational circular dichroism, Raman optical activity, two-photon absorption circular dichroism, and second-harmonic generation circular-dichroism (SHG-CD). The last one is the most studied nonlinear chiral effect since it shows significantly improved chiral contrast. An additional advantage of SHG-CD is its intrinsic optical sectioning due to nonlinearity. When combined with an infrared excitation, SHG-CD has

been demonstrated to provide high penetration depth for three-dimensional imaging. However, in recent studies, the signal origin of SHG-CD in biological tissue is ambiguous, since not only chirality, but also the anisotropy of molecules contribute to SHG-CD response. It will be of great importance to find an experimental skill that can distinguish the contribution between these two mechanisms.

Here we studied SHG-CD of collagen, which is the most abundant protein in human body. Inspired by linear CD where resonant wavelength is required to reveal chirality, we have carried out nonlinear microspectroscopy measurement and shown that when the excitation meets the resonant band of collagen, chirality-induced SHG-CD is strongly enhanced and can be easily identified versus the anisotropy-induced contribution. By slowly heating up the sample, we have further verified that there is a wavelength-independent anisotropy contribution of SHG-CD vanishing at around 40 – 50 degree Celsius, while the resonance-enhanced chirality component of SHG-CD remains until temperature rise to 60 degree. Our results feature the first quantitative identification of chirality-induced SHG-CD in an intact biological tissue, and will be a critical step toward nonlinear chiral microscopy.

10380-30, Session 8

Femtosecond pulse delivery through multi-core fibers for imaging and ablation *(Invited Paper)*

Demetri Psaltis, Eirini Kakava, Nicolino Stasio, Donald B. Conkey, Christophe Moser, Ecole Polytechnique Fédérale de Lausanne (Switzerland)

No Abstract Available.

10380-31, Session 8

Label-free mid-Infrared photothermal imaging: High spatial resolution beyond the mid-Infrared diffraction limit *(Invited Paper)*

Michelle Y. Sander, Boston Univ. (United States)

Photothermal spectroscopy in the mid-infrared can directly target vibrational modes in the fingerprint region and forms an attractive technique for label-free, bond-specific characterization of chemical and biological samples. Through a raster-scanning approach, local sample information can be combined with spectroscopic and spectral details. We will discuss how the spatial resolution of this technique benefits from the shorter wavelength fiber laser to obtain resolving powers beyond the diffraction limited mid-infrared pump wavelength. This is of particular interest to analyze biological tissue samples without a need for exogenous labels or thin-film samples at high spatial resolution. Studies based on the United States Air Force (USAF) resolution target patterned in PMMA as well as histopathological mouse brain tissue will be presented.

10380-32, Session 8

Practical masks for multimodel spatial frequency modulation imaging fabricated with femtosecond laser micromachining *(Invited Paper)*

Jeffrey A. Squier, Colorado School of Mines (United States); Randy A. Bartels, Colorado State Univ. (United States); Michael D. Young, Colorado School of Mines (United States); Jeffrey J. Field, Colorado State Univ. (United States); Nathan Worts, Colorado School of Mines (United States); Keith A. Wernsing, Patrick A. Stockton, Colorado State Univ. (United States); Alyssa M. Allende Motz, Colorado School of Mines (United States)

Spatial frequency modulation for imaging (SPIFI) is an important new imaging modality in linear and nonlinear microscopy. It uses an extended excitation source for optimal imaging speeds, and is compatible for use with scattering specimens. Significantly, this is a multimodal imaging modality: contrast can be achieved with the excitation laser or nonlinear excitation mechanisms such as second and third harmonic generation imaging and/or multiphoton excitation fluorescence. What is particularly exciting is that the SPIFI method can achieve enhanced resolution with any of the aforementioned modalities.

SPIFI requires a mask at an intermediate image plane to modulate the extended excitation source. We have been able to fabricate the masks used to achieve this modulation through femtosecond laser micromachining. Notably we have been able to create highly efficient masks that can be use in reflective or transmissive geometries. These masks produce high contrast images with enhanced resolution and can be produced inexpensively. Here we will show how a standard nonlinear microscope architecture can be adapted for use with these masks, making SPIFI conversion straightforward and easy to implement.

10380-33, Session 8

Sum frequency generation holography

Ding Ma, Pennsylvania State Univ. (United States); Christopher M. Lee, The Pennsylvania State Univ. (United States); Yizhu Chen, Nikhil Mehta, Seong H. Kim, Zhiwen Liu, Pennsylvania State Univ. (United States)

We demonstrate a sum frequency generation (SFG) holographic imaging method by integrating the capabilities of holography and SFG spectroscopy. SFG can probe the molecular vibrational resonance in non-centrosymmetric media. Holographic recording can capture both the amplitude and the phase of the SFG signal, thus leading to label-free spectroscopic three-dimensional imaging.

10380-34, Session 9

Non-degenerate two-photon excitation for increasing the fluorescence photon yield and maximum microscopy imaging depth *(Invited Paper)*

Mu-Han Yang, Christopher G. L. Ferri, Payam A. Saisan, Maxim Abashin, Univ. of California, San Diego (United States); Peifang Tian, John Carroll Univ. (United States); Yeshaiahu Fainman, Anna Devor, Univ. of California, San Diego (United States)

We investigate the utility of non-degenerate 2-photon excitation (ND-2PE) as a strategy for extending the 2-photon imaging depth. For the ND-2PE scheme, two pulsed, synchronized laser sources of different wavelength each provide a photon for the 2-photon absorption process. By independently tuning their wavelengths, we are able to tune the excitation to tissue transparency windows while maintaining resonant fluorescence excitation. These transparency windows reduce excitation power loss resulting from scattering. In addition, by having two sources we are able to displace the beams in space except at their common focus; thus, reducing background fluorescence excitation. Finally, we show that ND-2PE inherently results in increased 2-photon absorption cross sections, resulting in increased fluorescence intensity. By combining beam displacement, tissue transparency and increased absorption cross sections, we achieve increased imaging depths as compared to degenerate 2-photon excitation with commonly used fluorophores.

10380-35, Session 9

High resolution nonlinear imaging based on optical field engineering *(Invited Paper)*

Kebin Shi, Dashan Dong, Yanhui Cai, Wei Liu, Chendi Shao, Peking Univ. (China)

There have been increasing interests in nonlinear optical imaging technology, especially in biomedical and material research fields, where higher spatial resolution, better sensitivity, deeper penetration and faster data acquisition are always desired. Most recent examples include fluorescence microscopy, coherent Raman and nonlinear wave mixing imaging. In this talk, we will present our recent progresses on deep tissue fluorescence super-resolution and non-labeling chiral sum frequency generation imaging by utilizing optical field engineering mechanism.

10380-36, Session 9

Ultrafast all-optical laser scanning imaging with spatiotemporally encoded pulses *(Invited Paper)*

Kevin K. Tsia, The Univ. of Hong Kong (Hong Kong, China)

The holy grail of optical bioimaging is to gain quantitative understanding of the biological systems at different scales, from biomolecules to tissue, with high spatiotemporal resolution. However, this long-standing goal has been hampered by the intrinsic speed limit imposed by the prevalent image capture strategies, which involve the laser scanning technologies, (e.g. galvanometric mirrors), and/or the image sensors. Regarding live imaging, these factors explains the scarcity of video-rate volumetric microscopy and tomography platforms. Regarding high-throughput single-cell analysis, the speed-versus-sensitivity trade-off of the image sensor explains why the throughput of flow cytometry has to be scaled down from 100,000 cells/sec to 1,000 cells/sec when the imaging capability is incorporated.

This talk will describe our recent efforts on addressing these challenges by taking a generic imaging concept - ultrafast spatiotemporal encoding of laser pulses for all-optical laser-scanning. These techniques, including time-stretch imaging and free-space angular-chirp-enhanced delay (FACED) imaging, enable ultrahigh-throughput single-cell imaging with multiple image contrasts (e.g. quantitative phase and fluorescence imaging) at a line-scan rate beyond MHz (i.e. an imaging throughput up to ~100,000 cells/sec).

10380-37, Session 9

Coherence-domain imaging with harmonic holography *(Invited Paper)*

Ye Pu, Demetri Psaltis, Ecole Polytechnique Fédérale de Lausanne (Switzerland)

Observing the fast dynamics of specific molecules or targets in three-dimensional (3D) space and time inside a crowded and complex environment, such as living cells or tissues, remain one of the grand open challenges in modern science. Harmonic holography tackle this challenge by combining the 3D imaging capability of holography with the ultrafast, coherent optical contrast offered by second-harmonic radiating imaging probes (SHRIMPs). Similar to fluorescence, the second-harmonic signal emitted from SHRIMPs provides a color contrast against the uninterested background scattering, which can be efficiently suppressed by an optical filter. We review the latest developments in SHRIMPs and harmonic holography and discuss their further applications in fluidics and biofluidics.

10380-39, Session PMon

Research study of the treatment efficacy of staphylococcia in the palatine tonsils by using Raman-scattering spectroscopy method

Anna A. Asadova, Elena V. Timchenko, Pavel E. Timchenko, Elena G. Zarubina, Evgeniy S. Burenkov, Yuriy D. Ityaksov, Anna S. Tyumchenkova, Samara Univ. (Russian Federation)

These WHO statistics show that the world is suffering from tonsillitis from 10 to 15% of adults and from 20 to 25% of children. From 15 to 45% of cases is bacterial tonsillitis caused by ?-hematolytic streptococcus of group A. For the monitoring the effectiveness of treatment in medicamental practice was carried out a number of laboratory studies: common urine analysis and clinical blood analysis, and at the end of treatment: electrocardiogram and biochemical blood assay.

At the present time, optical methods in research are widely used in medical challenges. These methods are painless and fast, and can be performed in outpatient facilities. One of the alternative and promising methods of analysis of biological objects is Raman scattering method.

During the experiment, the 8 samples of different strains of staphylococcus ATCC ?25923 (Group I) and ATCC ?35591 (Group II) which are in the saliva of patients and normal saline. Half of the samples were subjected to treatment with antibiotics Amoxiclav dosage 500mg / 10ml, the second half was the control.

The spectral-response characteristics were studied using an experimental stand, which includes a high-resolution digital spectrometer Andor Shamrock sr-303i with built-in cooling chamber DV420A-OE, a fiber-optics probe for Raman spectroscopy RPB785, combined with laser module LuxxMaster LML-785.0RB-04 (with regulated power up to 500 mW, wavelength 785 nm).

The effectiveness of treatment of staphylococcus in the tonsils was analyzed using Raman spectroscopy (RS). The spectral changes were established in the treatment of palatine tonsils using antibiotic Amoxiclav. It is shown that at a dose of antibiotic 500mg / 10ml disappears lines at wave numbers 735 cm-1 and 783 cm-1, 986 cm-1 and 1635 cm-1, corresponding to adenine, cytosine, proteins and amide I, which indicates the treatment success. There are input optical criteria for evaluating the effectiveness of treatment.

10380-40, Session PMon

Research studies of aging changes of hyaline cartilage surface by using Raman-scattering spectroscopy

Anna S. Tyumchenkova, Elena V. Timchenko, Pavel E. Timchenko, Samara Univ. (Russian Federation); Larisa T. Volova, Dmitry A. Dolgyshkin, Samara State Medical Univ. (Russian Federation); Maria D. Markova, Elena F. Yagofarova, Samara Univ. (Russian Federation)

The articular hyaline cartilage is the unique tissue, which is due to its physical properties, is able to provide damper function throughout human life, supporting the possibility of movement in the joints. However, the destructive changes occur in cartilaginous tissue with aging. The ability to identify the characteristics of the cartilage surface using Raman spectroscopy makes it possible to carry out a comparative assessment of the spectral characteristics of the cartilaginous tissue of elderly people and children of 12 months and downwards.

For the research study were used cartilage samples of articular surface of knee joint of elderly people, obtained during the operations of endoprosthesis replacement and cartilaginous tissue of articular surfaces of the maniphalanx which children under 12 months of age were amputated because of polydactylia.

The research studies were carried out with the stand, actualized high-resolution digital spectrometer Shamrock sr-303i (Fig. 1), combined with a laser module LuxxMaster LML-785.0RB-04 (up to 500 mW, wavelength 785 nm), and built-in cooled chamber DV420A-OE, providing spectral resolution of 0.15 nm (spectral range 200-1200 nm). Isolation of the Raman spectra in the background of autofluorescence was carried out using polynomial approximation of fluorescence and its subtraction from recorded spectra in the program Wolfram Mathematica 9. In the chosen range 400-2200 cm-1 using an iteration algorithm [29] was determined approximating line (polynom of the fifth degree) of autofluorescence component then subtracted this component and obtained dedicated Raman spectrum. During treatment the experimental spectra was purified from the noise by smoothing median filter in 7 points.

The main differences of the spectral characteristics of cartilaginous tissue were observed in the lines 1244 cm-1 and 1660 cm-1 which corresponded to amide III and amide I. Optical coefficients that were input allow to allocate age features of hyaline cartilage surface.

10380-41, Session PMon

Research of vertical sections of rats' tubular bones in simulation of reduction bone tissue mineral density using Raman spectrum method

Yana V. Fedorova, Elena V. Timchenko, Pavel E. Timchenko, Samara Univ. (Russian Federation); Dmitry A. Dolgyshkin, Larisa T. Volova, Samara State Medical Univ. (Russian Federation); Anna A. Asadova, Anna S. Tyumchenkova, Samara Univ. (Russian Federation)

Density mineral reduction of bone tissue leads to the development of destructive processes in the bones and to reduction its mechanical strength, fracture. During preclinical study is needed to simulate animals' reduction bone tissue mineral density and to confirm the effectiveness of the various ways to treat this pathosis. One of the research methods to study bone tissue can be Raman spectroscopy.

24 rats' humeri were used as research materials. 12 of them were obtained from healthy animals and they became the first study group. Others were in the second group and were obtained from animals which at first we simulated density bone mineral reduction by doing ovariotomy, and then they were given a course of hydroxyapatite treatment. Bones were sawed longitudinally and measured in section. In each sample, Raman spectra were taken from three areas: the head area, neck and shaft of bone.

Experimental stand realizing the Raman spectroscopy method included a high-resolution digital spectrometer Shamrock sr-303i with built-in cooled chamber DV420A-OE, an optical fiber probe for Raman spectroscopy RPB785, combined with laser module LuxxMaster LML785.0RB-04 (with controlled output up 400 mW, wave length 785 nm). The radiation power of 400 mW did not cause any tissue destructive changes. The treatment of Raman spectra was carried out in program Wolfram Mathematica 9.

The spectrum analysis showed that the samples in the second group in comparison with the first group were observed the changes in intensity of the lines at wave numbers 956 cm-1 (phosphate ion PO43- (?1) (P-O symmetrical valent)), 1071 cm-1 (CO32- (?1) substitution of B-type (C-O valent planar)), 1246 cm-1 (amide III) and 1659 cm-1 (amide I).

10380-42, Session PMon

Optical surface evaluation of bone implants during its processing

Oleg O. Frolov, Pavel E. Timchenko, Elena V. Timchenko, Samara Univ. (Russian Federation); Larisa T. Volova, Dmitry A. Dolgyshkin, Violetta V. Boltovskaya, Samara State Medical Univ. (Russian Federation); Vadim D. Meshcheryakov, Yana Fedorova, Anna S. Tyumchenkova, Samara Univ. (Russian Federation)

Bone implants used in reconstructive surgery to restore structural integrity of bones and increase the osteogenetic potential of bone tissue. The quality of allogeneic bone tissue for transplantation depends on the way of its production, processing and keeping. Bone implants should be nonimmunogenic and bioresorbable.

The study objects were samples of spongy bone tissue (the size of 5 x 5 x 5 mm). In the manufacture process of bone bio-implants was carried out their low-frequency ultrasonic treatment, and as a result the samples deprived of fat and all the bone marrow cells were eliminated from interjoist bone spaces. Then, to obtain a demineralized biomaterial the bone tissue was placed in a spirit of salt.

In the capacity of essential method of biomplants research was used Raman spectroscopy method.

The features of the Raman spectra were studied for surfaces bone implants manufactured by different demineralization protocols. It has been established that the spectral characteristics of the surfaces bone implant manufactured by different demineralization protocols had difference at wavenumbers 428, 585, 960, 1065, 1243 and 1555 cm-1, corresponding to a significant for the implant quality of components. Raman-scattering spectroscopy can be used to evaluate the quality of the surface bone implants during its processing.

10380-43, Session PMon

Extension of supercontinuum spectrum, generated in photonic crystal fiber, by using chirped femtosecond pulses

Julius Vengelis, Vygandas Jarutis, Valdas Sirutkaitis, Vilnius Univ. (Lithuania)

We present results of experimental and numerical investigation of supercontinuum generation in polarization maintaining photonic crystal fiber (PCF) using chirped femtosecond pulses. The initial unchirped pump pulse source was a mode-locked Yb:KGW laser generating 52 nJ energy 110 fs duration pulses at 1030 nm with 76 MHz repetition rate. The nonlinear medium was a 32 cm long polarization maintaining PCF with zero dispersion wavelength at 800 nm manufactured by NKT Photonics A/S. The generated supercontinuum spanned through a wide spectral range ? from roughly 450 nm to 1400 nm. We showed the influence of various nonlinear phenomena on spectral characteristics of supercontinuum by changing unchirped pump polarization and pulse energy. Eventually, we experimentally demonstrated that by chirping pump pulses positively or negatively we can obtain broader supercontinuum spectrum than in case of unchirped pump pulses at the same peak power. The broadening of supercontinuum spectrum increases with the value of pump pulse chirp but the increase is different in cases of positively and negatively chirped pulses. In our case the supercontinuum spectrum width was extended by up to 115 nm (at maximum chirp value of +10500 fs2 that we could achieve in our setup) compared to the case of unchirped pump at the same peak power.

Numerical simulations of supercontinuum generation in PCF were also performed. The simulated supercontinuum spectra display the same qualitative features as the ones measured in the experiment. We also discuss possible physical mechanisms leading to additional spectrum broadening due to pump pulse chirp.

10380-44, Session PMon

Temporal focusing multiphoton excitation fluorescence imaging using the excitation wavelength-selected configuration

Fan-Ching Chien, National Central Univ. (Taiwan); Chi-Hsiang Lien, National United Univ. (Taiwan); Gerald Abrigo, National Central Univ. (Taiwan)

Temporal focusing multiphoton excitation microscopy (TFMPEM) has been presented the improvements in temporal and spatial resolutions of multiphoton excitation imaging by combined with the structured light illumination techniques and is a powerful platform for visualizing the dynamic distribution of molecules and cells and the architecture of subcellular structures in biotissues. However, TFMPEM is insufficient for performing efficient excitation of fluorophores with different two-photon absorption spectra in multifluorophore imaging through an illuminated configuration of fixed wavelength pulse light source. Therefore, TFMPEM with the fast excitation wavelength-selected configuration was implemented using an optical setup to change the incident angle of the light source at the diffraction grating depending on its central wavelength. The proposed system was used to observe two-photon excitation (TPE) fluorescent section images of the mouse muscle fibers through wavelength-selected excitation. Furthermore, the intensity enhancement of a TPE fluorescence image of multifluorophore-labeled specimens through optimum wavelength excitation in the proposed TFMPEM system was demonstrated.

10380-45, Session PMon

Imaging of thick, transparent samples by time-of-flight detection of optical pulse trains

Xing Lu, Jiarui Wu, Wentao Yu, Ziheng Ji, Qihuang Gong, Kebin Shi, Peking Univ. (China)

Imaging of transparent sample via optical phase contrast mechanism has been intensively investigated in biomedical and material science. Various methods were employed in this field, including Zernike phase contrast microscopy [1], Nomarski differential interference contrast microscopy [2], off-axis based digital holography (DH) imaging [3], diffraction phase microscopy (DPM) [4], common-path based Fourier phase microscopy (FPM)[5], quadriwave lateral shearing interferometry (QWLSI) [6], etc. While their axial resolution could reach nanometers, their axial imaging depth however is still limited to micrometers. In this paper, we report a novel imaging method that enables observing transparent specimen with thickness exceeding hundreds of micrometers. The new method employs 1550 nm femtosecond mode-locked fiber laser and is based on time of flight (TOF) detection of optical pulse trains. Although transparent sample is invisible under traditional bright-field microscope, its refractive index distribution exists. When optical pulse passes through different areas of the sample, the phase retardation is different. In this method, a new device – fiber loop optical-microwave phase detector (FLOM PD) [7] is employed. FLOM PD is capable of detecting optical-microwave phase, which is related to optical pulse delay, with high resolution and can help achieve tight synchronization between microwave and optical pulse train up to sub-femtosecond level [7]. And due to its microwave reference, this technique enables large detection range. In the experiment, we firstly use one FLOM PD to synchronize the optical pulse train and the microwave reference, and then use another identical FLOM PD to detect the optical-microwave phase (the same microwave signal acts as the reference) after the synchronized optical pulse passes through the sample. With the advantage of FLOM PD, we have achieved imaging of thick, transparent sample of hundreds of micrometers thick with sub-micrometer resolution.

Holographic imaging of two dimensional materials

Joshua Noble, Atriya Ghosh, Zhiwen Liu, The Pennsylvania State Univ. (United States)

Two-dimensional (2D) materials have recently attracted interest in the field of photonics. Here, we examine the phase response and thickness of 2D monolayers created by chemical vapor deposition onto Si/SiO2 substrates. These structures exhibit transverse dimensions on the order of tens of microns. Measuring the thickness along the axial direction, however, is much more challenging. We explore the feasibility of using digital holographic imaging to quantify the associated phase response.

Tomographic diffractive microscopy for better 3D imaging

Dashan Dong, Yanhui Cai, Ziheng Ji, Hong Yang, Qihuang Gong, Kebin Shi, Peking Univ. (China)

Tomography imaging is one of the most developing imaging technology in recent years; it has great capability for biopsy and living cell imaging. Lately, the diffraction tomography imaging based on the scatting theory has greatly promote the resolution of tomographic imaging. The need to visualize three-dimensional (3-D) structures noninvasively using this method is growing rapidly. In this studying, based on a commercial microscope, a holographic tomography microscope is built by combined with digital holography. The imaging speed is greatly boosted by simultaneously controlling the rotation of light and raw imaging logging. In the image processing stage, a fast and robust algorithm is used to mapping the data in frequency domain to reconstruct the 3-D reflection index. The result shows a valid 3-D reflection index measurement of polystyrene microspheres and INS-1 cells.

Molding and simulating of GaN step-up power switched capacitor converter

Ayoob Alateeq, Yasser A. Almalaq, Mohammad A. Matin, Univ. of Denver (United States)

According to the demand of low voltage DC-DC converter, a proposed step-up power switched capacitor converter (PSC) was designed and analyzed in this paper. The proposed two-level PSC converter has been proven to achieve high voltage gain by using fewer switches than other types of DC-DC switched capacitors converter. The proposed two-level PSC consist of 8 switches and 5 capacitors. The switches were selected to be GaN transistors in order to maintain the losses when either the switching frequency or the temperature increase. To validate the design outputs, the theoretical results were compared with LT spice simulator. Since the design combines semiconductor elements such (GaN transistor), then 10 % error is a reasonable difference between the mathematical and simulation results.

10381-18, Session PMon

Design and performance study of a DC-DC flyback converter based on wide bandgap power devices for photovoltaic applications

Salah S. Alharbi, Saleh S. Alharbi, Ali M. S. Al-bayati, Mohammad Matin, Univ. of Denver (United States)

This paper presents a high-performance dc-dc Flyback converter design based on GaN power devices for photovoltaic (PV) applications. The flyback converter is modeled with two different power devices: a GaN-transistor and a Silicon (Si) MOSFET. They are implemented individually in the flyback converter to describe the impact of these devices on the converter performance. The total power loss of the converter with different power devices is analyzed for various switching frequencies. The converter efficiency is evaluated at different operating conditions. The results show that the GaN-based converter has a higher efficiency level and lower total power loss compared to the conventional Si-based converter.

10381-19, Session PMon

Design of a high-performance cascaded boost converter with SiC power devices for photovoltaic applications

Saleh S. Alharbi, Ali M. S. Al-bayati, Salah S. Alharbi, Mohammad Matin, Univ. of Denver (United States)

This paper presents a comprehensive evaluation of the effects of Silicon Carbide (SiC) power devices on the performance of a dc-dc cascaded boost converter for photovoltaic (PV) applications. The converter is designed with SiC MOSFETs and compared to the conventional cascaded boost converter based on Silicon (Si) devices. The total power loss and efficiency of the converter are evaluated at different switching frequencies and load conditions. SiC power devices in the cascaded converter show a superior performance under wide switching frequency conditions. The results show that the cascaded converter with SiC devices significantly reduces total losses and improves the overall efficiency.

10381-20, Session PMon

Properties of reactively sputtered Alx Ny thin films for pyroelectric detectors

Nicholas P. Calvano, Philip C. Chrostoski, Andrew Voshell, Keesean Braithwaite, Delaware State Univ. (United States); Dennis W. Prather, Univ. of Delaware (United States); Murzy D. Jhabvala, NASA Goddard Space Flight Ctr. (United States); Mukti M. Rana, Delaware State Univ. (United States)

Pyroelectric detectors are class of uncooled infrared detectors whose polarization changes with change in temperature. Infrared radiation from objects falls on top of the sensing layer of the pyroelectric detector and absorbed radiation causes the temperature of to change. The polarization of the sensing layer changes this way. This work presents the deposition and characterization of Al_x N_y thin films for using them as pyroelectric detector material. To test the pyroelectric effect, capacitors of various sizes were fabricated. The diameter of the electrodes for capacitor used during testing of the device was 1100 ?m while the distances between these two electrodes was 1100 ?m. On a 3-inch diameter cleaned silicon wafer, 20 nm thick Ti adhesion layer was deposited followed by a 100 nm thick Au layer. On top of this Au layer, 100 nm Al_x N_y thin films were deposited. Finally, 100 nm thick Au layer was deposited and lifted off by conventional photo lithography to form the electrodes of capacitors. All the layers were deposited by radio frequency sputtering at room temperature. The thin film samples were annealed at 700 0C in N2 environment for 10 minutes. X-ray diffraction showed the films are poly-crystalline with peaks in (100), (002) and (101) directions. The pyroelectric current increased from 3.38 ? 10-14 A at 303 K to 1.75 ? 10-13 at 353 K. When the temperature varied between 303 K to 353 K, the pyroelectric coefficient was increased from 8.60 ? 10-09 C/m2K to 3.76 ? 10-08 C/m2K while the loss tangent remains almost constant to ~1.5 ? 10-5 when the temperature was varied in the same range. The room temperature pyroelectric coefficient, loss tangent, voltage responsivity figure of merit and detectivity figure of merit were found to be 8.60?10-9 C/m2K, 1.79?10-5, 1.25?10-4 C/m2K and 1.39?10-3 Pa-2 respectively.

10381-1, Session 1

Junction formation by laser irradiation through semiconductor substrate for CdTe and wide-band gap materials *(Keynote Presentation)*

Toru Aoki, Junichi Nishizawa, Jinwei Lee, Kento Tabata, Akifumi Koike, Shizuoka Univ. (Japan)

pn junction formation in the CdTe by laser irradiation doping has been developed. We could confirm the p-n diode can be formed by direct laser irradiation of CdTe-metal interface through semiconductor material irradiation and doping of CdTe and its performance as a gamma-ray detector with high reverse voltage bias. Moreover, it has been found that the number of irradiation and power of the laser affect condition of the doping. This method is suitable for wide-bandgap material for heavy doping and pn junction without high-temperature processes.

10381-2, Session 1

A study of the effect of surface pretreatment on atomic layer deposited Al2O3 Interface with GaN

Jianyi Gao, Wenwen Li, Srabanti Chowdhury, Univ. of California, Davis (United States)

Al2O3 has been an attractive gate dielectric for GaN power devices owing to its large conduction band offset with GaN (~2.13eV) [1], relatively high dielectric constant (~9.0) and high breakdown electric field (~10MV/cm). Due to exceptional control over film uniformity and deposition rate, atomic layer deposition (ALD) has been widely used for Al2O3 deposition. The major obstacle to ALD Al2O3 on GaN is its high interface-state density (Dit=1012~1013 eV-1cm-2) [2] caused by incomplete chemical bonds, native oxide layer and impurities at the Al2O3/GaN interface. Therefore, an appropriate surface pretreatment prior to deposition is essential for obtaining high-quality interface. In this study, we investigated the effect of TMA, H2O and Ar/N2 plasma pretreatment on Dit and border traps (Nbt). 5 cycles of TMA purge, 5 cycles of H2O purge and Ar (50sccm, 25W, 5min)/N2 (50sccm, 50W, 20min) plasma pretreatment were conducted respectively on MOCVD-grown GaN-on-sapphire consisting of 1µm n-GaN layer with doping of ~1?1017cm-3 on the top and 1µm n+ GaN layer with doping of ~3?1018cm-3 on the bottom prior to the Al2O3 deposition. Al2O3 was also deposited on as-received GaN for comparison. Au/Ni/Al2O3/GaN metal-oxide-semiconductor capacitors (MOS-C) were fabricated for the characterization of Dit and Nbt using UV-assisted capacitance-voltage (C-V) technique [3]. Integrated Dit over E-Ec=0.15eV to 1eV for as-received, TMA, H2O and Ar/N2 plasma pretreated samples were 1.09?1012cm-2, 1.48?1012cm-2, 1.77?1012cm-2 and 9.82?1011cm-2. Nbt for as-received, TMA, H2O and Ar/N2 plasma pretreated samples were 7.78?1012cm-2, 9.43?1012cm-2, 7.61?1012cm-2 and 1.66?1012cm-2. The results showed that TMA and H2O pretreatment had trivial effects on interface engineering whereas Ar/N2 plasma pretreatment slightly reduced Dit and significantly reduced Nbt.

3D analysis of thermal and electrical performance of wide bandgap VDMOSFETs

Mahesh Manandhar, Mohammad A. Matin, Univ. of Denver (United States)

Power electronics is based on the conversion and conditioning of electric power in its different forms. The need for higher operating voltages, temperatures and switching speeds have necessitated for the use of semiconductor materials more superior to Silicon for power electronics purposes. Wide bandgap (WBG) materials like SiC, GaN and Diamond have been known to demonstrate better material properties as compared to Silicon, like higher operating temperatures, higher breakdown voltages and reduced thermal and electrical resistances which make them ideal for high power electronic devices. This paper analyzes the thermal and electrical performance of WBG power MOSFETs, in particular the Vertical Double-diffused MOSFET (VDMOSFET) structure, modeled in the commercial simulation software COMSOL Multiphysics. VDMOSFETs are ideal for high power electronic applications owing to their higher voltage blocking capabilities as compared to the conventional lateral MOSFET structure. COMSOL uses Finite Element/Volume Analysis methods to approximate solutions to differential equations involved with complex geometries and physics. The 3D model investigated in COMSOL for this model solved for thermal and electrical variables for VDMOSFETs using SiC, GaN and Diamond as their semiconductor material. Only half of the 3D VDMOSFET structure was modeled for faster computational speed as the structure itself is symmetric about the vertical axis. The temperature profiles and current densities of each WBG material VDMOSFET were analyzed for different operating voltages. These profiles were compared with a Si VDMOSFET model to determine relative similarities and differences between each material.

10381-4, Session 2

Emission control of multilayered thin films of ZnO/CuO prepared by pulsed laser deposition *(Invited Paper)*

Hong-Kun Lyu, DGIST (Korea, Republic of); Bunyod Allabergenov, DGIST (Korea, Republic of) and Urgench State Univ. (Uzbekistan); Hyunseok Shim, Myoung-Jae Lee, Byeongdae Choi, DGIST (Korea, Republic of)

In this report, we present on a research result of the microstructural and optical properties of ZnO/CuO multilayered films. Three types of multilayer ZnO/CuO stacks were prepared by pulsed laser deposition (PLD) on amorphous SiO2/Si substrates, and then annealed at 500oC for 30 min to improve crystallinity. TEM and XRD analysis of the thin films revealed the formation of multiple crystallographic defects and modification of the dominant growth plane. Consequently, near-band-edge emission in ZnO can be controlled through the number of CuO layers. The detailed microstructure and electro optical properties of multilayered ZnO/CuO thin films will be discussed.

10381-6, Session 2

Development of an efficient DC-DC SEPIC converter using wide bandgap power devices for high step-up applications

Ali M. S. Al-bayati, Salah S. Alharbi, Saleh S. Alharbi, Mohammad A. Matin, Univ. of Denver (United States)

This paper presents the development of an efficient DC-DC single-ended primary-inductor converter (SEPIC) for high step-up applications. The SEPIC converter is designed using wide bandgap power devices and its performance is compared with the conventional silicon power device based converter. The behavior of the power devices is characterized and analyzed at the system level. The total power losses as well as the overall performance efficiency of the converter are measured and reported under different conditions. The analysis and results show the potential of the designed converter to operate efficiently and reliably at a wide range of operating conditions.

10381-7, Session 3

Defect-induced optical breakdown in aluminum nitride *(Invited Paper)*

Jae-Hyuck Yoo, Lawrence Livermore National Lab. (United States); Andrew Lange, Lawrence Livermore National Lab. (United States) and Univ. of California, Davis (United States); Selim Elhadj, Lawrence Livermore National Lab. (United States)

Aluminum nitride (AlN) has an extremely wide bandgap (~6 eV), making it a promising material for high power and deep ultraviolet applications. Aluminum nitride is also commonly used as a buffer layer for gallium nitride devices where its electrical breakdown characteristics can limit high voltage operation. The authors have investigated conductive gallium nitride on AlN films for use in high-power optoelectronics. It was found that damage

initiates in the AlN buffer or at the AlN-GaN interface when bi-layer films are exposed to sub-bandgap, high infrared laser fluences. Through subsequent optical damage studies, it was revealed that laser damage in single layers of intrinsic AlN occurs by either dielectric breakdown or discrete absorption processes thought to be initiated by extended defects. This understanding has motivated the use of laser-based probing to spatially resolve breakdown behavior in AlN over large areas for emerging power device applications.

This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344

10381-8, Session 3

Comparison between dielectric and p-GaN gates for CAVETs with Mg ion-implanted current blocking layers

Saptarshi Mandal, Univ. of California, Davis (United States)

Gallium Nitride power electronics has witnessed significant technological development in the last decade [1]. Commercial GaN power electronic devices are based on lateral channel AlGaN/GaN high electron mobility transistors (HEMTs) [2]. Despite their high mobility and channel charge, lateral HEMTs have key limitations when compared to vertical transistors like the current aperture vertical electron transistor (CAVET). Unlike lateral HEMTs, CAVETs do not exhibit surface state induced current collapse or dynamic RON during switching, due to a buried peak electric field [3]. The breakdown voltage in a HEMT scales with gate to drain distance (BVd) whereas in vertical transistors BVd scales with drift layer thickness, resulting in a higher current density per unit chip area for the same breakdown voltage [4]. In this work, a study of two different types of CAVETs with Mg ion-implanted current blocking layer are presented. The device fabrication and performance limitation of a CAVET with a dielectric gate is discussed, and the breakdown limiting structure is evaluated using on-wafer test structures. The gate dielectric limited the device breakdown to 50V, while the blocking layer was able to withstand over 400V. To improve the device performance, an alternative CAVET structure with a p-GaN gate instead of dielectric is designed and realized. The p-GaN gated CAVET structure increased the BVd to over 400V. Measurement of test structures on the wafer showed the breakdown was limited by the blocking layer instead of the gate p-n junction. The devices also showed no dc-RF dispersion when pulsed using 80 ?s wide pulses.

Highly efficient GaN HEMTs transformerless single-phase inverter for grid-tied fuel cell

Khaled S. Alatawi, Fahad M. Almasoudi, Mohammad A. Matin, Univ. of Denver (United States)

The interest in distributed generation systems based on solar PV and fuel cells (Fcs) has increased recently due to their low cost and high efficiency. Fuel cells are electrochemical devices that generate electrical energy without the burning process. Fuel cells use hydrogen and Oxygen as fuels which make them safe for the environment and very efficient. Transformerless inverters are the most efficient approach to utilize renewable energy sources for grid tied applications. Removing transformers will increase the efficiency and reduce the size, cost and the complexity of the system. In this paper, a new transformerless inverter equipped with GaN HEMTs is proposed. The new topology is derived from conventional H5 inverter. GaN HEMTs are used to enable the system to switch at high frequency, which will reduce the size, volume and cost of the system even more. Moreover, inverter control is designed and proposed to supply real power to the grid and to work as DSTATCOM to mitigate any voltage sag and compensate reactive power in the system. The new topology is investigated and compared to H5 inverter in terms of efficiency and power losses. The switching strategy of the new topology creates a new current path which reduces the conduction losses significantly. The analysis of the proposed system was carried out using MATLAB/SIMULINK and PSIM. The proposed controller improves voltage stability and mitigates voltage sag and compensates reactive power. The simulation results prove the effectiveness of the system for grid-tied applications.

10381-10, Session 3

The wide bandgap of optical absorption coefficient for optoelectronic materials

Subhamoy Singha Roy, JIS College of Engineering (India)

In both the cases, the OAC exhibits the singularity when the incident photon energy ( ) tends to and the magnitude of the OAC depends to a large extent on the numerical values of the energy band constants of the said compounds. In addition, the simplified results of the OAC for materials having parabolic energy bands have also been obtained form the present generalized analysis under convinced restrictive circumstances.

10381-11, Session 4

?-Ga2O3 films grown via oxidation of GaAs substrates and their device demonstrations *(Invited Paper)*

Ahmet Kaya, Daniel M. Dryden, Howard Mao, Dewyani Patil-Chaudhuri, Andrew Philip Lange, Subhash Mahajan, Jerry M. Woodall, M. Saif Islam, Univ. of California, Davis (United States)

We present a simple and inexpensive method for growing ?-Ga2O3 films by heating GaAs wafers at high temperature in a furnace in both argon and air ambient. Prolonged heating was found to completely oxidize a GaAs wafer into ?-Ga2O3 while shorter heating duration contributes to large-area, high-quality ?-Ga2O3 nanoscale thin films that spontaneously delaminates from the GaAs substrate. The films are characterized using x-ray diffraction, energy dispersive spectroscopy, Raman spectroscopy, and scanning electron microscopy. The ?-Ga2O3 film's optical band gap and Schottky barrier height with gold are 4.8 eV and 1.03 eV, respectively. The photoconductance of the ?-Ga2O3 films was found to increase by more than three orders of magnitude under 270 nm ultraviolet (UV) illumination with respect to the dark current.

10381-12, Session 4

Simulation and performance comparison of Si and SiC-based interleaved boost converter

Yasser A. Almalaq, Ayoob Alateeq, Mohammad A. Matin, Univ. of Denver (United States)

In this paper, simulation and performance comparison of Si and SiC based interleaved boost converter is presented. Wide band gap devices such as silicon carbide and gallium nitride are desirable and recommended in high-power applications because of their capability of operating under high temperature, high switching frequency, and high voltage with reduced switching losses. The main advantage of using SiC materials in interleaved boost converter is the ability to increase the switching frequency which will reduce the size. However, their cost is high compared to Si. In this paper, 60V input voltage is used to get 120V output voltage under 100 KHz switching frequency and 0.5 duty cycle. With the help of LTSpice software,

a comparison between silicon and silicon carbide by considering interleaved boost converter are simulated and studied.

10381-13, Session 4

High efficiency H6 single-phase transformerless grid-tied PV inverter with proposed modulation for reactive power generation

Fahad M. Almasoudi, Khaled S. Alatawi, Mohammad A. Matin, Univ. of Denver (United States)

Implementation of transformerless inverters in PV grid-tied system offer great benefits such as high efficiency, light weight, low cost, etc. Most of the proposed transformerless inverters topologies in literatures are verified for only real power application. Currently, international standards such as VDE-AR-N 4105 has demanded that PV grid-tied inverters should have the ability of controlling specific amount of reactive power. Generation of reactive power cannot be accomplished in H6 topology because the existing modulation techniques are not adopted for freewheeling path in the negative power region. This paper enhances a previous high efficiency proposed H6 trnasformerless inverter with SiC MOSFETs and demonstrates new operating modes for the generation of reactive power. A proposed pulse width modulation (PWM) technique is applied to achieve bidirectional current flow through freewheeling state. A comparison of the proposed H6 transformerless inverter using SiC MOSFETs and Si MOSFTEs is presented in terms of power losses and efficiency. The results show that reactive power control is attained without adding any additional active devices or modification to the inverter structure by taking the advantage of SiC MOSFET's body diode with small reverse recovery current. Also, the proposed modulation provides low leakage current by maintaining constant common mode voltage (CM) during every operating mode. The performance of the proposed system verifies its effectiveness in grid-tied applications.

10381-14, Session 4

Low-crosstalk optimization in 2D segmented waveguide crossings by evolutionary algorithms *(Invited Paper)*

Cosme Eustaquio Rubio Mercedes, Maicon de Souza Alcântara, Univ. Estadual de mato Grosso do Sul (Brazil); Anderson Dourado Sisnando, Vitaly Felix Rodriguez Esquerre, Univ. Federal da Bahia (Brazil)

A rigorous analysis of two-dimensional segmented waveguide (2D-SWG) crossing using evolutionary algorithms in conjunction with the two-dimensional finite element method (2D-FEM) is presented. The power transmission and crosstalk of the waveguide crossings are calculated, optimized and compared with other designs in the literature. The optimized crossing has been successfully and efficient designed using evolutionary algorithms based on artificial immune system (AIS) and the genetic algorithm (GA). Power transmissions above 98 % and crosstalk below 40 dB over a broadband interval of wavelength have been obtained with both evolutionary algorithms.

10381-15, Session 4

III-nitride based N-polar current aperture vertical electron transistors

Saba Rajabi, Saptarshi Mandal, Univ. of California, Davis (United States); Haoran Li, Univ. of California, Santa Barbara (United States); Matthew A. Laurent, Univ. of California, Davis (United States); Stacia Keller, Univ. of California, Santa Barbara (United States); Srabanti Chowdhury, Univ. of California, Davis (United States)

Gallium nitride (GaN) based transistors have been of interest to power electronics community because of their high breakdown voltage, high sheet carrier density, and the high saturation velocity of GaN. The low switching losses of GaN enable high-frequency operation which reduces bulky passive components with negligible change in efficiency [1,2]. The most established GaN electronic devices are fabricated on the Ga-polar orientation of GaN. Recently, N-polar GaN based devices are being explored for high frequency applications due to their advantages over Ga-face, such as lower contact resistance since the 2DEG is contacted through a lower bandgap material and better electron confinement due to natural back-barrier provided by the charge inducing barrier [3]. In this work, the first N-polar GaN current aperture vertical electron transistor is presented. The samples were grown by metal-organic chemical vapor deposition on c-plane Sapphire substrate. Mg ions were implanted at 80keV (dose: 1??10?^15 ?cm?^(-2)) into the top GaN layer, everywhere except the current aperture to form the current blocking layer. A 7 A^0 AlN to reduce alloy scattering followed by 150nm UID N-polar GaN as channel were regrown on top of the implanted structure. The 2DEG density and the mobility of the as-grown sample, determined using Hall measurement, were 1.1??10?^13 ?cm?^(-2) and 1800 ?cm?^2/(V-S) , respectively. The CAVET showed excellent device modulation and a maximum current of 2 KA?cm?^(-2) at V_G=2V. The maximum transconductance per mm of source was 140 mS. The device had a very large pinch-off voltage of -14V as calculated due to the presence of high charge density in the channel.

Inorganic nanocomposite films with polymer nanofillers made by the concurrent multi-beam multi-target pulsed laser deposition *(Invited Paper)*

Abdalla M. Darwish, Abdel Aziz Mohammed, Shaelynn Moore, Wydglif Dorlus, Tyler Bastian, Dillard Univ. (United States); Sergey S. Sarkisov, SSS Optical Technologies, LLC (United States); Paolo Mele, Muroran Institute of Technology (Japan); Shrikant Saini, The Univ. of Utah (United States); Junichiro Shiomi, Susumu Yada, The Univ. of Tokyo (Japan); Darayas N. Patel, Oakwood Univ. (United States); Brent Koplitz, Xiaodong Zhang, Tulane Univ. (United States)

We report on the new class of inorganic nanocomposite films with the inorganic phase hosting the polymer nanofillers made by the concurrent multi-beam multi-target pulsed laser deposition of the inorganic target material and matrix assisted pulsed laser evaporation of the polymer (MBMT-PLD/MAPLE). We used the exemplary nanocomposite thermoelectric films of aluminum-doped ZnO known as AZO with the nanofillers made of poly(methyl methacrylate) known as PMMA on various substrates such as $SrTiO_3$, sapphire, fused silica, and polyimide. The AZO target was ablated with the second harmonic (532 nm) of the Nd:YAG Q-switched laser while PMMA was evaporated from its solution in chlorobenzene frozen in liquid nitrogen with the fundamental harmonic (1064 nm) of the same laser (50 Hz pulse repetition rate). The introduction of the polymer nanofillers increased the electrical conductivity of the nanocomposite films (possibly due to the carbonization of PMMA and the creation of additional channels of electric current) three times and reduced the thermal conductivity by 1.25 times as compared to the pure AZO films. Accordingly, the increase of the thermoelectric figure-of merit ZT would be ~ 4 times. The best performance was observed for the sapphire substrates where the films were the most uniform. The results point to a huge potential of the optimization of a broad variety of optical, opto-electronic, and solar-power nanocomposite inorganic films by the controllable introduction of the polymer nanofillers using the MBMT-PLD/MAPLE method.

10382-2, Session 1

Analysis of photonic spot profile converter and bridge structure on SOI platform for horizontal and vertical integration

Rajib Chakraborty, Saikat Majumder, Univ. of Calcutta (India); Amit K. Jha, Aishik Biswas, Debasmita Banerjee, Dipankar Ganguly, Techno India (India)

Presently, high index contrast SOI platform is extensively used for integrated photonic circuits due to its CMOS compatibility and better light confinement. In this work the simple matrix technique is used to design structures for horizontal and vertical integration in such a platform. The designed structures are horizontal spot profile converter required for horizontal light coupling and vertical bridge structure required for vertical integration. Both the structures are considered to be made with multimode interference couplers. Multimode interference coupler is a promising waveguide structure having wide application as splitter, multiplexer, photonic switch etc. Spot profile converter can be realized of successive integration of multimode interference structures with reducing dimension on horizontal plane, whereas an optical bridge structure is a combination of two vertical multimode interference structure connected by a single mode section. The analyses of these two structures are carried out for both TE and TM modes at 1550 nm wavelength using the semi analytical matrix method due to its simple nature and fastness in computation time and memory. The computational results obtained from matrix method have been compared with the results obtained from different numerical method like BPM, FEM etc with the other researchers. This work shows that the matrix method is equally applicable for horizontally integrated photonic circuit as well as vertically integrated photonic circuit. The proposed spot profile converter can be used for different sensing application and the bridge structure can be used for optical signal routing in optical communication systems.

10382-3, Session 1

Enhanced nonlinear light conversion in globular photonic crystals at the band-gap pumping

Arsen Zotov, Stanislav O. Yurchenko, Kirill I. Zaytsev, Egor Yakovlev, Evgeny Gorbunov, Bauman Moscow State Technical Univ. (Russian Federation); Gleb M. Katyba, Institute of Solid State Physics RAS (Russian Federation); Nikita V. Chernomyrdin, Bauman Moscow State Technical Univ. (Russian Federation)

The problems of nonlinear process enhancement and high optical harmonic generation are of great importance in optics. Recently, photonic crystals (PCs) have attracted considerable interest as prospective media for this purpose. The PC has a structure characterized by a spatially periodic distribution of optical properties, which leads to the appearance of numerous physical effects . These effects allows us employing the PC structures for highly efficient waveguiding nonlinear light conversion, or active media pumping .

In this talk, we would consider the results of experimental and theoretical study of the structural light focusing effects in PCs . This effect appears as a result of strong redistribution of electromagnetic field in 2D and 3D PCs at the bang gap-pumping owing to the curvature of its nodes. It leads to strong localization of electromagnetic wave in certain regions of the PC volume and, as a consequence to the enhancement of non-linear optical phenomena. We discuss theoretical background of the structural light focusing effect, the results of numerical simulations, as well as its application for enhanced nonlinear light conversion in artificial opal-based PCs, including generation of second and third harmonics, Raman light scattering, and fluorescence.

10382-4, Session 1

Terahertz waves and its interaction with ferroics and multiferroics, for the design of modulators

Moumita Dutta, Soutik Betal, Xomalin G. Peralta, Amar S. Bhalla, Ruyan Guo, The Univ. of Texas at San Antonio (United States)

With the advancements in femto-second laser technology and the coherent generation and detection of Terahertz(THz) radiation (ranging from 0.1?THz to 30?THz), this spectral region is finding applications in various disciplines like imaging, communications, explosive-detection, spectroscopy of molecular vibrations etc. However, in order to realize full-

fledged THz applications, efforts need to be directed towards the design and implementation of efficient THz modulators and switches. In this work we study interaction of THz-waves with different ferroic and multiferroic materials, excited by external fields, to exploit that knowledge for the design of THz modulators. These modulators can be envisioned to be the opto-electronic units for the future optical-communication/computing.

10382-5, Session 1

Magnetoelectric nanorobot for therapeutic applications

Soutik Betal, The Univ. of Texas at San Antonio (United States)

In this study we illustrate a novel device named magnetoelectric nanorobot (MENR) which is a core-shell magnetoelectric nanoparticle. We fabricated the MENR and proposed it as a bio-switch which can be controlled remotely by biased ac magnetic field. When a threshold attractive ac magnetic field (F1) is applied, this bio-switch can permeate in a series of aligned cells one by one. This process is called magneto-elasto-electroporation (MEEP), which is a unique technique of remotely controlled electrically excited, nanopore opening on a cell membrane and permeation using MENR. These MENR can also be dynamically targeted to a particular area of cells/single cell avoiding any of the untargeted cells on the path, under the influence of (F2) attractive ac magnetic field. It has also been experimentally confirmed that when a repulsive biased ac magnetic field (F3) ac excitation is applied, a group of MENR can induce motion and actuate a group of cells as well as can transport them to an unlimited distance and through narrow bifurcation such as blood vessels or veins with variable pressure gradient.

10382-6, Session 1

Nonlinear optical crystalline structures grown by laser precipitation in glass

Carl M. Liebig, Jonathan T. Goldstein, Air Force Research Lab. (United States); Sean A. McDaniel, Air Force Research Lab. (United States) and Leidos, Inc. (United States); Douglas M. Krein, Air Force Research Lab. (United States) and General Dynamics Information Technology (United States); Gary Cook, Air Force Research Lab. (United States)

Over the last decade it has been demonstrated that nonlinear optical (NLO) crystals can be grown by laser precipitation in customized glasses and used for electro-optic applications [1]. It has been further demonstrated that this novel crystal growth technique is capable of fabricating nonlinear waveguide structures, where the polar axis of the crystal is aligned along the growth direction [2]. Femtosecond precipitation of NLO crystals in glass has the potential to be a low-cost method of creating functional optical elements. In order to realize this goal, the orientation of the NLO crystals must be carefully controlled. In the present study, a widely used electro-optical crystal, Lithium Niobate, was precipitated in $33LiO_2$-$33Nb_2O_5$-$34SiO_2$ (mol%) (LNS) glass, forming NLO crystalline structures in an amorphous matrix. Glass fabrication techniques for making high quality glass, and the crystallization parameter space were explored to determine the optimal conditions for smooth and continuous crystal growth. The crystalline orientation of the precipitated lithium niobate was determined for a variety of writing conditions, and the growth technique was extended to multi-dimensional structures.

10382-7, Session 1

Characteristic study on circularly bent plastic optical fiber based refractometer

Mayank Upadhyay, Aman Kumar Srivatsava, National Institute of Technology, Warangal (India)

Many areas of research such as biomedicine, food safety, environmental monitoring, chemical and bio chemical sensing demand a precise measurement of refractive index (R.I) of various chemicals and fluids. Inherent advantages of Optical fibers such as small size, immunity from electromagnetic interference, low cost, high sensitivity, potential for remote sensing, and fast responsiveness offer an easy and cost effective solutions for refractive index measurement. POF sensors exhibit additional advantages which includes negative thermo-optic coefficients, high fracture toughness, flexibility to bending, high sensitivity to strain along with the inherent advantages of silica optical fibers. Moreover, they show excellent compatibility with organic materials, enabling them for chemical and biomedical applications.

In the present study, an investigation is made for the realization of plastic optical fiber based refractometer by evanescent field modulation techniques. Clad-removing, thermal tapering are some of the techniques for maximizing the evanescence field there by causing more interaction with the surrounding medium. In this study, plastic optical fiber is bent into circular shape of an optimized radius and etched to a suitable thickness in order to enhance the evanescent field. To characterize the sensors performance, it has undergone various experimental studies. It is observed that sensitivity of the sensor is increased in comparison with a straight etched optical fiber sensor. The sensitivity of the sensor is found to be 400 RIU. The sensor is very low cost, fast responsive and highly flexible.

10382-8, Session 1

Study on u-bent plastic fiber optic sensor for nitrite compounds detection by evanescent field modulation techniques

Aruna Gupta, National Institute of Technology, Warangal (India)

Recent decades has been witnessing a rapid growth of nitrite compounds in environment and drinking water. Nitrite is a notorious chemical, known for detrimental effects on human health. When consumed in excess quantities, it can cause methemoglobinemia which is medically called “Blue Baby Syndrome” and different types of stomach cancers. Nitrates and nitrites mainly enter into environment due to the anthropogenic activities such as excess use of pesticides in agriculture and from the drain waters of industries. World health organization (WHO) has set an upper limit of 3ppm for presence of nitrite compounds in drinking water. These reasons provoking for the development of accurate, high sensitive and specific low cost detection systems. Optical fiber based sensors has become an attractive alternative technology, due to its inherent advantages such as high sensitivity, low cost, immunity towards electromagnetic interference, remote monitoring and small size. Evanescent field techniques are well known low cost intensity modulated sensors. In the present article, an investigation on utilization of plastic optical fiber for nitrite sensing is discussed. A U-bent optical fiber sensor is designed for the purpose. The working principle in sensing the nitrite concentration is modulation of the evanescent field of the fiber being absorbed or scattered by ambient medium. The interaction between evanescent field and surrounding chemical is maximized by removing the cladding or etching the U-bent portion of the fiber by suitable techniques. Nitrite concentrations even in trace amounts as low as 100 ppb can be measured by the method.

10382-9, Session 2

Computation of the total number of particles in a spherical microbubble in optical trapping using an equation

Arjun Krishnappa, Univ. of Dayton (United States)

In the previous research, an optical force equation for microbubbles is derived to compute the force on a microbubble that is steered in a liquid using an Optical Field. To compute the total number of particles in the spherical microbubble, a tabular method is used. Although the tabular method is not complex and provides the approximate value, it is necessary to derive an equation for the precise value in computing the number of particles. This research paper has derived an equation for computing the total number of particles in the spherical microbubble. The equation provides the precise and reliable results in the computation of the total number of particles. By computing the number of particles using the equation instead of the tabular method, the precision of the optical force equation for the microbubble is increased. The equation for computing the total number of particles has been verified both theoretically and experimentally.

10382-11, Session 2

Organic-metal hybrid nanostructures for toward high-performance photonic devices: Photo-detector and waveguide

Sunjong Lee, Korea Institute of Industrial Technology (Korea, Republic of); Seokho Kim, INHA Univ. (Korea, Republic of); Bo-Hyun Kim, DGIST (Korea, Republic of); Dong Hyuk Park, INHA Univ. (Korea, Republic of)

Organic-metal hybrid nanotubes (NTs), nanowires (NWs), and nanoparticles (NPs) using ϖ-conjugated polymers and small molecules are introduced. The fabrications, characteristics, and applications of the hybrid nanostructures (NSs) using the organic nanomaterials are intensively covered. The hybrid NSs were visualized and confirmed through SEM, TEM, HR-TEM, and elemental analysis. We observed nanoscale laser confocal microscope (LCM) PL characteristics of the hybrid materials drastically varied with metal NSs. The LCM PL intensity of the single unit of the organic-metal hybrid NTs/NWs/NPs increased considerably. We analyze that the huge enhancement PL of the organic-metal hybrid NSs might originate from energy transfer and/or charge transfer in a surface plasmon resonance (SPR) coupling, supported by ultraviolet and visible absorption spectra. We investigated the photo-responsive electrical characteristics using the single unit of the hybrid NSs for the high sensitive and fast responsive photo-detector. In optical waveguiding experiments, the propagation characteristics of optical signals along the single hybrid material were dependent on the existence of the silver NPs. For the hybridized with silver NPs, the waveguiding PL signals of hybrid material had relatively higher output. Additionally, the waveguiding characteristics such as decay constant along the hybrid material considerably decrease the optical loss in hybrid materials. It is remarked that the effective SPR coupling between organic crystal and nanoscale silver NPs can be significantly activating PL propagate without optical loss. These outstanding photonic performances may be applied to photo-detector and photonic optical communication through SPR coupling effect.

10382-12, Session 2

Optical fiber Fabry-Perot sensing system based on Blackbody radiation in high temperature applications

Xiaohua Lei, Tao Chen, Lei Xie, Yijun Deng, Weimin Chen, Chongqing Univ. (China)

High-temperature sensing or strain sensing at high temperature in harsh environments is a challenging industrial task. Optical fiber sensors, especially Fabry-Perot sensors, have attracted much attention because of their promising characteristics, such as miniaturization, thermal stability, and a corrosion resistant nature. In an optical fiber sensing system, the broadband light source is often needed to supply energy for sensing and demodulation. While at high temperature, the blackbody radiation energy of materials is strong, so it has the great potential to become the light source of an optical fiber sensing system. In this way, the optical fiber sensing system architecture can be simplified and system cost can be reduced.

In this paper, a blackbody radiation model based on cylindrical cavity is presented and radiation coupling efficiency from blackbody into multimode fiber has been investigated. Fiber Fabry-Perot sensing system based on light source of blackbody radiation has been set up and strain sensing experiment has been carried out. Results show that blackbody radiation is strong enough to support sensing of fiber Fabry-Perot sensors in high temperature (800~1000ºC), a sensitivity around 10nm/?? has been achieved.

10382-13, Session 2

Fiber-optic refractive index sensor based on tapered single mode-thin core-single mode fiber structure

Ameni Ben Khalifa, Amine Ben Salem, Rim Cherif, SUP'COM (Tunisia)

The refractive index measurement based on all-optical-fiber technology play an important role in chemical and biotechnological applications due to their intrinsic advantages such as immunity to electromagnetic interference, low cost, compact size, high sensitivity and fast response. Recently, the inline fiber sensors based on thin-core fiber modal interferometers have been introduced because of the advantages of lower transmission loss, sharper filter bandwidth, and better resolution compared with single mode-multimode-single mode fiber structure.

In this paper, we propose the design of fiber optic refractive index sensor based on a thin core fiber, characterized by cladding and core diameters about 125 μm and 3 μm, respectively, sandwiched between an input and output single mode fiber. We investigate numerically the dependence of the surrounding refractive index of the sucrose solution to the shift of re-imaging resonant wavelength of the proposed sensor where we have a refractive index sensitivity of the proposed sensor about 179.65 nm/RIU.

In order to enhance the sensitivity of the thin core modal interferometer structure, we reduce the diameter of the cladding of the sensing region. To the best of our knowledge, this is the first time that a tapered single mode-thin core-single mode fiber structure is designed. The sensors with different waist-diameters (90, 60, 45, 30 μm) are investigated, as a result the sensitivity to the surrounding medium increases when the waist diameters decreases. We obtained an ultra-high sensitivity of the tapered sensor about 891.31 nm/RIU in the refractive index range of 1.3346-1.3899 achieved for a waist diameter equal to 30 μm and a taper length of 675μm.

The designed structure shows the merits of high sensitivity which is 5 times higher than that of the basic structure without tapering.

10382-14, Session 2

Anti-resonant hollow core fiber for precision timing applications

Amy Van Newkirk, The Pennsylvania State Univ. (United States); J. Enrique Antonio Lopez, Rodrigo Amezcua Correa, Axel Schülzgen, CREOL, The College of Optics and Photonics, Univ. of Central Florida (United States); John Mazurowski, The Pennsylvania State Univ. (United States)

Many applications rely on the ultra-precise timing of optical signals through fiber, such as fiber interferometers, large telescope arrays, in phase arrayed antennae, optical metrology, and precision navigation and tracking. Environmental changes, specifically those caused by temperature

fluctuations, lead to variations in the propagation delay of optical signals and thereby decrease the accuracy of the system's timing.

The cause of these variations in delay is the change in the glass properties of the optical fiber with temperature. Both the refractive index of the glass and the length of the fiber are dependent on the ambient temperature. Traditional optical fiber suffers from a delay sensitivity of 39 ps/km/K. We are reducing the temperature sensitivity of the fiber delay through the application of a novel design of optical fiber, Anti-Resonant Hollow Core Fiber. The major improvement in the thermal sensitivity of this fiber comes from the fact that the light is guided in an air core, with very little overlap into the glass structure. This drastically reduces the impact that the thermally sensitive glass properties have on the propagation time of the optical signal. Additionally, hollow core fiber is inherently radiation insensitive, due to the light guidance in air, making it suitable for space applications.

10382-15, Session 2

High light extraction efficiency (LEE) LEDs with asymmetric patterned sapphire substrate

Shizhuo Yin, Chang-Jiang Chen, Wenbin Zhu, Ju-Hung Chao, Haonan Zhou, The Pennsylvania State Univ. (United States)

This letter presents the recent advances of GaN light emitting diodes (LEDs) on asymmetric patterned sapphire substrate (PSS) with high light extraction efficiency (LEE). Compared to the conventional GaN LED on PSS with symmetric micro-pyramids, the asymmetric PSS-LED can further improve its LEE from 60% to 71% by optimizing the oblique angle of the asymmetric micro-pyramid. This improvement of LEE is mainly dedicated to the increased surface area and better randomization on the direction of transmitted/reflected light, which enhances the escaping probability after multiple reflections.

10382-16, Session 3

Characteristics of gold nanorods in volume holographic nanocomposites *(Invited Paper)*

Liangcai Cao, Shenghan Wu, Song Zong, Guofan Jin, Tsinghua Univ. (China)

Gold nanorod has generated great research interests due to its tunable longitudinal plasmon resonance. The mechanism of its localized surface plasmon resonance (LSPR) effect on the enhancements of holographic performance for the volume holographic polymer is not clear till now. In this work, a theoretical model for the gold nanorods has been set up and the LSPR effects between light and narorods could be successfully simulated. The obtained resonance wavelength is dependent on not only aspect ratio but also rod radius. The acquired data could be a good reference to design advanced nanocomposite of volume holographic material. Besides, the doped gold nanorods can also decrease the shrinkage of the photopolymer, which reduce the deformation of the multiplexed gratings. The experimental evaluation of the material in our lab suggests a novel candidate for potential applications in high-density optical data storage and high-resolution holographic display.

10382-17, Session 3

Intermodal four-wave-mixing and multimode parametric amplification in km-long fibers

Massimiliano Guasoni, Francesca Parmigiani, Peter Horak, Optoelectronics Research Ctr., Univ. of Southampton (United Kingdom); Julien Fatome, Lab. Interdisciplinaire Carnot de Bourgogne (France); David J. Richardson, Optoelectronics Research Ctr., Univ. of Southampton (United Kingdom)

Multimode amplifiers and wavelength converters are of paramount importance in spatial division multiplexing schemes. In this framework, intermodal four-wave-mixing (FWM) in km-long fibers may provide a suitable way to design efficient all-optical parametric amplifiers and converters, where large degrees of nonlinearity – and thus amplification - can be achieved thanks to long fiber lengths while keeping low input powers. However, long fibers undergo random birefringence fluctuations that can strongly affect the FWM and related amplification processes. While several works have addressed this issue in single-mode fibers, there are currently very few studies for multimode fibers. In this work we theoretically and numerically analyse the two main intermodal FWM processes, namely Bragg-Scattering (BS) and Phase-Conjugation (PC), when weak random birefringence fluctuations are present along the fiber length. In particular, we estimate the amplification impairments induced by these unavoidable fluctuations. The system configuration of the processes is the following: two input pumps P1 and P2, coupled respectively to two distinct spatial modes m1 and m2, and a seed signal S1, coupled to m1, nonlinearly interact giving rise to idler signals in m2 for both the PC (idler I2-PC) and the BS (idler I2-BS) processes. We analyze the amplification of both idlers, identifying several operation regimes depending on the main fiber features. Each one of the regimes discloses different amplification impairments for the BS and PC processes, which offers important guidelines for an efficient design of multimode parametric amplifiers and wavelength converters.

10382-18, Session 3

Moderate temperature-dependent surface and volume resistivity and low-frequency dielectric constant measurements of pure and multi-walled carbon nanotubes (MWCNT) doped polyvinyl alcohol thin films

Matthew E. Edwards Sr., Padmaja Guggilla, Angela Reedy, Alabama A&M Univ. (United States); Quratulann Ijaz, Troy Univ. (United States); Afef Janen, Alabama A&M Univ. (United States)

Previously, we have reported measurements of the temperature-dependent surface resistivity of pure and multi-walled carbon nanotubes doped amorphous Polyvinyl Alcohol (PVA) thin films. In the temperature range from 22°C to 40°C with a humidity-controlled environment, we found the surface resistivity to decrease initially but to rise steadily as the temperature continued to increase. Also, electric surface current densities (Js) were measured on the surface of pure and MWCNT doped PVA thin films. At low voltages, these densities were found to be produced analogously to ohmic conduction. However, unlike ohmic conduction in metals where free electrons exist, some captive electrons are freed to become conduction electrons from increased thermal vibration of constituent atoms in amorphous thin films. Finally, we present conventional volume resistivity measurements in the same temperature range, with the recognition that nano-dopants, microscopic structure, and environmental conditions contributed to the unique physical properties of these material systems.

10382-19, Session 3

Opposite virtual objective

Yeh-Wei Yu, Szu-Yu Chen, Che-Chu Lin, Chinng-Cherng Sun, National Central Univ. (Taiwan)

4-pi microscopy applies bi-directional illumination to create axial

interference fringe to improve the axial resolution. Since all the 4-pi-related techniques require two opposite objectives at each side of the tissues, their applications in optically-thick tissues have never been proposed. Besides, the information carried by backward and forward harmonic generation signals are also proved to be different. Limited by the penetration depth of light, imaging of intact or live bio-tissues can only be achieved by using an epi-detection microscopic geometry. Applications which are based on forward-emitted signals or bi-directional illumination are restricted due to the lack of the objective lens on the other side of the tissues. In this paper, we propose a novel concept of generating an opposite virtual objective (OV-Obj). The OV-Obj serves as an objective at the other side of the observed tissue that generates the desired backward illumination inside the tissue. The concept is stated as follows. A physical objective (P-Obj) is used to forward focus a laser beam in the tissue and to collect the backward scattering light from the tissue. The backward scattering light is sent to the holography-based optical phase-conjugate mirror (HOPCM) to generate a phase conjugate wave. When the phase conjugate wave illuminates the tissue, the tissue is activated to form an inverse focusing light. This process is regarded as an OV-Obj. Under this configuration, the forward and inverse focusing beams not only focus at the same point but also inherently possess the same phase at the focal plane. This autopositioning and auto-phase-matching can benefit 4-pi-related applications. The proposed method is compatible to current supper-resolution imaging technologies including coherent and incoherent methods. Therefore, it open a window for forward-emitted signals and bi-directional illumination in thick specimens.

10382-20, Session 3

Time: The enigma of space *(Invited Paper)*

Francis T. S. Yu, The Pennsylvania State Univ. (United States)

In this article we have based on the laws of physics to illustrate the enigma time as creating our physical space (i.e., the universe). We have shown that without time there would be no physical substances, no space and no life. In reference to Einstein's energy equation, we see that energy and mass can be traded, and every mass can be treated as an Energy Reservoir. We have further shown that physical space cannot be embedded in absolute empty space and cannot have any absolute empty subspace in it. Since all physical substances existed with time, our cosmos is created by time and every substance including our universe is coexisted with time. Although time initiates the creation, it is the physical substances presented to us the existence of time. We are not alone with almost absolute certainty. Someday we may find a right planet, once upon a time, had harbored a civilization for a short period of light years.

10382-21, Session 3

Rapid silicon carbide (SiC) crystal growth by laser heating in a vacuum chamber

Shizhuo Yin, Haonan Zhou, Chang-Jiang Chen, Wenbin Zhu, Ju-Hung Chao, The Pennsylvania State Univ. (United States)

This paper reports a rapid crystal growth technique to grow up to 50 micrometer silicon carbide (SiC) crystal from nano-size SiC powder. By heating the nano-size SiC powder with a high power CO2 laser beam in a vacuum environment, the silicon carbide nanosize powder is quickly heated to a temperature closing to the melting temperature in a few seconds. The laser beam is then held for one minute and then cooling down slowly. Since the outer SiC powder can be served as the protected shell during this rapid heating and cooling down process, the inner SiC powder is largely not decomposed and/or oxidized in the vacuum chamber even at the elevated melting temperature. Instead, SiC nano-size powder grows to micro size crystal in minutes.

10382-22, Session 3

Projected fringe profilometry for transparent objects

Wei-Hung Su, National Sun Yat-Sen Univ. (Taiwan); Chau-Jern Cheng, National Taiwan Normal Univ. (Taiwan)

A full-field method using fringe projection techniques to perform the 3D profile measurement for a transparent object is proposed. A fringe pattern is illuminated onto the transparent object, and a CCD camera is employed to record the transmitted fringes on the screen. Fringes on the obtained image are deformed both by the refractive index and the topography of the object, and are analyzable to retrieve the 3D shape.

10382-23, Session 3

A scanning approach using a binary grid pattern for 3D shape measurements

Nai-Jen Cheng, National Kaohsiung Univ. of Applied Sciences (Taiwan); Wei-Hung Su, National Sun Yat-Sen Univ. (Taiwan)

A scanning pattern projection technique for 3D shape measurements is proposed. A binary grid pattern is employed as the projected pattern. The limited depth-of-focus of the pattern projection system makes the surface on the focused area can be clearly observed. Thus, a 2D contour of the inspected surface addressed by the in-focused fringes was obtained. By assembling the surface contours with their corresponding depths, the 3D shape of the object cab retrieved.

10382-24, Session 4

Highly efficient cladding-pumped double-clad fiber laser based on a concentrically co-grown Yb:YAG/YAG crystal structure *(Invited Paper)*

Jun Zhang, Youming Chen, U.S. Army Research Lab. (United States); Shizhuo Yin, The Pennsylvania State Univ. (United States); Claire Luo, General Opto Solutions, LLC (United States); Mark Dubinskiy, U.S. Army Research Lab. (United States)

We investigated double-clad (DC) optical fibers for high power laser applications, with concentrically co-grown 'Yb:YAG/YAG' crystal structure, for which 'crystalline core/crystalline clad' = CCCC = C4 fiber term was coined. The fibers were fabricated using a liquid phase epitaxial growth (LPE) of undoped single-crystalline YAG cladding around the 100 μm single-crystalline Yb:YAG core separately grown by a laser heated pedestal growth (LHPG) technique. Laser testing of the low-loss C4 fibers with direct diode-clad-pumping at 969 nm has demonstrated over 40 W of core-guided (NA $\approx$ 0.025) multimode laser output at 1030 nm with over 60% slope efficiency.

10382-25, Session 4

A large capacity time division multiplexed (TDM) laser beam combining technique enabled by nanosecond speed KTN deflector

Shizhuo Yin, Ju-Hung Chao, Wenbin Zhu, Chang-Jiang Chen, Adrian Campbell, Michael Henry, The Pennsylvania State Univ. (United States); Mark Dubinskiy, Robert C.

Hoffman, U.S. Army Research Lab. (United States)

In this paper, a large capacity time division multiplexed (TDM) laser beam combining technique enabled by nanosecond speed potassium tantalate-niobate (KTN) crystal electro-optic (EO) deflector was reported. An array of pulsed lasers could be combined together via TDM, which resulted in a significantly increased average power but without sacrificing the quality of the combined laser beam. Thus, extremely high energy lasers with diffraction limited beam quality could be realized by harnessing this TDM beam combining technique.

10382-26, Session 4

Crystal fiber lasers

Woohong Kim, Brandon Shaw, Shyam Bayya, U.S. Naval Research Lab. (United States); Charles G. Askins, John R. Peele, Sotera Defense Solutions, Inc. (United States); Daniel L. Rhonehouse, Univ. Research Foundation (United States); Jason D. Myers, Syed Qadri, U.S. Naval Research Lab. (United States); Rajesh Thapa, Sotera Defense Solutions, Inc. (United States); Jasbinder S. Sanghera, U.S. Naval Research Lab. (United States)

Crystal fibers offer several advantages over traditional glass fibers such as silica fiber due to their higher thermal conductivity and excellent thermal stability, higher stimulated Brillouin scattering (SBS) thresholds, and higher doping concentrations. Here, we report on the recent progress in the development of cladded single crystal fibers for high power single frequency lasers. Various rare earth doped single crystal YAG and sesquioxide fibers have been drawn using a state-of-the-art Laser Heated Pedestal Growth (LHPG) system equipped with high power stabilized CO2 laser, fiber diameter monitoring and feedback, and continuous feed-pull mechanism. High quality thin and long crystal fibers were successfully drawn from the LHPG system. Rare earth thin crystal fibers were further cladded using specially developed glasses where optical and physical properties were precisely controlled to form rugged and efficient single and double clad fibers. All crystalline core/clad fibers where thermal and optical properties are superior over glass based fibers have been successfully fabricated using various crystal growth and deposition methods. We report on the optical characterization and gain measurements on these clad fibers.

10382-27, Session 4

Nanosecond KTN varifocal lens without electric field induced phase transition

Shizhuo Yin, Wenbin Zhu, Ju-Hung Chao, Chang-Jiang Chen, Adrian Campbell, Michael Henry, The Pennsylvania State Univ. (United States); Robert C. Hoffman, U.S. Army Research Lab. (United States)

This paper presents a nanosecond speed KTN varifocal lens. The tuning principle of varifocal lens is based on the high-speed refractive index modulation from the nanosecond speed tunable electric field. A response time on the order of nanosecond was experimentally demonstrated, which was fastest varifocal lens reported so far. The results confirmed that the tuning speed of the KTN varifocal lens could be significantly increased by avoiding the electric field induced phase transition. Such kind of nanosecond speed varifocal lens can be a great beneficial to a variety of applications that demand high speed z-scanning, such as high resolution 3D imaging and high speed 3D printing.

10382-28, Session 4

Ultrafast laser written arrayed waveguide gratings with integrated photonic lanterns

Glen Douglass, Simon Gross, Michael J. Withford, Macquarie Univ. (Australia)

Arrayed waveguide gratings (AWGs) are typically used by the telecommunications industry as (de)multiplexers. However, recently they have successfully been demonstrated as integrated sensors for applications such as biomedical and astronomical spectrographs. Unfortunately, advancement is generally stalled by development costs and time; or restricted to spectral regions covered by off-the-shelf lithographic produced AWGs. To broaden the potential applications of integrated spectrographs employing AWGs, we utilise the femtosecond laser direct write technique as a rapid-prototyping platform for fabricating AWGs. The AWGs fabricated operate at 633nm, have a free spectral range of 22.4nm, resolution of 1.35nm, resolving power of 468.7, a throughput of 11.47% across the 5 main orders, and 3.97% in the central 28th order. This mask-less process enables complete design freedom, takes approximately 2hours from completed design to finalized device, thus facilitating design feedback to easily fine tune the device specifications.

In some applications multimode fibres are used for efficient light collection, thus leading to large losses when coupling into single mode devices such as AWGs. A solution is to utilize a 3-dimensional photonic lantern. A photonic lantern converts multimode light into multiple single-mode waveguides that can then be individually launched into an AWG. While the AWG is only a 2-dimensional device the laser direct write technique enables 3-dimensional fabrication. Thus supporting the integration of a photonic lantern and AWG into a single monolithic chip, removing coupling losses while increasing the functionality of the AWG. Currently we have demonstrated the integration of a 3 port photonic lantern.

1One shot profile sensing using a 2D fringe-encoded pattern

Wei-Hung Su, Sih-Yue Chen, National Sun Yat-Sen Univ. (Taiwan)

A one-shot profilometry for surfaces with color or reflectivity variation is presented. It uses 2D fringe-encoded pattern to illuminate the inspected object and a monochromatic camera to observe the deformed fringes at another view angle. The encoded pattern provides additional to identify the fringe order. For spatially isolated objects or surfaces with large depth discontinuities, unwrapping can be identified without ambiguity. Even though the surface color or reflectivity varies rapidly with position, it distinguishes the fringe order as well.

10382-31, Session 4

Phase-shifting projected fringe profilometry using binary-encoded patterns

Sih-Yue Chen, National Sun Yat-Sen Univ. (Taiwan); Nai-Jen Cheng, National Kaohsiung Univ. of Applied Sciences (Taiwan); Wei-Hung Su, National Sun Yat-Sen Univ. (Taiwan)

A fringe projection profilometry is presented. It uses the phase-shifting technique perform the phase-extraction and use the binary-encoded patterns to identify the fringe orders. Only five-shot measurements are required for data processing. Experiments show that absolute phases could be obtained with high reliability.

10382-32, Session PMon

1 kW fiber cladding light stripper with 36 dB attenuation coefficient

Shuzhen Zou, Han Chen, Haijuan Yu, Zhiyan Zhang, Institute of Semiconductors, Chinese Academy of Sciences (China); Jingyuan Zhang, Institute of Semiconductors, Chinese Academy of Sciences (China) and Georgia Southern Univ. (United States); Jing Sun, Pengfei Zhao, Ling Zhang, Xuechun Lin, Institute of Semiconductors, Chinese Academy of Sciences (China)

High power fiber cladding light stripper is one of the key devices in the high fiber laser for stripping out the residual pump light and the signal light which is leaked from the fiber core into the fiber cladding. It eliminates the thermal effect and the damage on the key fiber devices and ensures the high beam quality of the fiber laser. We present a continuous gradient etching processing technique for fabricating a high power fiber cladding light stripper without significant temperature rise. An experimental device was designed for achieving continuous gradient etching of the fiber surface. The corresponding axial distribution of the fiber cladding etching time was obtained through ray tracing simulation and experimental tests. A stripper with axial uniform scattering power and a low temperature was fabricated, which provided an attenuation coefficient of 36 dB when the test pumping power was 1.01 kW with NA of 0.46. The highest temperature of the stripper was only 78.5 ? and the temperature rising rate was 0.05 ?/W when such a high cladding power was extracted. The temperature and the residual output power showed no significant fluctuation in the stability test for one hour. The performance of stripper by using this axial uniform power stripping technique shows that it is very suitable for the higher power fiber lasers at about 10-kilowatt level.

The study of graphene thin film affects the heat conduction of HPLED

Ming Seng Hsu, Chinese Military Academy (Taiwan); Ching Yao Hsu, Cantwell-Sacred Heart of Mary High School (United States); Jen Wei Huang, Feng Lin Shyu, Chinese Military Academy (Taiwan)

Thin films were the best choice for microelectromechanical systems (MEMS) material. In this study, the graphene thin film was fabricated between the high power light emitting diodes (HPLED) source and 1070 aluminum alloy substrate by chemical reduction of exfoliated graphene oxide technology. It will be used to enhance both of the heat conduction and dissipation. In the process, thin films were characterized by several subsequent analyses to help the preparation of ggraphene thin films with high heat conduction. X-Ray photoelectron spectrometry (XPS), Raman spectra and atomic force microscopy (AFM) analyses reveal the ratio of carbon to oxygen (C/O) atoms, the ratio and the phase of sp2 bonds, and the morphology in the microstructure. The physical properties will characterized by Hardness measurement, Scratch test, and Sheet resistivity measurement. Thermal resistance test shall through the measurement of real work temperature of HPLED.

FBG sensing system to study the bridge weigh-in-motion

Sravanthi Alamandala, Putha Kishore, L. N. Sai Prasad Ravinuthala, Mayank Upadhyay, Rathish Kumar P., National Institute of Technology, Warangal (India)

In this paper, a Fiber Bragg Grating (FBG) based Weigh-in-Motion (WIM) sensing system is designed by using two FBGs, each one attached to the center tension position of the beam with an angle of 45o between two piers of the Bridge. To study the response of the designed WIM system, the vehicle is moved over the bridge with varying velocities and loads. The temporal response of the FBG1 and FBG2 and wavelength shift is recorded using interrogator of resolution 1pm. The wavelength shift of the FBG illustrates two peaks and one dip, it represents the position of the vehicle at that point of the FBG over the bridge. The difference between these points of the two FBGs measures the velocity of the vehicle. The load of the vehicle can be measured from the height of the FBG dip at a particular velocity. The response of the sensor system for velocity and load shows linear of around 0.99 upto 150m/sec velocity and 5N weight respectively . The results reveals that the proposed system is capable to monitor the dynamic response of the load and velocity of the moving vehicle over the bridge.

10382-35, Session PMon

A dual tapered Mach- Zehnder interferometer for magnetic field sensing

Emmanuel A. Hernandez, Julián Moisés Estudillo-Ayala, Juan Manuel Sierra-Hernandez, Daniel Jáuregui-Vázquez, Roberto Rojas-Laguna, José Ramón Martínez Angulo, Univ. de Guanajuato (Mexico)

A magnetic field sensor based on a Mach-Zehnder interferometer (MZI) is proposed. Developed using tapered optical fiber technique in a SMF-28 optical fiber. In the SMF-28 Fiber the Mach- Zehnder interferometer is manufactured with two tapers, with a waist diameter of 40 um and a length of 5 mm, and a separation between the tapers about of 3~4 cm. The MZI will be covered by a fluid with magnetic proprieties inside a capillary tube. Performing experiments with coils and transformers, hoping that the proposed sensor offers a good option to measure the magnetic field in electrical devices and measurements electrical current in transmission lines.

Detection of trace amounts of chromium (VI) using polymergel coated etched Fiber Bragg grating

Vayu Nandana Kishore Pabbisetti, National Institute of Technology, Warangal (India)

Chromium (VI) is a notorious metal ion well known for toxic and carcinogenic effects. In environment, chromium exists in two notable oxidation states, trivalent chromium (III) and hexavalent chromium (VI), of which hexavalent chromium ion Cr (VI) is known to be 500 times more toxic. Cr (VI) is highly active and easily binds with the DNA of human cells leading to various types cancers. The existing chromium sensors are suffering with drawbacks such as high time consumption, expensive instrumentation, and high maintenance costs. Thus eco-friendly, low cost, fast responsive and effective techniques are essentially required for the detection of Cr (VI) ion.

Stimulus responsive polymer gels swell or shrink in size in response to changes in surrounding physical and chemical parameters such as pH, electric and magnetic fields, light, salt concentrations and presence of specific ions. polymer gel coated FBG sensors, is an emerging area of research in which stimulus responsive property of hydrogels causes a swelling or contraction of the gel which in turn affects wavelength shift of FBG peak.

This article discusses a chemo- mechanical- optical sensing approach for detection of toxic chromium (VI) metal ion in environment. Stimulus responsive polymer gel which swell/deswell depending on ambient chromium ion concentrations is synthesized and agglutinated on an etched Fiber bragg grating (FBG) surface. To characterize performance of the sensor, it has undergone for various studies. The sensor shows good selectivity towards Chromium (VI) metal ion. Trace amount of chromium even down to 10ppb can be sensed by the method.

10382-37, Session PMon

Raman monitoring and evaluation of the aging effects of rocket propellant stabilizers

Jonathan A. Mills, Carlton W. Farley III, Aschalew Kassu, Michael Curley, Anup Sharma, Paul B. Ruffin, Alabama A&M Univ. (United States); Christopher A. Marshall, Jeremy Rice, Brian A. McDonald, U.S. Army Research, Development and Engineering Command (United States)

Stabilizers are added to nitrate ester based rocket motor propellants to form a stable product. The products added to stabilize the propellants react with NOx and are gradually exhausted over a period of time. In this paper, we demonstrate the efficacy of Raman spectroscopy technique for nondestructive, inexpensive, and rapid evaluation and monitoring of the depletion of rocket motor propellant stabilizers. The preliminary results show that, as low as 0.1% of both MNA and 2-NDPA dissolved in DMSO (Dimethyl sulfoxide) can easily be detected at 1 second integration time using a 785 nm wavelength Raman system. In addition, MNA concentrations between 0.37% and 0.54% are detected in live propellant samples using a 60 second integration time.

10382-38, Session PMon

An ultra-high contrast optical modulator with 30 dB isolation at 1.55 μm with 25 THz bandwidth

Mohsen Jafari, University of Michigan (United States); Mina Rais-Zadeh, University of Michigan (United States) and NASA Jet Propulsion Laboratory (United States)

Re-configurability employed in many optical shutters and modulators comes from either mechanical or optical change in the structure [1,2]. State-of-the-art electro-optical modulators use index changing materials such as liquid crystals [3], Germanium (Antimony) Telluride [4], [5], or Vanadium oxides [6]. Two significantly different refractive index values at two different phases available in these materials are exploited to achieve amplitude or phase modulation. Here, we present a high-contrast electro-optical modulator with record-breaking amplitude modulation index of 27 dB and forward loss of < 3 dB at 1.55 μm. The high contrast is achieved by utilizing slit and surface plasmon polariton (SPP) resonances in a two-layer stack of gold slits filled with a phase change material (Germanium Telluride-GeTe). Stacking multiple layers of the phase change plasmonic grating enabled the development of the high-index modulator in chip scale dimensions at telecommunication wavelengths. These sub-wavelength gratings are fabricated using two metal e-beam lithography (each 200 nm thick) separated with a thin (~300 nm) silicon nitride (Si_3N_4) spacing layer.

Extraordinary light transmission from the slit resonance in gratings [7] is employed to achieve high transmission (>50%) in the modulator OFF state when GeTe is amorphous. In the crystalline phase, however, the slit resonances are moved to longer wavelengths and the grating absorption is increased through coupling to SPPs. Each layer provides 14 dB isolation with a 27 dB total amplitude modulation for a two-layer device. Crystallographic phase transition of GeTe is achieved by applying a dc current through the same sub-wavelength array of gold lines (crystallization energy ~ 10 pJ @ 2 MHz switching frequency). FTIR spectroscopy of multiple fabricated devices verifies the theoretical transmission isolation of 30 dB.

Enhancement of terahertz generation in QD antennae by introduction of a silver nanoantennae pattern *(Invited Paper)*

Edik U. Rafailov, Sergei Lepeshov, Andrei Gorodetsky, Aston Univ. (United Kingdom)

Terahertz photoconductive antennae are one of the most promising sources of pulsed and CW THz radiation operated at room temperatures. However, antennae possess a low coefficient of optical-to-terahertz conversion due to the carrier screening effect and low quantum efficiency. To overcome these limitations, optical nanoantennae techniques can be used. Optical nanoantennae are resonant nanostructures capable of transforming incident optical waves in a strong near-field. Such nanoantennae can be used to enhance the electric field and increase the absorption cross section in the active layers of the antenna. We present results on pulsed and CW THz generation in quantum dot based photoconductive antennae (PCA) pumped by femtosecond and dual-wavelength semiconductor lasers. We also present results on enhancement of THz generation in QD-based log-periodic PCA with silver nanoantennae embedded in the antenna gap. 20-nm silver film was placed onto the surface of the antennae. Upon heating due to the thermal dewetting process the silver film folded into a disordered array of spheroid nanoparticles. By varying the thickness of the silver film, the size of the nanoparticles can be controllably changed. Our first results demonstrated that in the frequency range from 0.05 to 0.5 THz, the average output power gain value was 3, at the frequency of 0.5 THz there was no gain, and in the range from 0.5 to 1.1 THz, the average gain value was up to 5. Therefore, using silver spheroid nanoantennae fabricated by a relatively simple method can increase the coefficient of optical-to-terahertz conversion up to 4 times.

10383-2, Session 1

Backward wave oscillator for high power generation at THz frequencies *(Invited Paper)*

Diana Gamzina, SLAC National Accelerator Lab. (United States); Claudio Paoloni, Lancaster Univ. (United Kingdom); Ye Tang, Beijing Vacuum Electronics Research Institute (China); Xiang Li, Lancaster Univ. (United Kingdom); Xuejiao Hao, Yuan Zheng, Beijing Vacuum Electronics Research Institute (China); Branko Popovic, Logan Himes, Robert Barchfeld, Univ. of California, Davis (United States); Hanyan Li, Pan Pan, Beijing Vacuum Electronics Research Institute (China); Rosa Letizia, Lancaster Univ. (United Kingdom); Jinjun Feng, Beijing Vacuum Electronics Research Institute (China); Neville C. Luhmann Jr., Univ. of California, Davis (United States)

Generation of high power at Watt level in the sub-THz region remains a challenge. The advent of microfabrication techniques derived from MEMS technology and ultra-precision CNC milling with nanometric resolution are fostering the development of compact vacuum electron devices up to 1 THz with unprecedented output power level.

The Backward wave oscillator is one of the most promising vacuum THz sources. The physical mechanism is based on the transfer of energy from an electron beam traveling in a slow wave structure to an electromagnetic wave. It consists of an electron gun to generate the required electron beam, an interaction structure to support a wave at the operating frequency, a collector to collect the spent electron beam at the end of the tube, and a magnetic focussing field to keep the beam confined.

This paper describes the outstanding technological effort to design and realize a backward wave oscillator with 0.346 GHz operating frequency to be employed in fusion plasma diagnostics.

The dimensions of the parts require microfabrication processes with tolerance below a few microns and metal surface roughness below 50 nanometers. The latter constraint is fundamental to keeping the ohmic losses low.

In particular, the slow wave structure will be fabricated by nano CNC milling.

Different slow wave structures and beam shape are considered to produce a family of BWOs with different output power. In particular, the double corrugated waveguide is used with a cylindrical electron beam.

An output power higher than 0.5 W is obtained.

The BWO is in an advanced fabrication phase.

10383-3, Session 1

Coherent terahertz emission from nanomaterials without external bias *(Invited Paper)*

Lyubov V. Titova, Kateryna Kushnir, Worcester Polytechnic Institute (United States); Mengjing Wang, Brown Univ. (United States); Kristie J. Koski, Univ. of California, Davis (United States)

Recent theoretical studies predict that monolayer van der Waals mono-chalcogenides such as GeSe, GeS and SnS are ferroelectric, which makes them attractive candidates for bulk photovoltaic effect (BPVE), defined as production of a photocurrent at zero bias in the absence of traditional p-n junctions. The prevailing mechanism behind BPVE is a shift current, a zero-bias photocurrent resulting from excitation of quantum coherent carriers in noncentrosymmetric materials. We apply terahertz (THz) emission spectroscopy to probe shift currents in 2D chalcogenide nanomaterials. Shift current resulting from excitation with ultrafast pulses gives rise to THz emission, and detecting it allows electrical contact-free, all-optical monitoring of shift currents. In one example, we find that THz generation in GeS nanosheets is more efficient that in (110) ZnTe, which is a standard THz pulse source used for THz time-domain spectroscopy. Shift current photoexcitation in GeS nanosheets suggests applications of these new layered nanomaterials in third generation photovoltaics as well as in efficient, ultrathin THz sources.

Terahertz metasurface quantum-cascade VECSEL *(Invited Paper)*

Luyao Xu, Christopher A. Curwen, Daguan Chen, Univ. of California, Los Angeles (United States); John L. Reno, Sandia National Labs. (United States); Tatsuo Itoh, Benjamin S. Williams, Univ. of California, Los Angeles (United States)

Achieving high power in combination with high quality beam pattern is

a ubiquitous challenge for semiconductor lasers. The demonstration of vertical-external-cavity surface-emitting lasers (VECSELs) in 1997 for visible and near-infrared semiconductor lasers has been a very successful approach. Terahertz (THz) quantum-cascade (QC) lasers, also have the challenge of combining high power and good beam pattern into one device – even more so because they typically use sub-wavelength metallic waveguides. The concept of VECSEL has been impossible to implement for QC lasers, since the optical gain is based on intersubband transitions of electrons, which only interact with the electric field polarized perpendicular to the quantum wells plane according to the "intersubband selection rule". To address this issue, we have developed an amplifying metasurface reflector that can couple the incident THz wave with the QC gain medium via metal-metal micro-cavity antenna reflectarray. Pairing the active metasurface with an output coupler, we demonstrated the first VECSEL in the THz regime in 2015. Based upon the prototype design, we have achieved a number of improvements to the QC-VECSEL including designing an inhomogeneous focusing metasurface to achieve a near-diffraction limited beam pattern with M2 = 1.3 and high brightness of 1.86?106 Wsr-1m-2, designing compact cavities and optimizing metasurface bias area to achieve continuous-wave operation above 77 K, achieving record high slope efficiency of 745 mW/A, as well as extending the VECSEL concept to cover a broad frequency range from 2.5 - 4.4 THz.

10383-6, Session 2

High-performance broadly-tunable THz quantum cascade laser sources based on intracavity difference-frequency mixing on silicon substrates *(Invited Paper)*

Mikhail A. Belkin, The Univ. of Texas at Austin (United States)

We demonstrate that an application of a III-V-on-silicon hybrid concept to terahertz (THz) Cherenkov difference frequency generation (DFG) quantum cascade laser (QCL) sources (THz DFG-QCLs) can dramatically improve THz output power and mid-infrared-to-THz conversion efficiency. Completely processed THz DFG-QCLs grown on a InP substrate are transfer-printed onto a 1-mm-thick high-resistive Si substrate using a 100-nm-thick SU-8 as an adhesive layer. Room temperature device performance of the reference InP and hybrid Si THz DFG-QCLs of the same ridge width (22 µm) and cavity length (4.2 mm) have been experimentally compared. The target THz frequency of 3.5 THz is selected for both devices using the dual-period first order surface gratings to select the mid-infrared pump wavelength of 994 cm-1 and 1110 cm-1. At the maximum bias current, the reference InP and hybrid Si devices produced THz power of 50 µW and 270 µW, respectively. The mid-infrared-to-THz conversion efficiency corresponds to 60 µW/W2 and 480 µW/W2, respectively, resulting in 5 times higher THz power and 8 times higher conversion efficiency from the best-performing hybrid devices. A hybrid Si device integrated in a Littrow external-cavity setup showed wavelength tuning in the 1-6 THz range without THz beam steering.

10383-7, Session 3

Spintronic terahertz generation *(Invited Paper)*

Dmitry Turchinovich, Max-Planck-Institut für Polymerforschung (Germany)

In this presentation we will review the principles and applications of THz generation based on spintronic phenomena: coherent spinwave generation [1], Mott scattering [2], and inverse spin-Hall effect [3].

Tunable terahertz devices using graphene and metallic heterostructures

Yang Wu, Hyunsoo Yang, National Univ. of Singapore (Singapore)

Graphene is considered to be a promising candidate to replace indium tin oxide (ITO) as transparent conductive electrodes in optoelectronics applications. We use graphene films as transparent electrodes for THz applications such as phase shifters, reflector, and intensity modulators, leading to a low voltage operation and very small insertion loss.

First, we experimentally demonstrate the excellent performance of THz modulators based on graphene/ionic liquid/graphene sandwich structures. The modulation covers a broadband frequency range from 0.1 to 2.5 THz with the modulation depth of up to 99% by applying a small gate voltage of 3 V. To our knowledge, this is the highest modulation ratio from graphene based THz devices to date. We also report a highly efficient tunable THz reflector in graphene. By applying a small gate voltage (up to ± 3 V), the reflectance of graphene is modulated from a minimum of 0.79% to a maximum of 33.4% using graphene/ionic liquid structures at room temperature, and the reflection tuning is uniform within a wide spectral range (0.1 – 1.5 THz). In addition, we design and fabricate terahertz phase shifters based on thin liquid crystal cells sandwiched by two graphene layers. A maximum 10.8 degree phase shift is obtained with 5 V voltage. The proposed phase shifters are fully electrical controllable, continuous tunable, and require very low DC voltages for operation.

Finally, we show a high performance THz emitter based on ferromagnetic/nonmagnetic heterostructures. Our THz emitter based on nonmagnetic (NM) and ferromagnetic (FM) heterostructures has a peak intensity exceeding 500 ?m thick ZnTe crystals (standard THz emitters). We have also fabricated the devices on flexible substrates with a great performance, and demonstrated that the devices can be driven by low power lasers.

10383-9, Session 3

Design of a multistep phase mask for high-energy THz pulse generation in ZnTe crystal

Yuri H. Avetisyan, Armen Makaryan, Vahe Tadevosyan, Yerevan State Univ. (Armenia)

Optical rectification (OR) of the femtosecond laser pulses in nonlinear optical crystals has emerged as the most powerful way to generate high energy THz-pulses. The tilted-pulse-front pumping (TPFP) method is commonly used for phase-matched THz-pulse generation. By such way THz pulses with 0.4 mJ energy were obtained in lithium niobate crystal (LN) [1]. However, further increase of the THz energy is challenging due to many limiting factors. Recently it was shown that application of the grating on the surface of ZnTe crystal allows to overcome some of the limiting factors [2].

In this report we present a new design of THz source using a multi-step phase mask (MSPM) to provide discretely tilted pulse-front in ZnTe crystal. In essence, MSPM split a single input beam into many smaller time-delayed "beamlets", which together create a discretely tilted pulse front. In contrast to using of the gratings, here problems related to the introduction of large amounts of angular dispersion are eliminated.

We also calculate the steps horizontal and vertical dimensions that are needed to generate THz-pulse with maximal energy and high efficiency of

pump-to-THz conversion. The optimal number of the steps N is estimated taking in account the separate beamlets broadening in MSPM and problem of its fabrication. The proposed method is promising to realize highly efficient, monolithic, and alignment-free table-top THz source.

10383-10, Session 3

THz nonlinearities in semiconductor superlattices *(Invited Paper)*

Mauro F. Pereira, Sheffield Hallam Univ. (United Kingdom)

This paper is focused on nonlinear optics for the THz range in semiconductor superlattices. A Nonequilibrium Green's Functions approach [A. Wacker et a, IEEE Journal of Sel. Top. in Quantum Electron.,19 1200611, (2013),T. Schmielau and M.F. Pereira, Appl. Phys. Lett. 95 231111, (2009)] is used to deliver input to analytical expressions for the nonlinear polarization for arbitrary orders. A complex balance between superlattice bias and input field power rule is demonstrated. The theory presented here predicts the nonlinear polarization in excellent agreement with experiments up to the 21st order. These results open the possibility of extending nonlinear optics to the THz range for a large number of applications based on superlattices as the basic nonlinear medium as well as for sources and detectors.

10383-11, Session 4

Temperature-driven massless fermions in HgCdTe heterostructures *(Invited Paper)*

Frédéric Teppe, Sergey Krishtopenko, Sandra Ruffenach, Univ. Montpellier (France)

Bulk films and heterostructures based on HgCdTe compounds can be engineered to fabricate "gapped-at-will" structures. Therefore, 1D , 2D and even 3D massless particles can be observed in topological phase transitions driven by intrinsic (quantum well thickness, Cd content) and external (magnetic field, temperature or pressure) physical parameters. So far, the phases of 2D and 3D topological insulator have already been experimentally demonstrated in HgCdTe-based heterostructures. More recently, clear experimental evidence of the existence of 3D electronic states with conical-like spectrum was obtained in HgCdTe bulk films at specific Cd content . These 3D massless particles, called Kane fermions, have unique symmetry properties, which are not equivalent to any well-known case of massless particles in the relativistic limit of the quantum electrodynamics.

In this work, we report on our recent experimental results obtained by Terahertz and Mid-Infrared magneto-spectroscopy, on topological phase transitions driven by temperature in HgCdTe-based QWs and bulk films. These transitions are accompanied with the appearance of 2D and 3D massless electrons called Dirac and Kane fermions, respectively.

10383-12, Session 4

Complex delay dynamics of high power quantum cascade oscillators *(Invited Paper)*

Frédéric Grillot, Télécom ParisTech (France); Timothy C. Newell, Air Force Research Lab. (United States); Athanasios Gavrielides, The Univ. of New Mexico (United States); Mathieu Carras, mirSense (France)

Quantum cascade lasers (QCL) are semiconductor lasers based on ultrafast intersubband transitions with picosecond timescale that have become the most suitable laser sources from the mid-infrared to the THz range, due to their compactness, efficiency and high room temperature performances. In particular, high-power QCLs are powerful sources for optical countermeasures, including night vision blinding and missile out steering. However, some drawbacks arise with high power lasers that usually lead to a strong degradation of the beam quality. In this paper, we examine the effects of external feedback in different high power mid infrared QCL structures and discover that the incident angle of the feedback wave can produce complex dynamics hence stabilization, destabilization into strong mode-competition or undamping nonlinear oscillations. More particularly, with a feedback above a few percent, the laser beam can be steered in the far-field using the mirror as the control parameter. In a second regime, very strong mode competition takes place while the last regime shows strong evidence of small amplitude external cavity oscillations. The laser is stable near threshold and a bifurcation occurs with increasing power exciting such external cavity oscillations. As a dynamical system, reinjection of external light back into the cavity also can also provoke possible apparition of chaotic oscillations which must be avoided for a stable operation. To this end, the paper will also review the limiting conditions leading to chaotic light at mid-infrared and THz wavelengths.

10383-13, Session 4

Characterization of THz wave generated from air plasma induced by two-color laser with long wavelength

Shijing Zhang, Beijing Institute of Technology (China); LiangLiang Zhang, Capital Normal Univ. (China); Tong Wu, Beijing Institute of Technology (China); Hang Zhao, Capital Normal Univ. (China); Yuejin Zhao, Beijing Institute of Technology (China); Xiaomei Yu, Peking Univ. (China)

Terahertz wave generation from laser-induced air plasma is widely used due to its high electric field and broad frequency bandwidth. The most popular and efficient laser-plasma scheme used for THz generation is the two-color scheme, in which a laser pulse at the fundamental frequency is supplemented by its second harmonic that is obtained with the use of a nonlinear crystal. The type-I ?-barium borate (BBO) crystal plays a very important role in second harmonic generation. In this research, we investigate the terahertz generation efficiency and polarization with changing the thicknesses of the BBO crystals (from 60um to 100um with an interval of 10um). Moreover, the wavelength of the excitation laser is tunable from 1200nm to 1600nm. The THz generation efficiency is characterized by rotating the BBO crystal with the same tilt angle, changing laser wavelength with invariant pump power. And we also record the polarization variation of THz wave by using a wire grid THz polarizer. We think that the thickness of BBO crystal affects the phase difference between the ordinary axis and the extraordinary axis component, which leads to the change of the polarization state of the fundamental. Meanwhile, the frequency doubling efficiency of BBO has an impact on the power ratio of the two-color laser. This provides a practical way to control the polarization of terahertz pulses for potential applications.

10383-14, Session 4

Terahertz and x-ray generation in nano-cluster jets: Origin of nonlinear interaction *(Invited Paper)*

Alexander P. Shkurinov, M.V. Lomonosov Moscow SU (Russian Federation)

We have found that the yield of THz and X-ray radiation from the argon cluster beam, excited by high-intensity femtosecond laser pulses, depends differently on the laser pulse duration. THz yield strongly decreases when laser pulse duration is the shortest, whereas X-ray yield is maximal under these conditions. The formation of spatial distribution under 30 is connected with the dynamics of radial oscillations and, therefore, has such complex dependence on the pulse duration. X-ray emission does not depend on such dynamics and grows proportionally to the growth of the laser intensity.The

difference in the optimal laser pulse duration for the efficient generation of X-ray and THz radiation can be explained by the different time periods required for the formation of electron subsystems in argon cluster. The population of outer electrons rises quickly during the first 50 fs and they are responsible for the generation of X-ray, which explains the maximal X-ray yield at the minimal pulse duration in our experiments. The inner electrons multiply slowly and their population reaches maximum at the time scale of about hundreds femtoseconds, which can be attributed to the enhancement of THz yield at ? approx250 fs in our experiments. At the later stages, the population of outer electrons begins to rise again that may cause the decrease in the THz signal. The use of dual-color excitation scheme results in 5-fold enhancement of the THz yield while the yield of the X-ray radiation remains the same and energy conversion efficiency to the K-line is about 7·10?6.

10383-15, Session 4

Generation of ultra-broadband terahertz radiation from LiNbO3 waveguides excited by femtosecond optical pulses

Brett N. Carnio, Abdulhakem Y. Elezzabi, Univ. of Alberta (Canada)

Terahertz (THz) electric field pulses covering the frequency range of 100 GHz to >100 THz allow for the ultra broad exploration of molecular dynamics, elementary excitations, nanostructure phenomenon, devices operation, and photonic component properties. Here, ultra broadband THz radiation generation is investigated in waveguide structures having a lithium niobate (LN) core and SiO2 cladding layers. These materials have sub wavelength dimensions and are sandwiched between two bulk Si layers, allowing wide band THz electric field pulses to be emitted at a nearly constant angle of 49? (as determined by the Si refractive index). When the waveguides are excited by laser pulses having a central wavelength of 780 nm and a duration of <10 fs, electric field pulses containing frequency components between 0.1 and 120 THz can be generated that have kV/cm amplitudes and short (<1 ps) durations. Notably, the sub wavelength dimensions of LN minimizes the amount of THz absorption in the lossy frequency regions of this material, permitting more efficient radiation generation in these waveguide structures, opposed to bulk LN THz generation arrangements. These sub wavelength LN based waveguides have the potential to be used for on chip applications demanding an ultra wide frequency spectrum.

10383-16, Session 5

Substance identification by pulsed THz spectroscopy in the presence of disordered structure *(Invited Paper)*

Vyacheslav A. Trofimov, Irina G. Zakharova, Dmitry Y. Zagursky, Svetlana A. Varentsova, M.V. Lomonosov Moscow SU (Russian Federation)

We discuss an effective method for the detection and identification of substance, covered by disordered structure, using the pulsed THz signal. The insufficiency of the standard THz-TDS method, based on comparison of the substance absorption spectra from database with the absorption spectrum of a substance under investigation, is demonstrated. The discussed method is based on time-dependent integral correlation criteria calculated using spectral dynamics of a medium response. A new type of the integral correlation criterion, which is less dependent on spectral characteristics of a noisy signal under investigation, is used for identification. To explain a physical mechanism for false absorption lines appearance in the signal we make a computer simulation using 1D Maxwell's equations and density matrix formalism.

For the detection and identification of substance we propose using a substance emission at high frequencies corresponding to high energy levels excitation due to cascade mechanism of their excitation under the THz pulse action.

10383-17, Session 5

Using ultrafast terahertz spectroscopy to study low energy excitations in quantum materials *(Invited Paper)*

Pamela Bowlan, Kamaraju Natarajan, Dmitry A. Yarotski, Antoinette J. Taylor, Rohit P. Prasankumar, Los Alamos National Lab. (United States)

Low energy excitations can shed light on the interplay between different degrees of freedom in complex materials. Ultrashort terahertz (THz) pulses can be used to both drive and probe these excitations. This is particularly useful in quantum and Dirac materials, since these materials exhibit novel magnetic and lattice excitations that can potentially be used to control their properties. Here, the use of ultrafast THz spectroscopy to probe the cyclotron resonance frequency in two-dimensional (2D) electron and hole gases and drive nonlinear phonon dynamics in the topological insulator Bi2Se3 will be discussed.

We used terahertz magneto-optical spectroscopy to study two-dimensional (2D) electron and hole gases in semiconductor quantum wells. Our measurements reveal a nonlinear scaling of the cyclotron resonance frequency with magnetic field in 2D hole gases, due to the non-parabolicity of the valence band structure. Furthermore, optical photoexcitation of a 2D electron gas reveals not only photoinduced changes at the cyclotron frequency, but also unexpected higher frequency modes that are likely due to internal hydrogen-like transitions of ionized donor atoms.

Intense THz pulses can also be used to drive low energy excitations in Dirac materials. We used intense THz pulses to resonantly drive an IR active phonon in Bi2Se3 and probed the resulting ultrafast changes in surface symmetry using optical second harmonic generation. We then coherently controlled the lattice vibrations with a pair of THz pulses. Our work thus demonstrates a versatile, table-top tool for probing and controlling phonon dynamics in a range of systems, particularly at surfaces and interfaces.

10383-18, Session 5

Dual THz comb spectroscopy *(Invited Paper)*

Takeshi Yasui, Tokushima Univ. (Japan)

Terahertz (THz) frequency comb has attracted attentions as a powerful tool for frequency metrology in THz region because a series of the comb teeth can be used as frequency markers traceable to a frequency standard for the broadband spectrum. Dual THz comb spectroscopy opens a new door for the high-resolution, high-accuracy, broadband spectroscopy because THz comb posses both characteristics of narrow-linewidth radiation and broadband spectrum. Furthermore, absolute frequency of comb tooth is secured by the frequency standard. However, too discrete distribution of the comb tooth limits the spectral sampling to the frequency spacing between the comb teeth although the linewidth of each tooth is sufficiently narrow. Here, we demonstrated combination of spectrally interleaved THz comb with dual THz comb spectroscopy by precise sweeping of frequency interval in dual THz combs. Furthermore, the spectrally interleaved THz comb was effectively applied for high-precision spectroscopy of water vapor in low pressure.

10383-19, Session 6

Using a gate electrode to control the tunneling current in a geometrically-asymmetric nanoantenna

Mohammad S. Khalifa, Zewail City of Science and

Technology (Egypt) and Cairo Univ. (Egypt); Ashraf H. Badawi, Zewail City of Science and Technology (Egypt); Tamer A. Ali, Cairo Univ. (Egypt) and Zewail City of Science and Technology (Egypt); Nadia H. Rafat, Ahmed A. Abouelsaood, Cairo Univ. (Egypt)

Geometrically asymmetric nanoantennas have been demonstrated to have a good ability to convert electromagnetic waves, in the optical range, into a rectified electric current. In this work, we focus on a nanostructure that consists of two metallic electrodes separated by a vacuum channel, with one of them supporting a nanotip. The asymmetry in the geometry introduced by the nanotip allows the electrons driven by the incident electromagnetic waves to tunnel through the vacuum channel in one direction more than the other, resulting in a rectified current. In this work, we investigate the potentials of integrating a gate electrode into the nanoantenna, in order to control the tunneling current through the vacuum channel. A three-dimensional analysis is used to model the quantum tunneling of the electrons driven by the electromagnetic field between the nanoantenna electrodes. The current transport through the nanoantenna is computed based on a transfer-matrix methodology. This approach enables studying this novel triode-structure nanoantenna at such a miniaturized scale for the first time. The obtained results demonstrate the current dependence on the voltage applied on the gate electrode. It is also shown that the rectification properties of the nanoantenna at optical frequencies can be significantly enhanced by exploiting the gate electrode.

10383-20, Session 6

Spectral emission control of terahertz quantum cascade laser via injection seeding technique *(Invited Paper)*

Hanond Nong, Feihu Wang, Lab. Pierre Aigrain (France); Tobias Fobbe, Ruhr-Univ. Bochum (Germany); Valentino Pistore, Sarah Houver, Lab. Pierre Aigrain (France); Sergej Markmann, Nathan Jukam, Ruhr-Univ. Bochum (Germany); Maria Amanti, Carlo Sirtori, Univ. Paris 7-Denis Diderot (France); Souad Moumdji, Raffaele Colombelli, Institut d'Électronique Fondamentale (France); Lianhe H. Li, Edmund H. Linfield, Giles A. Davies, Univ. of Leeds (United Kingdom); Juliette Mangeney, Jérôme Tignon, Sukhdeep Dhillon, Lab. Pierre Aigrain (France)

As applications such as heterodyne spectroscopy require only single mode operation, the selection, suppression and tuning of individual lasing modes in THz QCLs has received considerable attention over the last decade. By periodically patterning the QCL in one- or two dimensions (e.g. distributed feedback (DFB) or photonic crystal lasers), single mode emission can be enforced. An alternative approach which requires no modification of the QCL waveguide is based on injection seeding technique with tunable narrowband THz seeds. Using this technique, we will show how the same QCL can be operated in both multi-mode and single mode regimes.

On the other hand, short pulses allow for time-resolved measurements and the generation of frequency combs. As the duration of a pulse is limited by its spectral bandwidth, a multimode operation of the QCL is highly desirable. By addition of a microwave modulation at the round-trip frequency, where the spacing and phase of the QCL modes is consequently fixed, results in active modelocking. This leads to laser emission of a train of THz pulses separated by the round-trip frequency. Coupled to coherent detection and a novel application of dispersion compensation, we demonstrate the generation of a stable 4 ps train pulse train. This opens up the possibility to reach sub-picosecond pulses and potentially the single cycle regime.

To conclude, we will show two methods to control the THz QCL emission from single mode regimes to the generation of short THz pulses.

10383-21, Session 6

Wavefront phase modulation based on terahertz wave polyethylene lens

Tielin Lu, Instrumentation Technology and Economy Institute (China); Xiaohu Guo, China North Vehicle Research Institute (China); Yuejin Zhao, Jingshui Zhang, Lingqin Kong, Beijing Institute of Technology (China)

THZ wave modulator, due to its important value of research and application widely attention. In the paper?we discuss the Polyethylene lens based the terahertz wavefront modulation?which is benefit the terahertz image technology.We present a novel method to design the optical terahertz image root and simulation verifies the modulation results.IThe results could be applied in terahertz imaging and sensing.

10383-22, Session 6

Band engineering of metal/semiconductor nanocomposites for longer wavelength high performance terahertz photoconductive switches *(Invited Paper)*

Joshua M. Zide, Univ. of Delaware (United States)

We present our recent work on the band engineering of semiconductor matrix materials to extend the wavelength of photoconductive switches for terahertz generation and detection. Recent work has shown that ErAs:GaAs is an excellent material for photoconductive switches, with bandwidth and performance exceeding that typically obtained in materials such as low-temperature-grown GaAs. Briefly, the ErAs nanoparticles serve as deep recombination centers, increasing dark resistance and decreasing carrier lifetimes. While this material is highly effective, longer (optical) wavelength devices are desirable to capitalize on the availability of low-cost, compact, high-performance fiber-coupled lasers with operating wavelengths of 1064nm or 1550nm. While ErAs:In0.53Ga0.47As and other related materials have been studied, the band alignment between the nanoparticles and the matrix typically results in lower dark resistance, reducing the performance of photoconductive switches.

We report on the incorporation of ErAs into GaBiXAs1-X semiconductors. The incorporation of bismuth reduces the bandgap of the material, enabling longer wavelength pumps. Because the reduction in bandgap occurs primarily in the valence band, the band alignments remain favorable for high dark resistance. We present a promising material for terahertz devices operating at 1064nm and discuss approaches the further extension of this wavelength. We will discuss opportunities enabled by improved materials for terahertz devices at longer optical wavelengths.

10383-23, Session 6

Superconducting thin film nanostructures as terahertz and infrared heterodyne and direct detectors *(Invited Paper)*

Gregory N. Goltsman, Moscow State Pedagogical Univ. (Russian Federation)

The superconducting hot electron bolometer (HEB) mixers based on ultrathin films of NbN combine the best sensitivity at the frequencies well above 1 THz and a gain bandwidth of about 6 - 7 GHz which make them suitable for most sensitive instruments.

Direct detectors made from NbN films are operated in 0.3-3 THz range exhibit response time as low as 50 ps with noise equivalent power (NEP) of 3x10^-13 W Hz^-1/2. A promising type of the photon counting detector is superconducting single-photon detector (SSPD). The SSPD is patterned from 4-nm-thick NbN film as 120-nm-wide and meander-shaped strip that covers a square area of 10 x 10 ?m^2. At wavelength ?≤1.5 ?m quantum

efficiency (QE) of our best devices approaches 80% at 2 K with 35 ps timing jitter. The single-photon counting was observed at wavelength up to 5.6 ?m with QE of ~1%. Simultaneously, at 2K the SSPD has negligibly low dark counts of 2x10^-4 s^-1. It provides NEP value of 10-20 W/Hz^1/2 at ?≤1.3 ?m and 10^-18 W/Hz^1/2 at 5 µm.

In addition to the chip SNSPD with normal incidence coupling, we use the detectors with a travelling wave geometry design. In this case a NbN nanowire is placed on the top of a Si3N4 nanophotonic waveguide, thus increasing the efficient interaction length. Our approach is fully scalable and, along with a large number of devices integrated on a single chip can be adapted to the mid and THz ranges where photon-counting measurement may be beneficial as well.

10383-24, Session 7

Near-field wave transformation in THz super-resolution imaging

Mariano Flammini, Michele Ortolani, Sapienza Univ. di Roma (Italy); Valeria Giliberti, Sapienza Univ. di Roma (Italy) and Istituto Italiano di Tecnologia (Italy); Chiara Ciano, Emanuele Pontecorvo, Eugenio Del Re, Sapienza Univ. di Roma (Italy)

According to rigorous diffraction theory, monochromatic electromagnetic waves reflected from a material surface form a mixture of propagating and evanescent waves. During propagation, light fields suffer a progressive spatial filtering that depends exponentially on the size of the subwavelength image detail, a peculiar multiscale distortion in the image that spans the near-field of the sources, occurs in vacuum and with no dissipation, and has never been reported before.

Here we explore this transition from super-resolved to diffraction-limited imaging for THz frequencies (? =1 mm). The experiment is carried out at 300 GHz using a knife-edge scan that allows subwavelength beam profiling in the near-field of emitters, here enacted remotely to produce super-resolved images on planes at different distances from the emitters. Compared to visible light imaging, the millimetric wavelength expands the near-field region to the point that single near-field imaging planes can be scanned using a mechanical free-standing blade.

From a fundamental perspective, our study provides first experimental observation of the stepwise transformation with increasing scatterer-to-emitter plane distance from near-field imaging to diffraction-limited imaging. From an applicative perspective, our experiments introduce an innovative free-space delivery and detection scheme that achieves super-resolution for monochromatic THz light based on a knife-edge scan along one axis.

10383-25, Session 7

Terahertz imaging for subsurface investigation of art paintings

Alexandre Locquet, Junliang Dong, Georgia Tech-Lorraine (France); Marcello Melis M.D., Profilocolore Srl (Italy); David S. Citrin M.D., Georgia Institute of Technology (United States)

Terahertz (THz) reflective imaging is applied to the stratigraphic and subsurface investigation of oil paintings, with a focus on the mid-20th century Italian painting, 'After Fishing', by Ausonio Tanda. THz frequency-wavelet domain deconvolution, which is an enhanced deconvolution technique combining frequency-domain filtering and stationary wavelet shrinkage, is utilized to resolve the optically thin paint layers or brush strokes. Based on the deconvolved terahertz data, the stratigraphy of the painting including the paint layers is reconstructed and subsurface features are clearly revealed. Specifically, THz C-scans and B-scans are analyzed based on different types of deconvolved signals to investigate the subsurface features of the painting, including the identification of regions with more than one paint layer, the refractive-index difference between paint layers, and the distribution of the paint-layer thickness. In addition, THz images are compared with X-ray images. The THz image of the thickness distribution of the paint exhibits a high degree of correlation with the X-ray transmission image, but THz images also reveal defects in the paperboard that cannot be identified in the X-ray image. Therefore, our results demonstrate that THz imaging can be considered as an effective tool for the stratigraphic and subsurface investigation of art paintings. They also open up the way for the use of non-ionizing THz imaging as a potential substitute for ionizing X-ray analysis in nondestructive evaluation of art paintings.

10383-26, Session 7

All-dielectric metamaterial resonators for room temperature terahertz imaging *(Invited Paper)*

Willie J. Padilla, Kebin Fan, Jonathan Y. Suen, Duke Univ. (United States)

Metamaterial electromagnetic wave absorbers have demonstrated extreme properties across electromagnetic spectrum. Traditional metamaterials are based on metals and thus the performance of traditional designs is strongly tied to the electrical conductivity. Here we present a metamaterial absorber fashioned entirely from sub-wavelength dielectric resonators, which act as isolated 'metamaterial atoms'. Many dielectric materials exhibit thermal conductivities orders of magnitude smaller than those for metals, and thus our approach breaks the fundamental connection between thermal and electrical conductivity providing new opportunities for applications. Here we demonstrate dielectric absorbers for terahertz imaging and highlight the future of this exciting field.

10383-27, Session 7

Compact solutions for spectroscopic solid-state based terahertz imaging systems *(Invited Paper)*

Gintaras Valu?is, Rimvydas Venckevi?ius, Linas Minkevicius, Antanas Reklaitis, Vincas Tamo?i?nas, Irmantas Ka?alynas, Bogdan Voisiat, Dalius Seliuta, Gediminas Ra?iukaitis, Ctr. for Physical Sciences and Technology (Lithuania)

Convenience in use of room-temperature terahertz (THz) imaging systems, reduction of dimensions and presence of on-chip solutions remains one of prime interests for their direct implementation aims.

In this communication, we consider solid-state-based solutions in miniaturization of spectroscopic THz imaging systems including novel semiconductor nanostructures bias-free emitters, THz optics components relying on zone plates and their on-chip integration with THz detectors.

Pulsed optoelectronic terahertz emitter based on a {delta}-doped p-i-n-i GaAs/AlxGa1?xAs heterostructure was studied experimentally. It is shown that the heterostructure can serve as efficient antenna- and bias-free surface emitter which power, at certain conditions, exceeds the emission from InGaAs and InAs surfaces.

Compact THz optics solutions were demonstrated via conventional, inverted and combined zone plates with integrated band-pass filters. Components were designed numerically using the 3D finite-difference time-domain method and produced using laser direct writing technique. Spatial profiles of the concentrated radiation in the focal plane at the resonant frequencies are recorded, effects of focal depth influence are considered as well. Influence of Fabry-Perot resonances is resolved using phase zone plate fabricated on silicon substrates.

It is evidenced that on-chip integration of secondary diffractive optics and bow-tie InGaAs-based terahertz detectors enables one order of magnitude detection enhancement at 0.76 THz frequency.

Implementation of compact spectroscopic THz imaging is demonstrated in post packages scanning and medical imaging experiments employing bow-tie diodes, nanometric field-effect transistors and microbolometers.

10383-28, Session PMon

Organic conjugated material-based THz wave modulators

Joong-Wook Lee, Chonnam National Univ. (Korea, Republic of); Hyung Keun Yoo, SAMSUNG Electronics Co., Ltd. (Korea, Republic of); Chul Kang, Chul-Sik Kee, In-Wook Hwang, Gwangju Institute of Science and Technology (Korea, Republic of)

The characteristics of transmission modulation of terahertz (THz) wave transmission under photoexcitation were studied in organic/silicon hybrid structures, such as pentacene/silicon, TIPS-pentacene/silicon, PCBM/silicon, organic/metamaterial/silicon, etc. The organic/silicon hybrid structures show extremely high modulation efficiencies and broadband modulation of the THz waves. In addition, metamaterial-based organic/silicon hybrid structures enable selective modulation in the range of THz-wave frequencies. We've also investigated the optimization conditions for improving the properties of the modulation efficiency and for realizing various functionalities in organic-based active THz devices.

10383-29, Session PMon

Optical properties and relaxation times of oil and fuel in frequency range of 0.2-0.8 THz

Anna Simonova, Uliya Komarova, Petr Demchenko, Roman Grigorev, Roman Orlov, Mikhail K. Khodzitsky, ITMO Univ. (Russian Federation)

Currently, there are a number of physical and chemical methods used in the oil industry to implement quality control of petroleum products. Terahertz time-domain spectroscopy (THz-TDS) is not among the standardized control methods. The less scattering and the higher penetration depth are significant advantages of THz radiation unlike to IR, X-rays and visible radiation. The investigation on the determination of the water content in the crude oil and polyglycolic oil using the information about the dispersion of the refractive index for different concentrations of water in the THz frequency range was performed earlier in the [1,2] and other works.

In this paper, the optical properties and the relaxation times of crude oil and different marks of motor fuel in the frequency range of 0.2-0.8 THz have been investigated. The transmission spectra of the studied substances were obtained using THz-TDS spectrometer. Relaxation times were determined by means of multicomponent Debye model of permittivity. It was shown that terahertz time-domain spectroscopy allows the identification of different brands and types of motor fuel by optical properties and relaxation times in the studied frequency range. The differences between the obtained values indicate on the features of the fuels chemical structures, having the responses in the THz frequency range. Thus, the results of the present studies indicate the possibility of using a terahertz time-domain spectroscopy as a method of analysis of oil products to control.

10383-30, Session PMon

Frequency division multiplexing THz light field imaging

Xianshun Ming, Tsinghua Univ. (China); Willie J. Padilla, Duke Univ. (United States); Liqun Sun, Tsinghua Univ. (China)

We present a single pixel frequency division multiplexing imaging system with two metamaterial spatial light modulators (SLMs) for THz light field imaging. One SLM is used for slicing/modulating the 4D light field from various sub-apertures, while the second one together with a single pixel detector to implement 2D multiplexing measurement. The modulation signal and carrier signal at each pixel of the two SLMs is a square wave with specific frequency, and we computationally reconstruct the light field voxel information from the spectra of measured time signals. With the consideration of hardware restrictions, we show how to design the modulation frequencies to uniquely determine each voxel and alleviate the effect of high order harmonics crosstalk, the gaussian white noise and the frequency drift. Meanwhile, we design a prototype based on the THz source, off-axis parabolic mirror, TPX lens and SLMs.

Conference 10384: Optical Data Storage 2017: From New Materials to New Systems

Sunday 6 –6 August 2017

Part of Proceedings of SPIE Vol. 10384 Optical Data Storage 2017: From New Materials to New Systems

10384-1, Session 1

Optical technologies for the Internet of Things era *(Invited Paper)*

Philip N. Ji, NEC Labs. America, Inc. (United States)

The Internet of Things (IoT) is the network of interrelated physical objects that can collect and exchange data with one another through embedded electronics, software, sensors, over the Internet. It extends Internet connectivity beyond traditional networking devices to a diverse range of physical devices and everyday things that utilize embedded technologies to communicate and interact with the external environment. The IoT brings automation and efficiency improvement to everyday life, business, and society. Therefore IoT applications and market are growing rapidly.

Contrary to common belief that IoT is only related to wireless technology, optical technologies actually play important roles in the growth of IoT and contribute to its advancement. Firstly, fiber optics provides the backbone for transporting large amount of data generated by IoT network in the core , metro and access networks, and in building or in the physical object. Secondly, optical switching technologies, including all-optical switching and hybrid optical-electrical switching, enable fast and high bandwidth routing in IoT data processing center. Thirdly, optical sensing and imaging delivers comprehensive information of multiple physical phenomena through monitoring various optical properties such as intensity, phase, wavelength, frequency, polarization, and spectral distribution. In particular, fiber optic sensor has the advantages of high sensitivity, low latency, and long distributed sensing range. It is also immune to electromagnetic interference, and can be implemented in harsh environment.

In this talk, the architecture of IoT is described, and the optical technologies and their applications in the IoT networks are discussed with practical examples.

10384-2, Session 1

Big data innovation hubs: Opportunities for optical data storage partnerships *(Invited Paper)*

Meredith M. Lee, West Big Data Innovation Hub (United States)

Launched in November 2015 by the National Science Foundation, the four Regional Big Data Innovation Hubs (Northeast, Midwest, South, and West) build and strengthen public-private partnerships to address societal challenges. Focus areas include Smart Cities / Metro Data Science, Precision Medicine, Natural Resources and Hazards, and Education. By convening stakeholders from academia, industry, nonprofits, and government, the Big Data Innovation Hubs help the community to identify collaboration opportunities, share best practices, and advance the implementation of big data technologies.

This talk will introduce the flagship initiatives of the West Big Data Innovation Hub, describing a series of projects and applications that could leverage next-generation optical data storage systems. Design issues including the integration of hardware, software, and human-computer interaction elements will be discussed, emphasizing practical testbeds and pilot projects that bridge sectors and spark community engagement.

10384-3, Session 1

The possibility of the market expansion of large capacity optical cold archive *(Invited Paper)*

Ikuo Matsumoto, Emiko Sakata, Fujiwara-Rothchild, Ltd. (Japan)

The field, IoT and Big data, which is activated by the revolution of ICT causes rapid increase of distribution data of various business application. As a result, cold data with low access frequency has been rapidly increasing into a huge scale that human has never experienced before.

The cold archive storage should be suitable for long-term and low cost preservation, but a balance between cost and latency for read request is concerned. And the choice between an active archive warm storage and a cold archive storage is determined by whether performance or cost is emphasized. Consequently, storage for cold data is determined by the application's request including access frequency, response speed and cost. But the boundary is ambiguous.

HDDs, tapes, optical disks are utilized as devices of cold archive storage, and the development to increase the capacity by further increasing the recording density in order to reduce the storage cost has been proceeded. In this gray area, proposals of storages will be most activated in the future. For example, the object storage and SDS (software defined storage) are one of the candidates for this gray area. A Cloud storage is also the important way in this gray area.

Taking into consideration of TCO, large-capacity optical disc storage can be the promising candidate of cold archive storage by its performance enhancement in the future. How to demonstrate the superiority of optical storage in this area is an important issue in the future.

In this presentation, the issue of active archive / cold archive and the challenges of each storage are discussed.

10384-4, Session 1

A rack-based optical storage system with inline accessibility for long-term data preservation *(Invited Paper)*

Jie Yao, Changsheng Xie, Huazhong Univ. of Science and Technology (China)

The combination of the explosive growth in digital data and the need to preserve much of this data in the long term has made it an imperative to find a more cost-effective way than HDD arrays and more easily accessible way than tape libraries to store massive amounts of data. While modern optical discs are capable of guaranteeing more than 50-year data preservation without migration, individual optical disks' lack of the performance and capacity relative to HDDs or tapes has significantly limited their use in datacenters. This talk presents a Rack-scale Optical disc library System, or ROS in short, that provides a PB-level total capacity and inline accessibility on thousands of optical discs built within a 42U Rack. A rotatable roller and robotic arm separating and fetching the discs are designed to improve disc placement density and simplify the mechanical structure. A hierarchical storage system based on SSD, hard disks and optical discs are presented to hide the delay of mechanical operation. On the other hand, an optical library file system is proposed to schedule mechanical operation and organize data on the tiered storage with a POSIX user interface to provide an illusion of inline data accessibility. Besides, ROS is able to effectively hide and virtualize internal complex operational behaviors and be easily deployable in datacenters.

10384-5, Session 2

Cavity enhanced eigenmode multiplexing for volume holographic data storage

Bo E. Miller, College of Optical Sciences, The Univ. of Arizona (United States); Yuzuru Takashima, The Univ. of Arizona (United States)

Previously, we proposed and experimentally demonstrated enhanced recording speeds by using a resonant optical cavity to semi-passively increase the reference beam power while recording image bearing holograms. In addition to enhancing the reference beam power the cavity supports the orthogonal reference beam families of its eigenmodes, which can be used as a degree of freedom to multiplex data pages and increase storage densities for volume Holographic Data Storage Systems (HDSS). While keeping the increased recording speed of a cavity enhanced reference arm, image bearing holograms are multiplexed by orthogonal phase code multiplexing via Hermite-Gaussian eigenmodes in a Fe:LiNbO3 medium with a 532 nm laser at two Bragg angles for expedited recording of four multiplexed holograms. We experimentally confirmed write rates are enhanced by an average factor of 1.1, and page crosstalk is about 2.5%. This hybrid multiplexing opens up a pathway to increase storage density while minimizing modifications to current angular multiplexing HDSS.

10384-6, Session 2

Cavity enhanced eigenmode multiplexing with spatial light modulators for volume holographic data storage

Guanghao Chen, The Univ. of Arizona (United States); Bo E. Miller, College of Optical Sciences, The Univ. of Arizona (United States); Yuzuru Takashima, The Univ. of Arizona (United States)

Spatial Light Modulators (SLMs) are incorporated along with cavity enhanced eigenmode and angular hybrid multiplexing in Holographic Data Storage Systems (HDSS). Orthogonal reference beams supported as cavity eigenmodes are created by SLM and image bearing holograms are multiplexed by orthogonal phase code multiplexing via Hermite-Gaussian eigenmodes in a Fe:LiNbO3 medium with a 532 nm laser at multiple Bragg angles.

10384-7, Session 2

Analytic function expression of signal wave for data retrieve in holographic data storage

Daisuke Barada, Shaqueeb Sarwar, Toyohiko Yatagai, Utsunomiya Univ. (Japan)

Holographic data storage is a data storage with large data amount recorded by volume holography. Holography is well known as a method to record three-dimensional scenes. The principle is roughly established and major characteristics are well understood. In the case of three-dimensional scenes, some noises are acceptable because they are compensated by our brain. However, in the case of holographic data storage, the recording images are minute two-dimensional coded patterns so that the images are not robust for noises. Therefore, rigorous expressions of recording signal is required. In this study, the recording signal wave is expressed by Taylor expansion for small argument and asymptotic expansion for large argument. Then, the filling factor of pixels in a spatial light modulator (SLM), the size and the position shift of a rectangular aperture at a Fourier plane are considered. When the signal wave is ideally reconstructed, the signal wave at an image plane is captured by using an image sensor. Then, the signal wave is integrated by the area of pixels in the image sensor. In this study, the integral is analytically calculated whereas it is numerically calculated in general because the signal wave is expressed by analytic functions. Therefore, interpixel crosstalk is easily evaluated. In our previous study, high-density recording method of binary data pages is proposed by using four-step phase mask. The high-density recording characteristics are evaluated by analytic functions. When parameters such as the filling factor of pixels in a SLM and an image sensor and the size and the position shift of a rectangular aperture can be known, the analytic functions are obtained. Then, the analytic functions are expected for error corrections.

10384-8, Session 2

Temperature tolerance analysis on the volume holographic data storage

Liangcai Cao, Shenghan Wu, Song Zong, Guofan Jin, Tsinghua Univ. (China)

Volume holographic data storage has significant advantages of large theoretical storage density and high data transfer rate. Terabyte holographic optical disk system is one of the promising solutions for the future mass and green archival data storage. The unique advantages come from the multiplexing techniques due to the Bragg selectivity of the volume hologram. Since the Bragg grating is very sensitive to the grating deformation, the range of the working temperature for the storage system is relatively as small as several degrees. The temperature tolerance is one of the main constraints for the commercialization of the holographic optical data storage. In this work, the temperature characteristics for the holographic storage system are analyzed by theoretical modeling in order to extend the range of the working temperature. Adaptive compensation conditions are derived based on the refractive index change and material deformation caused by the temperature changing. Preliminary experimental test shows that the range of the working temperature could be extended effectively by applying the adaptive compensation method.

10384-9, Session 2

Effect of temperature change in microholographic recording

Ryuichi Katayama, Fukuoka Institute of Technology (Japan)

The effect of the temperature change in microholographic recording was investigated through a numerical simulation. The diffraction efficiency of a microhologram was calculated using the coupled wave theory. The wavelength of the laser was 405 nm, the numerical aperture of the objective lenses was 0.85, and the thickness of the recording medium was 300 um. The thickness change of the recording medium due to the temperature change of 10 deg. was 0.5%. When there was no compensation, the diffraction efficiency was almost 0. When the wavelength was changed by 0.5% to compensate for the temperature change, the diffraction efficiency increased but it was only about 16% of that without the temperature change. The reason is as follows. The beam consists of multiple plane waves and the microhologram consists of multiple diffraction gratings. Regarding the center of the beam, the corresponding wave vector of the plane wave and grating vector of the diffraction grating are perpendicular to the recording medium. Therefore, it is necessary to change only the wavelength of the plane wave to compensate for the Bragg mismatch due to the temperature change. On the other hand, regarding the periphery of the beam, the corresponding wave vector of the plane wave and grating vector of the diffraction grating are slanted to the recording medium. Therefore, it is necessary to change both the wavelength and angle of the plane wave to compensate for the Bragg mismatch due to the temperature change. The above two conditions cannot be satisfied simultaneously.

10384-10, Session 2

Research of circular polarized holography with a large crossing angle under a common condition

Yifan Hong, Jinliang Zang, Yiying Zhang, Fenglan Fan, Ying Liu, Guoguo Kang, Xiaodi Tan, Beijing Institute of Technology (China); Tsutomu Shimura, The Univ. of Tokyo (Japan); Kazuo Kuroda, Beijing Institute of Technology (China) and Utsunomiya Univ. Ctr. for Optical Research & Education (Japan)

Polarization holography is the coherent interference of the beams that can have the different polarized states. The early-stage theory of polarization holography is based on Jones matrix, where the paraxial approximation is assumed, while the theory of polarization holography represented by dielectric tensor can describe the case with a large crossing angle. And it also depicts the relationship between diffraction light and interference light. During the research people find some extraordinary phenomenon, such as null reconstruction and inverse polarizing effect. But there is a disadvantage in this new polarization holography theory, where only under a peculiar circumstance can we get a faithful reconstruction. The circumstance can be expressed as "A+B=0", where A and B refer to the coefficients for intensity and polarization holograms respectively. In this research, we calculate the formula of diffraction light's polarization, and extract the A+B factor in it. Then we establish a series of equations which can let the diffraction light faithfully reconstruct, no matter what value of A plus B is. From the result, we can use an artificial reference beam which is corresponding to the signal beam to generate the hologram. Under this condition, the polarization of the diffraction light is similar to the signal. For simplification, we only discuss the signal wave with circular polarization and experimentally verify the result.

10384-11, Session 3

Near-field coupling and readout of nano recording marks *(Invited Paper)*

Din Ping Tsai, Research Ctr. for Applied Sciences - Academia Sinica (Taiwan) and National Taiwan Univ. (Taiwan)

Near-field optical disk (NFOD) is a novel and demanded developments of optical storage technology. The nonlinear plasmonic coupling effect of the complete nano recording unit is important for increasing the near and far field optical readout contrast. Here, we present a simple plasmonic near-field coupling optical disk system. The near-field coupling effect between two nano-recording marks with various thickness of the dielectric spacer layer are investigated.

10384-12, Session 3

The reduction of graphene oxide induced by rare-earth doped nanocrystals towards super-resolution optical data storage *(Invited Paper)*

Simone Lamon, Qiming Zhang, RMIT Univ. (Australia); Yiming Wu, Xiaogang Liu, National Univ. of Singapore (Singapore); Min Gu, RMIT Univ. (Australia)

The growing amount of data generated every year creates an urgent need for improved methods and new storage media. Far-field super-resolution techniques have provided the foundation for nanoscale 3D optical data storage towards a petabyte-level capacity on DVD-sized discs. However, a suitable recording medium for high-density information storage over long-term periods and with low energy consumption is still lacking. Rare-earth doped nanocrystals, which feature ladder-like-arranged energy levels enabling emission from ultraviolet to near-infrared, have a fluorescence lifetime two to three orders of magnitude longer than that of other fluorophores and offer the potential for low-power super-resolution data reading. Moreover, the reduction of graphene oxide to reduced graphene oxide induces permanent changes in its chemical and optical properties which can be used for data recording. Here, we demonstrate the reduction of graphene oxide induced by rare-earth doped nanocrystals via FRET towards super-resolution optical data storage with ultra-high capacity, ultra-long lifetime and ultra-low energy consumption. Yb^{3+}/Tm^{3+}-doped core-shell nanoparticles were synthesized via co-precipitation method and their fluorescence spectrum was obtained using a home-built microscope. A solution of rare-earth doped nanocrystals and graphene oxide nanoflakes was spin-coated on coverslip glass and fluorescence lifetime measurements were conducted to confirm efficient FRET. The reduction of graphene oxide was attributed to the transfer of energy quanta from up-converting rare-earth doped nanocrystals under 980-nm laser excitation. High-contrast images of the data bits were generated by super-resolution optical microscopy based on rare-earth doped nanocrystals due to the different degree of fluorescence quenching between graphene oxide and reduced graphene oxide.

10384-13, Session 3

Nanophotonics mediated ultra-high capacity optical memory towards big data storage *(Invited Paper)*

Xiangping Li, Jinan Univ. (China)

Even though optical storage has been well heralded as green techniques, the conventional optical memories have been constantly challenged as they reached theirs physical limits imposed by nonlinear effects. Recently, nanophotonics harnesses light's interaction with materials at the nanoscale including the generation of nanoscale optical probes and the interaction with nanocomposite materials, offering bottom-up new approaches far superior to the conventional technology. In this regard, nanophotonics has emerged as a major propellant for the next generation of ultra-high capacity optical memories for big data. In this talk, we present the recent development of ultra-high capacity optical memories multiplexing information in the physical domain of the writing beams through tailoring the interaction between a tightly focused pulsed laser beam and plasmonic materials [1]. To circumvent the diffraction limit of light discovered by Ernst Abbe, tremendous research approaches have been developed including stimulated emission depletion (STED) microscopy [2]. Through coherently manipulating the distribution of excitons in the fluorophore molecules by a dual-beam approach, where one Gaussian shaped beam can pump the molecules into the excited state while the second doughnut shaped beam can inhibit the subsequent emission through stimulated emission processes, STED microscopy enables superresolved imaging as well as laser lithography [3, 4]. Based on this principle, superresolution optical memories enabled by the dual-beam approach has been demonstrated with an ultra-high equivalent capacity [5].

10384-14, Session 3

SIL-STED microscopy technique enhancing super-resolution of fluorescence microscopy *(Invited Paper)*

No-Cheol Park, Geon Lim, Wonsup Lee, Yonsei Univ. (Korea, Republic of); Hyungbae Moon, Asan Medical Ctr. (Korea, Republic of); Guk-Jong Choi, Young-Pil Park, Yonsei Univ. (Korea, Republic of)

We characterize a novel fluorescence microscope which combines the high numerical aperture (NA) optical head of a solid immersion lens (SIL) with that of stimulated emission depletion (STED) microscopy and it is named SIL-STED microscopy in this research. Advantage of this combination is that the lateral resolution is better than common STED microscopy because of

the higher NA of SIL. Thus, it promises advanced super-resolution imaging of the structure and function of cell surface or membranes with overcoming optical diffraction limit at the macro-molecular scale. Here we present the first implementation of higher NA illumination into STED microscopy which limits fluorescence lateral resolution down to about 40 nm. The material of the SIL is KTaO3 and the refractive index is about 2.23 at the wavelength of 633 nm. A full theoretical description of the SIL-STED microscopy is fulfilled based on the vector diffraction theory so that we could analyze numerical result of the point spread function of the microscopy and expected resolution. For the further investigation, we used both synthetic and biological samples to demonstrate that the performance of this new microscope technique is improved by using the SIL. The used samples were fluorescent bead test samples and cell stained with fluorophores which is appropriate to STED imaging, respectively. Moreover, the SIL-STED microscopy provides superior lateral resolution capabilities with the potential to reduce photo-bleaching and photo-damage in live cell imaging.

10384-15, Session 4

Active metasurfaces for optical data storage *(Invited Paper)*

Cheng Hung Chu, Pin Chieh Wu, Research Ctr. for Applied Sciences - Academia Sinica (Taiwan); Hui-Hsin Hsiao, Hsiang-Chu Wang, National Taiwan Univ. (Taiwan); Hui Jun Wu, Research Ctr. for Applied Sciences - Academia Sinica (Taiwan); Din Ping Tsai, Research Ctr. for Applied Sciences - Academia Sinica (Taiwan)

Metasurfaces, the two-dimensional (2D) sub-wavelength artificial structures, where light is not required to have a deep penetration, have shown the ability to tailor the amplitude, phase and polarization of light. The functionalities of various optical components can be realized by metasurface-based design, such as beam splitters, filters, waveplates, deflector, lens and holograms. However, the optical properties of conventional metasurfaces are typically permanent once the devices are fabricated. There is obviously a need to develop tunable metasurface where their optical responses can be actively controlled with external applied measures, such as force, heat, electric or magnetic field. In this paper, we will review the recent developments of active metasurface from fundamental theory to their potential applications. We also present our recent work in reconfigurable gradient metasurface, which exhibits different anomalous reflection angles by controlling the combination of Ge2Sb2Te5 rods with different geometries and phase states. Further, a gate-tunable metasurface that enables dynamic control by electrically modulating the complex refractive index of conducting oxide layers will be discussed. We foresee that these results provide great interest in applications toward metasurface-based optical storage system.

10384-16, Session 4

Mastering multi-depth bio-chip patterns with DVD LBR’s *(Invited Paper)*

Doug Carson, DCA, Inc. (United States)

LBR’s can expose the entire surface of a wafer much faster than XY lithography. Silicon wafers can be coated with PR, exposed, developed and then etched to a certain feature depth.

The challenge to using LBR’s is to accurately write a second pattern onto the wafer after the first pattern has been recorded and etched.

One concern is how to recoat the etched wafer with PR. Conventional optical disc production uses spin coating, which is not suitable. There are several other coating technologies used in semi-conductor industry including spray. This will not be the subject of this presentation.

The biggest challenge is due to the fact that LBR’s were not designed to mechanically mount the recording wafer in exactly the same XY and rotational position, relative to the turntable center of rotation each time. It is therefore not possible to record a second pattern onto a wafer perfectly aligned to the first pattern after the wafer has been removed for develop and etching and remounted.

The subject of this presentation is how to accurately write a second or subsequent patterns that aligns to previously written and etched patterns. Most bio-chip patterns require 2 different feature depths, with some requiring up to 8 different feature depths. This would require 8 different coating, mounting, recording, development and etch steps.

DCA has developed Virtual Image Alignment technology and equipment to virtually align each recording pattern to the center of the wafer as opposed to the center of the LBR rotation turntable.

10384-17, Session 4

An application of OFDM method to optical disc recording

Kimihiro Saito, Kindai Univ. Technical College (Japan)

An application of Orthogonal Frequency Division Multiplexing (OFDM) method to optical disc recording/readout is presented. OFDM has been widely used in the field of telecommunication owing to its highly efficient frequency usage. However OFDM has not been applied to optical disc recording because it is a multiple data transfer method and needs to record analog signals. Partial Response Maximum Likelihood (PRML) used in the current optical disc systems requires a certain kind of analog recording. Although optical recording usually creates binary marks, it is possible to obtain arbitrary analog readout signals by using PWM method. Another technique to generate analog signals using the oversampled binary recording is described and applied to multiple level recording. In addition, it is found that the level adjustment of multiple carriers for OFDM leads to the advantage when it is applied to the optical disc system. Using the simple transfer function model of the optical disc system, two types of readout signals using PRML and OFDM are calculated and then their qualities are compared. Since Quadrature Amplitude Modulation (QAM) method can be combined with OFDM, it is possible to increase the recoding density of optical disc systems. A method employing OFDM with 64-QAM and the pre-enhance method to the high frequency carrier shows an ability of 1.5 times recording density of the conventional Bru-ray Disc (BD).

10384-18, Session 4

Adaptive optics for data recovery on optical disk fragments

Thomas D. Milster, Young Sik Kim, College of Optical Sciences, The Univ. of Arizona (United States)

An adaptive optics system is designed and constructed to recover information from damaged optical media. The system is based on an Olympus IX70 microscope with custom illumination and detection. A scanning 408nm laser beam provides both the reference beam for the adaptive optics system and the data beam for imaging of data marks. A two-dimensional galvanometer system is used to scan the focused laser over the sample, and a precision z stage is used to change focus planes. The adaptive optics system is based on a Thorlabs AO kit with a Shack-Hartman wavefront sensor and a deformable mirror. A custom objective lens using a solid immersion lens is implemented that provides NA up to 1.5. Several types of data storage substrates are examined, including partial DVD and BD substrates, small 2cm-square pieces of DVD and BD substrates, and dust fragments on the order of 2mm in size. In order to view the dust fragments, they are collected on a microscope slide and melted to reflow the plastic and reveal data-containing flakes.

10384-19, Session 4

Optical mapping of oscillatory stresses in transparent media

Igor A. Sokolov, Mikhail A. Bryushinin, Alexander A. Petrov, Ioffe Institute (Russian Federation); Anatoli M. Balbashov, National Research University “MPEI” (Russian Federation)

The phase-modulated optical signal produced by the light propagation through the stressed transparent media is detected using the non-steady-state photoelectromotive force technique. The mechanical system including the glass plate and piezoelectric transducer demonstrates the resonant behavior in the vicinity of 100 kHz. The measured distribution of the optical phase is a bell-shaped surface for these frequencies. The simulation of the piezooptic response shows the qualitative coincidence with the experimental data and provides the maps of the stress field. The characterization of the Ga_2O_3 adaptive detector is performed for the light wavelength 532 nm.

10385-1, Session 1

Single shot Talbot imaging for wavefront sensing and x-ray metrology

Walan C. Grizolli, Xianbo Shi, Lahsen Assoufid, Argonne National Lab. (United States)

APS has recently developed and commissioned a portable X-ray grating interferometer system [1]. The instrument is suitable for different experimental techniques, for instance grating interferometry in Moiré, single-shot and phase-stepping modes, and near-field speckle tracking method. Special efforts have been made in using single-shot imaging using single phase gratings, also known as the Talbot imaging. This is a differential phase contrast technique that can be used for wavefront characterization and for imaging phase objects. In this work, we describe the latest results using this instrument for the wavefront characterization and for imaging compound refractive lenses.

10385-2, Session 1

High-performance at-wavelength metrology with an efficient high-order suppression system

Franz Schäfers, Andrey A. Sokolov, Andreas Gaupp, Martin Luettecke, Helmholtz-Zentrum Berlin für Materialien und Energie GmbH (Germany)

The At-Wavelength Metrology Station in a clean-room hutch at the BESSY-II storage ring is in operation now since two years. It consists of a plane grating monochromator beamline in collimated light (c-PGM) at a bending magnet and a versatile UHV-reflectometer with 11 axes. The energy range covers the UV, EUV and soft x-rays. It is primarily used for characterization of the efficiency of our in-house produced diffraction gratings, but also to develop novel optical concepts employing as reflection zone plate optics, multilayer mirrors or multilayer coated gratings. The use of off-plane bending magnet to deliver elliptically polarized light to the sample for ellipsometry and polarimetry applications has been recently established. High-quality metrology requires in particular a very high spectral purity of the incident beam. This is performed by (1) a set of filters with suitable absorption edges to suppress the second order radiation in a limited energy range and (2) by a High-Order Suppressor system (HiOS) consisting of 4 mirrors which can be inserted into the incident beam. The two pairs of mirrors are aligned parallel not to disturb the original beam path and are rotated clockwise and counter-clockwise, respectively. Three sets of coatings are available for the different energy ranges and the incidence angle is freely tunable to find the optimum figure of merit for maximum suppression at maximum transmission for each photon energy required. The status of the metrology station and recent results will be shown.

Speckle-based portable device for in-situ metrology of x-ray mirrors at Diamond Light Source

Hongchang Wang, Tunhe Zhou, Yogesh Kashyap, Kawal J. S. Sawhney, Diamond Light Source Ltd. (United Kingdom)

The successful exploitation of X-ray beams generated by modern third-generation synchrotron light sources depends to a significant extent on developments in X-ray mirrors. The push toward higher spatial resolution requires diffraction-limited and coherence-preserved beams which demand accurate metrology on X-ray mirrors. Moreover, it is important to perform in-situ characterization and optimization of X-ray mirrors since their ultimate performance is critically dependent on the working conditions. Therefore, it is highly desirable to develop a portable metrology device, which can be easily implemented on any beamline for in-situ metrology. A speckle-based portable device for in-situ metrology of synchrotron X-ray mirrors has been developed at Diamond [1]. Ultra-high angular sensitivity is achieved by scanning the speckle generator in the X-ray beam [2, 3]. In addition to the compact setup and ease of implementation, a user-friendly graphical user interface has been developed to ensure that characterization and alignment X-ray mirrors is simple and fast. The functionality and feasibility of this device will be presented including the first results of this device's use on different beamlines at Diamond.

10385-4, Session 1

Investigation of HF-plasma-treated soft x-ray optical elements

Frank Eggenstein, Andrey A. Sokolov, Andrei Varykhalov, Maxim Krivenkov, Ivo Rudolph, Johannes Wolf, Mewael Giday Sertsu, Thomas Zeschke, Franz Schäfers, Helmholtz-Zentrum Berlin für Materialien und Energie GmbH (Germany)

Contamination of optical elements (mirrors and gratings) with carbon is still an issue using soft x-ray synchrotron radiation. With an in-house developed HF-plasma treatment we are able to decontaminate our optics in-situ very efficiently from carbon. The cleaning device, a simple Al-antenna, is mounted in situ inside the mirror- and grating vacuum chambers. A systematic study of the cleaning efficiency was performed using in-situ and ex-situ methods for monitoring: An atomic force microscope (AFM) and a scanning tunneling microscope (STM) were applied before and after the cleaning process to determine the surface roughness. Reflectivity scans ([theta]-2[theta]) with the reflectometer at the BESSY-II Metrology Station [1] [2] was used to estimate the thickness of the remaining C-layer after different cleaning steps and thereby the etching rate. Photon flux measurements in the range of 200 eV - 900 eV show the complete removal of C from the optics without contamination it with other elements created by the plasma treatment. The data will show that the plasma process improves the reflectivity and reduces the roughness. Moreover, the region of the optical surface where the carbon has been removed becomes passivated.

Intrinsic resolving power of XUV diffraction gratings measured with Fizeau interferometry

Samuel Gleason, Jonathan Manton, Janet Sheung, Taylor Byrum, Cody Jensen, Lingyun Jiang, Inprentus, Inc. (United States); Joseph Dvorak, Ignace Jarrige, Brookhaven National Lab. (United States); Peter Abbamonte, Inprentus, Inc. (United States)

Measuring the intrinsic resolving power R = q/dq of high-resolution diffraction gratings with R = 10^4 - 10^5 is a challenge for benchtop diffractometers.

On the other hand, real-space measurements face the difficulty of correlating line-spacing errors across the entire grating surface, as local measurements of periodicity are not sufficient to determine R.

To overcome these challenges, we introduce a method for using Fizeau interferometry, a real-space probe of the entire grating, to measure R.

By translating the native Fizeau `height' map into a map of phase errors in the grating pattern, we are able to compute the resolution function of the grating and determine R.

Furthermore, we show that it is possible to isolate contributions to R from either ruling or substrate imperfections.

Our results show excellent agreement with direct measurements of R obtained with a visible-light diffractometer, and we demonstrate R = 50,400 for a mechanically-ruled, XUV grating from Inprentus, Inc.

10385-7, Session 2

Characterization of a 150-mm long variable line spacing plane grating through interferometry

Maurizio Vannoni, Idoia Freijo-Martín, European XFEL GmbH (Germany)

The European XFEL is a large facility under construction in Hamburg, Germany [1]. It will provide a transversally fully coherent X-ray radiation with outstanding characteristics: high repetition rate (up to 2700 pulses with a 0.6 milliseconds long pulse train at 10Hz), short wavelength (down to 0.05 nm), short pulse (in the femtoseconds scale) and high average brilliance (1.6?1025 photons / s / mm2 / mrad2/ 0.1% bandwidth). It will have initially three main beamlines, named SASE1, SASE2 and SASE3. The last one is considered a “soft X-ray” beamline, with energies that will span from 0.25 to 3 keV, delivering photon pulses to SQS (Small Quantum System) and SCS (Spectroscopy & Coherent Scattering) experiments. The optical transport of the almost diffraction-limited beam is done using 950 mm long mirrors, cooled with InGa eutectic bath and super-polished (50 nrad RMS slope error and less than 3 nm PV residual height error).

A VLS-PG (variable line spacing - plane grating) monochromator is installed to enhance the spectral coherence of the beam. The final specifications for the grating substrates are 530 mm length, InGa eutectic bath cooled and ion-beam polished with gravity sag compensation. For the initial commissioning of the beamline, a shorter grating (150 mm long) will be installed.

We recently received the 150 mm long grating and we present here its characterization performed using Fizeau Interferometry and White-Light-Interferometry [2]. The VLS parameters are especially investigated and characterized. The result can be summarized that most of the measured parameters are fulfilling the requirements, with some exceptions. This study can give an interesting insight in present status of European XFEL metrology applied to gratings, but also additional information for the future development of the final 530 mm long grating.

10385-8, Session 2

Metrology of variable-line-spacing x-ray gratings using the APS Long Trace Profiler

Janet Sheung, Argonne National Lab. (United States) and Univ. of Illinois (United States); Jun Qian, Argonne National Lab. (United States); Muriel Thomasset, Synchrotron SOLEIL (France); Jonathan Manton, Inprentus, Inc. (United States); Sunil Bean, Argonne National Lab. (United States); Peter Z. Takacs, Joseph Dvorak, Brookhaven National Lab. (United States); Lahsen Assoufid, Argonne National Lab. (United States)

As resolving power targets have increased with each generation of beamlines commissioned synchrotron radiation facilities worldwide, diffraction gratings are quickly becoming crucial optical components for meeting performance targets. However, metrology of variable-line-spacing (VLS) gratings for high resolution beamlines is not widespread; in particular, no metrology facility at any US DOE facility is currently equipped to fully characterize such gratings. To begin to address this issue, the Optics Group at the Advanced Photon Source at Argonne, in collaboration with SOLEIL and with support from Brookhaven National Laboratory (BNL), has developed an alternative beam path addition to the Long Trace Profiler (LTP) at Argonne's Advanced Photon Source. This significantly expands the functionality of the LTP to not only to measure mirrors surface slope profile at normal incidence, but also to characterize the groove density of VLS diffraction gratings in the Littrow incidence up to 79°, which covers virtually all diffraction gratings used at synchrotrons in the first order. The LTP light source is a 20mW HeNe laser, which yields enough signal for diffraction measurements to be performed on low angle blazed gratings optimized for soft X-ray wavelengths. We will present the design of the beam path, technical requirements for the optomechanics, and our data analysis procedure. Results for diffraction gratings to be installed in BNL's future Inelastic X-ray Scattering beamline will also be presented. Finally, we discuss challenges still to be overcome and potential limitations with use of the LTP to perform metrology on diffraction gratings.

*Work done at Argonne National Laboratory and Brookhaven National Laboratory was supported by U.S. Department of Energy (DOE) Office of Science, under Contracts No. DE-AC02-06CH11357 and DE-AC02-98CH10886, respectively.

10385-9, Session 3

Recent developments on nanoradian-angle metrology

Tanfer Yandayan, TÜBITAK UME (Turkey)

The demands for angle measurement-generation at the nanoradian precision for scientific and industrial applications continue to grow with various numerical applications; e.g., to monitor the angles of telescope mirrors in astrometry (0.1 nrad sensitivity), to tune the angle between a pair of silicon crystals in gamma ray spectroscopy (0.1 nrad resolution), to calibrate accelerometers for space missions (20 nrad accuracy) and to determine the constant of gravitation G by use of a torsion balance etc,. Autocollimators, optical measurement devices which measure the angular tilt of reflecting surfaces are good candidates for this and also used in slope measuring profilers for the inspection of ultra-precise X-ray optical components; particularly for applications in synchrotron radiation and X-ray

Free Electron Lasers (XFELs). An angle metrology project (SIB58 Angles) addressing the challenging issues related to performance of autocollimators in slope measuring profilers run for three years and was completed recently with cooperation of a wide range of partners. Outcomes of the project which are for interest to the X-ray optics community will be presented; new aperture centring device (ACenD) for the accurate centring of a beam-limiting aperture in front of an autocollimator (with a positional accuracy of ±0.1 mm), performance of autocollimators with varying distances to reflector at small apertures, developed guides for calibration of autocollimators and reference angle encoders, first 2D calibration of autocollimators, new devices and novel methods for traceable generation and measurement of angles at nanoradian precision.

10385-10, Session 3

A new ultra-high-accuracy angle generator: current status and future direction

Christian F. Guertin, Vermont Photonics Technologies Corp. (United States); Ralf D. Geckeler, Physikalisch-Technische Bundesanstalt (Germany)

Lack of an extreme high-accuracy angular positioning device available in the U.S. has left a gap in industrial and scientific efforts conducted here. Specifically, in x-ray mirror metrology the global research community is advancing the state-of-the-art to unprecedented levels. We aimed to fill this U.S. gap by developing a versatile high-accuracy angle generator as a part of the national metrology tool set for x-ray mirror metrology and other important industries. Using an established calibration technique to measure the errors of the encoder scale graduations for full-rotation rotary encoders, we implemented an optimized arrangement of sensors positioned to minimize propagation of calibration errors. Our initial feasibility research shows that upon scaling to a full prototype we expect to achieve uncertainties at the level of 50 nrad or better and offer the immense advantage of a highly automatable and customizable product to the commercial market. We will present the current status and future direction of the project.

10385-11, Session 3

A portable device for calibration of autocollimators with nanoradian precision

Tanfer Yandayan, TÜBITAK UME (Turkey)

Autocollimator-based surface measuring profilers offer the state of the art capability for the inspection of ultra-precise X-ray optical components; particularly for synchrotron radiation (SR), X-ray Free Electron Lasers (XFELs). Demands for sub-nanometre topography measurement by these profilers require calibration of autocollimators with expanded uncertainties less than 0.01 arcsec (50 nrad) in the range of ±1000 arcsec (5 mrad). Also, regular in-situ checks of the performance of these autocollimators in these applications become more and more important. Such in-situ checks are able to uncover differences in the angle response of autocollimators between the calibration at a laboratory and their subsequent application in the slope measuring profilers. Apart from subtle changes in the autocollimator's measuring conditions, shocks, particularly during their transportation, may affect the previous calibration values. This requires on-site/in-situ calibrations of autocollimators with low uncertainties. A large range small angle generator (LRSAG) has been developed in TUBITAK UME to calibrate high precision autocollimators with nanoradian precision. The portable device can operate in the range of ±4500" which is far enough for the calibration of the available autocollimators and can generate ultra-small angles in measurement steps of 0.0005" (2.5 nrad). Description of the device with the performance tests using the calibrated precise autocollimators and novel methods will be reported. The test results indicate that the device is a good candidate for application to on-site/in-situ calibration of autocollimators with expanded uncertainties of 0.01 arcsec particularly those used in slope measuring profilers.

10385-12, Session 4

A new optics metrology laboratory at CNPEM: metrology capabilities, performance, and future plans

Bernd C. Meyer, Murilo B. da Silva, Harry Westfahl Jr., Ctr. Nacional de Pesquisa em Energia e Materiais (Brazil)

A new metrology and assembly facility was constructed at CNPEM and turned recently into operation. The facility includes an assembly area of 100 m?, a high-precision mechanical metrology laboratory and an optical metrology laboratory (OML), both of 50 m?, and provide improved environmental and instrumental conditions. All three laboratories sit on inertial blocks with special foundations originally developed and tested as prototype for the SIRIUS tunnel floor. The inertial blocks perform very well in attenuation of external vibrations. The OML is cleanroom ISO7 and has temperature stability better than ±0.1 K. Measurements of the surface under test (SUT) using NOM, Fizeau-Interferometer (FI), Micro-Interferometer (MI) and AFM as the four instruments inside the OML cover the full required range of spatial frequencies. We report on the performance of the NOM and FI, the first instruments installed in the OML.

10385-13, Session 4

X-ray optics laboratory at the ALS: current capabilities, new challenges, and tasks for further development

Ian Lacey, Lawrence Berkeley National Lab. (United States); Gary P. Centers, Helmholtz-Institut Mainz (Germany) and Lawrence Berkeley National Lab. (United States); Gevork S. Gevorkyan, Sergey M. Nikitin, Brian V. Smith, Valeriy V. Yashchuk, Lawrence Berkeley National Lab. (United States)

The R&D work on the ALS upgrade to a diffraction limited electron ring, ALS-U, has brought to focus the need for near-perfect x-ray optics, capable of delivering light to experiments without significant degradation of brightness and coherence. The desired quality of the optics is illustrated by the residual surface slope and height errors of <50?100 nrad (rms) and <1?2 nm (rms), respectively. This catalyzes the development at the ALS new ultra-high accuracy metrology methods. Fundamental to the optimization of beamline performance of such x-ray optics, metrology must be capable of characterizing the optics with accuracy even better than the specification. The major limiting factors of the current absolute accuracy are systematic errors inherent to the metrology instruments. Here, we discuss details of work at the Advanced Light Source (ALS) X-Ray Optics Laboratory (XROL) on the development of advanced experimental methods and techniques to suppress, measure, and eliminate the instrumental systematic errors. With examples, we show how the implementation of these methods allows us to significantly improve the capabilities and performance of the existing lab equipment used for characterization and optimal tuning of high quality x-ray optics. We will also review the ALS XROL plans for instrumentation upgrades and development of sophisticated methods for metrology data processing and usage. The discussion will be illustrated with the results of a broad spectrum of measurements of x-ray optics and optical systems performed at the lab. Supported by the U.S. Department of Energy under contract number DE- AC02-05CH11231.

10385-14, Session 4

Status of the metrology laboratory for the LCLS II project

May Ling Ng, Corey L. Hardin, Josep Nicolas, Daniele Cocco, SLAC National Accelerator Lab. (United States)

Along with the demanding requirements for the extreme limit pushing LCLS II project, comes the challenge in metrology work for qualifying the optical and mechanical components. Besides qualifying the components against specifications, it is also crucial to study performance, repeatability and stability of the mirror systems designed for meeting the LCLS II conditions. Therefore a dedicated metrology laboratory has been jointly funded by LCLS II project and LCLS facility.

The laboratory, located close to the experimental hall of LCLS, is currently equipped with a 6" Fizaeau interferometer (Zygo DynaFiz) and a Zygo NewView 8300 white light interferometer. A profilometer, hosting a Long Trace Profiler optic head, an autocollimator (Moller Wedel) and a Shack Hartman head (SHArPer, Imagine Optics), is under assembling.

The combination of these instruments will enable us to measure spatial periods from the μm scale up to 1.5 m. Further implementation in progress are the implementation of a stitching method for the 6" interferometer and reduction of environmental noise.

The results obtained from measuring 1-m long flat mirrors, with sub-nm shape errors, produced by Jtec, show a very high sensitivity of the interferometer. These results, as well as the results obtained in testing the bender prototype and some diffraction gratings, will be presented.

10385-15, Session 5

New surface slope profiler reaching sub-millimeter spatial resolution

Fugui Yang, Ming Li, Quan Cai, Ya Du, Dingxiao Liu, Xiaowei Zhang, Yuhui Dong, Peng Liu, Institute of High Energy Physics (China)

We introduce a novel (to the best of our knowledge) slope measurement system for long X-ray mirror surface characterization with enhanced spatial resolution. Different from traditional long trace profiler, the focused instead of collimated light beam was used to sample the mirror surface placed in the conjugate plane of the light source (pinhole), which ensures the spatial resolution of the system same with image size of the pinhole. Experimental studies show that high spatial resolution (?0.1?mm) and high angular accuracy (< 0.1??rad) has been achieved. The scanning measurement gives a repeatability as high as 0.05 nm by integration the slope profile. Not only ex-situ measurement, but also this new profiler offers an inexpensive and robust way to perform in-situ measurement due to long distance between sample and optical head

10385-16, Session 5

Development of a high-performance surface slope profiler for two-dimensional mapping of x-ray optics

Ian Lacey, Lawrence Berkeley National Lab. (United States); Jérôme Adam, Ecole Nationale Supérieure d'Ingenieurs de Caen et Ctr. de Recherche (France); Gary P. Centers, Helmholtz-Institut Mainz (Germany); Gevork S. Gevorkyan, Sergey M. Nikitin, Valeriy V. Yashchuk, Lawrence Berkeley National Lab. (United States)

The research and development work on the Advanced Light Source (ALS) upgrade to a diffraction limited electron ring, ALS-U, has brought to focus the need for near-perfect x-ray optics, capable of delivering light to experiments without significant degradation of brightness and coherence. The desired surface quality is characterized with residual (after subtraction of an ideal shape) surface slope and height errors of <50?100 nrad (rms) and <1?2 nm (rms), respectively. The ex-situ metrology that supports the optimal usage of the optics at the beamlines has to offer even higher measurement accuracy. At the ALS X-Ray Optics Laboratory, we are developing a new surface slope profiler, the Optical Slope Measuring System (OSMS), capable of two-dimensional (2D) surface-slope metrology at an absolute accuracy below 50 nrad. In this article we provide the results of comprehensive characterization of the key elements of the OSMS, a NOM-like high-precision granite gantry system with air-bearing translation and a custom-made precision air-bearing stage for tilting and flipping the surface under test. We show that the high performance of the gantry system allows implementing an original scanning mode for 2D mapping. We demonstrate the efficiency of the developed 2D mapping via comparison with interferometric measurements performed with the same plane test mirror. The details of the OSMS design and the developed measuring techniques are also provided. This work was supported by the U. S. Department of Energy under contract number DE- AC02-05CH11231.

10385-17, Session 5

Optomechanical development progress of high-accuracy long-trace profiler at the planning HEPS

Shanzhi Tang, Ming Li, Institute of High Energy Physics (China)

High accuracy long trace profiler (LTP) is one most important of many sub-projects for the planning High Energy Photon Source (HEPS, Beijing), which is crucial to test and fabricate advanced X-ray mirrors. LTP at HEPS will be a metrological instrument with high accuracy of <0.1?rad rms for components of length ≥1m in this paper. The development progress is introduced in the overall, in which the precision instrument designing, optical and mechanical manufacturing, assembling have been discussed and carried out based on a novel scheme of LTP. The several considerations are emphasized to reduce systematic errors and to strengthen the anti-jamming capability. The prototype and test experiments are presented to validate it. It will play a key role to X-ray optics metrology and fabrication for the construction of HEPS coming soon.

10385-18, Session 5

Surface slope metrology of highly curved x-ray optics with an interferometric microscope

Gevork S. Gevorkyan, Lawrence Berkeley National Lab. (United States); Gary P. Centers, Helmholtz-Institut Mainz (Germany) and Lawrence Berkeley National Lab. (United States); Kateryna S. Polonska, Yuriy Fedkovych Chernivtsi National Univ. (Ukraine) and Lawrence Berkeley National Lab. (United States); Ian Lacey, Valeriy V. Yashchuk, Lawrence Berkeley National Lab. (United States)

The development of deterministic polishing techniques has given rise to vendors that manufacture high quality three-dimensional x-ray optics. The surface metrology on these optics remains a difficult task. For the fabrication, vendors usually use unique surface metrology tools, generally developed on site, that are not available in the optical metrology labs at x-ray facilities. At the Advanced Light Source X-Ray Optics Laboratory, we have developed a rather straightforward interferometric-microscopy-based procedure capable of sub microradian characterization of sagittal slope variation of x-ray optics for two-dimensionally focusing (such as ellipsoids) and collimating (paraboloids). In the paper, we provide the mathematical foundation of the procedure and describe the related instrument calibration. We also present analytical expressions describing the ideal surface slope variation in both directions of a spheroid specified by the conjugate parameters of the optic's beamline application. The expressions are useful when analyzing data obtained with such optics. The high efficiency of the developed measurement and data analysis procedures is demonstrated in results of measurements with a number of x-ray optics with sagittal radius of curvature between 56 mm and 480 mm. We also discuss potential areas of further improvement. This work is supported by the U.S. Department of Energy under contract number DE-AC02-05CH11231 and, in part, by DOE BES STTR grant number DE-SC0011352.

10385-19, Session 5

New twist in the optical schematic of surface-slope measuring long-trace profiler

Gevork S. Gevorkyan, Lawrence Berkeley National Lab. (United States); Wayne R. McKinney, Diablo Valley College (United States); Ian Lacey, Sergey M. Nikitin, Lawrence Berkeley National Lab. (United States); Peter Z. Takacs, Brookhaven National Lab. (United States); Valeriy V. Yashchuk, Lawrence Berkeley National Lab. (United States)

The advent of fully coherent free electron laser and diffraction limited synchrotron storage ring sources of x-rays is catalyzing the development of new, ultra-high accuracy metrology methods. To fully exploit the potential of these sources, metrology needs to be capable of determining the figure of an optical element with sub-nanometer height accuracy. Currently, the two most prevalent slope measuring instruments used for characterization of x-ray optics are the auto-collimator based nanometer optical measuring device (NOM) and the long trace profiler (LTP) using pencil beam interferometry (PBI). These devices have been consistently improved upon by the x-ray optics metrology community, but appear to be approaching their metrological limits. Here, we revise the traditional optical schematic of the LTP. We experimentally show that for the level of accuracy desired for metrology with state-of-the-art x-ray optics, the Dove prism in the LTP reference channel appears to be one of the major sources of instrumental error. Therefore, we suggest returning back to the original PBI LTP schematics with no Dove prism in the reference channel. In this case, the optimal scanning strategies [Yashchuk, Rev. Sci. Instrum. 80, 115101 (2009)] used to suppress the instrumental drift error have to be used to suppress a possible drift error associated with laser beam pointing instability. We experimentally demonstrate the usefulness of the suggested approach via measurements with a number of x-ray optics with both face up and face down orientations. This work is supported by the U.S. Department of Energy under contract number DE-AC02-05CH11231.

10385-29, Session 5

Fabrication and metrology of OSAKA MIRROR for synchrotron applications

Yoshio Ichii, Hiromi Okada, Shinya Aono, Shinsaku Shiroma, Akihiko Ueda, Takashi Tsumura, JTEC Corp. (Japan)

We, JTEC Corporation, have been fabricating OSAKA MIRROR using EEM, nano-fabrication, and RADSI and MSI, nano-measurements, developed by Osaka University [1], and have delivered nearly 400 Super Precision Mirrors to synchrotron radiation facilities worldwide.

We will give an overview of our production technologies and the potentialities. In addition, we will report some focusing results using our OSAKA MIRRORs installed in SPring-8 and SACLA [2][3]. Furthermore, we will show fabrications of challenging mirrors which are developed in collaboration with Osaka University and SPring-8.

10385-30, Session 5

Development of measurement system for ellipsoidal mirrors

Hiroki Nakamori, JTEC Corp. (Japan) and Osaka Univ. (Japan); Yoshio Ichii, Hiromi Okada, Akihiko Ueda, Takashi Tsumura, JTEC Corp. (Japan); Satoshi Matsuyama, Kazuto Yamauchi, Osaka Univ. (Japan)

We manufacture ultra-precise X-ray mirrors (plane, cylinder, elliptic cylinder, parabolic cylinder and etc.) for synchrotron radiation and free-electron laser facilities with subnanometer accuracy. Such high-precision mirrors are achieved with our unique metrology and polishing techniques: the relative angle determinable stitching interferometry (RADSI); the microstitching interferometry (MSI); and the elastic emission machining. In recent years, ellipsoidal mirrors have drawn strong attentions; however, it is difficult to measure sagittal-curved mirrors with subnanometer accuracy using RADSI and MSI. We, therefore, develop a new measurement system for measuring ellipsoidal mirrors.

10385-20, Session 6

Development of relative angle determinable stitching interferometry for high-accuracy x-ray focusing mirrors

Yingna Shi, Xudong Xu, Qiushi Huang, Zhanshan Wang, Tongji Univ. (China)

X-ray focusing mirrors with elliptical shape are widely used in synchrotron facilities for micro-, nano-scale focusing experiments. Surface interferometry plays an important role in the x-ray mirrors figuring with subnanometer accuracy. To avoid the second order error in stitching interferometry, relative angle determinable stitching interferometry (RADSI) is under development. This method was first developed by Yamauchi et al from Osaka University, which uses a planar mirror to correct the relative stitching angle between the neighboring subapertures. Here, we use RADSI to measure the x-ray spherical and elliptical mirrors with 300mm aperture Fizeau interferometer. The interferometer is combined with 4 accurate rotation and tilt stages for the stitching measurement. To ensure the stitching accuracy, we first studied the measurement accuracy within every single subaperture. Multiple measurement is used to decease the random error of single subaperture and 2-D shearing method is proposed to obtain the reference surface error. The subaperture positioning is also carefully corrected to ensure the pixels of the adjacent subapertures in overlapping areas can be matched well. Finally, the profile of the mirror is stitched and compared with the measurement results using Nanometer Optical Component Measuring Machine (NOM) at Shanghai synchrotron radiation facility (SSRF).

10385-21, Session 6

Fizeau stitching at the ESRF

Amparo Vivo, Raymond Barrett, ESRF - The European Synchrotron (France)

X-ray mirror figure errors are commonly measured in the synchrotron community using long trace profiler (LTP) or nanometer optical measuring machine (NOM) instruments, both providing 2D slope measurement. 3D reconstruction is possible but is time consuming, requiring a high stability of environmental conditions over long periods which is not easy to achieve. Characterization of the complete topography of mirror surface is particularly valuable to reveal stresses or deformations such as twist that could be introduced by optomechanical mounting.

At the ESRF metrology laboratory Fizeau stitching methods are under development. A full automated mechanical setup dedicated to stitching measurement of long flat mirrors is now operational. We have already demonstrated accurate reconstruction by stitching 2D profiles acquired from Fizeau sub-aperture measurements . The current work is focused on 3D reconstruction of flat mirror sur-faces up to one meter long. Repeatability, accuracy and in particular the influence of the transmission element will be discussed.

10385-22, Session 6

Three-dimensional shape measurement for x-ray ellipsoidal mirror

Takehiro Kume, Yoshinori Takei, Satoru Egawa, Gota Yamaguchi, Hiroto Motoyama, Hidekazu Mimura, The Univ. of Tokyo (Japan)

An x-ray ellipsoidal mirror requires nanometer-level shape accuracy for its internal surface. Because of the difficulty in processing the surface, electroforming using a high precision master mandrel has been applied to mirror fabrication. To investigate replication accuracy of electroforming, a measurement method for the whole internal surface of the mirror needs to be developed.

The purpose of this study is to evaluate shape replication accuracy of electroforming.

In this paper, a three-dimensional shape measurement apparatus for an x-ray ellipsoidal mirror is developed. The apparatus is composed of laser probes, a contact probe, reference flats, a z-axis stage and a rotation table. First, longitudinal profiles of a mandrel or a mirror vertically placed on the rotation table are measured at several angular positions, and straightness of the center axis and a deviation of the diameter at each height are estimated. Next, without realignment of the measured sample, circularity at every height is measured at regular intervals of 0.1 mm. During each measurement, an effect of motion errors is calculated and subtracted from each profile by referring to distances between probes and the reference flats. Combining the circularity data with information on the straightness of the center axis and the diameter deviation, the three-dimensional error distribution of the whole surface is obtained.

Using a mandrel with nanometer-level shape accuracy and a replicated mirror, performance of the measurement apparatus and the replication accuracy are examined. Measurement repeatability of 1 nm order and a replication accuracy of sub-100 nm order are confirmed.

10385-23, Session 6

Testing Resistive Element Adjustable Length (REAL) cooling for sub-nanometer figure preservation in high-heat load FEL optics

Corey L. Hardin, May Ling Ng, Venkat N. Srinivasan, Daniel S. Morton, Peter M. Stefan, Nicholas M. Kelez, Josep Nicolas, Lin Zhang, Daniele Cocco, SLAC National Accelerator Lab. (United States)

SLAC National Accelerator Laboratory is developing a new high repetition rate free electron laser, LCLS-II, a superconducting linear accelerator capable of a repetition rate up to 1 MHz over a wide energy range (200- 5000 eV). To deliver the FEL beam with minimal power loss and wavefront distortion, the mirrors for the system need height errors below 1nm rms in operational conditions across this spectrum.

In order to maintain this figure error, thermal load effects due to the high repetition rate must be minimized. The absorbed thermal profile is highly dependent on the beam divergence, and this is a function of the photon energy. This leads to a large variation in the beam footprint on the mirror, leading to a large variance in the thermal bump throughout the energy range. In order to correct for this error, first order curvature correction is performed with an off-axis bender. Past this, the cooling system is designed to minimize higher order error. A technique has been developed at SLAC called Resistive Element Adjustable Length (REAL) cooling. This method uses variable length heaters on the mirror cooling system to control the effective cooling width. This allows the cooling footprint to closely match the beam footprint on the mirror, minimizing the thermal bump across a wide range of photon energies. Modeling has been performed which shows this technique could produce height errors below 1nm rms under a FEL power of 200W.

We present the design features, thermo-mechanical analysis and results from metrology tests of a prototype assembly as well as the effects of mirror figure errors, thermal deformation, and bending errors on wavefront propagation through the system.

10385-24, Session PMon

Calibration devices and methods for soft x-ray detector at Beijing Synchrotron Radiation Facility (BSRF)

Mingqi Cui, Yidong Zhao, Lei Zheng, Institute of High Energy Physics (China)

There are two beamlines (4B7A & 4B7B) used for calibration at Beijing Synchrotron Radiation Facility (BSRF). The 4B7A is a medium energy x-ray double-crystal monochrometer (DCM) beamline. It includes three type crystals (KTP (111), InSb (111) and Si (111)). The energy range is from 1.2keV to 6keV. The 4B7B is a VLS plane grating monochrometer (PGM) soft x-ray beamline. The photon energy range is 0.05keV-1.7keV. The monochrometer can be used for two working modes, variable and fix included angle. The high energy resolution (E/?E~5000) and high spectral purity (higher-harmonics suppressor ratio: 0.1%) have been carried out with these working modes, respectively. A lot of sensors have been absolutely-calibrated with the beamlines. For example, XRD, mirror and multilayer, filter, transmission grating, CCD, crystal and image plate etc.. And have been used for other fields, too. They are optics, material, astronomy, metrology etc..

10385-25, Session PMon

X-ray multilayer mid-frequency characterizations using speckle scanning techniques

Hui Jiang, Shanghai Synchrotron Radiation Facility (China)

Determination of multilayer structure was developed so much, but most of studies focused on the relationship between structural imperfections and reflectivity. These imperfections, whether interfacial roughness and interdiffusion or surface feature, measured by grazing X-ray scattering, atomic force microscopy or electric microscopy, reflect relatively high-frequency characteristics. The mid-frequency figure errors were regarded as the main factor to produce large satellite peaks near the focusing spot in the multilayer K-B mirror and were found to produce stripes in the far-field imaging. We report novel method to study mid-frequency interface and layer growth characterizations of multilayer structure using at-wavelength speckle scanning technique. This work is beneficial for matching multilayer manufacture technology to the optimization of beam performances.

10385-26, Session PMon

Optimization of pencil beam F-Theta lens for high-accuracy metrology

Chuanqian Peng, Yumei He, Jie Wang, Shanghai Institute of Applied Physics (China)

Pencil beam deflectometric profilers are common instruments for high accurate surface slope metrology of X-ray mirrors in synchrotron facilities. F-theta optical system is a key optical component of deflectometric profilers used to perform linear angle-to-position converting. Traditional optimization procedures of f-theta systems are not directly related to the angle to position converting relation and performed with large size stop at fixed working distance, which means they may not suitable for the design of f-theta systems working with a small size pencil beam within a working distance range for ultra high accuracy metrology. If an f-theta system is not well designed, aberrations of the f-theta system will introduce lots of systematic errors to the measurement. In this paper we propose a

least square fitting procedure to optimize configuration parameters of an f-theta system. ZEMAX simulation shows that the optimized f-theta system significantly suppressed the angle-to-position converting errors caused by aberrations. Any pencil beam f-theta optical system might be optimized with the help of our optimization method.

10385-27, Session PMon

A novel scanning deflectometry based on secondary light source normal tracing method

Chuanqian Peng, Yumei He, Jie Wang, Shanghai Institute of Applied Physics (China)

Scanning deflectometric profilers, e.g. ESAD, NOM, LTP, which based on an f-theta system are typical optical tools for measurements of mirror profiles in many synchrotron facilities. Unlike these profilers which based on pencil beam, in this paper we use a secondary light source and a pinhole to make up a beam select system to automatically select a beam which will always pass through the pinhole and propagates along the normal direction of the measured area on the surface under test. By measuring the angle variation of the selected beam the slope variation of the surface under test could be measured. Manufacture defects and aberrations introduced systematic errors of optical elements due to big beam lateral motion, which greatly degrade the performance of traditional profilers could be minimized by using this method. A simple example demonstrated that the measurement accuracy of 60nrad within an angle range of 10mrad is readily accessible.

10386-1, Session 1

Pd-based multilayer mirrors for 8-12nm soft x-ray region

Zhanshan Wang, Qiushi Huang, Yiwen Wang, Wenbin Li, Tongji Univ. (China); Igor V. Kozhevnikov, A.V. Shubnikov Institute of Crystallography (Russian Federation); Zhong Zhang, Tongji Univ. (China)

Multilayer mirrors working at the waveband of 8-12 nm are of particular interest for space telescopes, plasma diagnostics and free electron laser sources. Pd/Y and Pd/B4C are promising candidate for this region due to the high theoretical reflectance. To realize the high reflectance experimentally, the interface structure, stress property and temporal stability of these multilayers are investigated. Pd and Y layers have poor interfaces due to severe intermixing and compound formation. This can be solved by adding B4C barrier layers or using reactive sputtering with nitrogen for the fabrication. The Pd/B4C/Y/B4C and Pd(N)/Y(N) multilayers show high reflectance of 44% and 30%, respectively, at around 9.5 nm under near normal incidence. The Pd/B4C multilayer is also fabricated with reactive sputtering using Ar+N2. Although the compressive stress is essentially reduced, the soft X-ray reflectance (32%) is lower than the sample fabricated with pure Ar (45%). Moreover, a distinct deterioration of the nitridated Pd/B4C multilayer is observed after stored in air for 6-17 months. A large part of the top layers of the nitridated samples is degraded with severe interdiffusion and significant decrease in d-spacing. The deterioration is less pronounced for the multilayers fabricated with a higher ratio of N2. A primitive model of upward diffusion of nitrogen and boron is proposed to explain the aging effects of the nitridated structure.

10386-2, Session 1

Double multilayer monochromators for upgraded ESRF beamlines

Christian Morawe, Damien Carau, Jean-Christophe Peffen, ESRF - The European Synchrotron (France)

Following the recent upgrade programme of the ESRF experimental facilities, several new beamlines have become operational. Some of them include Double Multilayer Monochromators (DMM), operating at photon energies between 20 keV and 70 keV. The motivation to deploy a DMM on a 3rd generation light source can be two-fold: reducing the heat load on downstream optics such as high-resolution crystal monochromators while maintaining the beam direction with little offset; taking benefit from the broader bandwidth to transmit more flux to the experimental end station. In the latter case the bandwidth of the DMM needs to be well controlled and, to comply with certain experimental requirements, it has to stay below 0.5%. Multilayers providing this energy resolution while maintaining a decent peak reflectance require the deposition of an elevated number of layers, the use of materials with moderate electron density, and a coating uniformity close to 0.1% over a substrate area of about 300 mm x 100 mm. These boundary conditions impose severe constraints on the performance of both the deposition system and the available characterization technique.

This work will summarize the outcome of recent DMM deposition projects carried out for the ESRF beamlines ID01, ID15, ID19, and ID31. Several NiV/B4C and W/B4C DMMs with up to 500 repetition periods were coated using DC magnetron deposition. The multilayers were characterized by x-ray reflectivity scans at 8048 eV. The paper will highlight successful results and discuss persisting issues and potential approaches for technical improvements.

10386-3, Session 1

Laterally-graded multilayer as x-ray mirror for the laser-induced plasma x-ray sources

Xianchao Cheng, China Academy of Engineering Physics (China)

The laser-induced plasma sources give instantaneous 4ϖ divergent x-ray beams. The x-ray source size and pulse duration depend on the properties of the high-energy laser. Copper is the typical target material giving characteristic photon energies around 8.4keV for the Cu He-like emission line. Different shapes of bent crystals are widely used as imaging and monochromatizing optics. Focusing and collimating are normally functioned by polycapillary x-ray lenses. Especially, the laterally-graded multilayers are applied as x-ray mirrors, which can reflect hard x-rays with big grazing angles, moderate energy resolution and high reflectivities. To get larger acceptance angel, a higher gradient of bilayer thicknesses from 2nm to 3.6nm within 80mm length scale is designed and experimentally used. An alignment precision of 10?m along the direction perpendicular to the central beam is required to select the correct photon energy. The reflected monochromatic x-rays can enhance the traverse coherence for the phase contrast imaging. By using two mirrors symmetrically arranged, the object can be illuminated from two different directions. Multi-frames of the same object can be obtained instantaneously. The laterally-graded multilayer x-ray mirrors are also used for the pinhole imaging of a Z-pinch target, which benefits from the flat reflection surface with much smaller aberration comparing to the reflection of logarithmic-spiral bent crystal.

10386-4, Session 1

Fabrication and characterization of W/B4C lamellar multilayer grating and NbC/Si multilayer phase-shift reflector

Paresh C. Pradhan, Raja Ramanna Ctr. for Advanced Technology (India) and Homi Bhabha National Institute (India); S. Bhartiya, Raja Ramanna Ctr. for Advanced Technology (India); A. Singh, National Institute of Science Education and Research (India) and Homi Bhabha National Institute (India); A. Majhi, Raja Ramanna Ctr. for Advanced Technology (India) and Homi Bhabha National Institute (India); A. Gome, UGC-DAE Consortium for Scientific Research (India); R. Dhawan, Raja Ramanna Ctr. for Advanced Technology (India); M. Nayak, Raja Ramanna Ctr. for Advanced Technology (India) and Homi Bhabha National Institute (India); Pratap K. Sahoo, National Institute of Science Education and Research (India) and Homi Bhabha National Institute (India); S. K. Rai, Raja Ramanna Ctr. for Advanced Technology (India); V. R. Reddy, UGC-DAE Consortium for Scientific Research (India)

We present fabrication and structural analysis of two different multilayer grating structures. W/B4C based lamellar multilayer grating (LMG) was studied for high resolution monochomator application near soft x-ray region. Whereas NbC/Si based multilayer phase-shift reflector (MPR) was studied for high reflection at normal incidence near Si L-edge (~99 eV) and simultaneously to suppress the unwanted vacuum ultraviolet / infrared radiation. The grating patterns of different periods down to D=10 micron were fabricated on Si substrates by using photolithography, and multilayers of different periodicity (d= 9.5 to 2 nm) and number of layer pairs (15 to 100) were coated using sputtering techniques by optimizing the process parameters. For LMG and MPR samples, XRR measurements were carried

out using both incident planes are perpendicular to the grating lines and parallel to the grating lines, respectively. XRR results show successive higher order Bragg peaks that reveal a well-defined vertical periodic structure in LMG, MPR and multilayer structures. The lateral periodicity of the grating and depth of the rectangular groves were analysed using atomic force microscopy (AFM). The AFM results show good quality of lateral periodic structures in terms of groove profile. The effect of the process parameters on the microstructure (both on vertical and lateral patterns) were analysed and optimized to obtain good quality of both LMG and MPR structures and will be presented.

10386-5, Session 1

Ruthenium growth on B, C, and B4C studied by LEIS

Andrey Zameshin, Andrey E. Yakshin, Marko Sturm, Eric Louis, Fred Bijkerk, MESA+ Institute for Nanotechnology (Netherlands)

Ruthenium is one of the frequently used materials in the design of multilayers for EUV optics of different wavelengths, for example in Ru/B4C, Ru/B or Ru/C multilayers for 7-9 nm or Ru/Si as a specular broadband option for 12.5-14 nm, as well as a capping layer for various multilayers. Ruthenium forms very broad interfaces with Si, B4C, B and C. In this work the growth of magnetron sputtered Ru thin films on these materials was investigated by using in situ Low Energy Ion Scattering (LEIS). This technique has a unique sensitivity to the topmost atomic layer. Combination of in-vacuum transfer of samples and outermost surface sensitivity of LEIS allows us to quantify the surface composition for different thicknesses of Ru and therefore compose a “deposition depth profile”, which gives us knowledge of interface width, as well as the surface segregation effects and changes in surface density during compound formation. This method provides a much better depth sensitivity than traditional sputter depth profiles, and allows to resolve details that could not be seen before.
After adding chemical interaction information from in-vacuum X-ray Photoelectron Spectroscopy (XPS), we propose growth mechanisms of Ru on these substrate materials. Among interesting effects found in this work is extremely strong surface segregation of C on Ru, persisting even after 30 nm of Ru deposited on a carbon substrate layer.

10386-6, Session 1

Growth of x-ray multilayer coatings on sculptured surfaces

Dmitriy L. Voronov, Farhad H. Salmassi, Lawrence Berkeley National Lab. (United States); Peter Gawlitza, Fraunhofer IWS Dresden (Germany); Eric M. Gullikson, Lawrence Berkeley National Lab. (United States); Stefan Braun, Fraunhofer IWS Dresden (Germany); Howard A. Padmore, Lawrence Berkeley National Lab. (United States)

Multilayers grown on substrates with sculptured surfaces offer new functionalities and allow novel advanced x-ray optics and instrumentation. For example, multilayers deposited on saw-tooth substrates enable high efficiency Multilayer Blazed Gratings (MBG) which are a key component for high throughput and high resolution EUV and soft x-rays spectrometers. Understanding the fundamentals of x-ray diffraction in a sculptured multilayer stack and investigation of the growth of the multilayers on highly corrugated surfaces are of great importance for design optimization and performance of the MBGs. We found by simulations and confirmed by experiments that diffraction in MBGs corresponds to asymmetric Bragg diffraction of x-rays with specific refraction effects which depend on diffraction geometry and might significantly differ from the ones for the symmetrical diffraction in plane multilayers. The asymmetrical refraction alters the resonance wavelength, bandwidth, effective blaze angle, and diffraction efficiency of MBGs. Growth of multilayers at incline deposition which corresponds to growth geometry for highly faceted surface of a saw-tooth substrates has been investigated. A new growth mode which results in highly periodic ripple patterns was discovered. Optimization of the deposition aimed to mitigate shadowing effects, roughening of interfaces of the multilayer stack, and excessive smoothing of the triangular groove shape has been performed. The optimal growth regime provided almost perfect replication of the saw-tooth substrate by the multilayer interfaces and allowed absolute diffraction efficiency close to the theoretical one.
This work was supported by the US Department of Energy under contract number DE-AC02-05CH11231.

10386-7, Session 2

Ultra-high-aspect multilayer zone plates for even higher x-ray energies

Markus Osterhoff, Christian Eberl, Jakob Soltau, Hans-Ulrich Krebs, Georg-August-Univ. Göttingen (Germany)

Penetration lengths in the millimetre range make hard x-rays above 60 keV a well-suited tool for non-invasive probing of small specimens buried deep inside their surroundings, and enable studying individual components inside assembled, complex devices (solar cells, batteries etc.). The real-space resolution of typical imaging modalities like fluorescence mapping, scanning SAXS and WAXS depend on the available beam size. Although routine in the 5-25 keV regime [1-4], spot sizes below 50 nm are very challenging at x-ray energies above 50 keV: Compound refractive lenses lack in refractive power, the multilayer thickness of coated mirrors is bounded by interfacial diffusion, and lithographic Fresnel Zone Plates loose their efficiency in the two-digit keV regime.

Multilayer Laue Lenses and Multilayer Zone Plates (MZP) are promising candidates for high-keV focusing to small spot sizes; compared to Fresnel Zone Plates, the aspect ratio comparing outermost layer width (~focal spot size) to optical thickness (efficiency) is virtually unlimited by the fabrication. Using Pulsed Laser Deposition on a rotating wire (several millimetre long), we have fabricated an MZP with 10 nm outermost zone widths and optical thickness of 30 μm (optimum phase shift at 60 keV), yielding an unprecedented ultra-high aspect ratio of 1:3000 (outermost zone width compared to optical thickness).

We present experimental results obtained at ESRF’s high energy beamline ID31, where for the first time scanning experiments with real-space resolutions well below 100 nm, but at x-ray energies of 60 keV and above 100 keV have been achieved.

10386-8, Session 2

Development of EUV focusing system based on ellipsoidal mirror

Hiroto Motoyama, Hidekazu Mimura, The Univ. of Tokyo (Japan)

World’s free-electron laser facilities, FLASH, FERMI, and SACLA, have generated the intense extra ultra violet (EUV) pulses to investigate especially the light-matter interaction. Intense EUV pulses offered possibility to observe the multiple ionization or saturable absorption in short-wavelength region. Accessible peak intensity mainly depends on the pulse energy and size of focus beam. Pulse energy is physically limited by the beamline parameters of facilities. On the other hand, size of focus beam still has a room for improvement. The nonlinear phenomena between further intense EUV pulses and matters will lead to deeper understanding of optics.

Ellipsoidal mirror is one of the most ideal focusing optic for EUV region. It has a high-reflectivity (>70%) and shows extremely low chromatic aberration. In recent years, unique fabrication processes have been developed and applied to fabricate an ellipsoidal mirror. The glass mandrel which has an inversed shape of ellipsoidal mirror is replicated to mirror by

using accurate electro forming process. Using highly accurate glass mandrel, highly precise ellipsoidal mirror with the figure accuracy of more than 100 nm (PV) is possible to fabricate.

To test the focusing performance of the ellipsoidal mirror, we have been developed the focusing system at table-top EUV light source which uses high-order harmonic generation. We succeeded in making a 0.5 um focal spot stably. In addition, we are now planning to focus the EUV pulses at free-electron facility, SACLA. In this presentation, we introduce the current status of the performance of ellipsoidal focusing mirror and focusing system.

10386-9, Session 2

Perfect x-ray focusing via corrective glasses made to measure

Frank Seiboth, Deutsches Elektronen-Synchrotron (Germany) and SLAC National Accelerator Lab. (United States); Andreas Schropp, Maria Scholz, Felix Wittwer, Deutsches Elektronen-Synchrotron (Germany); Christian Rödel, Martin Wünsche, Tobias Ullsperger, Stefan Nolte, Friedrich-Schiller-Univ. Jena (Germany); Jussi Rahomäki, Karolis Parfeniukas, Stylianos Giakoumidis, Ulrich Vogt, KTH Royal Institute of Technology (Sweden); Ulrich H. Wagner, Christoph Rau, Diamond Light Source Ltd. (United Kingdom); Ulrike Boesenberg, Jan Garrevoet, Gerald Falkenberg, Deutsches Elektronen-Synchrotron (Germany); Eric C. Galtier, Hae Ja Lee, Bob Nagler, SLAC National Accelerator Lab. (United States); Christian G. Schroer, Deutsches Elektronen-Synchrotron (Germany)

Modern synchrotron radiation sources and XFELs provide highly-brilliant X-ray beams that allow studying the structure and dynamics of matter from atomic distances and a few femtoseconds to macroscopic dimensions and seconds. To fully exploit the potential of these sources the creation of small and intense X-ray beams is crucial. However, due to the short wavelength of X-rays, the fabrication of X-ray optics is very challenging and requires the most advanced technologies. Consequently, most X-ray optics are limited by fabrication limitations, and trade-offs need to be made in terms of aberration-free performance and highest possible NA. Here, we present a general scheme to assess aberrations of an X-ray optical system under working conditions and correct them by introducing an appropriate X-ray phase plate into the optical path to achieve diffraction-limited focusing. The phase plate operates in transmission and is based on refraction. Hence, it is largely insensitive to small shape and surface inaccuracies of a few micrometers and can correct residual aberrations originating from surface errors of reflective optics, zone deformations in diffractive optics and accumulated surface errors in larger refractive lens stacks. The method can be applied very generally to achieve diffraction-limited focusing, thus solving the X-ray focusing problem at synchrotron radiation sources and XFELs.

10386-10, Session 2

Refractive optics to compensate x-ray mirror shape-errors

Kawal J. S. Sawhney, David Laundy, Diamond Light Source Ltd. (United Kingdom); Vishal Dhamgaye, Raja Ramanna Ctr. for Advanced Technology (India); Ian Pape, Diamond Light Source Ltd. (United Kingdom)

X-ray mirrors are extensively used on X-ray beamlines at all synchrotron facilities. Increasingly, beamline users are demanding variable beam sizes [1] and shapes at the sample position on one hand; and aberration-free optics to achieve diffraction-limited focusing on the other. At Diamond, we are developing custom-designed refractive optical elements that modify the wavefront to either broaden the focus of the X-ray mirror or which corrects the X-ray wavefront in order to cancel out the errors in the focusing optics [2]. The optics uses structures made by micro-fabrication which utilise the weak refraction of X-rays. The structures are fabricated using the LIGA deep X-ray lithography technique [3]. Development involves design with wavefront-propagation simulations, precise nano-metrology, accurate fabrication by LIGA and finally testing on synchrotron beamlines. The concept has been successfully tested by measurements on the Diamond Test beamline B16. Design details of this novel concept and representative examples of their use will be presented.

10386-11, Session 3

Development of precision Wolter mirrors for solar x-ray observations

Taro Sakao, Institute of Space and Astronautical Science (Japan) and The Graduate Univ. for Advanced Studies (Japan); Satoshi Matsuyama, Takumi Goto, Jumpei Yamada, Shuhei Yasuda, Kazuto Yamauchi, Osaka Univ. (Japan); Yoshiki Kohmura, RIKEN Harima Branch (Japan); Ayumi Kime, Japan Aerospace Exploration Agency (Japan); Yoshinori Suematsu, Noriyuki Narukage, National Astronomical Observatory of Japan (Japan); Shin-nosuke Ishikawa, Institute of Space and Astronautical Science (Japan)

Fine structures of the hot corona, whose angular scale reaching down to sub-arcseconds, play a crucial role for the dynamics and heating of plasmas there. However, X-ray imagery of the Sun with such resolution has never been conducted due to severe technical difficulty in fabricating precision Wolter mirrors with a wide field of view exceeding several 100”.

For future observations of the solar X-ray corona, we are attempting to realize precision Wolter mirrors with sub-arcsecond resolution by utilizing state-of-the-art surface polish and measurement methods to segmented mirrors which consist of a portion of an entire circle.

X-ray evaluation of an engineering mirror in 2015 with BL29XUL coherent X-ray beam line of SPring-8 synchrotron facility yielded FWHM size of ~0.2” for the PSF core at 8 keV while its HPD (half power diameter) size still remained at ~3” due to a large amount of small-angle scattering right outside the core. Furthermore, large astigmatism was identified for the mirror.

By carefully reviewing these results, improvements in the precision polish, especially in the spatial scale from 0.3 mm to 5 mm, were adopted together with nm-level characterization of the mechanical measurement system for the polish. Preliminary analyes from the subsequent evaluation at SPring-8/ BL29XUL in December 2016 indicate that improved focusing performance of ~0.1” FWHM and ~0.5” HPD has been achieved, without noticeable astigmatism.

Our development activities for precision Wolter mirrors will be reported including at-wavelength evaluation results.

10386-12, Session 3

Development of concave-convex imaging mirror system for a compact and achromatic full-field x-ray microscope

Jumpei Yamada, Satoshi Matsuyama, Shuhei Yasuda, Yasuhisa Sano, Osaka Univ. (Japan); Yoshiki Kohmura, RIKEN Harima Branch (Japan); Makina Yabashi, Tetsuya Ishikawa, SPring-8, RIKEN Harima Branch (Japan); Kazuto Yamauchi, Osaka Univ. (Japan)

A full-field X-ray microscope utilizing an advanced Kirkpatrick-Baez (AKB) optics, which comprises four concave mirrors, provides a high-resolution X-ray image without chromatic aberration. However, it has required long distance, e.g., 10-45 m, between the mirrors and the detector to obtain sufficiently high magnification factor. To overcome the problem, the novel X-ray imaging mirror system consisting of two pairs of concave and convex mirrors was proposed, which enables effective focal length to be short by shifting the principal surface.

We designed a pairs of elliptical concave and hyperbolic convex mirrors, which follow Wolter type III optics, for the demonstration of the imaging system. These mirrors possess numerical aperture of 1.6 x 10^-3 and magnification factor of more than 300 with a total length of ~2m. The mirrors were fabricated with an ion beam figuring system, developed by our group, with an accuracy of ~2 nm peak-to-valley. A one-dimensional demagnification imaging test was performed at SPring-8. The demagnified image of a slit with 10 micron width, which leads to the point spread function of the imaging mirrors, was characterized with the wire scanning method. Consequently, the full width at half maximum value of 42.7 nm was achieved at an X-ray energy of 10 keV, which can never be achieved with the conventional AKB optics because of the limitation of the magnification. We also investigated the wavefront aberration of the reflected X-ray using the single-grating interferometer. Few wavefront aberrations were observed. Additionally, the wavefront aberrations hardly changed when changing the incident angle of the mirror pair. The results indicate that the new imaging system has wide field of view thanks to correction of the coma aberration.

10386-13, Session 3

Advances toward micron resolution optics for x-ray instrumentation and applications

Mark Cordier, Benjamin Stripe, Wenbing Yun, S. H. Lau, Alan Lyon, David Reynolds, Sylvia J. Y. Lewis, Sharon Chen, Vladimir A. Semenov, Richard I. Spink, Sigray, Inc. (United States)

Although the bottleneck of laboratory x-ray source brightness is well-known and discussed, the need for improvements to develop higher efficiency and higher resolution optics is not as often considered. Without optics with excellent FWHM, ultrahigh brightness x-ray sources cannot be utilized efficiently.

We present our novel x-ray mirror lens designs, enabled by high precision and sophisticated manufacturing techniques to enable advanced micronanalytical capabilities for focusing x-rays to microns-scale spot sizes. These axially symmetric x-ray mirror lenses provide advantages over conventional focusing optics such as polycapillary lenses and Fresnel zone plates in key performance attributes such as focusing efficiency, numerical aperture (NA), FWHM of point spread function, working distance, focus chromaticity, energy bandpass, energy transmission, percent of source brightness preservation, and phase space acceptance. The design of these optics allows micron-scale spot sizes even at low x-ray energies, enabling research into low atomic number elements and allows increased sensitivity of grazing incidence measurements and surface analysis.

We will discuss advances made in the fabrication of double parabolic mirror lenses designed for use in laboratory x-ray applications. We will additionally present results from as-built double paraboloids, including surface figure error, slope error and focal spot size achieved to-date.

10386-14, Session 4

Development of x-ray optical components for DLSRs

Makina Yabashi, Inoue Ichiro, Taito Osaka, RIKEN SPring-8 Ctr. (Japan); Hiroshi Yamazaki, Japan Synchrotron Radiation Research Institute (JASRI) (Japan); Kenji Tamasaku, RIKEN SPring-8 Ctr. (Japan); Haruhiko Ohashi, Shunji Goto, Japan Synchrotron Radiation Research Institute (JASRI) (Japan)

We will present our preliminary R&D on x-ray optics and diagnostics for a diffraction-limited storage ring (DLSR). One of the key challenges is to achieve ultimate angular stability in a 10-nrad range for beamline optics including high heatload monochromators. For this purpose, we propose to utilize a double channel-cut crystal monochromator (DCCM), which combines two channel-cut crystals in a (+,-,-,+) configuration. A plasma etching technique (PCVM) is applied to remove lattice strains and to gain smooth surfaces on inner walls of CCs. As another key device, we are developing harmonic separator optics. An important function of this device is to extract a specific harmonic of undulator radiation, enabling utilization of intense pink beam especially in a short wavelength range. Design and evaluation results with coherent x-ray illumination will be reported.

10386-15, Session 4

Current status and future plan of the soft x-ray beamline at SACLA

Shigeki Owada, RIKEN Harima Branch (Japan); Kyo Nakajima, Kensuke Tono, Yasumasa Joti, Tadashi Togashi, Kazuaki Togawa, Japan Synchrotron Radiation Research Institute (JASRI) (Japan); Takahiro Inagaki, RIKEN Harima Branch (Japan); Toru Hara, Japan Synchrotron Radiation Research Institute (JASRI) (Japan); Takashi Tanaka, RIKEN Harima Branch (Japan); Mitsuhiro Yamaga, Yasunori Senba, Hirokatsu Yumoto, Takahisa Koyama, Haruhiko Ohashi, Hitoshi Tanaka, Makina Yabashi, Japan Synchrotron Radiation Research Institute (JASRI) (Japan)

SACLA was inaugurated in March 2012 with two beamlines: BL3 for hard X-ray FEL and BL1 for wide range spontaneous emission. To enhance the research opportunities in soft X-ray region, the SCSS test accelerator, which was a prototype linac of SACLA and decommissioned in 2013, was upgraded, relocated to the SACLA undulator hall, and connected to BL1. The commissioning of this upgraded BL1 had been started from September in 2015, and user operation was started from June 2016. Currently, SASE-FEL pulses in the photon energy range of 20 to 150 eV are available and average pulse energy is about 70 ?J at 100 eV. We are developing beam diagnostic systems such as an arrival timing diagnostics between the SXFEL and the synchronized optical laser. We have further upgrade plans of the accelerator and the beamline. In this presentation, I will report the latest status and future upgrade plans of this beamline.

10386-16, Session 5

REAL cooled mirror for FEL application: FEA modelling and wavefront propagation simulation

Lin Zhang, Corey L. Hardin, Daniele Cocco, SLAC National Accelerator Lab. (United States)

To preserve the full coherence of the FEL, the acceptance of the optics should be at least 2*FWHM of the X-ray beam. The LCLS-II soft X-ray experiments cover a photon energy range from 250 eV to 1300 eV. The

photon beam footprint on the flat and KB mirrors varies from 150 mm to 1000 mm. The length of the mirror is chosen as 1 meter. Resistive Element Adjustable Length (REAL) cooling technique has been proposed to minimize the thermal deformation [1] for LCLS-II mirrors when the power FEL is above 200 W. The water cooling of the mirror is applied on the top-up-side [2]. The additional electric heater is adjustable both in length and power density to cope with the variable X-ray beam footprint length. A R&D project including the prototype of this REAL cooling technique is funded by DoE for FY2017 & FY2018.

In this paper, we will present the modeling results of this REAL cooled prototype mirror. The two parameters of the electric heater (length and power density) are optimized for the thermal deformation minimization of the mirror Finite Element Analysis (FEA) with ANSYS. This optimization of two parameters within ANSYS is not straight forward and necessity large number of FEA calculations. SRW software is used for the wavefront propagation simulation to compare the performance of REAL cooled mirror with other frequently used cooling techniques.

10386-17, Session 5

Finite element analysis for the Bragg crystal of D-line at SSRF

Zhongmin Xu, Limin Jin, Xiangjun Wei, Yajun Tong, Wei Li, Shanghai Institute of Applied Physics (China)

The Dynamic Beamline (D-line) is a combination of ED-XAS beamline and IR beamline. Among the D-line ED-XAS Branch, a Si (111) crystal with the thickness of 1 millimeter is used in Bragg geometry. The crystal has to be bent with a radius of curvature ranging from 2 to 20 m and receives heat load of 30 watts. To meet the need of dynamical focusing and heat cooling, the crystal is immersed in a water-cooled liquid eutectic In/Ga alloy bath. We perform bending and thermal analyses for the crystal, using Ansys software.

The size of crystal is 300mm*20mm and it is held in the four-point bender system. The footprint on the crystal is 0.46mm*78. To reduce its deformation, an indirect water cooled method is adopted. The water film coefficient is 3000W/mm2C, and the reference temperature is 17 degree Celsius. The thermal conductivity for Si and In/Ga is 149 W/mC and 28 W/mC, respectively. After thermal analysis, the maximum temperature is about 48 degree Celsius. By mean of structural analysis, the deformation and stress distribution of the crystal were calculated as well. The RMS tangential slope error of the centerline on the footprint is 5?rad or so, which can meet the need of beamline.

10386-18, Session 5

Development of hybrid adaptive x-ray focusing system based on piezoelectric bimorph mirror and mirror bender

Takumi Goto, Satoshi Matsuyama, Hiroki Hayashi, Osaka Univ. (Japan); Juniki Sonoyama, Kazuki Akiyama, TOYAMA Co., Ltd. (Japan); Hiroki Nakamori, JTEC Corp. (Japan); Yasuhisa Sano, Kazuto Yamauchi, Osaka Univ. (Japan)

In synchrotron radiation facilities and X-ray free-electron laser facilities, X-ray deformable mirrors have been used for X-ray beam conditioning and focusing. Various types of deformable mirrors based on mirror benders and piezoelectric bimorph mirrors have been reported. However, the existing deformable mirrors are not used widely because the bending systems do not have sufficient deformation accuracy at the high-spatial-frequency range and the piezoelectric bimorph mirrors lack long-term stability of deformation and suffer from the junction effect, i.e., deformation errors introduced by gaps between piezoelectric actuators. To overcome these problems, we proposed a hybrid adaptive focusing system based on a piezoelectric bimorph mirror and a bending system consisting of flexure hinges and a precise actuator. The flexure hinges can provide different bending moments to both ends of the mirror, which results in an approximate elliptical shape. The piezoelectric actuators attached on the mirror substrate correct with extreme precision the remaining deformation errors at the high-spatial-frequency range. We will present a simulation study of the mirror deformation and the performance test of a prototype bending system.

10386-19, Session 5

LCLS-II dynamically bendable and water-cooled KB mirrors

Lin Zhang, Daniel S. Morton, Daniele Cocco, Lance Lee, SLAC National Accelerator Lab. (United States)

The LCLS-II project will provide a 4 GeV superconducting (SC) linear accelerator to deliver high-repetition-rate FEL pulses, up to 1 MHz. The average power of the FEL beam from the SC linac will range from 20 to 200 W, and potentially to 600 W. The FEL beam has ultra-short pulse length (down to a few fs), narrow energy band width (down to less than 10-4, thanks to self-seeding technology), and is fully coherent beam. The preservation of the wavefront is essential to maintain the outstanding FEL beam properties. For the FEL beam focusing, we will use dynamically bendable and water cooled KB mirrors system. It is challenging to reach high performance bending of the mirror by minimizing the mechanical coupling with the water cooling.

In this paper, we will present the technical challenge of the KB design to preserve the FEL beam wave-front. We will discuss the aspects of cooling technology to minimize the thermal deformation, some preliminary test and modeling results in order to minimize the mechanical coupling between the mirror bending and the cooling. Finally, we will report some experiment results on a prototype mirror with bender.

10386-20, Session 6

Development of crystal-based split-and-delay optics with wavefront splitting at SACLA

Takashi Hirano, Osaka Univ. (Japan); Taito Osaka, Osaka Univ. (Japan) and RIKEN SPring-8 Ctr. (Japan); Yasuhisa Sano, Osaka Univ. (Japan); Yuichi Inubushi, Tadashi Togashi, Japan Synchrotron Radiation Research Institute (JASRI) (Japan); Ichiro Inoue, RIKEN SPring-8 Ctr. (Japan); Satoshi Matsuyama, Osaka Univ. (Japan); Kensuke Tono, Japan Synchrotron Radiation Research Institute (JASRI) (Japan); Kazuto Yamauchi, Osaka Univ. (Japan); Makina Yabashi, RIKEN SPring-8 Ctr. (Japan)

Ultra-intense and transversely coherent hard X-ray pulses with femtosecond duration provided from X-ray free-electron laser (XFEL) sources, such as SPring-8 Angstrom Compact free-electron LAser (SACLA) in Japan, are powerful tools to explore ultrafast phenomena at an atomic spatial scale. A split-and-delay optics (SDO), which produces two XFEL pulses with a time separation controlled with sub-femtosecond accuracy, have been developed for observing atomic scale dynamics at the time scale of up to hundreds picoseconds. The SDO is based on perfect diffraction of Si(220) single crystals, which enables the production of such a large time separation in a compact setup. We conducted performance tests of the SDO at SACLA, and investigated the capabilities for manipulating the split XFEL pulses in both space and time. In combination with the focusing mirror system, the two split pulses were successfully focused onto the same position with the focal spot size of 1 um. The almost ideal spot size confirmed that crystal components in the SDO had sufficiently high crystal perfection. Temporal overlapping of the split pulses was also achieved by observing interference fringes formed in a spatially overlapped area of the unfocused beams. It indicated that the time separation can be adjusted with a few femtosecond accuracy over the whole temporal range of the SDO.

10386-21, Session 6

Application of MEMS-based x-ray optics as tuneable nanosecond choppers

Pice Chen, Donald A. Walko, Il Woong Jung, Zhilong Li, Gao Ya, Daniel Lopez, Jin Wang, Argonne National Lab. (United States)

The fastest time-resolved synchrotron x-ray measurements rely on the isolation of a set of x-ray pulses. This functionality is often realized by a mechanical chopper. As an alternate method to manipulate x-ray beams, MEMS-based x-ray optics offer several advantages: they are compact, low-cost, and are adaptive in modulating the temporal, spatial and spectral characteristics of x-ray. In the application of x-ray pulse isolation, we recently achieved a pulse-picking time window of 1 ns, which is three orders of magnitude faster than mechanical choppers. The MEMS device consists of a comb-drive silicon micromirror whose resonance is at 67.88 kHz, a subharmonic of the cycling frequency at the Advanced Photon Source (APS). When operating the silicon micromirror at its 004 Bragg reflection, the brief period when the Bragg condition is met defines the pulse-picking window for incident x-rays. We will discuss the design we used to narrow down the temporal Bragg window to 1 ns. By tuning the driving voltage and thus the oscillation amplitude of the MEMS micromirror, we demonstrate the capability to select a set of several sequential pulses or even a single, isolated x-ray pulse out of a train of pulses with the densest fill pattern of the APS. The nanosecond pulse-picking window is far from the limit of the performance of MEMS optics. With a few technically accessible modifications, we expect to achieve a sub-100 ps window which will be a milestone for enabling slicing 100-ps x-ray pulses in synchrotron facilities.

10386-22, Session 6

The development of crystal fabrication in SSRF

Li Song, Shanghai Institute of Applied Physics (China)

In synchrotron field, single-crystal is key component for diffraction. There are huge demand for crystal in Shanghai Synchrotron Radiation Facility (SSRF) phase II project, ranging from simple rectangular plates to direct water cooling crystals and Bragg-Laue crystal wafers and nested channel-cut crystals. The requirement of crystal orientation accuracy is 1' , crystal surface slope error for crystal 2?rad and roughness 1nm(rms) . In order to meet the requirement of beamlines, SSRF will built a crystal fabrication lab, which can provide support, research and development in the field of crystal X-ray optics. The crystal fabrication lab will include crystal orientation, crystal surface grinding and polishing and chemical etching to remove the surface damage. Detailed crystal needs for SSRF Phase II, and the plan for the crystal lab are presented in this paper, some crystal we fabricated are also described.

10386-23, Session 7

Single-order diffraction grating for soft x-ray: state of the art and perspective

Leifeng Cao, China Academy of Engineering Physics (China)

All conventional x-ray dispersive elements including multilayers, crystals and diffraction gratings provide multi-order diffraction spectra, which bring problems in spectroscopy application especially in the region of from VUV to soft x-ray region. The emergence of the so-called soft x-ray single-order diffraction grating (SXSDG) changed such a situation and may bring promised big benefits in lots of fields such as laser plasma diagnostics, x-ray astronomy, synchrotron radiation beam monochromatic; laser generated high harmonics and etc.

In this presentation, the authors provid that the introduction of the concept of the so-called soft x-ray single-order diffraction grating, the evolution and development of such a new emergened dispersive elements, the state of the art and its application, the perspect and ets. A possible worldwide collaboration in future is also suggested.

10386-24, Session 7

Fabrication and test of quasiperiodic x-ray reflection gratings for high-order diffraction suppression

Yilei Hua, Lina Shi, Hailiang Li, Changqing Xie, Institute of Microelectronics (China)

X-ray diffraction gratings with periodic structures have been widely used in various x-ray instruments and systems, such as synchrotron radiation, x-ray interferometer, x-ray astronomy and plasma diagnostics in the field of laser fusion. However, conventional diffraction gratings suffer from so-called high order diffraction contamination. Here we present a large-area quasiperiodic x-ray reflection grating fabricated by high-speed electron beam direct writing technique. The grating consists of a large number of circular holes for the high order diffraction suppression. The 3rd and even order diffractions can be completely eliminated, and the 5th order diffraction is as low as 0.02% of the 1st order diffraction. Shipley SAL-601 with high-resolution, high sensitivity and good resistance is used for electron beam lithography, followed by dry silicon etching and Au thin film deposition using magnetron sputtering. Since the surface roughness and flatness of the x-ray reflection gratings have a great impact on the dispersion performance, we optimized the fabrication the inductively coupled plasma (ICP) silicon etching process, and tested the surface roughness and flatness of the x-ray reflection gratings by an atomic force microscope and a Zygo interferometer, respectively. The optical characterization of the fabricated quasiperiodic x-ray reflection gratings was performed at the spectral radiation standard and metrology beamline BL08B, national synchrotron radiation laboratory of China. The test results demonstrated the effectiveness of high order diffraction suppression. The capability of high order diffraction suppression and fabrication constraints and the limitation of the diffraction efficiency of the quasiperiodic x-ray reflection gratings are also discussed. The unique high order diffraction suppression properties of the quasiperiodic x-ray reflection gratings may provide a platform for x-ray spectroscopic instruments in laboratory sciences and synchrotron light sources.

10386-25, Session 7

Nanofabrication of free-standing spectroscopic photon sieves operating in soft-x ray region

Xiaoli Zhu, Institute of Microelectronics (China); Lai Wei, China Academy of Engineering Physics (China); Hailiang Li, Institute of Microelectronics (China); Leifeng Cao, China Academy of Engineering Physics (China); Changqing Xie, Institute of Microelectronics (China)

A hybrid lithographic method combining electron beam lithography (EBL), x-ray lithography (XRL) and ultra violet lithography (UVL) were adopted to realize a novel design of 1000 lines/mm x-ray spectroscopic photon sieves (SPS) which is able to eliminate the higher diffraction orders. SPS gratings consist of randomly distributed circular holes which form an approximately sinusoidal transmission function. The circularity of circular holes has effect on the far field diffraction pattern. Moreover, these gold holes must be free-standing without supporting membrane due to soft-x A hybrid lithographic method combining electron beam lithography (EBL), x-ray lithography (XRL) and ultra violet lithography (UVL) were adopted to realize a novel design of 1000 lines/mm x-ray spectroscopic photon sieves (SPS) which is able to eliminate the higher diffraction orders. SPS gratings consist of randomly distributed circular holes which form an approximately sinusoidal transmission function. The circularity of circular holes has effect on the far field diffraction pattern. Moreover, these gold holes must be free-standing without supporting membrane due to soft-x ray intensive absorption in any known material. In the process flow, an electron beam was focused to write patterns on membrane substrate to achieve a master mask. Using this mask XRL was performed to efficiently replicate SPS structures and followed by gold electroplating. After that, UVL was applied to define the supporting coarse mesh. In the replication process of XRL, the deviation of circle patterns caused by overheating problem in exposure has been resolved by inserting appropriate filter in x-ray beam path. The spectrum of x-ray source for exposure can be shifted to be higher, and in consequence less heat are produced in exposure due to less absorption of higher energy x-rays in resist. After the fabrication of SPS has been finished, the diffraction pattern was characterized using a soft x-ray beam line. The calibration results show that higher-order diffraction orders can be efficiently suppressed along the axis of symmetry. Our work has given the opportunity of SPS to replace the conventional transmission gratings in potential applications.

10386-26, Session 7

Soft x-ray grating compressors for free-electron-laser pulses

Paolo Miotti, Nicola Fabris, CNR-IFN Padova (Italy) and Univ. degli Studi di Padova (Italy); Fabio Frassetto, CNR-IFN Padova (Italy); Ennio Giovine, CNR-Istituto di Fotonica e Nanotecnologie (Italy); Luca Poletto, CNR-IFN Padova (Italy)

We discuss the design of grating compressors to be used for chirped pulse amplification on free-electron-laser (FEL) ultrashort pulses at energies higher than 100 eV. The compressor adopts gratings to introduce either positive or negative group-delay dispersion (GDD). The optical design originates from a compressor with plane gratings already tested at the FERMI FEL, that has been demonstrated capable to introduce tunable negative GDD to compress chirped FEL pulses in the extreme ultraviolet. Here, we compare two designs to be used in the 100-500 eV region : 1) the configuration with two plane gratings operated in an almost collimated beam, that gives only negative GDD, with an extended design able to operate at energies as high as 500 eV; 2) the configuration with two concave gratings and an intermediate focus between the twos, that is demonstrated capable to introduce positive GDD. Both the configurations are tunable in wavelength and GDD, by rotating and translating the two gratings. These instruments are designed for maximum throughput, since they have the minimum number of optical elements. The compressor efficiency is furthermore discussed, since it is one of the main parameters that is needed to calculate the final peak intensity at the output of the compressor. The transmission of the different configurations is calculated from measurements of grating efficiency done with synchrotron radiation in the 100-500 eV region. Laminar and blazed groove profiles have been measured to compare different gratings. The experimental results will be discussed.

10386-27, Session PWed

High-aspect ratio zone plate fabrication for hard x-ray nanoimaging

Karolis Parfeniukas, Stylianos Giakoumidis, Rabia Akan, Ulrich Vogt, KTH Royal Institute of Technology (Sweden)

High-resolution x-ray optics are of utmost importance for modern x-ray nanoimaging. High efficiency is also desirable to fully utilize the advantage of increased coherence on the optics at fourth generation synchrotron radiation facilities such as MAX IV. We will present our results in fabricating Fresnel zone plate optics for the NanoMAX beamline at MAX IV, to be used in the energy range of 6 – 10 keV.

We managed to manufacture diffraction-limited zone plates in tungsten with 30 nm outermost zone width and an aspect ratio of 21:1. These optics were successfully used for nanoimaging experiments at NanoMAX. However, we found it challenging to further improve resolution and diffraction efficiency for the tungsten process. Therefore, we started to investigate metal-assisted chemical etching (MACE) of silicon for nanofabrication of high-resolution and high-efficiency zone plates.

The first type of structures we manufactured use the silicon directly as the phase-shifting material. We could achieve etching of 5 um deep dense vertical structures 100 nm linewidth. The second type of optics use a heavy metal such as iridium as the phase material. The structures in the silicon substrate act as a mold for heavy metal coating via atomic layer deposition (ALD). A semi-dense pattern is used with line to space ratio of 3:1 for a so-called frequency-doubled zone plate. This way, it is possible to produce smaller structures with the tradeoff of the additional ALD step. We achieved 45 nm-wide and 3.6 um-thick silicon/iridium structures.

10386-28, Session PWed

Design and first commissioning results of the EMIL beamlines at BESSY-II

Stefan Hendel, Franz Schäfers, Helmholtz-Zentrum Berlin für Materialien und Energie GmbH (Germany); Michael Hävecker, Fritz-Haber-Institut der Max-Planck-Gesellschaft (Germany); Gerd Reichardt, Klaus Lips, Mihaela Gorgoi, Helmholtz-Zentrum Berlin für Materialien und Energie GmbH (Germany)

The beamlines for the Energy Materials In-Situ Laboratory Berlin (EMIL) at BESSY-II are currently under commissioning. They consist of two canted undulators, providing a wide energy spectrum of 70 – 10.000 eV, three monochromators (two plane grating monochromators and one LN2-cooled double crystal monochromator) and ten mirror chambers for radiation dispersion and focusing into two separate pathways of 65 m length. Split-mirror chambers distribute the desired photon energy to one (or simultaneously to two) of five experimental endstations. The maximum lateral distance between all beamline elements is less than one meter. This narrow design, selectable monochromators and several beam crossings require advanced modification of all vacuum chambers to enable variable beam routes. Long pathways demand a very high mechanical and thermal stability as well as a reproducible motion of all optical elements. The chosen constant strut-length hexapod design for the mirror chambers provides a wide range of movement in six degrees of freedom. We report on the optical and mechanical beamline design and present commissioning results.

10386-29, Session PWed

Design of the test beamline at SSRF

Zhongliang Li, Lian Xue, Zengyan Zhang, Hongxin Luo, Jie Wang, Shanghai Synchrotron Radiation Facility (China)

In order to ensure high performance beamline instruments & optics rapid successful operated, online measurement system, test beamline (09B) were designed. The beamline covers photon energy range from 4 to 30keV at a bending magnet, and it is highly flexible and versatile in terms of the available beam size and the range of energy resolution and photon flux. Four group 1D Compound refractive lens (CRL) were used for collimate 8, 12, 16 &20keV at a beamline aperture of 0.15?0.12 mrad2. A water cooling double crystal monochromator(DCM) were used Si(111) and Si(311), which could switched in vacuum chamber operates in a dynamic range of 4-20keV and 20-30keV, to produce monochromatic light. A cylindrical mirror with Rh film was bent to toroidal shape to focusing the monochromatic or white beam. The CRL, DCM & Toroidal mirror could combined to produce a white, monochromatic with and without focusing and collimation beam.

The focused light spot size at sample is 173?226?m2 with an acceptance divergence of 1.5?0.1mrad2 (H?V). The photon flux and resolution of the monochromatic light were 3?1011phs/s and 5?10-4 at 10keV. The white beam peak power density is 0.3W/mm2, that could positive incidence on optical components to study the deformation with high heat load. The test beamline could provide several operational modes, detectors and experimental techniques for the instruments and optics measurement. Details of the beamline optical design and its measured performance are presented in this paper.

10386-30, Session PWed

Thickness uniformity study on the ESRF multilayer deposition system

Damien Carau, Jean-Christophe Peffen, Christian Morawe, ESRF - The European Synchrotron (France)

The ESRF Multilayer Laboratory provides reflective X-ray optics using a deposition system where substrates are coated with well-defined multilayer stacks over a total length of up to 1 m. Such long coatings are obtained by moving the substrate in front of the sputter cathodes. The multilayer period is used to tune the photon energy of the reflected X-ray beam. In some applications, when high spectral resolution is required, the variation of the thickness profiles of the deposited materials must not exceed 0.1%. The aim of the study is to quantify the thickness uniformity of 1.2 m long single layer coatings with a spatial resolution of 10 mm or better.

Reflectivity spectra have been acquired with an X-ray reflectometer operating at 8048 eV and fitted using optical models. Genetic optimization algorithms have been employed to avoid converging to local minima.

The first coating under study consisted of a W single film. However, surface oxidation evolving with time had a considerable impact on the thickness measurements and limited their interpretation. To avoid surface oxidation effects, a similar Pt single layer coating was deposited. The measured thickness uniformity contained a relative standard deviation below 0.2% over the full length of 1.2 m. This value is probably overestimated, as it includes measurement uncertainty due to acquisition and modeling. Indeed, an investigation of a multilayer sample showing a d-spacing variation of about 0.05% over a length of 280 mm, has demonstrated the capability of the deposition system to respond to the present requirements.

10386-31, Session PWed

Development of multilayer-based reflection and diffraction optics for the XUV applications

Zhanshan Wang, Qiushi Huang, Zhong Zhang, Wenbin Li, Shengzhen Yi, Tongji Univ. (China); Igor V. Kozhevnikov, A.V. Shubnikov Institute of Crystallography (Russian Federation); Friedmar Senf, Alexei Erko, Helmholtz-Zentrum Berlin für Materialien und Energie GmbH (Germany); Hongchang Wang, Kawal J. S. Sawhney, Diamond Light Source Ltd. (United Kingdom); Eric Louis, Fred Bijkerk, Univ. Twente (Netherlands)

Multilayer-based optics are vital optical components in the extreme ultraviolet (EUV) and X-ray wavelength range which enable the reflection beyond the total reflection region. With the advancement of synchrotron radiation facility, space observation, dense plasma diagnostics, and EUV photolithography, new multilayer optics with higher performance are demanded. Here, some recent development of the multilayer optics and related system in the Institute of Precision Optical Engineering (IPOE) in Tongji University, China, will be presented.

High reflectance EUV mirrors are required below the Si-L edge (?=12.4nm) e.g. for EUV telescope and water window microscope. Pd/Y and Pd/B4C multilayers are promising candidates for the waveband of 8-12 nm. To improve the interface structure, interface engineering methods like reactive sputtering with nitrogen and B4C barrier layers are used and a high reflectance of 45% was measured at?=9.1nm. For the water window region, a new material combination of V/Sc is demonstrated working primarily at the Sc-L edge (?=3.11nm). The V/Sc multilayer with 1.59 nm d-spacing exhibits a reflectance of 18.4% at?=3.129 nm under near normal incidence of 9°. Besides the planar multilayer optics, three dimensional multilayer optics is explored. One notable example is the multilayer coated blazed grating for high efficiency soft X-ray monochromator. A 2000 line/mm blazed grating was coated with Cr/C multilayer which demonstrated a maximum efficiency of 35%-55% at 2-4 keV. Based on the good experimental results, a multilayer grating monochromator is designed for the soft X-ray imaging beamline. Multilayer based imaging system has also been developed for the diagnostics of high power laser produced plasma. Recently, an eight-channel KB microscope using multilayer mirrors was assembled and applied at the high power laser facility for real time X-ray imaging experiments.

10386-32, Session PWed

Spatial coherence measurement of hard synchrotron radiation using a combined pinhole and grating

Wenqiang Hua, Yuzhu Wang, Chunxia Hong, Fenggang Bian, Xiuhong Hong, Jie Wang, Shanghai Institute of Applied Physics (China)

A simple method to measure the spatial coherence of hard X-rays was developed. This method depends on the far-field Fraunhofer diffraction of a grating and the expansion ratio of diffraction peaks instead of the near-field diffraction of grating diffraction used in other available coherence measurements. According to optics, Fraunhofer fringes may be realized by confining an incident beam or observing at far enough location. The expansion effect of Fraunhofer fringes is a function of partial coherence, which in the case of synchrotron radiation can be simply described using a form of the Pythagorean theorem. As a result, transverse coherence can be obtained from the widths of the measured diffraction peaks of a grating with high accuracy and reliability. Good agreement between measurements and calculations based on the GSM in the horizontal direction verified the accuracy and reliability of this method, although there was some discrepancy between experimental and simulated results in the vertical direction. An advantage of the developed technique is that the influence of imperfections of the instrumentation on measurements is minimized. Furthermore, the theoretical analysis of the expansion effect is also expected to be useful for coherent X-ray experiments and coherence characterization of low-brilliance, high-energy X-ray sources despite their short coherence length and numerous distractions

10386-33, Session PWed

Diffraction effects in diamond x-ray refractive lenses

Maxim Polikarpov, Immanuel Kant Baltic Federal Univ. (Russian Federation); Irina Snigireva, Hermann Emerich, ESRF - The European Synchrotron (France); Nataliya Klimova, Anatoly A. Snigirev, Immanuel Kant Baltic Federal Univ. (Russian Federation)

Laser treatment nicely suits for the fabrication of diamond refractive lenses with large acceptance and high profile quality. Unique optical properties of diamond coupled with its excellent thermal stability allow such lenses to be applied as focusing, imaging and beam-conditioning elements at high-heat flux beams of today and future X-ray sources. However, as lenses are made from single crystal, the Bragg law can be satisfied, depending on crystallographic orientation of the lens substrate or on the photon energy of incident-to-lens X-rays. Due to the Bragg diffraction, transmitted intensity might be dramatically reduced. This problem is well known in X-ray spectroscopy and is called "glitch". In this paper, we demonstrate the existence of the diffraction in the focusing mode of the refractive lens and

measure the magnitude of the effect.

A corresponding experiment was done at the BM31 at the ESRF and we observed presence of X-ray spectral glitches by monitoring an intensity transmitted through the CRL. Predictably, the effect arises at certain energies and affects lens' gain factor while keeping invariable a transmitted wave front. We noticed that contribution of X-ray glitches may be minimized by manufacturing of single lenses from various diamond plates with slightly different crystallographic orientation. In such case, the intensity drops are relatively small and may be comparable to X-ray glitches from monochromators, which have the drop value of 2-3%. To summarize, one can say that X-ray glitches from single-crystalline X-ray lenses may only impact spectroscopy or like experiments while the main part of the experiments with refractive optics (focusing, imaging, microscopy and diffraction) should ignore this effect.

10386-34, Session PWed

Micromirror-based manipulation of synchrotron x-ray beams

Donald A. Walko, Pice Chen, Il Woong Jung, Daniel Lopez, Craig P. Schwartz, Gopal K. Shenoy, Jin Wang, Argonne National Lab. (United States)

Synchrotron beamlines typically use macroscopic, quasi-static optics to manipulate x ray beams. We introduce the use of dynamic microelectromechanical systems-based optics (MEMS) to temporally modulate synchrotron x-ray beams. We demonstrate this concept using single-crystal torsional MEMS micromirrors oscillating at frequencies of kHz and above. Such a MEMS micromirror, with lateral dimensions of a few hundred micrometers, can interact with x rays by operating in either grazing-incidence reflection geometry or high-angle diffraction geometry. X rays are deflected only when an x-ray pulse is incident on the rotating micromirror under appropriate conditions, i.e., at an angle less than the critical angle for reflectivity or at the Bragg condition for diffraction. The time window for such deflections depends on the frequency and amplitude of the MEMS rotation. We demonstrate that reflection geometry can produce a time window on the order of a microsecond, while the time window of diffraction geometry can be much shorter, even on the nanosecond scale. We compare the efficiency and the overall flexibility of the two geometries. We further demonstrate that these MEMS optics can be synchronized to the frequency of the Advanced Photon Source to reproducibly select x rays from a selected bunch or group of bunches. We discuss how such optics bring unprecedented design flexibility for future dynamic and miniature x-ray optics for focusing, wave-front manipulation, multicolor dispersion, and pulse slicing.

10386-35, Session PWed

A tool of X-LAB v1.5 for optical design and its application

Zuhua Yang, China Academy of Engineering Physics (China)

To design the monochorator beamlines of synchrotron radiation, XFEL and the X-ray diagnoses of inertia fusion, dynamic process in extreme physical conditions, we developed a useful tool and a platform for optical design, optimization and simulation, X-LAB v1.5 with the independent intellectual property rights. The present version, X-LAB v1.5 has more functions for only one optical element or optical system design and simulation than the old version. X-LAB v1.5 is a useful and friendly tool that comprises sequence ray-tracing, vector diffraction simulation and layout drawing of complex micro-structure optical element. Also, this tool is easy to operate and can provide accustomed service, characteristic functions for users to freely design, optimize an optical system. Currently, X-LAB v1.5 has been applied in designing and simulating of the 3B1 monochromatic beamline in Beijing synchrotron radiation facility with spectral resolution 1000, and spectral range 10eV~100eV, the X-ray diagnosis optical systems of inertia fusion and dynamic process in extreme physical conditions, the KB microscope with spatial resolution up to 6?m, and studying the single order diffraction property of grating photon sieves.

10386-36, Session PWed

Initial growth characteristics for Cr layer and Cr-based multilayers

Hui Jiang, Shanghai Synchrotron Radiation Facility (China)

Multilayers with short (several nm) or ultra-short (less than 2.5 nm) periods have particular applications from soft X-ray to X-ray regimes. Cr-based multilayers are one of most attractive material pairs for short periods to satisfying different energy ranges. In hard X-ray regime, Cr is the best material for energy lower than Cr K absorption edge (~6 keV) and important material for the energy higher than 20 keV. In water window regime, Cr has suitable optical constant as scattering layer and stable interface to combine with C, Sc, Ti and V to obtain high and uniform reflectivity. In this study, a series of Cr layers and Cr/C multilayers were deposited by magnetron sputtering and characterized by GIXR, AFM, XPS, XRF and XANES synthetically. The results reveal the evolution of Cr layer growth and interdiffusion in Cr-based multilayers.

APS modular deposition system

Raymond P. Conley Jr., Argonne National Lab. (United States)

The APS Modular Deposition System has recently been commissioned. The equipment consists of a 4.7 meter long linear substrate translator which is housed inside a vacuum chamber. This substrate translator uses a state of the art direct-drive in-vacuum servo system with velocity stability better than 99.9975%. An absolute optical encoder provides 5nm resolution over the entire length of travel. The design revolves around modularity and adaptability; where sources, metrology, or other instrumentation are easily changed or upgraded to adapt to future needs. The goals for the machine are not only to produce a wide variety of multilayer and other thin-film based x-ray optics, but also to allow the APS to initiate an ion-beam figuring (IBF) based mirror surface correction capability. Off-line surface metrology can be utilized for iterative feedback into the fabrication process. However, the prospect of obtaining surface figure information without the need to extract the substrate from the vacuum chamber provides a number of performance advantages. Such in-situ measurement capability would not only increase throughput for standard ion-beam figuring, but would also allow quasi-real time deposition feedback and more frequent monitoring of the IBF process to study its variability. Additionally, removing the requirement of venting the process chamber; thereby exposing the sample to atmosphere, would allow the flexibility to work with reactive materials. By utilizing an on-axis interferometer in place of a more conventional off-axis Fizeau phase-shifting interferometer, the interferometry transmission flat can be remotely located within the UHV system. This configuration reduces certain measurement errors induced by environmental factors such as air turbulence and humidity. Provisions for a dynamically-actuated aperture will be used to explore methods for 3-D multilayer deposition intended to enable the use of new optical geometries and allow for higher efficiency and mirror figure correction. Machine capabilities will come online in phases. Multilayer deposition will be the first priority for the machine, while the other features related to metrology, figuring, and the dynamic aperture will be brought online later as they are developed.

Conference 10387: Advances in Laboratory-based X-Ray Sources, Optics, and Applications VI

Monday 7 –7 August 2017

Part of Proceedings of SPIE Vol. 10387 Advances in Laboratory-based X-Ray Sources, Optics, and Applications VI

10387-1, Session 1

The Lyncean Compact Light Source: x-ray synchrotron radiation for analytical and imaging applications

Michael Feser, Lyncean Technologies, Inc. (United States)

The Lyncean Compact Light Source (CLS) is a true miniature synchrotron x-ray source with undulator output x-ray characteristics (inherently monochromatic, tunable, high flux). The compact size (8m x 4m) is accomplished by employing a low energy (45 MeV) electron beam storage ring combined with a sub-micrometer period "laser undulator" replacing the permanent magnets of traditional undulators. The output beam of the Lyncean CLS is axially symmetric with 4 mrad beam divergence, a 4% bandwidth and tunable from 8 to 35 keV by changing the energy of the stored electron beam. It delivers 1010 photons per second to experimental end stations located outside of the CLS shielded enclosure.

The first commercial installation of a Lyncean CLS is at the Technical University Munich (TUM) in Germany. Applications pursued there are primarily Talbot grating based multi-modal imaging and tomography (quantitative absorption/phase contrast, dark field) and high-resolution x-ray tomography. The Lyncean CLS is very well matched to these measurements due to the inherent coherence property, Monochromaticity (no beam hardening + quantitation) and the high flux. Analytical applications using specifically developed multilayer focusing optics have been demonstrated at the Lyncean factory in the USA. Protein crystallography with freely selectable x-ray energy to enable advanced phasing techniques such as single wavelength anomalous dispersion (SAD) are possible. Other examples include powder diffraction and small angle scattering to name a few.

Operating the Lyncean CLS has been made extremely simple for users. The complexity of the system is packaged into easy to use interfaces enabling non-experts to run the machine after one week of training. The special characteristic of the Lyncean CLS of producing a truly symmetric and monochromatic beam without contamination by higher x-ray energies (compared to traditional synchrotrons) allows very simple beam transport systems and experimental stations with relaxed shielding requirements to be utilized.

10387-2, Session 1

Compact Linac-driven light sources utilizing mm-period RF undulators

Filippos Toufexis, Valery A Dolgashev, Cecile Limborg-Deprey, Sami G. Tantawi, SLAC National Accelerator Lab. (United States)

Conventional synchrotron light sources and Free-Electron Lasers (FELs) utilize permanent magnet undulators with periods on the order of a few centimeters, and therefore need GeV scale electron beam energies to operate. Such facilities are very large and expensive. Inverse Compton scattering sources use a laser beam as an undulator with micrometer periods and produce X-ray energies on the order of tens of keV. These sources operate with MeV scale beam energies, and therefore they could fit in a lab. However, their average photon flux is typically small, especially in the EUV and soft X-ray regime.

We present a novel compact linac-driven light source, which could produce both incoherent and FEL radiation depending on its configuration. This source is based on a mm-period RF undulator. The RF undulator is a mm-wave cavity resonating at a deflecting mode. The source operates as follows: a train of electron bunches is generated in a thermionic X-band RF injector. These bunches are accelerated in an X-band linac and then interact with the RF undulator. The RF power that feeds the undulator is extracted from the electron beam in a decelerating RF structure, located downstream of the undulator. As an example, a light source with a 91.392 GHz RF undulator and a 124 MeV electron beam can generate incoherent EUV radiation at 13.5 nm. Such a light source could be less than 6 m long, and be used for EUV mask metrology. Similar approach will enable soft X-Ray imaging.

10387-3, Session 1

Developments in compact sources of synchrotron radiation

Timur Shaftan, Brookhaven National Lab. (United States)

Modern synchrotron light sources deliver intense flux of X-rays to many tens of beam lines with reliability above 95%. While the light source is capable of serving photons to many user experiments at once they require large construction and operating budgets, facilities on the scale of a stadium and expert engineering team dedicated to their support.

Since decades ago compact versions of synchrotron light source, perhaps less bright but delivering the same photon spectrum with similar reliability, was in focus of research of several scientific and industrial groups worldwide. Footprint of an electron machine fitting into a large university room with low power consumption and only few experts of the support staff were the quality of merits of the research and development programs.

In this presentation I will go over several types of compact light sources developed and operating in comparison with their large sister facilities. A summary of the user programs for compact light sources will be discussed.

10387-15, Session 1

5th-generation light source development based on inverse Compton scattering

James B. Rosenzweig, Univ. of California, Los Angeles (United States)

We describe recent advances in the experimental development of a high average flux inverse Compton scattering (ICS) source. There are three novel aspects of this research: use of an inverse free-electron laser (IFEL) accelerator; use of laser intensities that yield non-negligible nonlinear electrodynamic effects; and development of recirculation systems for re-use of the laser. In this presentation we concentrate first on the progress made in single-shot measurements of nonlinear effects, and the implications of the methods used for spectral tailoring of ICS. We then describe the achievement of ICS produced from an IFEL-accelerated electron beam, where the IFEL and ICS systems are enabled by a single laser source. We discuss the implications of application of the high flux ICS source in national security and medicine.

10387-4, Session 2

New developments in ultra-high brightness microstructured x-ray sources for applications in Talbot-Lau imaging and dual-energy microanalytical/microXRF

Wenbing Yun, David Reynolds, Vladimir A. Semenov, Janos Kirz, Alan Lyon, Sharon Chen, Benjamin Stripe, Richard I. Spink, Sigray, Inc. (United States)

The limitations to achievable x-ray brightness within the laboratory1 for x-ray spectra is a well-known problem for improving the throughput, sensitivity, and resolution of a wide variety of x-ray techniques. Specific examples of such challenges include: throughput in Talbot-Lau interferometry for medical applications, limits to sensitivity in micro x-ray fluorescence (microXRF), and resolution in x-ray microscopy.

We will present our patented x-ray source technology and recent developments. The major innovations in our x-ray source are the x-ray anodes, which are comprised of arrays of microstructured metal x-ray emitters embedded within a diamond substrate. The diamond substrate enables highly localized large thermal gradients that passively and rapidly cool the metal microstructures as heat is generated under the bombardment of electrons. Electron power densities, 4X higher than conventional solid metal targets can be achieved on the target even greater for metals of lower thermal conductivity. The thermal advantages of the anode design enables the use of many elements that were previously unsuitable as x-ray source materials, and will enable access to new x-ray characteristic lines to optimize performance in monochromatic x-ray analysis.

In addition, we will review practical benefits of our patented FAASTTM (fine array anode source technology) x-ray source over both conventional x-ray sources and newer schemes such as liquid metal anodes2. Advantages include the ability to produce a patterned microbeam optimized for Talbot-Lau interferometry (phase contrast imaging) and the ability to produce various characteristic lines through the incorporation of novel materials (e.g. Au, Pt, Cr) for dual energy capabilities.

10387-6, Session 2

120-kV and 5-watt compact x-ray source

Eric Miller, Sterling W. Cornaby, G. Smith, R. Steck, B. Harris, Kris Kozaczek, Sanjay Kamtekar, MOXTEK, Inc. (United States)

Moxtek has developed a 1kg monoblock 120 kV tube with high voltage power supply which is meant for use in portable devices. This small device with photon energies ranging from 70keV to 120keV expands the accessibility of miniature x-ray sources available for XRF, NDT, and imaging applications. The radiation self-shielding and battery powered design make it ideal for portable handheld devices. The bi-polar transmission window eliminates the heal-effect and the associated detriments in some imaging applications that are typical of reflection stationary anodes. This also enables the output angles easily configured to either cone or fan beam while maintaining the brightness output.

10387-7, Session 2

1D heat transfer problems for a CNT as an electron emitter

Yozo Mikata, Bechtel (United States); Scott Price, GE Global Research (US) (United States)

This paper will discuss three 1D heat transfer problems associated with both conduction and radiation, which are mathematical models for a CNT used as a field electron emitter. CNT has attracted an increasing attention as a potentially excellent material for an electron emitter since around mid-90's. Predicting the current density and the temperature profile of CNT caused by the Joule heating associated with the current density is the key to understanding the physics of CNT as a field electron emitter. This is the focus of this paper.

10387-17, Session 2

The compact x-ray source ThomX

Pierre Favier, Lab. de l'Accelerateur Lineaire, Ctr. Scientifique d'Orsay (France)

Inverse Compton Scattering provides a unique way to produce quasi-monochromatic X-rays via the interaction of relativistic electrons with a laser pulse. This process has the advantage of producing very high fluxes of X-rays with energies above a few tens of keV. In addition the output beam divergence is much larger than in classical synchrotron light sources and the X- ray beam is thus easier to manipulate. We present an X-ray source under construction at Paris- Sud University, ThomX. This source uses a 50 MeV electron beam that collides at 16.7 MHz with a few picoseconds pulsed laser beam whose power is enhanced at the state of the art 600 kW average power to produce X-rays between 30 and 50 keV with a flux of 1013 ph/s. This energy range as well as the energy-angular dependence coming from the physical process are suitable for societal applications like radiotherapy or art history.

We use a prototype Fabry-Perot cavity to perform R&D for the ThomX source. Various diagnostics like real time finesse measurements or passive coupling enhancement are under study on this test cavity to increase the achievable stored power. We will present the ongoing developments along with the results we obtained. A very high finesse optical cavity (F > 28 000) is used, which is one of the highest finesse cavities in pulsed regime. The numerous challenges and solutions to mitigate the related issues will be presented.

10387-8, Session 3

X-ray metrology in the semiconductor industry *(Invited Paper)*

R. Joseph Kline, Daniel F. Sunday, National Institute of Standards and Technology (United States)

The semiconductor industry has advanced technology through the continual shrinking of feature sizes in their integrated circuits. The industry is currently manufacturing the 14 nm node and will soon transition to the 10 nm node. The exact size, shape, and chemical placement in 3D nanodevices determine the performance of the transistors. Each microprocessor can contain billions of these transistors and all of them have to operate similarly for proper operation. Detailed metrology is critical to both the development of new process technologies and in process control during the product manufacturing. We will discuss how high brightness compact X-ray sources can provide critical metrology solutions to the semiconductor industry. We will cover the source requirements for a variety of X-ray measurements and will focus on one particular X-ray measurement for dimensional metrology, critical dimension small angle X-ray scattering (CDSAXS). CDSAXS has been demonstrated at the synchrotron to provide sub-nm resolution in average feature size and errors in the lithography. Commercially available lab-based sources have insufficient flux to satisfy the high throughput and small target requirements of an in-line process control measurement. CDSAXS is particularly demanding because it requires both collimation and a small spot size.

10387-9, Session 3

New developments in laboratory-based x-ray sources and optics

Bernd Hasse, Jenss N. Schmidt-May, Frank Hertlein, Carsten Michaelsen, Incoatec GmbH (Germany)

Many applications in the field of X-ray analytics require an X-ray beam with a high flux density at the sample position. Examples are single crystal diffraction or microdiffraction. An X-ray system comprising of an X-ray source with a small spot size of the electron beam combined with a 2-dimensional multilayer mirror is the ideal source for these applications. In this presentation we will show new developments of X-ray tubes and multilayer optics to achieve higher flux densities at the sample. We will further show applications of X-ray diffractometry and SAXS to show the power of new X-ray sources.

10387-10, Session 3

High-energy radiography of dense material with high flux Inverse-Compton x-ray source

Shouyuan Chen, Ping Zhang, Grigory Golovin, Baozhen Zhao, Colton Fruhling, Daniel Haden, Wenchao Yan, Cheng Liu, Sudeep Banerjee, Univ. of Nebraska-Lincoln (United States); Cameron Miller, Shaun Clarke, Sara A. Pozzi, Univ. of Michigan (United States); Donald P. Umstadter, Univ. of Nebraska-Lincoln (United States)

We report the high energy radiography of dense material using MeV all-optical-driven inverse Compton x-ray source. The properties of the inverse-Compton x-ray source are controlled by means of electron energy, electron charge, scattering beam focal spot size and pulse duration to obtain optimized x-ray energy and high flux for dense material radiography. In this experiment, the x-ray has a photon energy of 8 MeV for maximal steel penetration depth, and a flux of 1011 x-ray photons per shot. With this novel x-ray source, we are able to demonstrate radiography of a 10 cm thick "kite" object through a steel shielding with thickness up to 40 cm in a single exposure. The radiography image of the "kite" object though the 40 cm steel has signal to noise ratio of 2 and image contrast of 0.1, and the "kite" object can be clearly distinguished in the image. Combining its tunability, ultrafast pulse duration and micron meter resolution, the all-optical-driven inverse Compton x-ray source provides unique capacities for flash radiography of dense material, and is of interest for ultrafast nuclear physics study.

10387-16, Session 3

Lobster eye as a collector for water window microscopy

Ladislav Pína, Czech Technical Univ. in Prague (Czech Republic); Veronika Marsikova, Rigaku Innovative Technologies Europe (Czech Republic); Alexandr Jancarek, Radka Havlikova, Czech Technical Univ. in Prague (Czech Republic); Adolf Inneman, Daniela Doubravova, Rigaku Innovative Technologies Europe (Czech Republic); Rene Hudec, Astronomical Institute of the ASCR, v.v.i. (Czech Republic)

Imaging in EUV, SXR and XR spectral bands of radiation is of increasing interest. Material science, biology and hot plasma are examples of relevant fast developing areas. Applications include spectroscopy, astrophysics, Soft X-ray Ray metrology, Water Window microscopy, radiography and tomography. Especially Water Window imaging has still not fully recognized potential in biology and medicine microscopy applications. Theoretical study and design of Lobster Eye (LE) optics as a collector for water window (WW) microscopy and comparison with a similar size ellipsoidal mirror condenser are presented.

10387-5, Session 4

High-energy XRF device for heavy metal identification utilizing the triboelectric effect

T. Lopez, Eli Van Cleve, Matthew Ibbotson, M. Dahl, Carlos G. Camara, Tribogenics, Inc. (United States)

In 2015 Tribogenics introduced a low cost XRF device utilized the triboelectric effect. This revolutionary device is capable of measuring the elemental composition of steel and aluminium alloys. Currently all XRF devices that are used to measure the concentration of heavy elements in materials, such as gold and lead, utilize radioactive decay to generate the x-rays. We have been able to generate x-rays at sufficient energy, above 120 keV, to utilize our current x-ray tube for concentration of gold and lead in materials. We are working to improve our flux output of these devices and by the end of this year we will be introducing this new device into the market. Our device will not only be cheaper than current heavy element XRF devices as well as safer because it does not utilize dangerous radioactive materials. This also reduces the cost and complexity of regulation for the devices.

Strain-free polished channel-cut crystal monochromators: a new approach and results

Elina Kasman, Jonathan Montgomery, Xianrong Huang, Lahsen Assoufid, Argonne National Lab. (United States)

The use of channel-cut crystal monochromators has been traditionally limited to applications that can tolerate the rough surface quality from wet etching without polishing. We have previously presented and discussed the motivation for producing channel cut crystals with strain-free polished surfaces [1]. Afterwards, we have undertaken an effort to design and implement an automated machine for polishing channel-cut crystals. The preliminary effort led to inefficient results. We have since conceptualized, designed, and implemented a new version of the channel-cut polishing machine, the CCPM V2.0. The new machine design no longer utilizes Figure-8 motion that mimicked manual polishing. Instead, the polishing is achieved by a combination of rotary and linear functions of two coordinated motion systems. Here we present the new design of channel-cut polishing machine, its capabilities and features.

Multiple channel-cut crystals polished using the CCPM V2.0 have been deployed into several beamlines at the Advanced Photon Source. We present the measurements of surface finish, flatness, as well as topography results obtained at 1-BM of APS, as compared to results typically achieved when polishing flat-surface monochromator crystals using conventional polishing processes.

Limitations of the current machine design, capabilities and considerations for strain-free polishing of highly complex crystals will be also discussed, together with an outlook for future developments and improvements.

X-ray microscope with refractive x-ray optics and microfocus laboratory source

Dmitry Serebrennikov, Immanuel Kant Baltic Federal Univ. (Russian Federation); Yuriy I. Dudchik, Belarusian State Univ. (Belarus); Aleksandr Barannikov, Anatoly A. Snigirev, Nataliya Klimova, Immanuel Kant Baltic Federal Univ. (Russian Federation)

High penetration depth makes X-ray microscopy very useful research tool and enable to obtain information even inside the sample. The idea of X-ray microscope has already been proposed and even tested at synchrotron radiation sources and laboratory sources. However the majority of works is found Fresnel zone plates to be the best solution for focusing optics. The alternative is Compound Refractive X-ray Lens (CRL), which consists of several elementary biconcave elements. The CRL can be used either as a condenser lens for sample illumination or as an objective lens for imaging. Especial attention attracts two lens systems, which can operate in full-field X-ray microscopy mode or scanning X-ray microscopy mode.

This work demonstrates possibility of X-ray microscopy using CRL based on beryllium and bubble epoxy lens at laboratory microfocus X-ray Metajet source. The main feature of the source is a liquid-metal gallium anode that is able to support high electron-beam power and therefore generates microfocus X-ray source with higher flux than at conventional solid-metal anodes. Single lens and two lens schemes are considered. Images of Cu 2000-grid mesh recorded at different experimental setups are presented.

This work is supported by the Russian-Belarusian Research Grant RFBR (project 16-52-00212, F16R-070).

10387-14, Session PMon

Moxtek's compact x-ray sources

Rick Steck, Sterling W. Cornaby, B. Harris, T. Parker, Kris Kozaczek, C. Smith, Eric Miller, Sanjay Kamtekar, MOXTEK, Inc. (United States)

The XRF and XRD benchtop instrumentation face increasing demand for lowering the detection limits and increasing the accuracy and precision of the measurements. The x-ray tube is a vital component of XRF instruments, which affects the aforementioned characteristics. Moxtek is a leader in developing miniature X-ray sources for portable and handheld XRF instruments. We will present on our current x-ray sources which run from 4 to 70 kV and up to 12 watts. Additionally, we will presenting on prototype x-ray tubes listed below.

1. A compact 75 kV 350 watt x-ray tube, which provides an unprecedented x-ray flux from a compact, air cooled device.

2. A compact 60 kV 30 watt microfocal x-ray tube, with a 50 microns or less focal spot size, for close coupling with the polycapillaries, multilayer mirrors.

3. A portable and compact 120 kV & 5 Watt x-ray tube and high voltage power supply, an air cooled device in a hand size package for backscatter imaging.

In this presentation we will be covering some of the basic functionality of each one of these sources, as well as some of the intended applications.

Conference 10388: Advances in Computational Methods for X-Ray Optics IV

Wednesday - Thursday 9 –10 August 2017

Part of Proceedings of SPIE Vol. 10388 Advances in Computational Methods for X-Ray Optics IV

10388-1, Session 1

Computational methods in development of modern synchrotrons and their applications *(Keynote Presentation)*

Qun Shen, Brookhaven National Lab. (United States)

Advanced analysis and modelling methods has been an essential part of X-ray optics advances and X-ray techniques development at synchrotron light sources. These methods not only help researchers develop designs of X-ray sources and beamlines, diagnose and identify problems and issues in operations, but also enable advanced modelling and simulations of novel X-ray optics and experiments. Recent development rends in diffraction-limited sources and in coherence applications further illustrate the community interests and increased needs in advanced wavefront-based analysis and modelling capabilities. This presentation will provide an overview of this growing area of X-ray optics and techniques and its impact on synchrotron science in general.

10388-2, Session 1

Data handling at SACLA x-ray free electron laser facility and future SPring-8-II synchrotron radiation facility *(Keynote Presentation)*

Tetsuya Ishikawa, RIKEN (Japan)

Only one end-station of X-ray free electron laser or next-generation synchrotron radiation facilities will produce more than 10 TB data in a near future. At SACLA x-ray free electron laser facility, we have installed a acquisition/handling system to cope with the huge amount of data. We have developed a 60 Hz Multi-Port CCD detector for the image sensor of SACLA which is used for most applications. On the other hand, we are developing a new type of pixel detector for the future synchrotron radiation applications. Data handling system, including the dataway to K-computer, has been developed.

10388-4, Session 2

Recent progress of the synchrotron radiation calculation code SPECTRA *(Invited Paper)*

Takashi Tanaka, RIKEN (Japan)

SPECTRA is an application software to compute the optical properties of synchrotron radiation (SR) emitted from bending magnets, wigglers (conventional, elliptical) and undulators (conventional, helical, elliptical, figure-8, etc.). Computations of SR emitted from an arbitrary magnetic field distribution are also available. Parameters and specifications related to the electron beam and light source can be edited completely in fully graphical user interfaces (GUIs) and several methods to visualize the computation results are also implemented.

SPECTRA is written in standard C++ language, with the assistance of the wxWidgets GUI tool kit and OpenGL graphic library for the GUI part. Thanks to portability of these libraries, SPECTRA will run on most available operating systems such as Microsoft Windows, Mac OS X, Linux, and most unix-like operating systems. As of 2017, more than 2,000 users have downloaded SPECTRA.

Since the first official release in 2000, a lot of improvements have been made to the algorithms for faster and reliable computations and a number of new functions have been implemented to meet the increasing demands from the users. In this presentation, we focus on the new functions recently implemented, which we hope help the users to design the components in the SR beamline in the upcoming low-emittance storage rings.

10388-5, Session 2

Main functions, recent updates, and applications of Synchrotron Radiation Workshop code *(Invited Paper)*

Oleg Chubar, Maksim S. Rakitin, Brookhaven National Lab. (United States); Yu-Chen Chen-Wiegart, Brookhaven National Lab. (United States) and Stony Brook Univ. (United States); Yong S. Chu, Andrei Fluerasu, Dean Hidas, Lutz Wiegart, Brookhaven National Lab. (United States)

The presentation will include an overview of main functions of the “Synchrotron Radiation Workshop” (SRW) code, dedicated to calculation of different types of synchrotron radiation, and simulation of propagation of fully-coherent radiation wavefronts, partially-coherent radiation from a finite-emittance electron beam of a storage ring source, and time-/frequency-dependent radiation pulses of a free-electron laser, through X-ray optical elements of a beamline. A special attention will be paid to updates in the library of physical-optics “propagators” for different types of reflective, refractive and diffractive X-ray optics with its typical imperfections, enabling simulation of practically any X-ray beamline in a modern light source facility. High accuracy of calculation methods used in SRW allows for multiple applications of this code, not only in the area of development of instruments and beamlines for new light source facilities, but also in areas such as electron beam diagnostics, commissioning and performance benchmarking of insertion devices and individual X-ray optical elements of beamlines. Applications of SRW in these areas, facilitating development and advanced commissioning of beamlines at the National Synchrotron Light Source II, will be described.

10388-6, Session 2

Recent progress of the XRT: ray tracing and wave propagation toolkit *(Invited Paper)*

Roman Chernikov, Deutsches Elektronen-Synchrotron (Germany); Konstantin Klementiev, Max IV Lab. (Sweden)

Xrt is a python-based software library for beamline simulation and analysis in x-ray regime. We provide classes for many beamline elements, propagation engine in ray and wave approximations with full account for shapes and material properties, and high quality visualization capabilities. Recently added support for the GPGPU calculations via OpenCL not only allowed us to speed up the existing ray tracing routines but to qualitatively extend the limits of the theoretical models involved at all stages. As an example for the sources: we managed to increase the integration precision at high magnetic fields and high energies, which allows to calculate wigglers as undulators, an important case for the next-generation low-emittance synchrotrons. For the optics: wave propagation is implemented in the most general Kirchhoff integral form, therefore diffraction efficiency can be derived for multiple diffraction orders in gratings and zone plates. For the materials: reflectivity curves are calculated for the deformed crystals by solving the Takagi-Taupin equations numerically for each photon in the beam.

We also introduce an XML-based file format to store the ray tracing project parameters and an interactive GUI tool, xrtQook, which we recommend for the project configuration editing and automatic ray tracing script generation.

10388-7, Session 3

RAY, RAY-UI, and REFLEC: new developments *(Invited Paper)*

Franz Schäfers, Peter Baumgaertel, Helmholtz-Zentrum Berlin für Materialien und Energie GmbH (Germany)

The raytrace program RAY developed and continuously upgraded at BESSY since the 1980th is a well-known versatile synchrotron radiation simulation tool, well established since many years with comparable capabilities like the widely used SHADOW-program. Recently a comfortable and powerful graphical user interface RAY-UI has been added, which makes it an attractive and easy-to-use program for every-day use. Special helpful features have been added here like the mono-capillary optics and instantaneous calculation of mirror reflectivities and grating efficiencies of the central beam. A built-in DO-loop helps optimizing certain features such as focal spot or energy resolution as function of e.g. slope errors. The capabilities and new developments will be demonstrated with recent simulations ranging from complex soft x-ray elliptical undulator beamlines to hard x-ray beamlines at diffraction-limited storage rings. The Fresnel-reflectivity program REFLEC which accesses the same optics data-basis as RAY will also be shown. REFLEC is a program to calculate synchrotron radiation features, mirror or crystal reflectivities and grating efficiencies. It can easily be run as well as RAY in an outside DO loop (LOOPER) for optimizing e.g. grating design parameters or mirror reflectivities. Recent approaches to handle interference and coherence phenomena are also shown.

10388-8, Session 3

Interoperability and complementarity of simulation tools for beamline design in the OASYS environment *(Invited Paper)*

Luca Rebuffi, Elettra-Sincrotrone Trieste S.C.p.A. (Italy); Manuel Sanchez del Rio, ESRF - The European Synchrotron (France)

In the next years most of the major synchrotron radiation facilities around the world will upgrade to 4th-generation Diffraction Limited Storage Rings using multi-bend-achromat technology. Moreover, several Free Electron Lasers are ready-to-go or in phase of completion. These events represent a huge challenge for the Optics physicists responsible of designing and calculating optical elements and systems capable to exploit the revolutionary characteristics of the new photon beams. Reliable and robust beamline design is only possible by lumping together different simulation tools. The OASYS (OrAnge SYnchrotron Suite) [1] suite drives several simulation tools providing new mechanisms of interoperability and communication within the same software environment. OASYS has been successfully used during the conceptual design of many beamline and optical designs for the ESRF and Elettra-Sincrotrone Trieste upgrades. Some examples are presented showing comparisons and benchmarking of simulations against calculated and experimental data.

10388-9, Session 3

McXtrace 1.4: latest developments in the new release

Erik B. Knudsen, Peter K. Willendrup, Technical Univ. of Denmark (Denmark)

We present the new features included in McXtrace 1.4 - the latest release of the open source x-ray tracing software package[1]. McXtrace is an open source ray-tracing package designed for simulating X.ray scattering experiments at synchrotrons, FELs, and lab sources, but recently it has found use in other areas such as the astrophysics community for telescope design.

Among the interesting new features are:

1. A set of synchrotron source models including Bending Magnet, Wiggler, and Undulator.
2. Several new optics modules.
3. Divergence monitors.
4. Flat & bent Darwin-limited Bragg-monochromator crystal components.
5. A new python/qt-based GUI.
6. Full-size mode of the DanMAX[2] beamline (in construction at the MAX IV synchrotron).
7. Full-size model of FXE[3] beamline at XFEL.
8. Redesigned and faster data-file reading lib.
9. SAS-view based SAXS-sample components.
10. Redesigned installation procedure.
11. A particle list output interface file-format (MCPL[4]) to enable simpler integration with other software packages such as SimEX[5] and MCNP6[6].
12. Generalized multilayer mirrors, with an option for graded profiles.
13. A Polycrystal model.

We will show examples of using these new features, and how they may be utilized in a beamline design process as has been done for the DanMAX[2] beamline.

10388-10, Session 4

Application of x-ray simulations in development of instruments at Linear Coherent Light Source (LCLS) at National Accelerator Laboratory (SLAC) *(Invited Paper)*

Jacek Krzywinski, Lin Zhang, Gabriel Marcus, Yiping Feng, SLAC National Accelerator Lab. (United States)

Development of X-ray Free Electron Lasers (XFEL) opens new era in X-ray science. The full exploitation of unique properties of the XFEL radiation require challenging solutions that preserves radiation properties from a coherent, diffraction limited source under unprecedented instantaneous and average power load. We will present properties of simulated XFEL radiation such as coherence, source shape, divergence and longitudinal location inside the undulator. Recently, a construction of the LCLS II project has started as a major upgrade to the LCLS facility that will increase the average power of

the XFEL up to 1 kW level. We will show how the X-ray simulations are used for minimizing thermal distortions on focusing of the LCLS II X-ray beams by 1 meter long Kirkpatrick-Baez mirrors. We will discuss and compare accuracy of simulations using different simulation methods and packages applied to focusing optics. The design of instruments should mitigate the damage to the optics caused by the tremendous instantaneous XFEL power. We will present X-ray simulation of the damage to the diffraction grating coatings and compare it with experimental results obtained at LCLS. The self-seeded mode of the LCLS operation increases temporal coherence and reduces greatly the bandwidth of the X-ray radiation. The results of time dependent X-ray simulations of the LCLS radiation passing through the seeding monochromator will be presented. We will compare two different approaches: Fourier Optics and an approach based on a dispersive system described by 6x6 pulse ray matrixes.

10388-11, Session 4

European XFEL optics: current status *(Invited Paper)*

Liubov Samoylova, Harald Sinn, Maurizio Vannoni, European XFEL GmbH (Germany)

The European X-ray Free Electron Laser (XFEL) is a high repetition rate source that will deliver the most powerful hard X-ray short pulses in the world, up to 1e14 photons per 100 fs pulse. The end stations at the European XFEL are designed to carry out cutting edge scientific research in such areas as the deciphering the structure of biomolecules; studying ultra fast processes in real time, e.g. chemical reaction, dynamics of phase transitions; investigation of matter under extreme conditions; non-linear effects such as multi-photon ionization, etc. To enable such experiments, the optical components of 1 km beam transport and focusing optics downstream should provide ultra-short and almost fully transversely coherent laser pulses to experiments with minimal losses and distortions.

One of the main special features of the beam transport system is the use of 800 mm long mirrors to offset and distribute the beam at propagation distances many hundreds meters. Performance of the beamlines depends critically on these components, since profile errors and unwanted deformations at level of few nanometers, e.g. due to mounting and heat load, will cause severe beam distortions at experimental stations. In the talk we will present the up-to-date status of EuXFEL X-ray optics in the beam transport system and at specific experimental stations. We will present a thorough analysis of awaited beam parameters, calculated from metrology data for real optics components. Besides, we will discuss the modification of the beams after such mirrors by effects of spatial frequency filtering in free space propagation.

10388-12, Session 4

X-ray optics simulation and beamline design for the APS upgrade *(Invited Paper)*

Xianbo Shi, Ruben Reininger, Dean R. Haeffner, Argonne National Lab. (United States)

The upgrade of the Advanced Photon Source (APS) to a Multi-Bend Achromat (MBA) will increase the brightness of the APS by between two and three orders of magnitude. The upgrade project includes approximately eight feature beamlines that will take full advantages of the new machine. Many of the existing beamlines will be upgraded to profit from this significant machine enhancement. Optics simulations are essential in the design and optimization of the new and existing beamlines. In this presentation the simulation tools used and developed at APS, ranging from analytical to numerical methods, are summarized. Three general optical layouts are compared in terms of their coherence control and focusing capabilities. The concept of zoom optics, where two sets of focusing elements (e.g., CRLs and KB mirrors) are used to provide variable beam sizes at a fixed focal plane, is described in detail. Finally, simulation studies of a few APS upgrade beamlines are presented.

10388-13, Session 4

Simulation and optimization of the Sirius IPE soft x-ray beamline

Bernd C. Meyer, Tulio C. R. Rocha, Sergio A. L. Luiz, Artur Clarindo Pinto, Harry Westfahl Jr., Ctr. Nacional de Pesquisa em Energia e Materiais (Brazil)

The soft X-ray beamline IPÊ is one of the first phase SIRIUS beamlines at the LNLS, Brazil. Divided into two branches, IPÊ is designed to perform ambient pressure X-ray photo-electron spectroscopy (AP-XPS) and high resolution resonant inelastic X-ray scattering (RIXS) for samples in operando/environmental conditions inside cells and liquid jets. The aim is to maximize the photon flux in the energy range 200-1400 eV generated by an elliptically polarizing undulator source (EPU) and focus it to a 1 ?m vertical spot size at the RIXS station and 10 ?m at the AP-XPS station. In order to achieve the required resolving power (40.000 at 930 eV) for RIXS both the dispersion properties of the plane grating monochromator (PGM) and the thermal deformation of the optical elements need special attention. The grating parameters were optimized with the REFLEC code to maximize the efficiency at the required resolution. Thermal deformation of the PGM plane mirror limits the possible range of cff parameters depending of the photon energy used. Hence, resolution of the PGM and thermal deformation effects define the boundary conditions of the optical concept and the simulations of the IPÊ beamline. We compare simulations performed by geometrical ray-tracing (SHADOW) and wavefront propagation (SRW) and show that wavefront diffraction effects (apertures, optical surface error profiles) does not significantly change the beam spot size and shape.

10388-14, Session 4

Optical design and simulation of a new coherence beamline at NSLS-II

Garth J. Williams, Oleg Chubar, Ian K. Robinson, Brookhaven National Lab. (United States)

High spectral brightness X-ray sources, whose development and construction were driven in large part by demonstrable improvements to experimental efficiency, are now providing X-ray beams with unprecedented spatial and temporal characteristics. These beams, in turn, are driving the refinement and development of instrumentation capable of fully exploiting their novel properties. Whether the advanced instrumentation meets the need to provide very-high spatial or energy resolution through existing techniques or strives to explore new methods, our tools for its design must accurately account for the source properties and the effects of beamline optics on the X-ray probe.

We will discuss the optical design of a proposed beamline at NSLS-II, an optimized third generation storage ring source, designed to exploit the coherence of the X-rays to extract high-resolution spatial information from ordered and disordered materials through Coherent Diffractive Imaging (CDI), executed in the Bragg- and forward-scattering geometries. This technique offers a powerful tool to image sub-10 nm spatial features and, within ordered materials, to map deformation fields with sub-Angstrom sensitivity. Inspired by the opportunity to apply CDI to a wide range of samples, with sizes ranging from sub-micron to hundreds-of-microns, an optical design has been proposed and simulated under a variety of optical configurations using Synchrotron Radiation Workshop. The design, its goals, and the result of simulations of the beamline performance as a function of its variable optical components will be presented.

10388-15, Session 4

Theory of x-ray echo spectrometers *(Invited Paper)*

Yuri V. Shvyd'ko, Argonne National Lab. (United States)

X-ray echo spectroscopy is a recently proposed inelastic x-ray scattering

(IXS) technique, a space-domain counterpart of neutron spin-echo. X-ray echo spectroscopy involves imaging of the IXS spectra without requiring x-ray monochromtization. Due to this, the echo-type IXS spectrometers have a potential to simultaneously provide dramatically increased signal strength, reduced measurement times, and higher resolution compared to the traditional scanning-type IXS spectrometers. Here we develop further the theory of the x-ray echo spectrometers initially presented in [1] with an emphasis on questions of practical importance, which could help to design and assess feasibility and performance of the echo spectrometers such as: echo spectrometers tolerances, tuning up the refocusing condition, effective beamsize on the sample, spectral window of imaging and scanning range, the impact of the secondary source size on the spectral resolution, etc.

Examples of optical designs of the echo spectrometers with an 1-meV and 0.1-meV resolution will be presented as well.

[1] Yuri Shvyd'ko, Phys. Rev. Lett. 116, 080801 (2016).

10388-32, Session PWed

Numerical analysis of partially coherent radiation at soft x-ray beamline

Xiangyu Meng, Chaofan Xue, Huaina Yu, Yong Wang, Renzhong Tai, Yanqing Wu, Shanghai Synchrotron Radiation Facility (China)

A new model for numerical analysis of partially coherent x-ray at synchrotron beamlines is presented. The model is based on statistical optics. Four-dimensional coherence function, Mutual Optical Intensity (MOI), is applied to describe the wavefront of the partially coherent light. The MOI propagation through the beamline is developed. First, the plane is separated into many elements. It is assumed that in every element the beam has full coherence and constant complex amplitude, which is reasonable as long as the dimension of element is much smaller than the coherent length and beam spot size. Second, the propagation of MOI for every element can be analytical solved with Fraunhofer or Fresnel approximations. Finally, the total MOI propagation through free space can be obtained by summing the contribution of all elements. Local stationary phase approximation is implemented to simulate MOI propagating through ideal mirrors and gratings. In this theory, path length is used to describe the phase shift through the optics. The source is not necessary to be Gaussian Schell type. Any MOI distribution can be applied in this model. The STXM beamline at SSRF was analyzed with this model. The diffraction experiment of a single slit was performed and the diffraction pattern was simulated to get the coherence length, (31 ± 3.0) μm ? (25 ± 2.1) μm (H ? V), which had a good agreement with the theoretical results, (30.7 ± 0.6) μm ? (31 ± 5.3) μm (H ? V). It indicates that the model is applicable in the analysis of partial coherence propagation in soft x-ray beamlines.

10388-33, Session PWed

A fast and reliable approach to simulating the output from an x-ray tube used for developing security backscatter imaging

Anna Vella, Andre M. A. Munoz, Matthew J. F. Healy, David W. Lane, Cranfield Univ. (United Kingdom); Joseph G. Zhou, VJ Technologies, Inc. (United States); David Lockley, Defence Science and Technology Lab. (United Kingdom)

The PENELOPE Monte Carlo simulation code was used alongside the SpekCalc code to simulate X-ray energy spectra from a VJ Technologies' X-ray generator at a range of anode voltages. The PENELOPE code is often utilised in medicine but is here applied to develop coded aperture and pinhole imaging systems for security purposes. The greater computational burden of PENELOPE over SpekCalc is warranted by its greater flexibility and output information. The model was designed using the PENGEOM sub-tool and consists of a tungsten anode and five layers of window materials. The photons generated by a mono-energetic electron beam are collected by a virtual detector placed after the last window layer, and this records the spatial, angular and energy distributions which are then used as the X-ray source for subsequent simulations. The process of storing X-ray outputs and using them as a virtual photon source can then be used efficiently for exploring a range of imaging conditions as the computationally expensive electron interactions in the anode need not be repeated. The modelled spectra were validated with experimentally determined spectra collected with an Amptek X-123 Cadmium Telluride detector placed in front of the source.

10388-34, Session PWed

The use of simulation to optimize the pinhole diameter and mask thickness for an x-ray backscatter imaging system

Anna Vella, Andre M. A. Munoz, Matthew J. F. Healy, David W. Lane, Cranfield Univ. (United Kingdom); David Lockley, Defence Science and Technology Lab. (United Kingdom)

The PENELOPE Monte Carlo simulation code was used to determine the optimum thickness and aperture diameter of a pinhole mask for use in coded aperture backscatter security imaging. The thickness of the mask needs to be sufficient to prevent any X-ray leakage, and the pinhole diameter wide enough to maximise the field of view. The model consisted of an extended X-ray source, a pinhole mask, and a detector. The X-ray source was modelled as a thin wire emitter; the X-rays passed through the pinhole mask and were collected at a simulated 1040 x 1340 pixels' area detector, placed inside a lead lined aluminium camera housing. Each mask was model irradiated with X-rays with a flat energy distribution across a defined energy range. This artificial source was used to avoid being specific to a particular source technology. To generate the image, the integrated energy was calculated from the phase-space file to correlate the energy of the photons with their positions in the real pixels of the real detector. A MATLAB routine was written to accomplish this mapping and integration. The image contrast, signal to background ratio, spatial resolution, and collimation effect were calculated at the simulated detector as a function of the thickness and the pinhole diameter of three different mask materials: tungsten, tungsten/epoxy resin composite and a low melting point bismuth alloy.

10388-36, Session PWed

Alignment of KB mirrors with at-wavelength metrology tool simulated using SRW

Lei Huang, Brookhaven National Lab. (United States); Bo Gao, Shanghai Institute of Applied Physics (China) and Univ. of Chinese Academy of Sciences (China); Maksim S. Rakitin, Brookhaven National Lab. (United States); Junpeng Xue, Brookhaven National Lab. (United States) and Sichuan Univ. (China); Oleg Chubar, Mourad Idir, Brookhaven National Lab. (United States)

Synchrotron Radiation Workshop (SRW) is a powerful synchrotron simulation tool and has been widely used at synchrotron facilities all over the world. During the last decade, many types of x-ray wavefront sensors has been developed and used. In this work, we will present our recent effort on the development of at-wavelength metrology simulation based on SRW mainly focused on the Hartmann Wavefront Sensor (HWS). Various conditions have been studied to verify that the simulated HWS is performing as expected in terms of accuracy. This at-wavelength metrology simulation tool is then used to align KB mirrors by minimizing the wavefront aberrations. We will present our optimization process to perform an 'in situ' alignment using conditions as close as possible to the real experiments (KB mirrors with different levels of figure errors or different misalignment geometry). Present status of this simulation tools will be presented and future foreseen extensions will be discussed, like Grating Shearing

Interferometry (GSI) and the possibility to use Transport of Intensity Equation (TIE).

10388-37, Session PWed

Collaborative simulation of x-ray optics and electron beam dynamics

David L. Bruhwiler, RadiaSoft LLC (United States); Paul Moeller, RadiaSoft LLC (United States) and Bivio LLC (United States); Robert Nagler, RadiaSoft LLC (United States); Maksim S. Rakitin, Oleg Chubar, Brookhaven National Lab. (United States); Gerard Andonian, RadiaBeam Technologies, LLC (United States) and Univ. of California, Los Angeles (United States)

Modern synchrotron light sources are an efficient source of X-ray, UV and infrared beams, enabling scientific research with a wide range of applications. State-of-the-art low-emittance facilities like NSLS-II produce partially-coherent X-ray beams that enable new research with more sophisticated X-ray optics. We present a browser-based GUI for X-ray optics [1] and electron beam dynamics [2], which is available for beta testing. The open source code SRW [3,4] is used to simulate synchrotron radiation sources and the subsequent transport of coherent and partially-coherent radiation beams through optical systems of beamlines. We are presently implementing support for the open source code Shadow3 [5,6] to simulate incoherent synchrotron radiation via geometrical ray-tracing. Electron beam dynamics in the electron storage ring is simulated with the Pelegant code [7]. Examples will be presented and the open source cloud computing framework Sirepo [8] will be described, with emphasis on features that enable instantaneous collaboration. Lightweight and extensible, Sirepo could become a community resource for use with other codes.

10388-38, Session PWed

Simulation of experiments with partially-coherent x-rays using Synchrotron Radiation Workshop

Oleg Chubar, Maksim S. Rakitin, Brookhaven National Lab. (United States); Yu-Chen Chen-Wiegart, Brookhaven National Lab. (United States) and Stony Brook Univ. (United States); Andrei Fluerasu, Lutz Wiegart, Brookhaven National Lab. (United States)

High-accuracy physical optics calculations methods used in the “Synchrotron Radiation Workshop” (SRW) allow for multiple applications of this code in different areas, covering development, commissioning, diagnostics and operation of instruments at light source facilities. This presentation will focus on applications of SRW for determining of important physical characteristics of micro-spectroscopy and coherent scattering beamlines, and on the simulation of experiments at these beamlines. The most complete and most detailed simulation of experiments with SRW is possible in the area of elastic coherent scattering, where the interaction of radiation with samples can be described with the same transmission-type “propagators” that are used for the simulation of fully- and partially-coherent radiation propagation through X-ray optical elements of beamlines. Besides the examples of forward-simulation of such experiments, performed at beamlines of NSLS-II, new developments in the SRW code, facilitating solution of the corresponding inverse problems, will be described.

10388-39, Session PWed

Hard x-ray FEL SASE pulses propagation through perfect single crystals diffracting in Bragg and Laue geometry

Angel Rodriguez-Fernandez, Paul Scherrer Institut (Switzerland); Liubov Samoylova, European XFEL GmbH (Germany); Alexey V. Buzmakov, A.V. Shubnikov Institute of Crystallography (Russian Federation)

With the commissioning of three new hard x-ray Free Electron Lasers (X-FEL), European XFEL (Hamburg), PAL (Pohang) and SwissFEL (Zurich), comes a time when a better knowledge of hard x-ray optics for high brilliant sources will be needed. Due to the high coherence and the femtosecond range of these types of photon pulses, the dynamical diffraction effects in perfect crystals, use as monochromators, have more relevance in the interaction between the crystal structure and the wave field under propagation. To tackle this problem, we have used Synchrotron Radiation Workshop (SRW), a well-known tool based on Fourier optics approach, to simulate the propagation of different FEL SASE pulses along perfect crystals in Laue and Bragg geometry. Different thicknesses (between 30 and 100 um) have been studied for two different photon energies 8 KeV and 12 KeV. The FEL SASE beams were generated by GENESIS and FAST code. These types of models could help in the understanding of the Self-Seeding modes of operation at FEL facilities, where the common large SASE bandwidth mode is reduced from the typical bandwidth on the order of 0.2-0.5 % of the fundamental energy (20 eV at 8 KeV) to 0.005% (0.4 eV at 8 KeV). This mode also introduce an increment of the brilliance power and an improvement of the jittering stability of the photon beam , which is of great interest for photon energy techniques as resonant x-ray scattering as well as observation of nonlinear x-ray–matter interactions.

10388-40, Session PWed

Simulation of x-ray images of an IXS echo spectrometer

Alexey Y. Suvorov, Oleg Chubar, Yong Q. Cai, Brookhaven National Lab. (United States); Yuri V. Shvyd’ko, Argonne National Lab. (United States)

A recently advanced concept of an X-ray echo spectrometer allows to overcome limitations of spectral resolution and weak signals of the traditional inelastic x-ray scattering (IXS) instruments [1]. The spectrometer illuminates a sample with a spatially expanded beam due to energy dispersion of its monochromator. After the sample, the spectrometer analyzer recombines the beam into an image in a detector plane. The enhanced strength of the spectrometer signal allows to speed up the acquisition process and obtain the IXS spectrum with a very high energy resolution. The design of the echo spectrometer is based on a combination of crystal and focusing optics. The spectrometer analyzer requires an X-ray focusing optics with a high numerical aperture which is capable to collect radiation scattered by the sample into a wide solid angle. The required numerical aperture can be achieved with a graded multilayer mirror. To collect the scattered intensity from a solid angle, we considered the mirrors with a single reflection 2D parabolic shape. We simulated the images and investigated the performance of the echo spectrometer with the above mentioned mirrors using numerical computations in the SRW software package.

10388-41, Session PWed

Advanced commissioning of the Soft Matter Interfaces Beamline at NSLS-II

Mikhail Zhernenkov, Elaine DiMasi, Oleg Chubar, Maksim S. Rakitin, Brookhaven National Lab. (United States)

We report on the results of the advanced commissioning of the Soft Matter Interfaces (SMI) beamline, a long energy range canted in-vacuum undulator (IVU) beamline at NSLS-II. We compare the complete beamline simulation results performed with SRW software and the beam parameters measured during the technical and scientific commissioning. In particular, we will present the outcome of the recent IVU optimization (spectrum-based alignment resulted in a considerable increase of flux at beamline), bimorph horizontal and vertical focusing mirror tuning and profile optimization, as well as the commissioning of the microfocusing CRL transfocator.

10388-16, Session 5

Modelling imperfect x-ray optics *(Invited Paper)*

David Laundy, Kawal J. S. Sawhney, Diamond Light Source Ltd. (United Kingdom)

Geometrical optics and physical optics simulations are two methods for modelling the transport of X-rays through optical systems. Physical optics simulations include the coherent wave properties of the radiation and allow modelling of focusing near to the diffraction limit and also where interference of the wave-field occurs. With reductions in source emittance at modern X-ray storage rings, there are greater demands placed on X-ray optical elements to minimize distortion of the X-ray wavefront. We have related the perturbation of the wavefront following reflection from elliptically profiled X-ray mirrors to the figure error of the mirror surface.

We show the results of geometrical and physical optics simulations of mirrors whose surface figure had been measured by nanometer optical metrology (NOM). Simulation results are compared with measurements carried out on the Diamond Test Beamline.

10388-17, Session 5

Mutual optical intensity propagation through non-ideal optics

Xiangyu Meng, Shanghai Institute of Applied Physics (China); Xianbo Shi, Argonne National Lab. (United States); Yong Wang, Shanghai Institute of Applied Physics (China); Ruben Reininger, Lahsen Assoufid, Argonne National Lab. (United States); Renzhong Tai, Shanghai Institute of Applied Physics (China)

We continue to develop MOI method to analyze the mutual optical intensity (MOI) propagation through non-ideal optics. Local stationary phase approximation is implemented to calculate the MOI propagating through a non-ideal mirror. The phase generated by the path length from the incident to exit plane is the key to solve the MOI propagation through the mirror. The effect of figure error can be expressed as phase shift. There are two methods to deal with the figure error, the analytical method and numerical one. The two methods are compared at different spatial frequency range of the figure error. An APS beamline is analyzed with the developed MOI model, in which a partially coherent beam with 10keV energy is focused to ~20nm by a non-ideal elliptical mirror. The MOI at the focal plane is acquired after propagation through the non-ideal mirror. The intensity profile, the wavefront and the global coherence degree can be get from the MOI. The results indicate that the figure error with low spatial frequency generates oscillations, redistributes coherence property and damages the wavefront on the image plane. However, the figure error does not change the global coherence degree. Comparison with other codes such as Hybrid and SRW was performed. The results show that MOI model and SRW have similar intensity profiles. The apparent oscillations from MOI model and SRW indicate high coherence. Limitation on the beam size by the BDA and mirror will increase the coherence, which can be quantitatively analyzed by global coherence degree from MOI.

10388-18, Session 5

Speckle-based at-wavelength metrology of x-ray optics at Diamond Light Source *(Invited Paper)*

Hongchang Wang, Tunhe Zhou, Yogesh Kashyap, Kawal J. S. Sawhney, Diamond Light Source Ltd. (United Kingdom)

Over the last few decades, significant progress has been made to improve both the optical quality and metrology accuracy of X-ray optics. Although ex-situ measurement of X-ray optics is routinely performed, the ultimate performance of X-ray optics is critically dependent on the exact nature of working conditions. Therefore, it is equally important to perform in-situ metrology at the optics' operating wavelength ('at-wavelength' metrology) to optimize the performance of X-ray optics and correct and minimize the collective distortions of upstream beamline optics, e.g. monochromator, windows, etc. Several at-wavelength metrology methods have been implemented and further improved at Diamond [1]. The method based on speckle scanning technique is the most promising as we have demonstrated that the angular sensitivity for measuring the slope error of an optical surface can reach accuracy in the range of two nanoradians[2, 3]. The recent development of the speckle-based at-wavelength metrology technique implemented at the Diamond will be presented [4, 5]. Representative examples of the application of the speckle-based technique will also be given – including in-situ at-wavelength metrology of X-ray mirrors and characterization of compound refraction lenses. Such a high-precision metrology technique will be extremely beneficial for the manufacture and in-situ alignment / optimization of x-ray mirrors for next-generation synchrotron beamlines.

Stochastic surface metrology analysis

Anastasia Y. Tyurina, Yury N. Tyurin, Second Star Algonumerix, LLC (United States); Valeriy V. Yashchuk, Lawrence Berkeley National Lab. (United States)

The design and evaluation of the expected performance of new optical systems requires sophisticated and reliable information about the surface topography for planned optical elements before they are fabricated. The problem is especially complex in the case of x-ray optics, particularly for the X-ray Surveyor under development and other missions. Modern x-ray source facilities are reliant upon the availability of optics with unprecedented quality (surface slope accuracy < 0.1?rad). The high angular resolution and throughput of future x-ray space observatories requires hundreds of square meters of high quality optics. The uniqueness of the

optics and limited number of proficient vendors makes the fabrication extremely time consuming and expensive, mostly due to the limitations in accuracy and measurement rate of metrology used in fabrication. We discuss improvements in metrology efficiency via comprehensive statistical analysis of a compact volume of metrology data. The data is considered stochastic and a new statistical model called Invertible Time Invariant Linear Filter (InTILF) is developed to provide compact description of the data. It captures faint patterns in the data and serves as a quality metric and feedback to polishing processes, avoiding x-ray high resolution metrology measurements over the entire optical surface. The modeling, implemented in our Beatmark software, allows simulating metrology data for optics made by the same vendor and technology. The forecast data is vital for reliable specification for optical fabrication, to be exactly adequate for the required system performance. Supported by NASA SBIR NNX16CM09C and the USDOE AC02-05CH11231.

10388-20, Session 6

Latest developments of x-ray refractive optics for coherent applications *(Invited Paper)*

Anatoly A. Snigirev, Immanuel Kant Baltic Federal Univ. (Russian Federation)

In the past two decades, there has been a rapid development in our ability to control, manipulate and focus x rays by refractive optics. The emergence of x-ray free electron lasers and diffraction-limited synchrotron radiation sources has increased demands on coherence compatible optics, where refractive lenses as in-line optics have obvious advantages. In addition, the past few years have been witness to significant advances in the development of new coherent techniques based on refractive optics: x-ray microscopy, diffraction imaging and interferometry. For utilizing these new techniques, scientists in the field are taking the first steps toward the development of new optical concepts of beamlines. Details of these developments are discussed.

10388-21, Session 6

Aberrations in compound refractive lens systems: analytical and numerical calculations

Markus Osterhoff, Georg-August-Univ. Göttingen (Germany); Carsten Detlefs, Claudio Ferrero, ESRF - The European Synchrotron (France)

Hard x-ray beams can be focused using refractive lenses, but depending on energy, a large number N of individual lenses stacked in a row is needed.

Such a stack can be either composed of single lenses in cartridges, or lithographically fabricated lenses in a row. With N in the three-digit regime, the question arises which tolerances on lens alignment and shape have to be met not to disturb the focus. Here we use analytical and numerical calculations based on a Zernike polynomial expansion to give such error bounds for typical set-ups.

10388-22, Session 7

Simulations of x-ray free-electron laser experiments with the SIMEX platform *(Invited Paper)*

Carsten Fortmann-Grote, European XFEL GmbH (Germany); Zoltan Jurek, Ctr. for Free-Electron Laser Science (Germany) and The Hamburg Ctr. for Ultrafast Imaging (Germany); Beata Ziaja-Motyka, Ctr. for Free Electron Laser Science (Germany) and The Hamburg Ctr. for Ultrafast Imaging (Germany) and Institute of Nuclear Physics (Poland); Robin Santra, Ctr. for Free-Electron Laser Science (Germany) and The Hamburg Ctr. for Ultrafast Imaging (Germany) and Hamburg Univ. (Germany); Adrian P. Mancuso, European XFEL GmbH (Germany)

We present a generic software platform for simulations of experiments at modern light sources, e.g. free electron lasers, synchrotrons, and optical laser facilities. In our complete start--to--end simulations, we track the radiation from the source through the beam transport optics to the sample under investigation, the photon-matter interaction within the sample, and detection of scattered or transmitted photons in a detector.

We apply our simulation tools to model coherent diffractive imaging of single biomolecules with x-ray free electron lasers. This technique is expected to yield new structural information about biologically relevant macromolecules thanks to the ability to study the isolated sample in its natural environment as opposed to crystallized or cryogenic samples.

Establishing the optimal experimental parameters (e.g. x-ray pulse duration, photon energy, and fluence) as well as the level of radiation damage acceptable for electron density reconstructions are among open questions that we address with our simulation capabilities as well as the effect of the solvent on the diffraction pattern and interpretability of the data. We present first results of calculations in which the solvent has been taken into account.

10388-23, Session 7

X-ray optical simulations supporting advanced commissioning of the coherent hard x-ray beamline at NSLS-II

Lutz Wiegart, Oleg Chubar, Andrei Fluerasu, Maksim S. Rakitin, Brookhaven National Lab. (United States)

The presentation will showcase the application of fully- and partially-coherent synchrotron radiation wavefront propagation simulation functions, implemented in the “Synchrotron Radiation Workshop” (SRW) computer code, to create a ‘virtual beamline’, mimicking the Coherent Hard X-ray (CHX) scattering beamline at NSLS-II. The beamline simulation includes all optical beamline components, such as the insertion device, mirror with metrology data, slits, double crystal monochromator and refractive focusing elements (compound refractive lenses and kinoform lenses). A specialty of the CHX beamline is the exploitation of X-ray beam coherence, boosted by the low-emittance NSLS-II storage-ring, for techniques such as X-ray Photon Correlation Spectroscopy (XPCS) or Coherent Diffraction Imaging (CDI). The key performance parameters are the degree of X-ray beam coherence and photon flux, and the trade-off between them needs to guide the beamline settings for the specific experimental requirements. Simulations of key performance parameters will be compared to measurements obtained during beamline commissioning, and will include the spectral flux of the undulator source, the degree of transverse coherence, focal spot sizes and simulated and measured coherent scattering patterns.

10388-24, Session 7

Nano-focused hard x-ray beam measured by ptychography

Xiaojing Huang, Hanfei Yan, Evgeny Nazaretski, Mingyuan Ge, Nathalie Bouet, Juan Zhou, Weihe Xu, Petr P. Ilinski, Yong S. Chu, Brookhaven National Lab. (United States)

With the progress of achieving diffraction-limited X-ray focus, ptychography offers a unique and powerful tool to provide quantitative reconstruction of the complex-valued wavefront of a focused beam. Propagation of the reconstructed wavefront essentially describes complete performance characterization of the optics. We will present the accumulated efforts at

NSLS-II on exploring the capability of ptychography to quantify focusing performance of a variety of hard X-ray optics, including K-B mirrors, zone plates, multilayer Laue lenses [1-3]. Presentation will also elaborate on our recent development of monolithically bonded MLLs as a signal optical component for scanning probe microscope applications [4,5].

10388-25, Session 7

A Monte Carlo simulation of scattering reduction in spectral x-ray computed tomography

Matteo Busi, Ulrik L. Olsen, Erik B. Knudsen, Jan Kehres, Technical Univ. of Denmark (Denmark); Erik D. Christensen, Niels Bohr Institute (Denmark); Mohamad Khalil, Jeppe Revall Frisvad, Kristoffer Haldrup, Technical Univ. of Denmark (Denmark)

In X-ray computed tomography (CT), scattered radiation plays an important role in the accurate detection of the object's mass attenuation coefficients, leading particularly to a loss of contrast and streaking artifacts. We develop a Monte Carlo based simulation of a spectral CT tool, to predict the effect of different modes of collimation of a fan-beam geometry. The collimation is designed specifically to study and reduce the detected energy distribution of scattered radiation. Spectral CT is a novel technique implementing photon-counting detectors able to discriminate the energy of incoming photons, enabling real time spectral analysis of observables. It is therefore useful to efficiently extract more information on energy dependent quantities (e.g. mass attenuations) and processes (e.g. X-ray scattering, photoelectric absorption, etc.). Having a good knowledge of the spectral distribution of scattering is fundamental to establish methods for attempting to correct it. The simulations are then validated by real measurements with the use of different novel CdTe spectral detectors (Multix ME-100, Advacam Modupix). Notably, we found a shift of the scattered distribution towards lower energies, becoming of particular relevance in the energy range where the photoelectric absorption is dominant (i.e. below 50keV). We found a good match between simulations and experiments.

10388-27, Session 8

Sirepo: a web-based interface for physical optics simulations - its deployment and use at NSLS-II *(Invited Paper)*

Maksim S. Rakitin, Oleg Chubar, Brookhaven National Lab. (United States); Paul Moeller, RadiaSoft LLC (United States) and Bivio LLC (United States); Robert Nagler, David L. Bruhwiler, RadiaSoft LLC (United States)

"Sirepo" is an open source cloud-based distributed software framework which provides a convenient and user-friendly web-interface on the client side for scientific codes such as Synchrotron Radiation Workshop (SRW) running on the server side. SRW is a physical optics code allowing to simulate the synchrotron radiation from various insertion devices (undulators and wigglers) and bending magnets. Another feature of SRW is a support of high-accuracy simulation of fully- and partially-coherent radiation propagation through X-ray optical beamlines, facilitated by so-called "Virtual Beamline" module. In the present work, we will discuss the most important features of Sirepo/SRW interface with emphasis on their use for commissioning of beamlines and simulation of experiments at National Synchrotron Light Source II. In particular, "Flux through Finite Aperture" and "Intensity" reports, visualizing results of the corresponding SRW calculations, are being routinely used for commissioning of undulators and X-ray optical elements. Material properties of crystals, compound refractive lenses, and some other optical elements are dynamically obtained for the desired photon energy from the databases publicly available at Argonne National Lab (http://x-server.gmca.aps.anl.gov/x0h.html) and at Lawrence Berkeley Lab (http://henke.lbl.gov/optical_constants/). In collaboration with the Center for Functional Nanomaterials (CFN) of BNL, a library of samples for coherent scattering experiments has been implemented in SRW and the corresponding Sample optical element was added to Sirepo. Electron microscope images of artificially created nano-scale samples can now be uploaded to Sirepo to simulate scattering patterns created by synchrotron radiation in different experimental schemes that can be realized at beamlines.

10388-28, Session 8

OASYS (OrAnge SYnchrotron Suite): an open-source graphical environment for x-ray virtual experiments *(Invited Paper)*

Luca Rebuffi, Elettra-Sincrotrone Trieste S.C.p.A. (Italy); Manuel Sanchez del Rio, ESRF - The European Synchrotron (France)

The evolution of the hardware platforms, the modernization of the software tools, the access to the codes of a large number of young people and the popularization of the open source software for scientific applications drove us to design OASYS (ORange SYnchrotron Suite) [1], a completely new graphical environment for modeling X-ray experiments. The implemented software architecture allows to obtain not only an intuitive and very-easy-to-use graphical interface, but also provides high flexibility and rapidity for interactive simulations, making configuration changes to quickly compare multiple beamline configurations. Its purpose is to integrate in a synergetic way the most powerful calculation engines available. OASYS integrates different simulation strategies via the implementation of adequate simulation tools for X-ray Optics (e.g. ray tracing and wave optics packages). It provides a language to make them to communicate by sending and receiving encapsulated data. Python has been chosen as main programming language, because of its universality and popularity in scientific computing. Orange [2] is the high level workflow engine that provides the interaction with the user and communication mechanisms.[1] http://www.elettra.eu/oasys.html [2] http://orange.biolab.si/

Propagation-based phase-contrast imaging using laboratory sources *(Invited Paper)*

William Vågberg, Daniel H. Larsson, KTH Royal Institute of Technology (Sweden); Mei Li, Anders Arner, Laszlo Szekely, Jonas Persson, Karolinska Institutet (Sweden); Andre Yaroshenko, Technische Univ. München (Germany); Ali Önder Yildirim, Helmholtz Zentrum München GmbH (Germany); Hans M. Hertz, KTH Royal Institute of Technology (Sweden)

Liquid-metal-jet x-ray sources have vastly increased the achievable brightness from a laboratory microfocus source. This development has paved the way for bio-imaging that was previously only possible at synchrotrons. We describe three biomedical phase-contrast imaging applications: First, imaging of juvenile zebrafish to allow observation of sub-5 µm muscle structures. Secondly, imaging of human coronary arteries to evaluate the vulnerability of lipid-rich atherosclerotic plaques. Finally, short exposure and low dose imaging of whole mouse and mouse lungs.

10389-2, Session 1

Increasing spatial resolution in full-field soft x-ray nanotomography of cells *(Invited Paper)*

Eva Pereiro, ALBA Synchrotron (Spain); Joaquín Otón, Ctr. Nacional de Biotecnologia (Spain); Javier Conesa, ALBA Synchrotron (Spain); Javier Chichon, Ctr. Nacional de Biotecnologia (Spain); Ana Perez-Berna, Andrea Sorrentino, ALBA Synchrotron (Spain); Jose L. Carrascosa, Jose Maria Carazo, Ctr. Nacional de Biotecnologia (Spain)

We have explored two ways to improve the spatial resolution and/or visibility of cellular ultrastructure in full field soft X-ray nanotomography at the Mistral beamline (ALBA light source). The first one consists on a new data collection method and processing framework to computationally extend the depth of field (XTEND) of a Fresnel zone plate objective lens based on focal series projections and deconvolution. Visual details of a 3D-reconstructed eukaryotic cell that is affected by depth of field artifacts in standard tomographic reconstruction are recovered. The second one consists on diminishing the missing wedge inherent to flat sample supports (rotation range ±70deg) by performing dual axis tomography. Both strategies clearly show a spatial resolution and visibility improvement on the reconstructed volumes while complying with radiation dose limitation. Examples of these methods on relevant biological applications will be presented.

10389-3, Session 1

Coherent high-energy x-ray microscopy for mesoscopic materials

Irina Snigireva, ESRF - The European Synchrotron (France); Anatoly A. Snigirev, Immanuel Kant Baltic Federal Univ. (Russian Federation)

Coherent high energy X-ray microscope was employed to study the wide range of natural and artificial mesoscopic materials that are structured on scales of the order of a few to a few hundred nanometers. The microscope operates under a coherent illumination where a diffraction pattern of the specimen is formed in the back focal plane of the condenser and an inverted two-dimensional image of the object is formed by objective lens in the image plane. Functioning at 10 – 30 keV, the microscope consists of the condenser, the objective lens and two X-ray CCD cameras – large area detector for diffraction and high resolution CCD for imaging. Condenser and objective assemblies are comprised of Be parabolic refractive lenses. Switching from the diffraction mode to the imaging is achieved by placing the objective lens into the beam, and the chosen detector. The tunable objective lens offers full-field imaging with variable resolution and field of view.

The microscope was applied for study of natural and synthetic opals, metal inverted photonic crystals and colloidal suspensions. The combination of the direct-space imaging and high resolution diffraction provide a wealth of information on their local structure and the long range periodic order. The development of the hard x-ray microscope emerged concomitantly with the realization of the ESRF source upgrade which greatly enhanced brilliance and fraction of coherent light, and this will open entirely new frontiers in materials imaging.

10389-4, Session 1

The imaging and coherence beamline I13L at DIAMOND

Christoph Rau, Diamond Light Source Ltd. (United Kingdom) and Manchester Univ. (United Kingdom) and Northwestern Univ. (United States); Ulrich H. Wagner, Malte Ogurreck, Xiaowen Shi, Darren Batey, Silvia Cipiccia, Shashidhara Marathe, Andrew J. Bodey, Diamond Light Source Ltd. (United Kingdom); Marie-Christine Zdora, Diamond Light Source Ltd. (United Kingdom) and Univ. College London (United Kingdom); Irene Zanette, Diamond Light Source Ltd. (United Kingdom); Mirna Saliba, Diamond Light Source Ltd. (United Kingdom) and Univ. Zürich (Switzerland); Venkata S. C. Kuppili, Diamond Light Source Ltd. (United Kingdom) and Univ. College London (United Kingdom); Simone Sala, Stefanos H. Chalkidis, Univ. College London (United Kingdom); Pierre Thibault, Univ. of Southampton (United Kingdom) and Univ. College London (United Kingdom)

The Diamond Beamline I13L is designed to imaging on the micron- and nano-lengthsale with X-rays of energies between 6 and 30 keV [1]. Two independently operating branchlines and endstations have been built at distance of more than 200m from the source for this purpose. The imaging branch is dedicated for imaging in real space, providing In-line phase contrast imaging and grating interferometry with micrometre resolution and full-field transmission microscopy with 50nm spatial resolution.

On the coherence branch coherent diffraction imaging techniques such as ptychography, coherent X-ray diffraction (CXRD) and Fourier-Transform holography are currently developed. Because of the large lateral coherence length available at I13, the beamline hosts numerous microscopy experiments. The coherence branchline in particular contains a number of unique features. New instrumental designs have been employed such as a robot arm for the detector in diffraction experiments and a photon counting detector for diffraction experiments. The so-called 'mini-beta' layout in the straight section of the electron storage ring permits modulating the horizontal source size and therefor the lateral coherence length.

We will present the recent progress in coherent imaging at the beamline and the sciences addressed with the instrumental capabilities.

10389-5, Session 1

Development of full-field x-ray fluorescence microscope using total-reflection mirrors

Satoshi Matsuyama, Jumpei Yamada, Shuhei Yasuda, Osaka Univ. (Japan); Yoshiki Kohmura, Makina Yabashi, Tetsuya Ishikawa, RIKEN Harima Branch (Japan); Kazuto Yamauchi, Osaka Univ. (Japan)

A full-field X-ray fluorescence microscope was developed at SPring-8. It consists of advanced Kirkpatrick-Baez mirrors with four total-reflection mirrors as an objective and a CCD camera. The imaging optics has the following specifications: magnifications of 84 x 26 (horizontal x vertical), numerical aperture of 0.0015, whole length of ~6 m. In this system, the four total-reflection mirrors can also function as an energy filter that selectively reflects only low energy X-rays. This energy filter has reflectivity of 50 % at around 10 keV, but 3 x 10^-7 % at 20 keV, which can reduce excitation X-rays down to the weak fluorescence signal level. X-ray fluorescence imaging of a Siemens star chart (Ta) and micron-size particles (Ni, Cu, Zn, Ge and Bi) was demonstrated using excitation energy of 20 keV. The fluorescence signals were acquired with whole exposure time of 3.3 h, in which each exposure was selected to be 10 s to perform the photon counting method using the CCD. The samples were successfully visualized with a resolution of 500 ~ 1000 nm. Also, it was confirmed that the excitation X-rays were blocked well as expected.

10389-6, Session 2

Double-sided Fresnel zone plates for high-efficiency x-ray nanofocusing *(Invited Paper)*

Istvan Mohacsi, Deutsches Elektronen-Synchrotron (Germany) and Synchrotron SOLEIL (France) and Paul Scherrer Institut (Switzerland); Ismo Vartiainen, Paul Scherrer Institut (Switzerland) and Univ. of Eastern Finland (Finland); Manuel Guizar-Sicairos, Vitaliy A. Guzenko, Paul Scherrer Institut (Switzerland); Ian McNulty, Robert P. Winarski, Martin V. Holt, Argonne National Lab. (United States); Elisabeth Mueller, Paul Scherrer Institut (Switzerland); Andréa Somogyi, Synchrotron SOLEIL (France); Christian David, Paul Scherrer Institut (Switzerland)

Diffractive X-ray optics, like Fresnel zone plate lenses, are widely employed X-ray optics for collimation and focusing. While they are extremely versatile and easy to use optical elements, they generally suffer from limited efficiency due to limitations in fabrication possibilities. Near-field stacking is an established concept for overcoming fabrication limitations, yet its existing implementations suffer from issues regarding complexity and stability. In this work, an alternative stacking concept is explored, by patterning both the front and back sides of a single membrane. Such double-sided zone plates are shown to exchange conventional zone plate stacks in increasing the efficiency or resolution of conventional zone plate optics. In conventional stacking, they achieve 9.9% focusing efficiency at 9 keV with 30 nm smallest half-pitch and diffraction limited optical performance. Following the blazed stacking scheme, they are shown to provide up to 54.7% diffraction efficiency at 6.2 keV. Finally, using the novel concept of interlaced stacking, they demonstrate the feasibility of large aperture X-ray optics for sub-10 nm X-ray nanofocusing.

10389-7, Session 2

Development of 2D monolithic multilayer Laue lens nanofocusing optics for x-ray microscopy

Evgeny Nazaretski, Weihe Xu, Nathalie Bouet, Juan Zhou, Hanfei Yan, Xiaojing Huang, Yong S. Chu, Brookhaven National Lab. (United States)

We have developed an experimental approach to bond two independent linear Multilayer Laue Lenses (MLLs) together. A monolithic MLL structure was characterized using ptychography at 12 keV photon energy, and we demonstrated 12nm and 24 nm focusing in horizontal and vertical directions, respectively. Fabrication of 2D MLL optics allows installation of these focusing elements in more conventional microscopes suitable for x-ray imaging using zone plates, and opens easier access to 2D imaging with high spatial resolution in the hard x-ray regime. During the presentation technical steps of the fabrication and characterization process will be reviewed. Novel approach utilizing microfabrication methods suitable for the MLL bonding will be discussed.

10389-8, Session 2

Focus of a multilayer Laue lens with an aperture of 102 microns determined by ptychography at beamline APS/1-BM

Albert T. Macrander, Michael Wojcik, Jörg Maser, Argonne National Lab. (United States); Nathalie Bouet, Brookhaven National Lab. (United States); Raymond P. Conley, Argonne National Lab. (United States)

Ptychography was used to determine the focus of an MLL at beamline 1-BM at the Advanced Photon Source [1]. The MLL had a record aperture of 102 microns [2,3]. The focal length was 9.6 mm, and the outer-most zone was 4 nm thick. MLLs with ever larger apertures are under continuous development since ever longer focal lengths , ever larger working distances, and ever increased flux in the focus are desired. A focus size of 52 nm was determined by ptychographic phase retrieval from a gold grating sample with 1 micron lines and spaces over 6.0 microns horizontal distance. The probe function determined from the ptychography was used to measure the focus. The MLL was set to focus in the horizontal plane of the bending magnet beamline. A CCD having 13.0 micron pixels was used to collect data at 1.3 m downstream distance. The beam incident on the MLL was sized 10 micron (H) x 20 micron (V). 100 iterations of the difference map algorithm were sufficient to obtain a good reconstructed image as shown in the figure below. Here the amplitude and phase are represented by brightness and color, respectively. The units on the horizontal axis are 25.9 nm and the phase difference between lines and spaces is 2.00 radians corresponding to a gold thickness of 1.78 microns. The present work highlights the utility of a bending magnet source at the APS for performing coherence-based experiments. Use of ptychography at 1-BM on MLL optics opens the way to study other hard x-ray optics. We acknowledge the use of the ptychography tools of J. Clark and the assistance of R. Harder in implementing them. We also acknowledge T. Mooney for implementation of the software to scan over illumination views. This work was supported by the U.S. Department of Energy, Office of Basic Energy Sciences under contract No. DE-AC-02-06CH11357 for work at the APS and under contract No. DE-SC00112704 for work at NSLS II.

10389-9, Session 2

Commissioning of the Montel nano-optics for the x-ray nanoprobe at Taiwan Photon Source

Gung-Chian Yin, Shi-Hung Chang, Bo-Yi Chen, Chien-yu Lee, Bi-Hsuan Lin, Shao-Chin Tseng, Xiao-Yun Li, Huang-Yeh Chen, Jian-Xing Wu, Mau-Tsu Tang, National Synchrotron Radiation Research Ctr. (Taiwan)

The diffraction-limited Montel mirrors, equipped at the X-ray Nanoprobe (XNP) at Taiwan Photon Source (TPS), provide a 40 nm focal spot and working distance 55 mm under the total beamline length of 69 m. The underneath holder supporting for the Montel mirrors is a 12 axes flexure based manipulators in which 10 out of the 12 axes are motorized. To monitor the position and stability of individual holder motion, a monitoring system consisted of three optical encoders and three- axes laser interferometers for angle movement is implemented. The gap width between the two mirrors and their orthogonality can be adjusted by a tilting sensor and a high magnification optical microscope. The focusing properties, phase and amplitude, after the Montel mirrors will be investigated by means of coherent Ptychography, as well as by zone plate imaging. An SEM in close cooperation with laser interferometers is equipped to precisely position the samples and conduct the on-the-fly scan. A high speed FPGA based circuit is developed to address signal from XRF, XAS, XEOL and XRD. Data is in tag with position and time information and been processed by computers to allow 5nm precision stage scanning free from mechanical feedback. The XNP at TPS is under commissioning since February 2017. The commissioning result, particularly the performance of the Montel mirrors will be reported in this presentation.

10389-10, Session 3

Integration of ptychography with the nanoscale multimodality imaging instrument at HXN of NSLS-II *(Invited Paper)*

Xiaojing Huang, Hanfei Yan, Evgeny Nazaretski, Mingyuan Ge, Nathalie Bouet, Juan Zhou, Petr P. Ilinski, Yong S. Chu, Brookhaven National Lab. (United States)

Nano-focused hard X-ray probe offers a suite of analytic tools for quantitative characterization of specimen under investigation. Scanning probe operated in a multi-modality imaging mode evokes fluorescence, absorption, phase contrasts, and potentially diffraction contrast as well. Without introducing extra instrumental complexity, ptychography technique can be seamlessly integrated into the scanning probe imaging system, since it shares the same data collection procedure and even shares the exactly the same dataset with absorption- and differential-phase-contrast imaging. We will present our implementation of ptychography method for nano-Mii (Nanoscale Multimodality Imaging Instrument) at the Hard X-ray Nanoprobe (HXN) Beamline of the National Synchrotron Light Source II (NSLS-II). The ptychography reconstruction assist aligning optics to achieve diffraction-limited focus and provide quantitative images with enhanced resolution. The on-the-fly operation mode maximizes the experimental throughput, and make it timely realistic to conduct three-dimensional high-resolution imaging.

10389-11, Session 3

Multislice x-ray ptychography towards 3D high-resolution imaging

Kei Shimomura, Makoto Hirose, Osaka Univ. (Japan) and RIKEN SPring-8 Ctr. (Japan); Nicolas Burdet, RIKEN SPring-8 Ctr. (Japan); Yukio Takahashi, Osaka Univ. (Japan) and RIKEN SPring-8 Ctr. (Japan)

X-ray ptychography is a lensless imaging method to access inner information of a sample with high-spatial-resolution. In X-ray ptychography, the projection image of the sample is reconstructed by iterative phasing methods from multiple diffraction patterns. Moreover, X-ray ptychography combined with computed tomography provides high-resolution 3D images, which has been demonstrated with the 3D resolution of better than 20 nm. However, it is difficult to observe samples thicker than 1 ?m with the resolution of better than 10 nm due to the limitation of the depth of field. To eliminate this limitation, a new phase retrieval algorithm using multislice approach has been proposed and demonstrated in visible light and X-ray regime. Multislice approach models the object as multiple axial sections and calculates the wave propagation effects within a sample. In addition, mutlislice X-ray ptychography combined precession measurement has been demonstrated to improve the longitudinal resolution, in which a tilt-series diffraction patterns is collected and the multiple sections are reconstructed from them. Until now, precession multislice X-ray ptychography has been applied to a sample composed of discrete layers with a gap more than 10 ?m. To extend applications to discrete samples with a narrow gap between layers and continuous samples, we performed the feasibility study by numerical simulations using 2-?m-thickness sample composed of two Cu TEG tips and 3-?m-thickness Au nanoporous. In this presentation, we intend to show experimental results at SPring-8.

10389-12, Session 3

Nanoscale x-ray imaging using the GINIX Instrument: combining zoom-holography and nano-scanning

Markus Osterhoff, Georg-August-Univ. Göttingen (Germany); Michael Sprung, Deutsches Elektronen-Synchrotron (Germany); Tim Salditt, Georg-August-Univ. Göttingen (Germany)

The Göttingen Instrument for Nano-Imaging with X-ray (GINIX) is a holography endstation located at the P10 beamline at PETRA III, designed and operated by the University of Göttingen in close collaboration with DESY Hamburg [1-2]. GINIX is designed as a waveguide based holography experiment with a Kirkpatrick-Baez pre-nanofocus. Its versatility has stimulated a great manifold of imaging modalities. Today, users choose the GINIX setup not only for its few nm coherent waveguide beams (e.g. for ptychography or holography), but also to carry out scanning SAXS measurements to probe local anisotropies with sub-micron real-space and even higher reciprocal space resolution. In addition, it is possible to combine different detectors for e.g. simultaneous SAXS/WAXS and fluorescence measurements [3].

We present latest experimental results obtained with GINIX, focusing on the unique capabilities offered by its versatile and flexible design. The overview includes results from different imaging schemes such as waveguide based zoom-tomography and user examples in WAXS geometry. We show how to correlate complementary techniques like holography and scanning SAXS and present first results obtained using a new fast sample scanner for Multilayer Zone Plate imaging. We conclude by summarizing the ongoing upgrades and discussing new possibilities for our users.

10389-13, Session 3

PtyNAMi: Ptychographic nano-analytical x-ray microscope at PETRA III

Christian G. Schroer, Deutsches Elektronen-Synchrotron (Germany) and Univ. Hamburg (Germany); Andreas Schropp, Ralph Döhrmann, Stephan Botta, Deutsches

Elektronen-Synchrotron (Germany); Dirk Samberg, TU Dresden (Germany); Maik Kahnt, Mikhail Lyubomirskiy, Juliane Reinhardt, Maria Scholz, Martin Seyrich, Felix Wittwer, Dennis Brückner, Jan Garrevoet, Gerald Falkenberg, Deutsches Elektronen-Synchrotron (Germany)

In recent years, ptychography has revolutionized x-ray microscopy in that it is able to overcome the diffraction limit of x-ray optics, pushing the spatial resolution limit down a few nanometers. However, due to the weak interaction of x-rays with matter the detection of small features inside a sample require a high coherent fluence on the sample, a high degree of mechanical stability, and a low background signal from an x-ray microscope. The x-ray scanning microscope PtyNAMi at PETRA III at DESY in Hamburg, Germany, is designed for high-spatial-resolution 3D imaging with high sensitivity. To optimize the coherent flux density on the sample, a two-stage focusing scheme matches the coherence length to the aperture of the nanofocusing optic. The sample is scanned (also continuously) with a high-precision scanner and the sample position is tracked interferometrically with respect to the x-ray optical axis, also under the rotation needed for tomographic scanning. Finally, the optical path behind the sample is evacuated up until the sensor of a four-megapixel pixel detector that is placed into the vacuum. In this way, parasitic scattering from air and windows close to the detector are avoided. A beamstop can be used to suppress scattering inside the detector in order to capture even weakest scattering signals from small features inside a sample. The new instrument is presented together with some applications.

10389-14, Session 3

High-energy cryo x-ray nano-imaging at the ID16A beamline of ESRF *(Invited Paper)*

Julio C. da Silva, Alexandra Pacureanu, Yang Yang, Florin Fus, Maxime Hubert, Leonid Bloch, Murielle Salome, ESRF - The European Synchrotron (France); Sylvain Bohic, ESRF - The European Synchrotron (France) and Grenoble Institut des Neurosciences (France); Peter Cloetens, ESRF - The European Synchrotron (France)

The ID16A nano-imaging beamline at ESRF offers unique capabilities for X-ray imaging at nanometer scale and currently produces the world's brightest diffraction-limited nanofocus. Such a nanoprobe was designed for quantitative 3D characterization of the morphology and the elemental composition of specimens at the nanoscale. As the endstation is located at 185 m from the source, the beamline is optimized for coherent hard X-ray imaging with very high photon flux (1012 photons/s at ?E/E~1%), at the ultimate spatial resolution (~20 nm). Billions of photons per second can be delivered in a diffraction-limited focus spot size of about 13 nm. The two discrete energies of operation, 17.05 keV and 33.6 keV, are well suited for applications in biomedicine, materials science and nanotechnology. Coherent X-ray imaging techniques, as magnified holographic tomography and ptychographic tomography, provide the distribution of the electron density at length scales ranging from ~130 nm down to ~10 nm, while keeping a relatively large field of view. Complementary, X-ray fluorescence microscopy delivers label-free highly efficient trace element quantification with detection limit down to ppm level. In addition, an integrated cryogenic system operating under high vacuum has been installed to preserve biological samples from radiation damage at temperatures close to 120 K. Finally, we will show the latest developments in coherent and spectroscopic X-ray nano-imaging implemented at our beamline and important applications.

10389-15, Session 3

X-ray fluorescence nanotomography of single cells at 20-nm voxel resolution

Tiffany W. Victor, Stony Brook Univ. (United States); Lindsey M. Easthon, Katherine H. O'Toole, Boston Univ. (United States); Hanfei Yan, Xiaojing Huang, Mingyuan Ge, Brookhaven National Lab. (United States); Karen Allen, Boston Univ. (United States); Barbara Imperiali, Massachusetts Institute of Technology (United States); Yong S. Chu, Lisa M. Miller, Brookhaven National Lab. (United States)

X-ray Fluorescence (XRF) microscopy is a powerful method for imaging trace element concentration, distribution, and speciation in biological cells at the nanoscale. Moreover, nanotomography provides the added advantage of imaging subcellular structure and chemistry in 3D without the need for staining or sectioning the cells. To date, technical challenges in X-ray optics, sample preparation, and detection sensitivity have limited the use of XRF nanotomography on biological cells.

In this work, XRF nanotomography was used to image individual E. coli bacterial cells for the first time at ~20 nm voxel resolution. The measurement was performed using nano-Mii (Nanoscale Multimodality Imaging Instrument) at the Hard X-ray Nanoprobe (HXN, 3-ID) beamline at NSLS-II. Typically, cryo-fixation is used to prevent radiation damage and preserve integrity of biological samples. Instead, we embedded cells in small (5-20 µm) NaCl crystals, which provided a nonaqueous matrix to retain the 3D structure of the E. coli while minimizing radiation damage. Tomography was performed from +/- 90 degrees in 3 degree increments with a dwell time of 100 ms per pixel.

Results showed the distribution of Ca, K, S, P, Fe, and Zn with sufficient resolution to visualize cell membranes. Our work demonstrates that XRF nanotomography can be performed on unfrozen biological cells to co-localize and quantify elements and show their distribution and speciation in whole cells at very high spatial resolution.

10389-16, Session 4

Rapid alignment of projection images in x-ray nanotomography: extension to phase-contrast imaging *(Invited Paper)*

Doga Gürsoy, Argonne National Lab. (United States); Young Pyo Hong, Kuan He, Karl Hujsak, Seunghwan Yoo, Northwestern Univ. (United States); Si Chen, Vincent De Andrade, Argonne National Lab. (United States); Kai He, Oliver Cossairt, Aggelos K. Katsaggelos, Chris J. Jacobsen, Northwestern Univ. (United States)

As x-ray tomography is pushed farther into the nanoscale, the limitations of rotation stages become more apparent leading to challenges in the alignment of the acquired projection images. We have developed an approach for rapid post-acquisition alignment of these projections based on a joint estimation of alignment errors, and the object, using an iterative refinement procedure, and have demonstrated it on x-ray absorption and fluorescence nanotomography. However, phase contrast offers a stronger signal for hard x-ray imaging than either absorption or fluorescence provide, and its potential for low-dose x-ray fluorescence tomography has already been explored in previous studies. We describe here our first tests of using our iterative re-projection approach with phase-contrast images included in the alignment iterate.

10389-17, Session 4

Self-absorption correction in x-ray fluorescence nanotomography

Mingyuan Ge, Xiaojing Huang, Hanfei Yan, Evgeny Nazaretski, Li Li, Petr P. Ilinski, Brookhaven National Lab. (United States); Wilson K. S. Chiu, Univ. of Connecticut (United States); Kyle S. Brinkman, Clemson Univ. (United States); Yong S. Chu, Brookhaven National Lab. (United States)

The Hard X-ray Nanoprobe (HXN) at NSLS-II provides a nanoscale 3D multi-modality imaging capability, useful for investigating diverse material systems. The multi-modality scanning-probe imaging utilizes a variety of imaging contrasts such as fluorescence, transmission, scattering, and diffraction. Images taken simultaneously using different contrast mechanisms can provide 3D visualization of a sample, producing complementary information about the sample. Such comprehensive 3D characterizations are extremely useful in studying materials with multiple phases or complex internal structures. An important scientific problem is to investigate phase or grain boundaries of multi-component materials during or after material processing such as sintering, since re-organization of these boundaries due to annealing or phase-separation often result in profound impact on material property or functionality. However, accurate quantification of 3D elemental concentration is hampered by a well-known self-absorption problem, particularly severe for the low energy fluorescence x-rays. Correcting absorption is non-trivial and requires an iterative and three-dimensional solution. In this presentation, we will describe our approach using experimental data taken from mixed ionic ceramic membrane samples and elaborate on how accurate absorption correction led to discovery of a new material phase in this material system.

10389-29, Session PMon

Faster scanning and higher resolution: New setup for multilayer zone plate imaging

Markus Osterhoff, Christian Eberl, Jakob Soltau, Hans-Ulrich Krebs, Georg-August-Univ. Göttingen (Germany)

Hard x-ray imaging methods are routinely used in two and three spatial dimensions to tackle challenging scientific questions of the 21st century, e.g. catalytic processes in energy research and bio-physical experiments on the single-cell level [1-3]. Among the most important experimental techniques are scanning SAXS to probe the local orientation of filaments and fluorescence mapping to quantify the local composition. The routine available spot size has been reduced to few tens of nanometres; but the real-space resolution of these techniques can degrade by (i) vibration or drift, and (ii) spreading of beam damage, especially for soft condensed matter on small length scales.

We have recently developed new Multilayer Zone Plate (MZP) optics for focusing hard (14 keV) and very hard (60 keV to above 100 keV) x-rays down to spot sizes presumably on 5 or 10 nm scale. Here we report our progress on a new MZP based sample scanner, and how to tackle beam damage spread. The Eiger detector synchronized to a piezo scanner enables to scan in a 2D continuous mode fields of view larger than 20 μm squared, or for high resolution down to (virtual) pixel sizes of below 2 nm, in less than three minutes for 255?255 points (90 seconds after further improvements). Nano-SAXS measurements with more than one million real-space pixels, each containing a full diffraction image, can be carried out in less than one hour, as we have shown using a Siemens star test pattern.

PyXRF: Python-based x-ray fluorescence analysis package

Li Li, Brookhaven National Lab. (United States)

We developed a python-based fluorescence analysis package (PyXRF) at the National Synchrotron Light Source II (NSLS-II) for the X-ray fluorescence-microscopy beamlines, including Hard X-ray Nanoprobe (HXN), and Submicron Resolution X-ray Spectroscopy (SRX). This package contains a high-level fitting engine, a comprehensive command-line/GUI design, rigorous physics calculations, and a powerful visualization interface. PyXRF offers a method of automatically finding elements, so that users do not need to spend extra time selecting elements manually. Moreover, PyXRF provides a convenient and interactive way of adjusting fitting parameters with physical constraints. This will help us perform sensitivity analysis, and find an appropriate initial guess for fitting. Furthermore, we also create an advanced mode for professional users to construct their own fitting strategies with a full control of each fitting parameter. PyXRF runs single-pixel fitting at a fast speed, which opens up the possibilities of viewing the results of fitting in real time during experiments. A convenient I/O interface was designed to obtain data directly from NSLS-II's experimental database. PyXRF is under open-source development and designed to be an integral part of NSLS-II's scientific computation library.

10389-31, Session PMon

Device for interferometric characterization of rotation stages for x-ray nanotomography

Stefan Kubsky, Synchrotron SOLEIL (France); Tomas Stankevic, Max IV Lab. (Sweden); Christer Engblom, Florent Langlois, Filipe Alves, Alain Lestrade, Nicolas Jobert, Gilles Cauchon, Synchrotron SOLEIL (France); Ulrich Vogt, KTH Royal Institute of Technology (Sweden)

State-of the art X-ray nanoanlyses in 3D, such as XRF, Ptychography and Tomography require not just brilliant and focussed x-rays, but also fine-positioning on a nm-level during experiment. A key difficulty is the need to rotate the sample by 360° to obtain a 3D reconstruction. We have designed and built a new, compact device which characterizes mechanical errors of rotation stages: we demonstrate that repeatable and non-repeatable radial- and angular errors (wobble) can be quantified without relying on a nm-level precise metrology standard-object. This approach comprises an optomechanical setup with several interferometric sensors and a mathematical method to separate the abovementioned errors of the rotation stage from the (non-perfect) cylindrical shape of the measuring object. Obtained precision with active feedback via additional correction stages yields down to 40nm, other examples show even much lower values, down to the nm-level. For less demanding applications, a fixed Look-up-table (LUT) can be employed, simplifying metrological requirements during experiment. Furthermore, the measurement procedure is fully automated and integrated into the SOLEIL software architecture (TANGO). Time requirements are compatible with systematic, repeated measurements (approximately 15 min. per scan). Nm-level precision on macroscopic lenght scales calls for dedicated thermal monitoring and stabilization (mK-level), which is integrated as well.

Applications include live-error correction during experiment, but also production of better rotation stages for industry.

10389-32, Session PMon

Quantitative analysis of the reoxidation stability of Ni-Fe anode for solid ox-ide fuel cells using x-ray nanotomography

Yong Guan, Yangchao Tian, Univ. of Science and Technology of China (China)

Ni-Fe alloy as anode for solid oxide fuel cells (SOFCs) has attracted much attention recently. Ni-Fe alloy anode has a better tolerance to redox cycling as compared to the Ni-YSZ cermet anode and porous Ni metal. X-ray nanotomography had been applied to investigate porous nickel-yttria-stabilized zirconia (Ni-YSZ) composite anode. The quantitative analysis methods had been devel-oped and used to characterize and quantify the key structural parameters. In the present work, the mechanisms of redox stability of Ni-Fe alloy anode had been studied by X-ray nanotomography at beamline 4W1A at the Beijing Synchrotron Radiation Facility (BSRF), China. The resolution is about 30 nm and field of view (FOV) is 15 um. The results indicated that a small amount of Fe ad-dition can affect the microstructure of anode during redox cycling. After a redox cycling, the microstructure of

Ni-YSZ anode was different from that of Ni-Fe-YSZ anode with 9.4 wt% Fe . For example, Ni grain in Ni-Fe-YSZ anode was smaller than that of Ni-YSZ anode. This can be said that the microstructure of Ni-Fe-YSZ anode was better compared to Ni-YSZ anode after a redox cycling, which had been further proved by the calculation on the three phase boundary length. This indicated that 9.4 wt% Fe can improve the redox stability of Ni-YSZ anode.

10389-33, Session PMon

An analytical method for extending the depth-of-focus in x-ray microscopy

Yangchao Tian, Yong Guan, Univ. of Science and Technology of China (China)

X-ray microscopy (XRM) as a powerful, nondestructive and three dimensional (3D) imaging tool has been applied in many fields. However, for the high-resolution X-ray microscopy, to image large size samples is restricted due to a limited depth of focus (DOF). In this study, an analytical method for extending the depth of focus of X-ray microscopy was proposed. By moving the ZP, many sets of projections are collected. Then these sets of projections are reconstructed respectively by filtered back-projection (FBP) reconstruction algorithm to get the 3D reconstructions. Based on the features of 3D reconstruction data, the slices of 3D reconstruction data are regarded as different focus-stacked images, which contain different in-focus and defocus information. By analyzing the slices stack of 3D reconstruction data along the optical axis, the slices are fused by the image fusion algorithm. Through the slices stack image fusion, the slices stack at same position are fused into a fully in-focus image. When all slices are fully in-focus, a new 3D reconstruction data with all-focused is achieved. The simulation and experimental results demonstrate the novel method is effective and reliable in extending the DOF of high-resolution X-ray microscopy and can be applied to image the large sample for high resolution X-ray microscopic system.

10389-34, Session PMon

Three-dimensional imaging of biological samples and nanomaterials using soft x-ray nanotomography

Gang Liu, Jianhong Liu, Yong Guan, Univ. of Science and Technology of China (China)

The full-field Transmission X-ray Microscopy beamline BL07W at NSRL is devoted to cryo nano-tomography for biological applications in the water window (284 - 530 eV) and for imaging of nanomaterials from 200 to 2500 eV. An ellipsoidal capillary used as condense to focus monochromatic light onto the sample. Two Ni zone plate (ZP) lenses made by Zeiss with 40 nm and 25 nm outer most zone widths, respectively, are available, giving spatial resolution in 2D of down to 40 nm and 30 nm, respectively. Hydrated biological specimens had been imaged in the water window photon energy range without chemical fixation, dehydration, chemical staining and physical sectioning. A tilt series images were collected from ? 60o + 60o at 1o intervals at 520 eV X-ray energy. Each projection was collected with an exposure time of 1 seconds. Alignment and reconstruction of the tilt series were carried out with filtered back-projection algorithm from Carl Zeiss X-ray Microscopy Inc and some algorithms developed in-house based on algebraic reconstruction techniques[1-2]. We had demonstrated cryo soft X-ray tomography of frozen hydrated biological samples in the water window energy range with spatial resolution down to 40 nm and the studies of nano-materials. The results shown that soft X-ray nanotomography can provide an alternative tool for people to study hydrated biological specimens and nano-materials.

Fully automatic sample alignment with VLM at the STXM beamline of SSRF

Xiangzhi Zhang, Zhi Guo, Limei Ma, Zijian Xu, Haigang Liu, Zhenhua Chen, Jiefeng Cao, Yong Wang, Renzhong Tai, Shanghai Institute of Applied Physics (China)

Three-dimensional fine structure of the sample with high spatial resolution is very important in many area. Nano-CT system based on the STXM BL08U soft X-ray spectromicroscopy station of Shanghai Synchrotron Radiation Facility has been developed. STXM is based on two dimensions image the focal length is about 2um, 1um accuracy is necessary for the beam direction. The scanning area of sample is several um scale sample which drifted seriously during the rotation, the accuracy and efficiency be reduced seriously which waste much beamtime. Fully automatic sample alignment involves the application of optical methods to identify the sample with Visible Light Microscope be founded. The relative axis positon of sample and rotation motor can be calculated by the VLM data, then make it two coincidence and move into the X-ray beam. All the alignment process can be completed before experiment automatic.This can be used in many other CT experiment.

10389-36, Session PMon

Detection limits for the inverse analysis of Bragg coherent diffraction data

Hande Öztürk, Xiaojing Huang, Hanfei Yan, Yong S. Chu, Brookhaven National Lab. (United States)

Bragg Coherent Diffraction has been an increasingly used, non-destructive imaging technique that can characterize the structure of isolated nanocrystals and their apparent strain distributions. Although numerous successful reconstructions of nanomaterial samples have been published in the literature, where nano-scale spatial resolution and ultimate sensitivity have been reported, there is currently no systematic study on the inherent limits of this technique.

In this presentation, I will introduce a framework that is capable of numerically simulating Bragg Coherent Diffraction Imaging (Bragg CDI) experiments. The three-dimensional rocking-curve diffraction data are generated using first-principle forward modeling algorithm that considers crystalline lattice structure, shape function and dislocation field inside an irradiated particle. The simulated data can then be inverted with established phase recovery techniques to deliver real-space images. By systematically investigating the performance of the Bragg CDI method using this framework, the detection limits of dislocation field under various oversampling conditions, noise levels and detection dynamic range are explored. These results have the potential to improve the assessment of reconstructed phases from Bragg CDI experiments and to optimize practical guidelines for experimental scenarios.

10389-38, Session PMon

Progress of ptychography method at STXM beamline of SSRF

Zijian Xu, Haigang Liu, Chunpeng Wang, Xulei Tao, Renzhong Tai, Shanghai Institute of Applied Physics (China)

We have been developing the methodology of soft X-ray ptychographic coherent diffraction imaging (PCDI) in recent years based on the STXM beamline of SSRF. A series of algorithmic and experimental studies of PCDI methodology were carried out in depth, and a PCDI platform with relatively low dose, high resolution and high efficiency have been developed at STXM endstation of SSRF. Compared to other FZP-based PCDI setups, we used a much larger illumination spot with 3-5 ?m diameter by moving

samples downstream from ZP focus, and a larger step size of 500-1000 nm in our platform, which would result in fewer scanning positions and lower radiation dose when imaging the same sample area, but leading to a more difficult reconstruction due to the highly curved wavefront of the probe. By combining the mixed-state method or up-sampling method with the position-correction algorithm in our home-developed ptychography reconstruction software, we can obtain high-quality images (10 nm resolution) from our PCDI platform with much lower radiation dose (1/12 of STXM) and less data acquisition time (1/3 of STXM). In addition, we systematically investigated the effects of beamstop-induced low frequency signal loss on both the PCDI and plane-wave CDI by simulations, finding that PCDI can tolerate much more low-frequency signal loss than plane-wave CDI, and the PCDI robustness to missing signals is further improved when a larger overlap or a smaller probe is adopted. This work suggests that a beamstop can be applied in PCDI to further improve the imaging resolution. We also developed practical background noise removal methods for ptychography datasets including the difference minimization, thresholding and local erasing techniques, which could notably improve the reconstruction image quality and would be helpful in most ptychography experiments.

10389-39, Session PMon

Complementing cryo x-ray microscopy with a compatible confocal microscope for biological applications

Si Chen, Oliver Schmidt, Argonne National Lab. (United States); Qiaoling Jin, Northwestern Univ. (United States); Amanda Petford-Long, Chris J. Jacobsen, Argonne National Lab. (United States)

Hard X-ray fluorescence microscopy (XFM) and visible light fluorescence microscopy (VLFM) provide complimentary information for biological studies. While XFM allows one to measure the distribution and total content of an element regardless of its valence and chemical binding state, VLFM enables imaging of certain elements in specific chemical states via fluorophore labeling. By using cryo specimen preparation, biological samples can be studied in a frozen hydrated state with both the ultrastructure and elemental distribution preserved closest to their natural state.

There is a rapid growth of activity in correlative cryo light and electron microscopy (CLEM)1,2, and this has been followed by correlative light and soft X-ray microscopy3-6. Compared to CLEM, where cryosections thinner than 100 nm are examined, or soft x-ray microscopy where depth of focus and absorption limit the sample thickness to ~10 ?m, XFM is particularly suitable for studies of thick samples such as tomography of whole cells or of tissues that are tens of microns thick. The Bionanoprobe (BNP)7 is the only cryo-XFM instrument in the US, dedicated to studying soft materials, in particular biological samples in a frozen hydrated state (other cryo XFM instruments have been demonstrated at Spring-8, ESRF, and Petra III). To complement the BNP, we are developing a correlative cryo confocal light microscope (C3LM), which we believe will be the first of its kind for studies alongside cryo XFM. The C3LM system incorporates a Nikon confocal system (340 nm lateral and 700 nm depth resolution) and a cryo sample cartridge and transfer system compatible with the BNP. Confocal imaging capability is important for imaging of thick samples, and will allow correlative 3D studies coupled with the BNP. In this presentation, we will discuss the design philosophy of the C3LM system and show progress towards its operation.

Streamlining data analysis for x-ray fluorescence microscopy

Arthur Glowacki, Argonne National Lab. (United States)

X-ray fluorescence microscopy (XFM) experiments involve attention and time to set up a proper experiment and analyze the results. The accurate analysis of XRF data requires multiple parameters and deep knowledge of the scanning equipment. While simple, fast approaches exist (eg, 'spectral ROIs') these tend not to do work well with more complex data (eg, overlapping peaks). We have implemented several different fast and more accurate analysis methods. To streamline the analysis, and make optimum use of dedicated analysis machines, we created a web interface to submit XRF analysis jobs, and give feedback on processing status and results of specific jobs. The interface significantly simplifies the analysis process and can be expanded to pass jobs from one technique to another such as tomography. Additional processes submit jobs automatically for user experiments that are in progress, as scans finish. Future work will utilize Globus to transfer results off site automatically for users, as well as allow users to remotely use analysis servers for additional processing.

10389-41, Session PMon

Fast hierarchical length-scale morphological, compositional, and speciation imaging at the Nanoscopium Beamline Synchrotron Soleil

Kadda Medjoubi, Gil Baranton, Synchrotron SOLEIL (France); Maria Sancho-Tomas, Synchrotron SOLEIL (France) and Institut de Physique du Globe de Paris (France); Pascal Philippot, Institut de Physique du Globe de Paris (France); Andréa Somogyi, Synchrotron SOLEIL (France)

The Nanoscopium [1] 155 m-long nanoprobe beamline of Synchrotron Soleil (St Aubin, France) is dedicated to scanning multi-modal imaging in the 5-20 keV energy range. It offers 2D/3D information on the elemental composition, speciation and morphology through the combination of complementary techniques such as X-ray fluorescence, X-ray absorption near edge structure spectroscopy (XANES), absorption, phase contrast and dark field imaging. The fast (down to 3 ms per pixel dwell time) and multi-technique Flyscan acquisition scheme [2] is implemented at the beamline and opens the possibility of hierarchical length-scale multi-technique imaging. Fast measurements also provide access to XANES imaging and 3D XRF tomography for user experiments.

The understanding of real complex geological and geo-biological processes depends increasingly on such in-depth chemical studies. We present here such a multi-technique, hierarchical length-scale approach, including the study of the variation of the elemental composition, morphology and chemical speciation combined with multivariate statistical data-treatment in order to understand the processes determining the sub-micron scale variation of As speciation in complex highly heterogeneous samples in natural conditions.

10389-19, Session 5

Current status of the Hard X-Ray Nanoprobe beamline at the SSRF *(Invited Paper)*

Aiguo Li, Hui Jiang, Yan He, Hua Wang, Zhaohong Zhang, Gaofeng Zhao, Shanghai Institute of Applied Physics (China)

The hard X-ray nanoprobe beamline (HXN) designed at the Shanghai Synchrotron Radiation facility (SSRF) will be of capability to realize a focal spot size of 10 nm for hard X-rays to satisfy requirements in biology, environmental, material sciences and etc. The beamline includes two modes of operation, high energy resolution mode and high flux mode respectively. High energy resolution mode uses a total-reflection KB system to reach 50 nm with the energy of 5-25 keV. High flux mode utilizes the multilayer KB system to obtain high-flux diffraction-limited focusing of ~10nm. Diffraction-limited focusing requires an ultra-high-precision figure fabrication to satisfy the Rayleigh Criterion. In this case, the allowed PV roughness for KB mirror cannot be polished directly. An idea to overcome this problem is to introduce a phase compensator system [1] upstream of the KB system to compensate the wavefront errors in the beamline. At wavelength speckle-based method [2] will be used to measure the wavefront error in the beamline and feedback to the phase compensator to adjust the figure shape by PZT elements. Related studies were being carried out and demonstrated in our hard X-ray mirco-focusing beamline.

10389-20, Session 5

First x-ray nanoimaging experiments at NanoMAX

Ulrich Vogt, Karolis Parfeniukas, KTH Royal Institute of Technology (Sweden); Tomas Stankevic, Sebastian Kalbfleisch, Zdenek Matej, Alexander Björling, Marianne Liebi, Gerardina Carbone, Max IV Lab. (Sweden); Anders Mikkelsen, Lund Univ. (Sweden); Ulf Johansson, Max IV Lab. (Sweden)

NanoMAX is a hard x-ray nanoprobe beamline at the new Swedish synchrotron radiation source MAX IV that became operational in 2016. Being a beamline dedicated to x-ray nanoimaging in both 2D and 3D, NanoMAX is the first to take full advantage of MAX IV's exceptional low emittance and resulting coherent properties. We will present results from the first experiments at NanoMAX that took place in December 2016. These did not use the final endstations that will become available to users during 2017, but a temporary arrangement including a zone plate and order-sorting aperture stage and a piezo-driven sample scanner. We used zone plates with outermost zone widths of 100 nm and 30 nm and performed experiments at 8 keV photon energy on x-ray fluorescence and ptychography, both in step-scan and fly-scan mode. Moreover, we investigated stability and coherence with a Ronchi test method. Despite the rather simple setup, we could demonstrate spatial resolution below 50 nm after only few hours of beamtime. The results showed that the beamline is working as expected and experiments approaching the 10 nm resolution level or below should be possible in the future.

10389-21, Session 5

Development of the PtychoProbe Beamline at the Advanced Photon Source

Volker Rose, Jörg Maser, Junjing Deng, Barry Lai, Argonne National Lab. (United States); Tonio Buonassisi, Massachusetts Institute of Technology (United States); David Fenning, Univ. of California, San Diego (United States); Ross Harder, Chris J. Jacobsen, Argonne National Lab. (United States); Rafael Jaramillo, Massachusetts Institute of Technology (United States); Antonio Lanzirotti, The Univ. of Chicago (United States); Eugene M. Lavely, BAE Systems (United States); Karen Mulfort, Argonne National Lab. (United States); Conal E. Murray, IBM Thomas J. Watson Research Ctr. (United States); Stephen R. Sutton, David Tiede, Curt A. Preissner, Argonne National Lab. (United States); Gayle Woloschak, Northwestern Univ. (United States); Stefan Vogt, Argonne National Lab. (United States)

The multiscale and multi-modal understanding of advanced materials via x-ray microscopy has been recognized as one of the great challenges of science end engineering in the coming decades. It will lead to dramatic changes in the ways materials, devices, and systems are understood and created. The goal of the PtychoProbe (Ptychography + Nanoprobe) beamline is to realize the highest possible spatial resolution in x-ray microscopy both for structural and chemical information with scan rates up to 1,000 times faster than currently possible. This will enable visualization across all relevant length scales, nanoscale, mesoscale, and macroscopic, using a single experimental technique. The unprecedented brightness of the future multi-bend achromat lattice for the Advanced Photon Source will be exploited to produce a nanoscale beam of focused hard X-rays (e.g., 5 nm in size) to achieve the highest possible sensitivity to trace elements. Ptychography will be used to further improve the spatial resolution for structural components to its ultimate limit at the 1-nm-scale, only limited by the radiation hardness of the sample. The proposed beamline will enable high-resolution two- and three-dimensional imaging of thick objects, and bridge the resolution gap between contemporary x-ray and electron microscopy. Pushing x-ray microscopy into the nanoscale is crucial for understanding complex hierarchical systems on length scales from atomic up to meso and macroscales, and time scales down to the microsecond level, and is applicable to scientific questions ranging from biology to earth and environmental materials science, to electrochemistry, catalysis and corrosion, and beyond.

10389-22, Session 5

The Velociprobe: A fast hard x-ray nanoprobe for ptychographic imaging

Junjing Deng, Curt A. Preissner, Christian Roehrig, Michael Wojcik, Shane Sullivan, Argonne National Lab. (United States); David J. Vine, Lawrence Berkeley National Lab. (United States); Barry Lai, Stefan Vogt, Argonne National Lab. (United States)

Motivated by the Advanced Photon Source Upgrade (APS-U), a new hard X-ray microscope called "Velociprobe" has been recently designed and built for fast ptychographic imaging with high spatial resolution. We are addressing the challenges of high-resolution and fast scanning with novel hardware/stage designs, new positioner control designs, and new data acquisition strategies, including the use of high bandwidth interferometric measurements. The use of granite, air-bearing-supported stages provides the necessary long travel ranges for coarse motion to accommodate real samples and variable energy operation while remaining highly stable during fine scanning. Scanning the low-mass zone plate enables high-speed high-precision motion of the probe over the sample. Our primary goal is to use

this instrument to demonstrate sub-10 nm spatial resolution ptychography over a 1-square-micron area in under 10 seconds. We have also designed the instrument to take advantage of the upgraded source when the APS-U is completed. This presentation will describe the unique designs and characteristics of this instrument, and some preliminary data obtained during the instrument commission.

10389-23, Session 5

High-resolution chemical imaging using hard x-ray spectro-ptychography

Makoto Hirose, Kei Shimomura, Osaka Univ. (Japan) and Japan Synchrotron Radiation Research Institute (JASRI) (Japan); Nicolas Burdet, Japan Synchrotron Radiation Research Institute (JASRI) (Japan); Yukio Takahashi, Osaka Univ. (Japan) and Japan Synchrotron Radiation Research Institute (JASRI) (Japan)

X-ray ptychography is a method for reconstructing the complex-valued image of an extended specimen from multiple diffraction dataset by using iterative phase retrieval calculation. Hard X-ray spectro-ptychography, which involves multiple-energy ptychogrphy measurements around the absorption edge of a specific element, allows us to visualize the chemical composition mapping of micrometer-sized bulk materials since X-ray absorption fine structure (XAFS) can be reconstructed. A major difficulty of hard X-ray spectro-ptychography is due to the weak absorption of hard X-rays. We here propose the use of the Kramers-Kronig relation as an additive constraint (KKR constraint) to improve the convergence of phasing method of spectro-ptychography. A proof-of-principle experiment was carried out at SPring-8 BL29XUL. A 600-nm-thick Mn_2O_3 layer was deposited on a 500-nm-thick SiN membrane, and then both a pattern comprising the characters of 'SPring-8' and a square hole were fabricated using a focused ion beam. Fourteen X-ray energies were selected between 6.530 keV and 6.588 keV, around the K absorption edge of Mn. The incident X-rays were two-dimensionally focused to a 500 nm (FWHM) spot size using a pair of Kirkpatrick-Baez mirrors. Ptychographic coherent diffraction patterns were collected in a 7 by 7 overlapping view with a 400 nm step width. Sample images were reconstructed with a spatial resolution of 41.1 nm and reconstructed XAFS was improved by using KKR constraint. Hard X-ray spectro-ptychography using KKR constraint can be applied heterogeneous bulk materials, such as oxygen storage/release particles used in three-way catalyst system.

10389-24, Session 6

Time-resolved x-ray diffraction microscopy at Advanced Photon Source

Zhonghou Cai, Yi Zhu, Haidan Wen, Martin V. Holt, Argonne National Lab. (United States)

The high tendency of structural response to external stimuli and the spontaneity in structural heterogeneity require that the investigation of the structural dynamics of a material to be performed both spatially and temporally. Phenomena such as solid-solid phase transition, colossal magnetoresistance, and ferroelectricity/ferromagnetism are often characterized by the spontaneous formation of spatially separated regions with distinct structures that support material properties. The length scales of such phase heterogeneities range from nanometers to micrometers and have roles in the dynamics of phase transition, electron transport, and structural response to applied fields. The dynamics of non-equilibrium heterogeneity including ferroelectric and magnetic domains, nucleation and growth, and short-range electronic ordering cover time scales from picoseconds to microseconds. Fast time-resolved X-ray nanoprobe techniques are thus necessary to address many questions in domain dynamics, nanoscale energy transport, and phase separation and competition. We will present recent development at several APS beamlines of time-resolved diffraction microscopy, their applications in studies of device materials, and its future in the layout of APS Upgrade.

10389-25, Session 6

A new cryo scanning transmission x-ray microscope at the Canadian Light Source

Jan Geilhufe, Adam F. G. Leontowich, Russ Berg, Chris Regier, Darwin M. Taylor, Jian Wang, John Swirsky, Chithra Karunakaran, Robert Peters, Canadian Light Source Inc. (Canada); Mirwais Aktary, Applied NanoTools Inc. (Canada); Adam P. Hitchcock, Brockhouse Institute for Materials Research (Canada); Stephen G. Urquhart, Univ. of Saskatchewan (Canada)

A new scanning transmission X-ray microscope (STXM) optimized for cryo-spectro-tomography with soft X-rays has been designed, built and commissioned at Canadian Light Source (CLS) beamline 10ID1 (130-2700 eV). It is controlled via a new python-based software package, pySTXM. A liquid N2 goniometer (Gatan 630, -80° to 80°), mounted on a computer controlled (x,y,Theta) tilt stage allows for spectro-tomographic measurements at cryogenic temperatures (-180°C) which reduces radiation damage. The CLS cryo-STXM is unique among the set of soft X-ray STXMs currently installed around the world. Details of the cryo-STXM design and examples of its performance will be presented.

10389-26, Session 6

New type of on-the-fly scanning data acquisition system for x-ray nanoprobe at Taiwan Photon Source

Chien-yu Lee, Gung-Chian Yin, Bo-Yi Chen, Bi-Hsuan Lin, Shao-Chin Tseng, Shi-Hung Chang, Jian-Xing Wu, Xiao-Yun Li, Mau-Tsu Tang, National Synchrotron Radiation Research Ctr. (Taiwan)

This on-the-fly scanning control system is for the x-ray nanoprobe endstation at Taiwan Photon Source(TPS) and built base-on the high speed Hardware (H/W), high throughput data stream and multi-channel control interfaces. The main idea is to tag each data with information of time and position, which generates by circuit and laser interferometer. The data is then processed by a computer to be analyzed and visualized.

By using high speed FPGA with embedded processer to process the input and output data which includes the DAC, ADC, Gigabit Ethernet (GbE), X-ray fluorescence (XRF) and laser interferometer control interfaces. Three DAC control the X,Y and Z axes of the flexure stage, four ADCs and sensor interfaces gather the data and packet it into data packet. GbE send data back to computer to do image processing then reconstruct the scanning image. The numerous data not only for rebuild the image but also good for information analysis. Including the vibration, time slide analysis.

Our demo system is built by an e-beam source, flexure stage and laser interferometer. The current maximum scanning speed is up to 5 lines/sec which is limited by the mechanical, the sample rate can be as high as 20M samples/sec which limited by laser interferometer, and the maximum data rate is close to 100M bytes/sec which is limited by the GbE. Interferometer information combine with position data in data packet, makes easy for data analysis and also for image stitching. The system is going to commission on beamline at March, 2017. The commission result for this system will be presented.

10389-27, Session 6

X-ray beam stabilization for nanoscale imaging

Yong S. Chu, Petr P. Ilinski, Hanfei Yan, Xiaojing Huang, Mingyuan Ge, Joseph Mead, Alfred Dellapenna, Anthony Caracappa, Brookhaven National Lab. (United States)

Achieving sufficient stability of the incidence beam is a major technical challenge for nanoscale x-ray imaging, in particular for scanning x-ray microscopy. A typical approach for guarding against beam instability is to create a secondary source in conjunction with a secondary source aperture. This method is highly effective against positional instability of an x-ray source but is only partially effective against angular instability. Since incidence wavefront typically contains contributions from imperfect optics, angular instability introduces undesired time-varying phase in nanoscale imaging experiments. Negative effects not only depends on the magnitude of the angular instability but also the type of nanoscale imaging methods. Negative impact is rather mild for nano-fluoresce imaging, since the measurement is performed at the nanobeam focus. On the other hand, the impact is much more significant for the imaging techniques analyzing the diffracted or transmitted beam. At the Hard X-ray Nanoprobe at NSLS-II, we have achieved angular stability better than 100 nrad in the horizontal direction and 20 nrad in the vertical direction. Presentation will illustrate the impact of the beam instability on different nanoscale imaging methods and describe instrumentation methods used for achieving a stable x-ray beam.

10389-28, Session 6

Beamline for extremely high-resolution Bragg coherent x-ray diffraction imaging with in-situ and operando capabilities

Wonsuk Cha, Evan Maxey, Ross Harder, Argonne National Lab. (United States)

A unique feature of Bragg Coherent Diffractive Imaging (BCDI) is extremely high sensitivity to strain and the ability to image local strain distributions in three dimensions with nanoscale spatial resolution. In-situ and operando imaging has been a major driver for BCDI in recent years. Chemistry and catalysis have been understood through the changes induced in the lattice of nanoscale crystalline materials. BCDI has also been used to study morphological changes in nano-diamond during annealing in-situ. Modern synchrotron x-ray sources, such as that proposed in the upgrade of the Advanced Photon Source (APS), will deliver two orders of magnitude greater coherent x-ray flux. As a result, there is a realistic opportunity for BCDI to reach toward atomic spatial resolution. In this talk, I will discuss current status of the 34-ID-C beamline at the APS. This instrument is dedicated for BCDI, and is pushing the limits of in-situ and operando imaging at high resolution. A new beamline, called ATOMIC, has been proposed as part of the upgraded APS. This new instrument and its potential to impact our sub-nanoscale understanding of science across many disciplines will be introduced.

10390-15, Session PMon

Implementation of the next-generation Gas Cherenkov Detector at the National Ignition Facility

Jorge A. Carrera, Arthur C. Carpenter, Hans W. Herrmann, Alex B. Zylstra, Bart V. Beeman, Hesham Y. Khater, Jose E. Hernandez, Lawrence Livermore National Lab. (United States); Frank E. Lopez, Jeffrey R. Griego, Yong Ho H. Kim, Los Alamos National Lab. (United States); E. Kirk Miller, National Security Technologies, LLC (United States); Steve A. Gales, Colin J. Horsfield, AWE plc (United Kingdom); James S. Milnes, Photek Ltd. (United Kingdom); Jonathan D. Hares, Kentech Instruments Ltd. (United Kingdom)

The Gas Cherenkov Detector version 3 (GCD-3) diagnostic has completed its phase one commissioning/milestone at the National Ignition Facility (NIF). Several key challenges to implementing GCD-3 at the NIF and their resolutions are discussed. In phase one GCD-3 required rigorous mechanical design efforts to prepare it to be installed in a 3.9m well at the NIF. Shielding solutions have been simulated, installed, and tested. Initial Photo Multiplier Tube (PMT) and Photo Diode (PD) measurements using a double and triple stacked Mach-Zehnder based recording system will be presented. Preliminary test results from the ultra-high bandwidth Pulse Dilation Photo Multiplier Tube (PD-PMT) will also be discussed.

This work performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344

10390-20, Session PMon

Solid-state streak camera prototype electronic performance testing and characterization

Yekaterina P. Opachich, Lawrence P. MacNeil, National Security Technologies, LLC (United States); John L. Porter, Sandia National Labs. (United States); Alicia Alarie, National Security Technologies, LLC (United States); Mark W. Kimmel, Joel Long, Quinn Looker, Sandia National Labs. (United States); Don Max, National Security Technologies, LLC (United States); John W. Stahoviak, Sandia National Labs. (United States); Vu Tran, National Security Technologies, LLC (United States); Caleb Wolf, Northwest Nazarene Univ. (United States); Thomas B. Waltman, National Security Technologies, LLC (United States)

Streak Cameras are an essential diagnostic tool used in shock physics and high energy density physics experiments. Such experiments require well calibrated temporally resolving diagnostics for studying events that occur on the nanosecond to microsecond time scales. Although streak cameras are the most common detectors used within the scientific community, they require routine calibration and typically lack reproducibility. A solid state device with similar performance characteristics could provide several advantages to current streak camera systems. NNSS has built a 24-channel solid state streak camera (SSSC) prototype, in collaboration with Sandia National Laboratories, as part of an ongoing project to develop the technology to a level competitive with analog streak cameras. The device concept and results from electronic testing will be discussed in this poster. These measurements will be used as a base for future SSSC development projects.

10390-1, Session 1

Design of a line-VISAR interferometer system for the Sandia Z-Machine

Justin D. Galbraith, John R. Celeste, Todd J. Clancy, Simon J. Cohen, Michael K. Crosley, Phillip S. Datte, Dayne Fratanduono, James Hammer, John L. Jackson, Lawrence Livermore National Lab. (United States); Michael C. Jones, Sandia National Labs. (United States); Don Koen, Jeremy Lusk, Thomas J. McCarville, Harry S. McLean, Kumar Raman, Samuel Rodriguez, Lawrence Livermore National Lab. (United States); Decker Spencer, Sandia National Labs. (United States); Paul T. Springer, Nan J. Wong, Lawrence Livermore National Lab. (United States); Kevin Austin, Jacob Baker, Drew Johnson, Sandia National Labs. (United States)

A joint team comprised of both Lawrence Livermore National Laboratory (LLNL) and Sandia National Laboratory (SNL) personnel is currently designing a line-VISAR (Velocity Interferometer System for Any Reflector) for the Sandia Z Machine, Z Line-VISAR. This system is composed of the following: a two-leg line-VISAR interferometer, an eight-channel Gated Optical Imager (GOI), and a fifty-meter transport beampath to the target of interest.

The Z Machine presents unique design constraints on the optomechanical design. The machine utilizes magnetically driven pulsed power to drive a target to high temperatures and pressures useful for high energy density science. Shock loads exceeding thirty g and a strong electromagnetic pulse (EMP) are generated during the shot event as the machine discharges currents of over twenty-five million amps. Sensitive optical components must be isolated from the shock load path, and electrical equipment must be adequately shielded from the EMP. Additionally, temperature and humidity fluctuations as well as airborne hydrocarbons present in the Z facility pose unique challenges to optical performance.

We will describe the engineering design and concept of operations of the Z Line-VISAR system. Focus will be on optomechanical design.

10390-2, Session 1

An optically passive method that rate doubles 2-GHz timing fiducials

Joshua D. Kendrick, Robert Boni, Charles Sorce, Univ. of Rochester (United States)

Solid-state optical comb-pulse generators provide a convenient and accurate method to include timing fiducials in streak-camera images for time-base correction. Commercially available vertical-cavity surface-emitting lasers (VCSEL's) emitting in the visible can be modulated up to 2 GHz. An optically passive method is presented to interleave a delayed path of the 2-GHz comb with itself, producing a 4-GHz comb. A fiber-delivered, randomly polarized 2 GHz VCSEL comb pulse is polarization split into s-pol and p-pol paths. One path is delayed relative to the other by twice the 2-GHz rate with ?1-ps accuracy, and the two paths recombine at the fiber coupled output. High throughput (>90%) is achieved through the careful use of polarization beam-splitting cubes, a total internal reflection beam path steering prism, and antireflection coatings. The glass path-length delay block and turning prism are optically contacted together. The beam-polarizer cubes that split and recombine the paths are precision aligned and permanently cemented into place. We expect the palm-sized, inline fiber-coupled, comb-rate doubling device to maintain its internal alignment indefinitely.

This material is based upon work supported by the Department of Energy National Nuclear Security Administration under Award Number DE-NA0001944, the University of Rochester, and the New York State Energy Research and Development Authority.

10390-3, Session 1

Using S-parameters for calibration of deployed cables on NIF

Alexander Wargo, California Polytechnic State Univ., San Luis Obispo (United States); Bart V. Beeman, Lawrence Livermore National Lab. (United States) and California Polytechnic State Univ., San Luis Obispo (United States)

Measuring the x-ray environment and other physics phenomena generated at the center of the NIF target chamber is a core capability required for understanding target implosions and other physics experiments. Many of these diagnostic systems include a detector at or near the target chamber with long cables transporting the signal to remote recording devices. As the cables cause distortions in the recorded signal a precise method of in-situ calibration is required. Scattering parameters (S-Parameters) are the gold standard for device characterization but can be difficult to obtain on deployed cables as both ends of the cable are usually required at the measuring instrument. We present an alternate method capable of gathering the required information for full characterization of deployed cables with the main recording instrument on one end and simple, small terminators at the remote end.

Lawrence Livermore National Laboratory is operated by Lawrence Livermore National Security, LLC, for the U.S. Department of Energy, National Nuclear Security Administration under Contract DE-AC52-07NA27344.

10390-4, Session 1

Recording system upgrade for the Dante x-ray diagnostic on NIF

Bart V. Beeman, Alastair S. Moore, Perry M. Bell, Klaus Widmann, Todd J. Clancy, Lawrence Livermore National Lab. (United States)

Measuring the X-ray environment generated at the center of the NIF target chamber is a core capability required for understanding target implosions and other physics experiments. Recently an upgrade was performed to the recording systems employing modern digital technology and additional remote control capabilities. Together significantly decreasing manual setup burdens, increasing accuracy, stability and availability while contributing to shot rate improvement, overall efficiency and cost of operations reduction on NIF. We present the systems chosen, improved calibration techniques employed and some of the key features including the addition of self-test capabilities.

Lawrence Livermore National Laboratory is operated by Lawrence Livermore National Security, LLC, for the U.S. Department of Energy, National Nuclear Security Administration under Contract DE-AC52-07NA27344.

10390-5, Session 1

Performance of a 2ns gated hybrid CMOS burst mode imager

Pratik Patel, Arthur C. Carpenter, Matthew S. Dayton, Brad T. Funsten, Jeremy Hill, Christopher C. Macaraeg, Brian Pepmeier, Lawrence Livermore National Lab. (United States); Brandon Mitchell, Liam D. Claus, Marcos Sanchez, Sandia National Labs. (United States)

An overview of a hybrid CMOS (hCMOS) image sensor, with nanosecond integration time, is presented.

This sensor named “Icarus” was developed with under the Ultra-Fast X-ray imager program collaborated with Sandia National Lab. It will be used for capturing images during high energy density experiments on NIF (National Ignition Facility) at Lawrence Livermore National Lab and on the OMEGA Laser at the Laboratory for Laser Energetics (LLE). The sensor is 1024x512 with 25umx25um pixel size. Same photodiode can be connected to multiple frames and thus ultra-fast frame rate is achieved. Gate profiles as short as 2ns were characterized. The sensor also has ability to time left and right hemisphere independently (so can be used as two sensors with one device). This paper gives basic architecture, function and some characterization and performance results such as gain, linearity, noise floor, full well, gate profile, and hemisphere skew and tuning.

10390-6, Session 1

Radiation effects on active camera electronics in the target chamber at the National Ignition Facility *(Invited Paper)*

Matthew S. Dayton, Arthur C. Carpenter, Hesham Y. Khater, Philip S. Datte, Perry M. Bell, Lawrence Livermore National Lab. (United States)

The camera electronics for Sandia’s nanosecond gated CMOS xray imager are exposed to a large neutron flux at NIF during high yield DT experiments. Most of the non-radhard components in the camera’s prototype were not expected to survive this radiation environment, however the fluence thresholds for failure were unknown. A good understanding of radiation tolerances for the components benefit the final design since non-radhard parts are typically lower cost and readily available. The first tests where done at Cobham Rad instead of the NIF chamber because high yield shots are not performed often at NIF and placing large sets of electronics near TCC can be challenging. Cobham Rad’s 14.1MeV neutron source produces a flux 20 neutrons/ns into 4pi. We were surprised to find that there were no component failures during an active test of the camera for a total fluence on the board of 1.4e12 neutrons/cm^2, which is equivalent to 28 NIF shots. During the experiment one hour was approximately equal to a single shot at NIF. The next set of tests made a link between test results taken at Cobham and test results taken in NIFs high flux environment of 5e15 neutrons/ns into 4pi. These test results combined with the performance of the boards in NIF provide insight into the development of a test strategy for qualifying commercially available components to survive in NIF.

10390-7, Session 2

X-ray Doppler velocimetry for diagnosis of fluid motion in ICF implosions *(Invited Paper)*

Jeffrey A. Koch, National Security Technologies, LLC (United States); John E. Field, Lawrence Livermore National Lab. (United States); Joseph D. Kilkenny, General Atomics (United States); Eric Harding, Gregory A. Rochau, Sandia National Labs. (United States); Aaron M. Covington, Univ. of Nevada, Reno (United States); Eric C. Dutra, Richard R. Freeman, National Security Technologies, LLC (United States); Gareth N. Hall, Lawrence Livermore National Lab. (United States); Michael J. Haugh, James A. King, National Security Technologies, LLC (United States)

We describe a novel technique for measuring bulk fluid motion in materials that is particularly applicable to very hot, x-ray emitting plasmas in the high energy density physics (HEDP) regime. This X-ray Doppler Velocimetry technique relies on monochromatic imaging in multiple closely-spaced wavelength bands near the center of an x-ray emission line in a plasma,

and utilizes bent crystals to provide the monochromatic images. Shorter wavelength bands are preferentially sensitive to plasma moving toward the viewer, while longer wavelength bands are preferentially sensitive to plasma moving away from the viewer. Combining multiple images in different wavelength bands allows for reconstruction of the fluid velocity field integrated along the line of sight. Extensions are also possible for absorption geometries, and for three dimensions. We describe the technique, and we present the results of simulations performed to benchmark the viability of the technique for implosion plasma diagnosis as well as of ongoing efforts to demonstrate the technique with experiments.

10390-8, Session 2

On the design of the NIF Continuum Spectrometer

Daniel B. Thorn, Andrew MacPhee, Jay J. Ayers, Justin D. Galbraith, Michael C. Hardy, Nobuhiko Izumi, David K. Bradley, Lousia A. Pickworth, Benjamin Bachmann, Otto L. Landon, Marilyn B. Schneider, Perry M. Bell, Hesham Y. Khater, Joseph D. Kilkenny, Lawrence Livermore National Lab. (United States)

On inertial confinement fusion (ICF) experiments on the NIF, measurements of average ion temperature using DT neutron time of flight broadening and of average electron temperature using time-integrated differentially-filtered x-ray images are sometimes discrepant. Some of this may be due to time and space dependent temperature profiles in the imploding capsule which are not taken into account in the analysis. As such, we are attempting to measure the electron temperature a second way, by recording the continuous electron bremsstrahlung spectrum from the tail of the Maxwellian temperature distribution. This new NIF Continuum Spectrometer (NCS) spans the x-ray range of 20 keV to 30 keV (where any opacity corrections from the remaining mass of the ablator shell are negligible) and will be sensitive to temperatures between 3 keV and 6 keV. The NCS is designed to be compatible with an x-ray streak camera to record time resolved free-free electron continuum spectra for direct measurement of the dT/dt evolution across the burn width of a DT plasma. The spectrometer is a conically bent Bragg crystal focusing geometry that allows for the dispersion plane to be perpendicular to the spectrometer axis and provides 1:1 imaging. Additionally, to address the spatial temperature dependence, both time integrated and time resolved pinhole and penumbral imaging will be provided along the same polar angle. The optical and mechanical design of the spectrometer is presented along with estimates for the dispersion, solid angle, photometric sensitivity, and performance.

*This work was performed under the auspices of the U.S. Department of Energy by LLNL under Contract DE-AC52-07NA27344.

10390-9, Session 2

Design and characterization of an improved 2-ns multi-frame imager for the Ultra-Fast X-ray Imager (UXI) program at Sandia National Laboratories

Liam D. Claus, Marcos Sanchez, Gideon A. Robertson, Mark W. Kimmel, John L. Porter, Lu Fang, Douglas Trotter, John W. Stahoviak, Troy England, Andrew Montoya, Brandon Mitchell, Gregory A. Rochau, Sandia National Labs. (United States); Arthur C. Carpenter, Matthew S. Dayton, Pratik Bhogilal, Lawrence Livermore National Lab. (United States)

The Icarus camera is an improvement on past imagers (Furi and Hippogriff) designed for the Ultra-Fast X-ray Imager (UXI) program to deliver ultra-fast, time-gated, multi-frame image sets for High Energy Density (HED) physics experiments. Icarus is a 1024 x 512 pixel array with 25 ?m spatial resolution containing 4 frames of storage per pixel. It has improved timing generation and distribution components and has achieved 2 ns time gating. Design improvements and initial characterization and performance results will be discussed.

10390-10, Session 3

X-ray penumbral imaging diagnostic developments at the National Ignition Facility *(Invited Paper)*

Benjamin Bachmann, Lawrence Livermore National Lab. (United States); Hatim Abu Shawareb, Neil B. Alexander, General Atomics (United States); Jay J. Ayers, Christopher G. Bailey, Perry M. Bell, Laura R. Benedetti, David K. Bradley, Laurent Divol, Tilo Doeppner, John E. Field, Lawrence Livermore National Lab. (United States); Andrew Forsman, General Atomics (United States); Justin D. Galbraith, Michael C. Hardy, Lawrence Livermore National Lab. (United States); Terance Hilsabeck, General Atomics (United States); Nobuhiko Izumi, Leonard C. Jarrot, Lawrence Livermore National Lab. (United States); Joseph D. Kilkenny, General Atomics (United States); Steve Kramer, Otto L. Landen, Tammy Ma, Andrew MacPhee, Nathan D. Masters, Sabrina R. Nagel, Arthur E. Pak, Pravesh K. Patel, Louisa A. Pickworth, Joseph E. Ralph, Lawrence Livermore National Lab. (United States); Christopher Reed, General Atomics (United States)

X-ray penumbral imaging has been successfully fielded on a variety of inertial confinement fusion (ICF) capsule implosion experiments on the National Ignition Facility (NIF). We have demonstrated sub-5 micrometer resolution imaging of stagnated plasma cores (hot spots) at x-ray energies from 6 to 30 keV [1, 2]. These measurements are crucial for improving our understanding of the hot deuterium-tritium fuel assembly, which can be affected by various mechanisms, including complex 3-D perturbations caused by the support tent, fill tube or capsule surface roughness. Here we present the progress on several approaches to improve x-ray penumbral imaging experiments on the NIF. We will discuss experimental setups that include penumbral imaging from multiple lines-of-sight, target mounted penumbral apertures and variably filtered penumbral images. Such setups will improve the signal-to-noise ratio and the spatial imaging resolution, with the goal of enabling spatially resolved measurements of the hot spot electron temperature and material mix in ICF implosions.

10390-11, Session 3

X-ray calibration and characterization at NNSS Livermore operations

James A. King, Michael J. Haugh, Richard R. Freeman, Kenneth D. Jacoby, Gabe Torres, Peter Torres III, Patrick W. Hillyard, Jeffrey A. Koch, National Security Technologies, LLC (United States)

X-ray calibration is a primary component of the services provided by the Nevada National Security Site / Livermore Operations (NNSS/LO). The four X-ray calibration labs at NNSS/LO provide characteristic and Bremsstrahlung

X-ray output ranging in energy from 500 eV to 110 keV. These labs are capable of calibrating a variety of X-ray detectors and components including CCD's, streak cameras, spectrometers, and filters. Many of the calibration measurements are NIST-traceable. Calibrations and characterizations include quantum efficiency, sensitivity, dynamic range, and flat field measurements. Historically these labs have performed calibrations for various institutions and national laboratories such as Lawrence Livermore National Laboratory, Los Alamos National Laboratory, and Sandia National Laboratories. In addition, NNSS/LO has in-house diagnostic development capabilities, resulting in new techniques, such as high-energy curved crystal X-ray imaging. This presentation will describe the services provided by these labs, the operation and layout of the labs, and in-house, NVLAP accredited calibration of the various X-ray sources and diagnostics used.

This work was performed by National Security Technologies, LLC, under Contract No. DE-AC52-06NA25946 with U.S. Department of Energy. DOE/NV/25946--3130

10390-12, Session 3

Offline metrology and alignment of a passive neutron imaging pinhole on the National Ignition Facility

Jay J. Ayers, Nick Shingleton, Robin L. Hibbard, David N. Fittinghoff, David A. Barker, Lawrence Livermore National Lab. (United States); Valerie E. Fatherley, Frank E. Merrill, Los Alamos National Lab. (United States); Daniel H. Kalantar, Lawrence Livermore National Lab. (United States)

Neutron imagers have been used on many ICF experiments at the National Ignition Facility. To complement the existing equatorial view on the NIF target chamber a North Pole view was added in FY16. The North Pole neutron imaging system is the first Diagnostic Instrument Manipulator (DIM) based system that is passively aligned. The North Pole neutron imager is a snout based instrument that is positioned approximately 200mm from target chamber center (TCC). The neutron imaging snout contains a set of pinholes along the center axis of the snout positioned 100mm from TCC that relay x-ray images onto a gated framing camera. The neutron imaging pinhole is positioned at 5.75° off the center axis of the snout and relays images onto image plate 8177mm away. The successful deployment of the North Pole neutron imaging system required careful attention to insure that both the neutron line of sight (LOS) and the x-ray LOS were both looking at the same point in space. Additionally it was critical that the neutron LOS be parallel to its nominal to enable small systematic alignment corrections without negative impact to the location of where the images fall at the image plane. This paper will discuss the offline alignment methodology which includes coordinate measurement machine (CMM), analysis using spatial analyzer software and laser tracking systems.

10390-13, Session 3

Pulsed x-ray sources for characterization of gated framing cameras

Catalin Filip, Jeffrey A. Koch, Richard R. Freeman, James A. King, National Security Technologies, LLC (United States)

Gated x-ray framing cameras are used to measure important characteristics of ICF implosions, such as size and symmetry, with ~ 50 ps time resolution in two dimensions. These detectors require a variety of tests and calibration exposures to allow quantitative data to be obtained and analyzed. A pulsed source of hard (> 8 keV) x-rays, other than the NIF laser, would be a valuable calibration device, for example for gain-droop measurements of the variation in sensitivity along the length of the gated strips. We have explored the requirements for such a source, and have explored a variety of source options that could meet these requirements. We find that a small-size dense plasma focus machine could be a practical single-shot x-ray source for this application if timing uncertainties can be overcome. We will present expected performance for a variety of sources compared with known requirements.

10390-14, Session 4

System design of the NIF neutron imaging system North pole *(Invited Paper)*

Valerie E. Fatherley, Los Alamos National Lab. (United States); Jay J. Ayers, David A. Barker, Lawrence Livermore National Lab. (United States); Steve H. Batha, Christopher R. Danly, Los Alamos National Lab. (United States); David N. Fittinghoff, Lawrence Livermore National Lab. (United States); Lynne A. Goodwin, Hans W. Herrmann, Los Alamos National Lab. (United States); Robin L. Hibbard, Los Alamos National Lab. (United States) and Lawrence Livermore National Lab. (United States); Justin J. Jorgenson, John I. Martinez, Frank E. Merrill, John A. Oertel, Derek W. Schmidt, Los Alamos National Lab. (United States); Nick Shingleton, Michael Vitalich, Lawrence Livermore National Lab. (United States); Petr L. Volegov, Carl H. Wilde, Los Alamos National Lab. (United States)

A new neutron imager, known as Neutron Imaging System North Pole, has been fielded to image the neutrons produced in the burn region of imploding fusion capsules at the National Ignition Facility. The resolution and alignment requirements and parameters that drive the design of this system are similar to the pre-existing equatorial system, there are significant changes. This work describes the parameters and limitations driving the design of this system. In addition discussion of the alignment and metrology solutions are discussed. This is intended as a full review of the characteristics of the NIS-NP.

10390-16, Session 4

Fielding the LANL Gas Cherenkov Detector (GCD-3) at the National Ignition Facility: The mechanical engineering challenges of designing, analyzing, fabricating, testing, and commissioning the next-generation GCD detector and WellDIM3.9m insertion manipulator within a 3.9 meter well on the National Ignition Facility target chamber

Frank E. Lopez, Hans W. Herrmann, Ramon J. Leeper, Steve H. Batha, John A. Oertel, Jeffrey R. Griego, Brian C. Steinfeld, Paul J. Polk, Lynne A. Goodwin, Valerie E. Fatherley, Thomas N. Archuleta, Robert J. Aragonez, Benjamin J. Pederson, Los Alamos National Lab. (United States); John R. Celeste, Robin L. Hibbard, Arthur C. Carpenter, Jose E. Hernandez, Jorge A. Carrera, Hesham Y. Khater, Lawrence Livermore National Lab. (United States); Justin J. Jorgenson, Los Alamos National Lab. (United States)

Abstract: The design and commissioning of the next-generation LANL Gas Cherenkov Detector (GCD-3) for fielding at the National Ignition Facility resulted in an array of unique engineering challenges. To field the GCD-3 Detector in an existing 3.9m Well on the NIF Target Chamber required a specialized deployment system. This deployment system transports the existing GCD-3 (currently fielded at LLE/OMEGA) within an existing 3.9m

conical Well (64-275) outside the NIF Target Chamber. The GCD-3, outfitted with additional shielding to mitigate higher NIF backgrounds, serves as the operational payload/prototype for the future, heavily shielded "Super-GCD".

The GCD-3 is a third-generation Gas Cherenkov Diagnostic that provides important information about Inertial Confinement Fusion (ICF) implosions including fusion burn and imploded capsule conditions. The GCD-3 converts gamma rays into Compton electrons, which generate Cherenkov photons inside of the pressurized gas cell. Pressurized gases include CO2, SF6 and C2F6. The Cherenkov photons are then focused onto a photomultiplier tube (PMT) using a Cassegrain optic. Conflat™ knife-edge, crushed-metal seals in conjunction with explosion-bonded Bi-metallic flanges became essential aspects of this vessel design to achieve a low leak-rate specification. The LANL Pressure Safety Program in compliance with DOE Order 10CFR851 invokes the ASME Boiler and Pressure Vessel Code, Section VIII, Division I/II for the design of all pressure vessels. As the B&PV Code can be characterized as a "one size fits all" standard, the tendency toward conservatism is typical. Vessel-wall and flange thicknesses are routinely robust, although inconsequential to refineries, are atypical of pressurized ICF diagnostics. A detailed review of these engineering challenges, correlated with the resulting experimental data, emphasizes the successful collaborative mix of engineering and physics expertise within the ICF Diagnostic Development arena.

10390-17, Session 4

Large-area solid radiochemistry collector (LASR) at the National Ignition Facility

Cory Waltz, Donald R. Jedlovec, Michael C. Hardy, Dawn Shaughnessy, Narek Gharibyan, Cal A. Smith, Lawrence Livermore National Lab. (United States)

The flux of neutrons and charged particles produced from inertial confinement fusion experiments at the National Ignition Facility (NIF) can induce measurable concentrations of nuclear reaction products in various target materials. The collection and radiochemical analysis of the post-shot debris can be utilized as an implosion diagnostic to obtain information regarding fuel areal density and ablator-fuel mixing. Furthermore, assessment of the debris from specially designed targets, material doped in capsules or mounted on the external surface of the target assembly, can support experiments relevant to nuclear forensic research.

To collect the shot debris, we have deployed the Large Area Solid Radiochemistry Collector (LASR) at NIF. LASR uses a main collector plate that contains a large collection foil with an exposed 20 cm diameter surface located ~50 cm from the NIF target. This covers ~0.12 steradians, or about 1% of the total solid angle. We will describe the design, analysis, and operation of this experimental platform as well as the initial results. To speed up the design process 3-dimensional printing was utilized. Design analysis includes the dynamic loading of the NIF target vaporized mass, which was modeled using LS-DYNA.

This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

10390-18, Session 4

Measuring the down scattered neutron ratio using the NiToF detector system at the National Ignition Facility *(Invited Paper)*

Gary P. Grim, Lawrence Livermore National Lab. (United States); George L. Morgan, Carl H. Wilde, Los Alamos National Lab. (United States); Edward Hartouni, Robert Hatarik, Mark J. Eckart, Lawrence Livermore National Lab. (United States)

The National Ignition Facility neutron time-of-flight diagnostic suite is comprised of five independent detector systems, including the neutron imaging time-of-flight diagnostic, NIToF. Because of unique capability to measure both the foreground and background system with the NIToF system, a novel method for determining the neutron downscatter ratio (DSR), defined to be the ratio of the integrated flux of 10-12 MeV neutrons to the 13-15 MeV neutrons, has been developed. This constrained least squares unfold methodology will be described, along with current systematic uncertainty studies, and comparisons with other approaches.

10390-19, Session 4

Development of the Real-Time Neutron Activation Diagnostic System for NIF

Jaben Root, Phil Adams, Gordon K. Brunton, Ellen R. Edwards, Tony Golod, Jose E. Hernandez, Donald R. Jedlovec, Charles Yeamans, Lawrence Livermore National Lab. (United States)

The National Ignition Facility (NIF) is one of the highest-fluence 14.1 MeV neutron sources provided by the nuclear fusion of deuterium and tritium nuclei. One of the resultant products is 14.1 MeV neutrons, which provide key information to the conditions in which they were formed. The degree of polar and azimuthal symmetry of the neutron yield is a key metric for the performance of the capsule, thus a spatially-resolved measurement of the neutron distribution is critical. A suite of 48 lanthanum bromide detectors with zirconium activation samples around the target chamber is being implemented to measure the neutron distribution. The system provides rapid estimates of the neutron fluence distribution. It is designed to operate over six orders of magnitude of neutron yield, providing relative yield estimates precise to 1.3%. The system is designed to operate continuously through the NIF shot cycles, accommodating high data rates. We will describe the nuclear counting system, data acquisition and archiving, analysis, and results for some NIF high yield shots.

This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344. Lawrence Livermore National Security, LLC.

Conference 10391: Developments in X-Ray Tomography XI

Tuesday - Thursday 8 –10 August 2017

Part of Proceedings of SPIE Vol. 10391 Developments in X-Ray Tomography XI

SPIE. OPTICS+ PHOTONICS OPTICAL ENGINEERING+ APPLICATIONS

10391-1, Session 1

Recent trends in high-resolution X-ray tomography

Bert Müller, Univ. Basel (Switzerland)

X-ray tomography is a non-destructive technique. It provides three-dimensional data with a spatial resolution down to the nanometer scale. There are several fields of improvement, which include (i) the detectors being more and more efficient and having an increasing number of pixels, (ii) the development of methods beyond the conventional attenuation contrast, (iii) the realization of fast set-ups to study processes such as loading of scaffolds, and (iv) the implementation of X-ray optics to reach a spatial resolution of about 10 nm. These developments will be discussed on the basis of current literature.

10391-2, Session 1

A comparison study: image-based vs. signal-based retrospective gating on microCT

Xuan Liu, Phil L. Salmon, Kjell Laperre, Alexander Sasov, Bruker microCT (Belgium)

Retrospective gating on animal studies with microCT has gained popularity in recent years. Traditionally, we use ECG signals for cardiac gating and breathing airflow or video signals of abdominal motion for respiratory gating. The 2 methods are adequate and work well for most applications. However, through the years, researchers have noticed some pitfalls in the method. For example, the additional signal acquisition step may increase failure rate in practice. X-Ray image-based gating, on the other hand, does not require any extra step in the scanning. Therefore we investigate image-based gating techniques. This paper presents a comparison study of the image-based versus signal-based approach to retrospective gating. The two application areas we have in mind are respiratory and cardiac gating.

Image-based respiratory gating on microCT is relatively straightforward and has been done by several other researchers and groups. This method retrieves an intensity curve of a region of interest (ROI) in the lung area. Our initial tests show very promising results. Further investigation will be done on the automatic or semi-automatic placing and definition of the ROI. A detailed comparison between image-based and signal-based methods will be made.

For cardiac gating, the image-based method is less obvious. The difficulty in cardiac gating is due to the relatively smaller amplitude of cardiac movements comparing to the respirational movements, and the higher heart rate. Higher heart rate requires high speed image acquisition. We have been working on our systems to improve the acquisition speed. Analysis techniques have been studied to separate cardiac and respirational signals. Comparison on image-based cardiac gating and ECG-based gating will be conducted.

10391-3, Session 1

Improving Material Identification by Combining X-ray and Neutron Tomography

Jacob M. LaManna, Daniel S. Hussey, Elias M. Baltic, David L. Jacobson, National Institute of Standards and Technology (United States)

X-rays and neutrons provide complementary non-destructive probes for the analysis of structure and chemical composition of materials. Contrast differences between the modes arise due to the differences in interaction with matter. Due to the high sensitivity to hydrogen, neutrons excel at separating liquid water or hydrogenous phases from the underlying structure while X-rays resolve the solid structure. Many samples of interest, such as fluid flow in porous materials or curing concrete, are stochastic or slowly changing with time which makes sequential imaging with X-rays and neutrons difficult as the sample may change between scans. To alleviate this issue, NIST has developed a system for simultaneous X-ray and neutron tomography by orienting a 90 keVpeak micro-focus X-ray tube orthogonally to a thermal neutron beam. This system allows for non-destructive, multimodal tomography of dynamic or stochastic samples while penetrating through sample environment equipment such as pressure and flow vessels. Current efforts are underway to develop methods for 2D histogram based segmentation of reconstructed volumes. By leveraging the contrast differences between X-rays and neutrons, greater histogram peak separation can occur in 2D vs 1D enabling improved material identification. This talk will discuss the simultaneous X-ray and neutron tomography system at NIST and current efforts in multimodal, 2D histogram segmentation with several case studies that have been conducted at NIST.

10391-4, Session 1

Nanoscale holographic tomography based on x-ray waveguide optics

Tim Salditt, Malte Vassholz, Mareike Toepperwien, Aike Ruhlandt, Markus Osterhoff, Georg-August-Univ. Göttingen (Germany)

We describe the optics and state-of-the-art applications of nanoscale holographic tomography based on x-ray waveguide optics. The combination of high gain x-ray nano-focusing with optimized coherence and wavefront filtering by waveguide optics, with recent improvements in phase retrieval and tomographic reconstruction have enabled full-field x-ray tomography at the nanoscale with unprecedented resolution and image quality. Compared to ptychography, the tomographic scans are faster, can easily cover larger volumes and are recorded at significantly reduced dose. In this contribution, we present state-of-the art examples, from materials characterisation to biomedical imaging, and discuss the optimum choice of optical parameters. To this end, the instrumental setting at the GINIX endstation of the PetraIII storage ring, waveguide optics and photon energy, as well as phase retrieval approaches are addressed in view of different experimental requirements: resolution, sensitivity, quantitative contrast, dose minimization, and high speed tomographic scan in view of time-resolved studies.

10391-5, Session 1

High energy near- and far-field ptychographic tomography at the ESRF *(Invited Paper)*

Julio C. da Silva, Alexandra Pacureanu, Leonid Bloch, Yang Yang, Peter Cloetens, ESRF - The European Synchrotron (France)

X-ray ptychographic imaging in synchrotron sources has already shown great potential for high-resolution quantitative microscopy. Such a technique, which can be implemented in the near- and far-field regimes, enables not only high-resolution imaging, but also high sensitivity to the electron density of the sample. A sequence of diffraction patterns in the far-field or holograms in the near-field is collected for different lateral translations of the sample with respect to an unknown illumination. The transverse diversity added to the phase retrieval enables the image reconstruction taking into account the incoming beam information. Iterative algorithms carry out the phase-retrieval. The combination with tomography makes 3D imaging possible via ptychographic X-ray computed tomography

(PXCT), which can provide a 3D map of the refractive index of the sample. To do so, several pre-processing steps are needed before the actual tomographic reconstruction. We present here the latest developments in near- and far-field PXCT implemented at the ESRF. We exploit the coherence of the X-ray at the ID16A beamline to perform such a technique at high energy (17.05 keV and 33.6 keV). We discuss the challenges of implementing PXCT with high energy and high flux and how we tackle them. The most recent algorithm developments enable us to circumvent the non-ideal experimental conditions and allow broad bandwidth coherent X-ray imaging. We will also show the results of applications of PXCT to important problems of materials science, for example, applications in heterogeneous catalysis and metallurgy.

10391-6, Session 2

Fast and low-dose phase contrast CT with non-microfocal laboratory x-ray sources *(Invited Paper)*

Alessandro Olivo, Paul C. Diemoz, Marco Endrizzi, Charlotte K. Hagen, Fabio A. Vittoria, Alberto Astolfo, Peter R. T. Munro, Peter Modregger, Gibril K. N. Kallon, Dario Basta, Ian Buchanan, Charlotte Maughan Jones, Anna Zamir, Univ. College London (United Kingdom)

The implementation of X-Ray Phase Contrast (XPC) imaging at synchrotrons has demonstrated transformative potential on a wide range of applications, from medicine and biology to materials science. However, translation to conventional laboratory sources has proven more problematic, because of XPC's stringent requirements in terms of spatial coherence. This has imposed the use of either micro-focal sources, or collimators (e.g. source gratings) where sources with extended focal spots were used. This reduces the available x-ray flux leading to long exposure times, which is often exacerbated by the use of additional optical elements that need to be scanned during image acquisition. Where these elements are placed downstream of the object, they also lead to an increase in the delivered dose.

XPC has also been successfully adapted to full 3D, computed tomography (CT) implementations, which has however exacerbated the above concerns in terms of acquisition times and delivered doses.

We tackled this problem by developing an incoherent approach to XPC that works with non micro-focal laboratory sources without requiring any additional collimation. The method uses one or two low aspect ratio x-ray masks that are built on low-absorbing graphite substrates for maximum transmission through the mask apertures. The combination of this with a "single-shot" phase retrieval algorithm has enabled the development of a lab-based XPC-CT system that can perform a full scan in a few minutes while delivering low radiation doses. The talk will briefly describe how the method works, then show application examples including direct comparisons with the synchrotron gold standard.

10391-7, Session 2

High-Resolution Grating Interferometer for Phase-Contrast Imaging at PETRA III

Alexander C. Hipp, Helmholtz-Zentrum Geesthacht (Germany); Matthias Vogelgesang, Jürgen Mohr, Andreas Kopmann, Karlsruher Institut für Technologie (Germany); Felix Beckmann, Helmholtz-Zentrum Geesthacht (Germany)

Phase-contrast imaging has proven to be a valuable tool for the investigation of weak absorbing materials like soft tissue, due to its increased contrast compared to conventional absorption-contrast imaging. While propagation-based phase-contrast is ideal to achieve highest resolution at a good contrast for almost non-absorbing material, it has limitations for demanding applications that require contrast with a high dynamic range. For those applications grating-based phase-contrast is preferable, although it lacks of spatial resolution compared to inline phase-contrast or attenuation-based microCT. To reduce the gap in spatial resolution we equipped the two PETRA III beamlines P05 and P07 with a customized mechanics to maximize the performance of the interferometer. The optimized system enables phase-contrast measurements in a continuous energy range between 10 keV and 80 keV. Dependent on the investigated material and energy the setup is capable to achieve a spatial resolution of 5 μm on a field of view of 6.5 mm. We will present our implementation of grating-based phase-contrast computed tomography for fast and high-resolution measurements at the PETRA III along with its recent optimizations, and demonstrate its performance for different kinds of applications.

10391-8, Session 2

Quantitative phase contrast and x-ray scattering micro-tomography with the 9.2 keV liquid metal jet anode: applications on materials and life science

Simon A. Zabler, Fraunhofer-Institut für Integrierte Schaltungen (IIS) (Germany); Andreas Balles, Jonas Dittmann, Julius-Maximilians-Univ. Würzburg (Germany); Christian Fella, Randolf Hanke, Fraunhofer-Institut für Integrierte Schaltungen (IIS) (Germany)

Grating-based X-ray phase contrast and scattering contrast tomography were pioneered by Pfeiffer and David at synchrotron beamlines as well as for laboratory applications [1]. While volume image reconstruction from the refractive phase contrast is straight forward, interpretation and appropriate reconstruction from scattering contrast (so called dark-field image contrast DIC) long remained an issue vividly discussed in the scientific community [2]. Based on its interpretation as ultra-small angle scattering by microscopic interfaces (e.g., fibers, pores or particles) we select filtered back-projection with an adaptive filter-kernel as the appropriate reconstruction method. The data which will be shown is acquired downstream of a liquid metal-jet Gallium anode which features quasi-monochromatic 9.2 keV radiation from the K-emission line. High spatial resolution is achieved through 2.7 μm/pixel and 0.6 μm/pixel indirect X-ray cameras coupled to a two-grating interferometer.

Examples of this three-contrast CT from various micro-structured materials are presented along with interpretation, in particular of the DIC signal with respect to the sub-pixel micro structure (e.g. pores in compresses, chloroplasts in plant cells and fibers in high-grade filter materials).

While most of our results confirm the abovementioned theories, we find some unexpected discrepancies, e.g. between propagation-based and grating-based phase contrasts. An additional experiment on a microscopic gradient structure clearly reveals the structural sizes which produce the strongest DIC signal. Such calibration samples might be used for absolute calibration of DIC in a large variety of X-ray interferometers.

10391-9, Session 2

Tomography with energy dispersive diffraction

John S. Okasinski, Russel Woods, Antonino Miceli, Argonne National Lab. (United States); David P. Siddons, Brookhaven National Lab. (United States); Jonathan D. Almer, Argonne National Lab. (United States); Stuart R. Stock, Northwestern Univ. (United States)

X-ray diffraction can be used as the signal for tomographic reconstruction and provides a cross-sectional map of the crystallographic phases and

related quantities. Diffraction tomography is typically performed with monochromatic x-radiation and an area detector. This paper reports tomographic reconstruction with polychromatic radiation and an energy sensitive detector array. The energy-dispersive diffraction (EDD) geometry, the instrumentation and the reconstruction process are described and related to the expected resolution. Results of EDD tomography are presented for two samples containing hydroxyapatite (hAp). The first is a 3D-printed sample with an elliptical cross-section and contains synthetic hAp. The second is a human second metacarpal bone from the Roman-era cemetery at Ancaster, UK and contains bio-hAp which may have been altered by diagenesis. Reconstructions with different diffraction peaks are compared. Prospects for future EDD tomography are also discussed.

10391-10, Session 3

Microanatomy of the cochlear hook
(Invited Paper)

Claus-Peter Richter, Changyow Claire Kwan, Xiaodong Tan, Stuart R. Stock, Northwestern Univ. (United States); Carmen Soriano Hoyuelos, Argonne National Lab. (United States)

To examine the cochlear hook of mice, micro-CT was carried out at beamline 2-BM of the Advanced Photon Source at Argonne National Laboratories. All cochleae were imaged using monochromatic radiation with photon energies of 22 keV. The separation between the detector and the tomography rotation axis was 600 mm for phase contrast. 5x and 10x objective lenses were used in the detector system. Specimens were placed such that they were in the visual field at all times. A series of X-ray projections were taken over a range of 180 degrees at increments of 0.12 degrees. The exposure time for a single image was 0.2-0.3 s. At the beginning and end of each image series, flat field images (no object in the beam path) were recorded; after the series, a dark field image (the X-ray beam was blocked) was captured. At the conclusion of the experiment, the projections were used to reconstruct the cochlear hook region. Custom written phase retrieval software was used for the reconstructions. Reconstructions were on a 2048 x 2048 grid. The reconstructions resulted in 1.45 μm / 0.78 μm isotropic voxels. Detailed evaluation of the bony and soft tissue structures showed for the first time specific configurations of the bony structures and the anchoring of the basilar and tectorial membranes at the very base of the cochlea. The data will be used in cochlear models to further describe linear and nonlinear processing of acoustical information in the inner ear.

10391-11, Session 3

Microcomputed tomography and x-ray diffraction of intact archeological human second metacarpal bones as a function of individuals' age at death

Stuart R. Stock, Northwestern Univ. (United States); J. S. Park, Argonne National Lab. (United States); Malene Laugesen, Aarhus Univ. (Denmark); Simon Mays, Historic England (United Kingdom); Jonathan D. Almer, Argonne National Lab. (United States); Henrik Birkedal, Aarhus Univ. (Denmark); Carmen Soriano Hoyuelos, Argonne National Lab. (United States)

Bones recovered from archeological sites provide information on past human health, and destructive sampling is often not an option, making x-ray methods invaluable. This paper uses two high energy x-ray methods to study human second metacarpal (Mc2) bones from Roman (Ancaster) and from medieval (Wharram Percy) Britain. MicroComputed Tomography (microCT) and position resolved x-ray scattering (wide angle – WAXS – and small angle – SAXS) provide quantitative data on six Mc2 from each site with two Mc2 from each of three age (at death) cohorts and on a modern Mc2 and two synthetic hAp phantoms.

Laboratory microCT imaged trabecular bone, and synchrotron microCT (2-BM, Advanced Photon Source - APS) imaged cortical bone from these Mc2. A series of WAXS and SAXS patterns covering the cross-section of these Mc2 and phantoms were collected simultaneously with a 50 ?m wide beam at 1-ID, APS. Rietveld refinement was applied to the WAXS patterns, and cAp lattice parameters and crystallite size and microstrain determined. From SAXS, collagen D-period was quantified.

We seek to answer the following questions: 1) How does the microCT and scattering data correlate in defining bone "quality"? 2) How much has diagenesis altered the bone material and changed quantities measured by x-ray scattering (cAp lattice parameters; crystallite size, microstrain; collagen D-period)? 3) If diagenetic changes are minor or non-existent, do the above quantities change with age in Roman and medieval era populations, and are these changes similar to those observed for bone from modern sedentary populations?

10391-12, Session 3

3D mapping grain morphology and grain orientations by laboratory diffraction contrast tomography

Christian Holzner, Carl Zeiss X-ray Microscopy, Inc. (United States); Nicolas Gueninchault, Florian Bachmann, Xnovo Technology ApS (Denmark); Hrishikesh Bale, Leah Lavery, Carl Zeiss X-ray Microscopy, Inc. (United States); Erik Lauridsen, Xnovo Technology ApS (Denmark)

Determining crystallographic microstructure of a given material in 2D can be challenging. Further extending such an investigation to 3D on meaningful volumes (and without sample sectioning) can be even more so. Yet reaching this insight holds tremendous value for 3D materials science since the properties and performance of materials are intricately linked to microstructural morphology including crystal orientation. Achieving direct visualization of 3D crystallographic structure is possible by diffraction contrast tomography (DCT), albeit only available at a limited number of synchrotron X-ray facilities around the world. Recent developments, however, have made DCT possible on an X-ray microscope with a laboratory source.

The introduction of diffraction contrast tomography as an additional imaging modality on the ZEISS Xradia 520 Versa laboratory X-ray microscope has opened up a whole new range of possibilities for studies of the effect of 3D crystallography on materials performance. The capability to link directly the crystallographic and grain microstructure information with that obtained via conventional absorption or phase contrast imaging, non-destructively in three-dimensions and all in the laboratory, creates a powerful and easy to access tool [1-2]. Using a polychromatic X-ray source, laboratory diffraction contrast tomography technique (LabDCT) takes advantage of the Laue focusing effect, improving diffraction signal detection and allows handling of many and closely spaced reflections.

Additionally, LabDCT opens the way for routine, non-destructive and time-evolution studies of grain structure to complement electron backscatter diffraction (EBSD). Crystallographic imaging is performed routinely by EBSD for metallurgy, functional ceramics, semi-conductors, geology etc. However, EBSD is an end-point characterization technique and prevents any investigation of microstructure evolution when subject to either mechanical, thermal or other environmental conditions.

Combination of grain information with microstructural features such as cracks, porosity, and inclusions all derived non-destructively in 3D presents new insights for materials characterization of damage, deformation and growth mechanisms. Furthermore, 3D grain orientation data is a valuable input into multi-scale, multi-layered modeling platforms that can virtually evaluate mechanical properties to produce high fidelity simulation results.

Recent developments of the LabDCT technique have extended its capabilities to include full reconstruction of the 3D grain structure including both grain morphology and crystallographic orientation, thereby making the LabDCT more comparable to conventional 3D-EBSD data – while still supporting 4D time dependent studies. We will present a selection of results of LabDCT with particularly emphasis on its non-destructive operation,

demonstrated through 4D evolutionary studies obtained by repeating the imaging procedure numerous times on the same sample. We will discuss the boundary conditions of the current implementation, point to the future of the technique and discuss ways in which this can be correlatively coupled to related techniques for a better understanding of materials structure evolution in 3D.

10391-13, Session 3

In-situ observation of phase separation of polymer blend using x-ray Talbot-Lau interferometer

Yanlin Wu, Hidekazu Takano, Atsushi Momose, Tohoku Univ. (Japan)

X-ray phase tomography was used to follow the time evolution of the structure of polymer blend experiencing phase separation with respect to heating treatment.

In this work, we performed high-speed X-ray phase imaging and tomography with X-ray Talbot-Lau interferometer using synchrotron radiation white beam, which has the advantage that broad energy bandwidth X-rays can be used.

The X-ray Talbot-Lau interferometer consists of a source grating (30 ?m), a ϖ/2 phase grating (4.5 ?m) and an amplitude grating (5.3 ?m) and high speed camera. A polymer blend system of polystyrene (Mw = 76,500) and polymethylmethacrylate (PMMA) (Mw = 33,200) was used for the CT observations. A compound of PS and PMMA were made by a twin-screw extruder and put into an Al tube, which inner diameter was 5 mm. The sample temperature can be maintained at desired temperature sequence, and corresponding CT scans were repeated to track the changes in the sample structures.

The phase separation structure of PS / PMMA blends was observed during heating at a temporal time resolution of 5 seconds. PS-rich phase and PMMA-rich phase and their change with time evolution can be observed.

10391-14, Session 4

Numerical study on simultaneous emission and transmission tomography in the MRI framework

Lars Gjesteby, Wenxiang Cong, Ge Wang, Rensselaer Polytechnic Institute (United States)

Multi-modality imaging methods have greatly advanced diagnostic and therapy assessment capabilities in medicine. Specifically, hybrid systems that combine positron emission tomography (PET) with computed tomography (CT) and magnetic resonance imaging (MRI) respectively deliver valuable complementary functional and structural/morphological information. A novel imaging method was recently demonstrated that combines MRI principles with nuclear medicine techniques to reconstruct the concentration of a polarized ?-ray emitting radioisotope. The resultant images achieved better spatial resolution than standard nuclear imaging and higher sensitivity than MRI. In our work, we propose to acquire this form of MRI-modulated nuclear data for simultaneous image reconstruction in terms of both emission and transmission parameters, suggesting the potential for simultaneous CT-MRI-SPECT. The simultaneous information provides insight into tissue forms and molecular/cellular functions of features being imaged. We describe the methodology involving the system design with emphasis on the imaging protocol and the formulation for image inversion. Polarized radiotracers are used to serve as internal sources for attenuation-based imaging. In the presence of a main magnetic field with alteration by gradient coils, a region of radiotracers emitting directionally-specific x-rays can be targeted for measurement by collimated detectors. Initial numerical results demonstrate the feasibility of our technique for reconstructing concentration and attenuation images of a water phantom with various radio-labeled tissue types. Additional considerations regarding the radioisotope half-life, ?-branching ratio, and longitudinal relaxation are needed to find the best material.

10391-15, Session 4

A spectral CT reconstruction algorithm based on weighted block matching 3D filtering

Morteza Salehjahromi, Yanbo Zhang, Hengyong Yu, Univ. of Massachusetts Lowell (United States)

In spectral CT, an energy-resolving x-ray detector is capable of counting the number of received photons in different energy channels with appropriate post-processing steps. Because the received photon number in each energy channel is low in practice, the generated projections suffer from low signal to noise ratio. This makes it a challenging task to reconstruct spectral CT images. Because the reconstructed multi-channel images are technically from the same object but in different energies, there is a high correlation among these images and one can make full use of this redundant information. In this work, we propose a weighted block matching 3D (BM3D) filtering-based method for iterative spectral CT reconstruction. It is based on denoising of small 3D data arrays formed by grouping similar 2D blocks from the whole 3D data image. This method consists of the following steps in each iteration. First, a 2D image is updated by the OS-SART for each energy channel. Second, we perform the weighted BM3D filtering-based method to not only denoise each channel image but also exploit the correlation among the channel images. The proposed method is evaluated by using both numerical simulation and realistic preclinical datasets, and its merits are confirmed by the promising results.

10391-16, Session 4

Applications of compressed sensing image reconstruction to sparse-view phase tomography

Ryosuke Ueda, Hiroyuki Kudo, Jian Dong, Univ. of Tsukuba (Japan)

It is known that x-ray phase microscopy CT as well as x-ray phase micro CT require a long measurement time so that the so-called sparse-view CT data acquisition is an attractive way to shorten the measurement time. This paper applies two major compressed sensing (CS) approaches to image reconstruction in the x-ray sparse-view phase tomography where the projection data is undersampled. The first CS approach is the standard Total Variation (TV) regularization, in which the cost function for image reconstruction is expressed as f(x)=beta*TV(x)+|DAx-b|_W^2, where x is the image, b is the phase differential projection data, A is the projection matrix, and D is the differentiation operator. The major drawback of TV regularization is patchy artifact and loss in smooth intensity changes and textures due to the piecewise constant nature of image model. The second CS method is a relatively new approach of CS which uses a non-linear smoothing filter to design the regularization term. In this approach, the cost function is expressed as f(x)=beta*NL(x)+|DAx-b|_W^2 with the regularizer NL(x) having the form of |x-Mx|_1^1, where M is an arbitrary non-linear smoothing filter such as median, non-local mean (NLM), bilateral (BL), and anisotropic diffusion filter. The non-linear filter based CS is expected to reduce the major artifact in the TV regularization. The both cost functions can be minimized by using an iterative algorithm based on the so-called proximal gradient optimization method. However, in the past research activities, it is not clearly demonstrated 1) how much image quality difference occurs between the TV regularization and the non-linear filter based CS and 2) effect of used non-linear filter to image quality in the

non-linear filter based CS, with CT applications. We clarify these two points by applying the two CS applications to the case of x-ray tomography. We provide results with numerically simulated data as well as results with real data. The results demonstrate that the non-linear filter based CS using the NLM and BL filter significantly outperforms the TV regularization in terms of preserving edged, textures, and smooth intensity changes.

10391-17, Session 4

Deep learning for low-dose CT *(Invited Paper)*

Hu Chen, Yi Zhang, Jiliu Zhou, Sichuan Univ. (China); Ge Wang, Rensselaer Polytechnic Institute (United States)

The great biomedical utilities of the CT technology have led to an increasingly high number of CT scans, and at the same time an elevated public concern over the potential radiation damage to the patients. The well-known guiding principle is abbreviated as ALARA (as low as reasonably achievable), which is seriously taken in the medical community. The most common way to minimize the radiation dose is to reduce the x-ray flux, which can be implemented by adjusting the tube voltage, current, and operating time, process photon-limited raw data and/or reconstruct an image iteratively in a statistical and compressed sensing framework. Different from the sinogram-based filtering and iterative reconstruction methods, post image processing does not rely on the raw data format (normally unavailable) and the scanner imaging protocol (depending on vendors and protocols), and can be directly applied on low-dose CT images. This means that the denoising work can be easily integrated into the current CT workflow. The main problem of this post-processing method lies in that the distribution of the noise in the image domain cannot be statistically well modeled at this stage, which is a current challenge to achieve the optimal tradeoff between structure preservation and noise suppression. Fortunately, the machine learning approach is immune to this problem. Here we propose a deep neural network model for low-dose CT. While traditional convolutional neural network (CNN) with cascaded pooling operations will lose important details, we are inspired by the idea behind the auto-encoder, and include deconvolutional layers in the network to construct a symmetrical auto-encoder CNN model. Shortcut connections are used to compensate for the lost details and suppress the impact of gradient diffusion for training. Our results from both simulated and clinical data have demonstrated that the proposed scheme is promising for low-dose CT via image restoration.

10391-18, Session 4

Machine learning for micro-tomography *(Invited Paper)*

Dilworth Y. Parkinson, Daniela M. Ushizima, Daniel Pelt, Talita Perciano, Harinarayan Krishnan, Holden Parks, Alexander Hexemer, Harold S. Barnard, Alastair A. MacDowell, Lawrence Berkeley National Lab. (United States); James A. Sethian, Univ. of California, Berkeley (United States)

Machine learning has revolutionized a number of fields, but many micro-tomography users have never used it for their work. The micro-tomography beamline at the Advanced Light Source (ALS), in collaboration with the Center for Applied Mathematics for Energy Research Applications (CAMERA) at Lawrence Berkeley National Laboratory, has now deployed a series of tools to automate data processing for ALS users using machine learning. This includes new reconstruction algorithms, feature extraction tools, and image classification and recommendation systems for scientific image. Some of these tools are either in automated data pipelines that operate on data as it is collected. Others are deployed on computing resources at Berkeley Lab--from workstations to supercomputers--and made accessible to users through either scripting or easy-to-use graphical interfaces. I will present a progress report on this work.

10391-19, Session 5

Imaging human brain tissue using tomography with conventional and synchrotron x-ray sources *(Invited Paper)*

Anna Khimchenko, Georg Schulz, Christos Bikis, Simone E. Hieber, Marzia Buscema, Hans Deyhle, Univ. Basel (Switzerland); Gabriel Schweighauser, Jürgen Hench, Univ. Hospital Basel (Switzerland); Alexandra Pacureanu, ESRF - The European Synchrotron (France); Peter Thalmann, Natalia Chicherova, Bert Müller, Univ. Basel (Switzerland)

Brain tissue has a complex, multi-scale organization down to its individual sub-cellular components. Hard X-ray imaging is a powerful method for three-dimensional (3D) investigations, providing a (sub-)cellular resolution in a non-destructive and time-efficient manner. As recently shown, laboratory-based microtomography in absorption contrast of formalin-fixed paraffin-embedded (FFPE) human cerebellum yields an image contrast, comparable to conventional histological sections; even the individual Purkinje cells are clearly seen [1]. For the 3D visualization of soft tissues phase contrast yields better data quality compared to conventional absorption contrast mode. Synchrotron radiation based X-ray phase-contrast imaging enabled the visualization of non-stained Purkinje cells down to the sub-cellular level and their automatic counting [2]. In this communication, we present the study of brain tissue ultra-structure using magnified phase contrast holotomography. As an example, we present images of human cerebellum and cortex blocks embedded in JB-4 (water-soluble, GMA based, plastic resin), epoxy resin and paraffin in which structures at nanometer scale such as the nucleoli of Purkinje, granule or pyramidal cells are resolved. We expect that absorption and phase contrast tomography can provide valuable information on human tissues in health and disease for many medical applications as well as for basic research.

10391-20, Session 5

Assessment of imaging quality in magnified phase CT of human bone tissue at the nanoscale

Boliang Yu, Max Langer, Institut National des Sciences Appliquées de Lyon (France); Alexandra Pacureanu, ESRF - The European Synchrotron (France); Remy Gauthier, Institut Francais des Sciences et Technologies des Transports de l'amenagement et des Reseaux (France); Cécile Olivier, ESRF - The European Synchrotron (France); Helene Follet, Institut National de la Santé et de la Recherche Médicale (France); David Mitton, Institut Francais des Sciences et Technologies des Transports de l'amenagement et des Reseaux (France); Peter Cloetens, ESRF - The European Synchrotron (France); Françoise Peyrin, Institut National des Sciences Appliquées de Lyon (France) and ESRF - The European Synchrotron (France)

The investigation of bone properties has a major impact on the prediction of fracture risk in disease such as osteoporosis. However, there are still few 3D quantitative data on bone tissue at the cellular scale. Here we propose to use magnified X-ray phase nano-CT to quantify bone ultra-structure in human bone, by using the new ID16A beamline at the ESRF to reach a voxel size of 10nm. Obtaining 3D images requires the application of phase retrieval prior to tomographic reconstruction. Phase retrieval is an ill-posed problem for which various approaches have been developed. Image quality being essential for the further quantification of bone tissue, our aim, here,

is to evaluate different phase retrieval methods for imaging bone samples at the nanoscale. Samples from femurs of female donors were scanned using magnified phase nano-CT at voxel sizes of 120 and 30 nm with an energy of 33 keV. Four CT scans at varying sample-to-detector distances were acquired for each sample. We evaluated three phase retrieval methods adapted to these conditions: Paganin method at single distance, Paganin method extended to multiple distances, and the contrast transfer function (CTF) approach for homogeneous objects. These methods were followed by an iterative refinement step. Our results based on visual observation and quantitative assessment show that the use of several distances (as opposed to one) decisively improves image quality and the two considered phase retrieval methods give similar results. First results on the segmentation of osteocyte lacunae and canaliculi from such images will be presented.

10391-21, Session 5

Micro-CT in situ study of carbonate rock porosity for CO2 storage

Yi Zheng, Technical Univ. of Denmark (Denmark); Melania Rogowska, Yi Yang, Univ. of Copenhagen (Denmark); Carsten Gundlach, Technical Univ. of Denmark (Denmark)

To achieve the 2?°C target made in the 2016 Paris Agreement, it is essential to stop emitting CO2 and the other greenhouse gases into the atmosphere. Carbon Capture and Storage (CCS) has been given increasing importance over the last decade. One of the suggested methods for CCS is to inject CO2 into geologic settings such as carbonate reservoirs in the North Sea. Micro-CT imaging is a non-destructed 3D method that can be used to study the storage properties of carbonate rocks. The advance in lab source based micro-CT has made it capable of in situ experiments. In this paper, we used a commercial bench top micro-CT (ZEISS Xradia 410 Versa) to study the change of porosity and permeability during CO2 injection in chalk. The aim is to determine an effective way to control the change of porosity during CO2 injection, such as by controlling the flow rate, injection pressure or chemical solutions. Fast CT technique is also being investigated during the study. The results show that the bench top CT system, combined with a specially designed pressure cell is capable in the in situ study of CO2 injection in chalk.

10391-22, Session 5

Establishment of metrological traceability in porosity measurements by x-ray computed tomography

Petr Hermanek, Simone Carmignato, Univ. degli Studi di Padova (Italy)

Internal porosity is an inherent phenomenon to many manufacturing processes, such as casting, additive manufacturing, and others. Since these defects cannot be completely avoided by improving production processes, it is important to have a reliable method to detect and evaluate them accurately. The accurate evaluation becomes even more important concerning current industrial trends to minimize size and weight of products on one side, and enhance their complexity and performance on the other. X-ray computed tomography (CT) has emerged as a promising instrument for this application offering several advantages over equivalent methods already established in the detection of internal defects. The main shortcomings of the conventional techniques pertain to too general information about total porosity content (e.g. Archimedes method) or the destructive way of testing (e.g. microscopy of cross-sections). On the contrary, CT is a non-destructive technique providing complete information about size, shape and distribution of internal porosity.

However, due to the lack of standards and the fact that it is relatively new measurement technique, CT as a measurement technology has not yet reached maturity. This study proposes a procedure for the establishment of measurement traceability in porosity measurements by CT including the necessary evaluation of measurement uncertainty. The traceability transfer is carried out through a novel reference standard calibrated by optical and tactile coordinate measuring systems. The measurement uncertainty is calculated following several methods and the results are compared upon. In addition, the accuracy of porosity measurements by CT with the associated measurement uncertainty is evaluated using the reference standard.

10391-23, Session 5

Biodegradable magnesium-based implants in bone studied by synchrotron-radiation microtomography *(Invited Paper)*

Julian Moosmann, Jörg U. Hammel, Felix Beckmann, Diana Krüger, Helmholtz-Zentrum Geesthacht (Germany); Silvia Galli, Malmö Univ. (Sweden); Regine Willumeit-Römer, Florian Wieland, Berit Zeller-Plumhoff, Helmholtz-Zentrum Geesthacht (Germany); Martin Bech, Niccolo Peruzzi, Lund Univ. (Sweden)

Permanent implants made of titanium or its alloys are the gold standard in many orthopedic and traumatological applications due to their good biocompatibility and mechanical properties. However, a second surgical intervention is required in order to remove the implant, e.g., in the case of children or because of detrimental effects due to stress shielding or wear debris. Here, magnesium-based materials which degrade under physiological conditions have become increasingly attractive due to their mechanical stability, biocompatibility, and degradation properties. A major challenge, however, is tailoring the degradation in a manner that is suitable for a biological environment and such that stabilization of the bone is provided until the bone defect is healed and implant removal can be avoided. In order to understand failure mechanisms of magnesium-based implants in orthopedic applications, bone-implant samples are studied under mechanical and cyclic load conditions by means of a push-out device installed at the imaging beamline (IBL) P05 at PETRA III at DESY. Implants from titanium and PEEK serve as control. The materials are implanted in bone and harvested after various healing times. Conventional absorption contrast microtomography and phase-contrast techniques are applied in order to monitor the bone-implant interface in three dimensions. Analyzing the morphological adaptations of bone and soft tissue and the degradation and biocompatibility of the screw material, we present results of how different materials influence the integration of implants into the bone.

10391-24, Session 6

The NOVA project: maximizing beamtime efficiency through synergistic analyses of SRuCT data *(Invited Paper)*

Sebastian Schmelzle, Technische Univ. Darmstadt (Germany); Vincent Heuveline, Ruprecht-Karls-Univ. Heidelberg (Germany); Jürgen Becker, Karlsruher Institut für Technologie (Germany); Michael Heethoff, Technische Univ. Darmstadt (Germany); Thomas van de Kamp, Karlsruher Institut für Technologie (Germany)

Beamtime and resulting SR?CT data are a valuable resource for researchers of a broad scientific community working with tomographic data. Most research groups, however are only interested in a specific organ and thus use only a fraction of their data. The rest of the data usually remains untapped. By using a new collaborative approach, the NOVA project (Network for Online Visualization and synergistic Analysis of tomographic data) aims to create possibilities, that allow for a more efficient use of the valuable beam time through the coordination of research on different organ systems. The biological partners in the project cover different scientific aspects and thus serve as model community for the collaborative approach. As prove of principle, different aspects of insect head morphology will be investigated (e.g., biomechanics of the mouthparts and neurobiology with the topology of sensory areas). This effort is accomplished by development of advanced analysis tools for the ever-increasing quantity of tomographic datasets. In the preceding project ASTOR, we already successfully demonstrated considerable progress in semi-automatic segmentation and classification of internal structures. Further improvement of these methods is essential for an efficient use of beamtime and will be refined in this project. Significant enhancements are also planned at the PETRA III instrumentation (phase contrast), on the reconstruction algorithms (based on intensity as well as absorption), and the tools for subsequent analyses and management of the data. All improvements made on key technologies within this project will be equally beneficial for all users of tomography instrumentations.

10391-25, Session 6

Detector response artefacts in spectral reconstruction

Ulrik L. Olsen, Jan Kehres, Yun Gu, Technical Univ. of Denmark (Denmark); Erik D. Christensen, Univ. of Copenhagen (Denmark); Mohamad Khalil, Technical Univ. of Denmark (Denmark)

Energy resolved detectors are gaining traction as a tool to achieve better material contrast. K-edge imaging and tomography is an example of a method with high potential that has evolved on the capabilities of photon counting energy dispersive detectors. Border security is also beginning to see instruments taking advantage of energy resolved detectors. The progress of the field is halted by the limitations of the detectors. The limitations include non-linear response for both x-ray intensity and x-ray spectrum. In this work we investigate how the physical interactions in the energy dispersive detectors affect the quality of the reconstruction and how corrections restore the quality. We have modelled detector responses for the primary detrimental effects occurring in the detector; escape peaks, charge sharing/loss and pile-up. The effect of the change in the measured spectra is evaluated based on the artefacts occurring in the reconstructed images. We also evaluate the effect of a correction algorithm for reducing these artefacts on experimental data acquired with a setup using Multix ME-100 V-2 line detector modules. The artefacts were seen to introduce 20% deviation in the reconstructed attenuation coefficient for the uncorrected detector. We performed tomography experiments on samples with various materials interesting for security applications and found the SSIM to increase >5 % below 60keV. Our work shows that effective corrections schemes are necessary for the accurate material classification in security application promised by the advent of high flux detectors for spectral tomography.

10391-26, Session 6

Simulated data for synchrotron radiation based microtomography at the imaging beamline P05/PETRA III

Felix Beckmann, Helmholtz-Zentrum Geesthacht (Germany)

The Helmholtz-Zentrum Geesthacht, Germany, is operating the user experiments for microtomography at the beamlines P05 and P07 using synchrotron radiation produced in the storage ring PETRA III at DESY, Hamburg, Germany. In recent years the software pipeline and sample changing hardware for performing high throughput experiments were developed. To test and optimize the different measurement techniques together with quantification of the quality of different reconstruction algorithms a software pipeline to simulate the experiment was implemented. Within this this talk the current status of the beamline P05 and a comparison of simulated data with measured data will be given.

10391-27, Session 6

Comparison of data processing techniques for single-grating x-ray Talbot interferometer data

Shashidhara Marathe, Diamond Light Source Ltd. (United Kingdom); Marie-Christine Zdora, Diamond Light Source Ltd. (United Kingdom) and Univ. College London (United Kingdom); Irene Zanette, Silvia Cippicia, Christoph Rau, Diamond Light Source Ltd. (United Kingdom)

For over a decade, the X-ray Grating Talbot interferometer (XGTI) has been at the forefront of X-ray phase-contrast imaging due to its ability to visualize very small density variations of bulk objects with the possibility of extracting three imaging modalities from a single interferogram image or a data set. Most widely used XGTI data acquisition techniques, namely the two grating phase-stepping and Moiré techniques, suffer from poor signal to noise ratio (SNR), which is mainly due to about 50% reduction in scattered sample signal by the second amplitude grating. Consequently, longer exposure times are required for an improved SNR, which comes at the cost of an increased dose to the sample.

To overcome this problem, we can use a setup with only a single phase grating in combination with a high-resolution detector system. Data acquisition and analysis can be performed either in phase-stepping mode or from a single reference and sample image. The latter technique makes use of the fact that a Talbot interferogram consists of carrier frequency spectrum of the grating overlapping with the sample spectrum and by Fourier transforming the interferogram we can separate the two. We will compare these two single grating data processing techniques using a single data set measured with mouse embryo heart and discuss advantages and disadvantages of each technique. These two techniques can be used as complementary; one for high resolution, and the other for high-speed imaging.

10391-28, Session 6

Micro- and nano-tomography at the DIAMOND beamline I13L imaging and coherence

Christoph Rau, Andrew J. Bodey, Malte Ogurreck, Shashidhara Marathe, Silvia Cipiccia, Marie-Christine Zdora, Irene Zanette, Ulrich H. Wagner, Xiaowen Shi, Darren Batey, Diamond Light Source Ltd. (United Kingdom)

The Diamond Beamline I13L is dedicated to imaging on the micron- and nano-lengthsale, operating in the energy range between 6 and 30 keV [1]. For this purpose two independently operating branchlines and endstations have been built. The imaging branch is fully operational for micro-tomography and in-line phase contrast imaging with micrometre resolution. Grating interferometry is currently implemented complementing the instrumental capabilities on the micron lengthscale. In addition, a full-field microscope providing 50nm spatial resolution over a field of view of 100microns is being tested. The instrument provides a large working distance between optics and sample to adapt a wide range of customised sample environments. On the coherence branch coherent diffraction imaging techniques such as ptychography, coherent X-ray diffraction (CXRD) are currently developed for three dimensional imaging.

The imaging branch is operated in collaboration with Manchester University, called therefore the Diamond-Manchester Branchline. The scientific applications cover a large area including bio-medicine, materials science, chemistry geology and more. We will present the current status of the beamline and an overview of the science addressed at the beamline.

Design of 4D x-ray tomography experiments based on reconstruction analysis *(Invited Paper)*

K. Aditya Mohan, Lawrence Livermore National Lab. (United States)

4D computed tomography (4DCT) using X-rays is widely used to perform non-destructive characterization of time varying physical processes in material and biological samples. The conventional approach to improving temporal resolution in 4DCT revolves around developing expensive and complex instrumentation that acquire views faster with reduced noise. It is customary to acquire fully sampled data that satisfy the Nyquist sampling criteria at a high signal to noise ratio. This approach is sub-optimal as there exist advanced iterative algorithms that are less sensitive to noise and limited data but can benefit from optimization of other experimental parameters. Guided by quantitative analysis of the sample reconstruction, these algorithms allow us to achieve significant gains by optimizing the view sampling strategy while reducing the number of view angles and/or the detector exposure time. Such algorithms can be formulated using the framework of model-based iterative reconstruction (MBIR). Most of the existing and widely used iterative algorithms can also be described and analyzed using the MBIR framework. This talk discusses the design of 4DCT experiments based on analysis of sample reconstructions.

10391-30, Session 7

Reduction of metal artifacts in x-ray CT images using fully convolutional networks

Yanbo Zhang, Ying Chu, Hengyong Yu, Univ. of Massachusetts Lowell (United States)

Patients usually contain various metallic implants (e.g. dental fillings, prostheses), causing severe artifacts in x-ray CT images. Although a large number of metal artifact reduction (MAR) methods have been proposed in the past four decades, MAR is still one of the major problems in clinical x-ray CT. Recently, deep learning methods have been successfully applied to various fields, where fully convolutional networks (FCN) is a powerful tool for semantic segmentation. In this work, we apply FCN to reduce metal artifacts. In specific, our method includes three consecutive steps. First, metals are segmented from the original uncorrected CT images, and a pre-correction procedure (e.g. linear interpolation) is carried out. Then, the original CT image, the pre-corrected image and the segmented metal image are combined as a multi-channel image. It is segmented into different types of tissues using FCN to generate a prior image. Finally, the metal contaminated projections are replaced by the forward projection of the prior image, and the corrected image is reconstructed. The merits of the proposed approach are threefold. First, this method is able to combine useful information in both the original and pre-corrected images. Second, because this method is based on big data, the larger the training database is, the better the artifacts removal performance is. Third, different from other MAR methods, the proposed algorithm is in an open framework, and the performance can be further improved by introducing other MAR corrected results into the multi-channel image. Our results show that the proposed method can remarkably suppress metal artifacts and avoid introducing new artifacts

10391-31, Session 7

Deep learning methods for CT image-domain metal artifact reduction

Lars Gjesteby, Qingsong Yang, Rensselaer Polytechnic Institute (United States); Yan Xi, Shanghai Jiao Tong Univ. (United States); Bernhard E. H. Claus, Yannan Jin, Bruno De Man, GE Global Research (United States); Ge Wang, Rensselaer Polytechnic Institute (United States)

Artifacts resulting from metal objects have been a persistent problem in computed tomography (CT) images over the last four decades. A common approach to overcome their effects is to replace corrupt projection data with values synthesized from an interpolation scheme or by reprojection of a prior image. Then, reconstruction of the corrected data is expected to yield better image quality than the original reconstructed image. A state-of-the-art interpolation and normalization-based algorithm is NMAR. In some clinical applications, methods like NMAR still do not produce sufficient results. Residual artifacts remain in challenging cases and even new artifacts can be introduced by the interpolation scheme. Radiation therapy planning is one task that is very sensitive to image reconstruction errors due to the high image quality needed for accurate tumor volume estimation. A possible new solution to the long-standing metal artifact reduction (MAR) problem is deep learning, which has been successfully applied to medical image processing and analysis tasks. Deep networks have the ability to extract detailed features from large datasets to map an input to an output. In this study, we combine a convolutional neural network (CNN) with the state-of-the-art NMAR algorithm to reduce metal streaks in critical image regions. The CNN is able to map metal-corrupted images to artifact-free monoenergetic images to achieve additional correction on top of NMAR for improved image quality. Our results indicate that deep learning is a novel tool to address CT reconstruction challenges, and may enable more accurate tumor volume estimation for radiation therapy planning.

10391-32, Session 7

Sliding ordered-subset algorithm for real-time x-ray tomography *(Invited Paper)*

Doga Gürsoy, Tekin Bicer, Daniel Ching, Vincent De Andrade, Argonne National Lab. (United States)

As the sophistication and speed of today's experiments grow, collecting the most informative data become of great relevance, necessitating development of algorithms that can provide good quality reconstructions from data streams. However, almost all conventional reconstruction algorithms work exclusively off-line, requiring for complete data to be collected and available before they can successfully be applied. We describe here a streaming algorithm, based on sliding ordered-subsets, and present our first tests of using it on tomography datasets generated at the Advanced Photon Source. We will also evaluate the quality of reconstructions live using multiple quality metrics, as data are being collected, and discuss ways of steering experiment based on the information gained during acquisition.

10391-33, Session 8

Recent Advance in grating-based x-ray phase tomography *(Invited Paper)*

Atsushi Momose, Tohoku Univ. (Japan) and Japan Science and Technology Agency (Japan) and Japan Synchrotron Radiation Research Institute (JASRI) (Japan); Hidekazu Takano, Tohoku Univ. (Japan) and Japan Science and Technology Agency (Japan); Yanlin Wu, Tohoku Univ. (Japan) and Japan Synchrotron Radiation Research Institute (JASRI) (Japan); Masato Hoshino, Japan Synchrotron Radiation Research Institute (JASRI) (Japan) and Japan Science and Technology Agency (Japan)

X-ray phase tomography based on grating interferometry is attractive because of its flexible optical configuration and the potential of various applications even with laboratory X-ray sources other than synchrotron radiation. Since grating interferometers functions with X-rays of a broad energy band, polychromatic X-rays are used for high-speed or four-dimensional X-ray phase tomography. We have recently installed a multilayer bandpass fileter to produce a pink beam sutable for a Talbot

interferometer at BL28B2, SPring-8. Pilot experimental results of four-dimensional X-ray phase tomography will be presented for revealing dynamical properties of samples, for instance under laser irradiation. Another activity is the development of nanoscopic phase tomography by comging FZP-based X-ray full-field microscopes and gratings both at SPring-8 and laboratory. An X-ray microscope with a spatial resolution around 200 nm with a field of view of 300 μm has been constructed at BL37XU, SPring-8. High-resolution phase tomograms of mouse bone samples will be presented. Another X-ray microscope (Zeiss Xradia 800 Ultra), whose best spatial resolution is 50 nm, has been combined with a Lau interferometer. The system is operated with an incoherent X-ray source at laboratory, and a twin phaes image rather than a differential phase image is obtained. A special algorithm is developed for generating a single phase image from the twin image, and a pilot result of nanoscopic phase tomography at laboratory will be presented.

10391-34, Session 8

Thomson scattering x-ray source: a novel tool for x-ray imaging *(Invited Paper)*

Yingchao Du, Zhijun Chi, Chuanxiang Tang, Wenhui Huang, Lixin Yan, Zhen Zhang, Tsinghua Univ. (China)

As a powerful complement of large scale synchrotron radiation and free electron laser (FEL) facilities, Thomson scattering x-ray source, also called inverse Compton scattering x-ray source, can produce quasi-monochromatic, continuously tunable, high brightness, small spot size, polarization precisely controllable, and ultrashort (ps or sub-ps) x-ray pulse in the energy regime ranging from tens keV to several MeV or even higher. The excellent beam quality combined with room scale or tabletop footprint and relative low cost provides the prospect for and will help to prosper a myriad of x-ray imaging applications, such as mono-chromatic, dual-energy and multi-energy computed tomography (CT), phase-contrast imaging and phase-contrast CT, x-ray fluorescence (XRF) or nuclear resonance fluorescence (NRF) analysis, pump-probe diagnostic of ultrafast processes, and new dimensional x-ray imaging (e.g. charge and spin orientation) with further use of the straightforward controllable polarization. In this paper, we will introduce recent progress of x-ray imaging based on Tsinghua Thomson scattering X-ray source (TTX). Based on the mono-chromaticity of x-rays generated by Thomson light source, beam hardening effect seen with commercial polychromatic x-ray source can be resolved fundamentally, and quantitative CT becomes possible. Monochromatic CT of a peanut (Arachis hypogaea L.) has been reconstructed, and different compositions of the peanut have been segmented by quantitative analysis of reconstructed attenuation coefficients. Taking advantage of the continuous tunable x-rays, dual energy x-ray imaging has been carried out, and the effective atomic numbers (i.e. Zeff) of different materials have been retrieved and compared with theoretical values. Since the small spot size of Thomson light source makes the x-ray pulse highly spatially coherent, phase-contrast x-ray imaging (PCI) of different sample (e.g. shrimp, fish, and peanut) and preliminary phase-contrast CT imaging of a simple Teflon sample have been accomplished. Clear edge-enhancement effect has been witnessed in in-line PCI, which provides an exact way for interface diagnosis between different materials. Besides, XRF imaging has also been carried out to quantitatively analyze the content of some trace elements. Our results demonstrate the potential of Thomson scattering x-ray source for a variety of x-ray imaging, and pave the way towards practical application of this type of x-ray source, such as preclinical radiography and tomography, and industrial material analysis.

10391-35, Session 8

High spatial resolution x-ray phase tomography based on laboratory source

Hidekazu Takano, Yanlin Wu, Atsushi Momose, Tohoku Univ. (Japan)

X-ray microscopy is important technique for X-ray tomography to increase the spatial resolution. Also, phase-contrast technique is important to increase the sensitivity. We developed phase quantitative method by using grating interferometer, and combined it to full-field X-ray microscope. These techniques are capable to apply for laboratory-based optics by introducing Lau interferometer.

Zeiss Xradia 800 Ultra, which can achieve 50 nm resolution with a laboratory source of Cu target, is adopted as a basic microscope to be installed the interferometer. The Lau interferometer consists of an absorption grating (G0) and a ϖ/2 phase grating (G1). G0, set in front of sample, is formed an image by the microscope objective. It functions as a source array to yield a spatial coherence. G1, set at behind of the image of G0, is magnified and projected on detector, which is set to form the self-image G1 by Talbot effect. The parameters are optimized so that the self-image projected by each source overlaps in phase. As the results, interference fringes with visibility better than 0.6 were obtained. By conventional fringe scanning procedure, phase-differential image, which is superposition of a separated image with opposite contrast, is obtained. Phase quantitative image can be retrieved by calculation, and the optical system can be applied for phase tomography.

In the presentation, we will introduce about results of evaluation in spatial resolution and sensitivity, and CT images with high resolution.

10391-36, Session 8

Seeing inhomogeneous buried layers and interfaces: image reconstruction from x-ray reflection projections *(Invited Paper)*

Jinxing Jiang, Univ. of Tsukuba (Japan) and National Institute for Materials Science (Japan); Keiichi Hirano, High Energy Accelerator Research Organization, KEK (Japan); Kenji Sakurai, National Institute for Materials Science (Japan) and Univ. of Tsukuba (Japan)

Exotic functions of thin films are quite often connected to the unique atomic and molecular features of buried layers and interfaces. In reality, they are far from uniform, but seeing such inhomogeneity is extremely difficult. The present talk describes how we have solved the difficulties. The novel technique developed is the X-ray reflectivity imaging. Ordinary X-ray reflectivity gives very precise information such as the number of layers, the density and the thickness of each layer, and the roughness of each interface. The method can have imaging capability, by combining with the image reconstruction scheme. While the illuminated area size is around 8 mm x 8mm, the obtained typical spatial resolution is below 20 micron. The inhomogeneity can be quantitatively imaged with very high depth-resolution of the order of Å. The present method can also provide X-ray reflectivity data for all points in the viewing area, even without the use of micro beam. Not only instrumental details but also many practical application will be reported.

10391-47, Session PWed

Development of high-energy micro-tomography system at SPring-8

Kentaro Uesugi, Masato Hoshino, Japan Synchrotron Radiation Research Institute (JASRI) (Japan)

A high energy X-ray micro-tomography system has been developed at BL20B2 in SPring-8. The available range of the energy is between 20keV and 113keV. The system enables us to image large or heavy materials such as fossils. The X-ray image detector consists of visible light conversion system and sCMOS camera. The effective pixel size is variable by changing a tandem lens between 12.2um/pixel to 25.5um/pixel discretely. The format of the camera is 2048 pixels x 2048 pixels.

As a demonstration of the system, a nodule from Bolivia was imaged. The experimental conditions are follows, X-ray energy: 73keV, exposure time: 200msec, number of projections: 900, single scan time: 20min, pixel size: 31um/pixel (2x2 binning mode) and field of view: 31.0mm x 5mm. The field of view is restricted by the beam size.

A Trilobite and some other fossils were successfully imaged without breaking the fossil.

At the conference, the detail of the system and some demonstration will be shown.

Spectral CT material decomposition in the presence of poisson noise: a KL approach

Tom Hohweiller, Nicolas Ducros, CREATIS (France); Françoise Peyrin, CREATIS (France) and ESRF - The European Synchrotron (France); Bruno Sixou, CREATIS (France)

Spectral computed tomography (SPCT) is a new imaging modality able to measure the energy of the X-rays hitting the detector. This new information allows to identify the materials in an object since the attenuation of any atomic element depends on energy. A large number of methods have been proposed for SPCT. A conventional approach is to perform a decomposition step, followed by standard tomographic reconstructions of the decomposed projections.

Our group recently introduced a regularized weighted least square (WLS) decomposition algorithm that allows material-specific regularization of the projection images. However, the WLS data fidelity term is not optimal when low counts are measured in some of the energy bins of the detector.

In this work, we evaluate a data fidelity term based on the Kullback-Leibler (KL) distance, which is the metric adapted to Poisson noise. A nonlinear image formation model is considered. The cost function is minimized iteratively using the Gauss-Newton (GN) method. Our nonlinear KL-GN decomposition algorithm is evaluated on a numerical mouse phantom with two materials, namely soft tissue and bone. Our results show that the KL distance is more effective than the WLS data fidelity. For the same amount of time, it provides reduced material error when low numbers of photon counts are available. We also show that accurate 3D map of each material can be reconstructed from the decomposed projections.

Evaluating the precision of intraoral scans by means of micro-computed tomography measurements and three-dimensional rigid registration

Christoph Vögtlin, Georg Schulz, Kurt Jäger, Univ. Basel (Switzerland); Dieter Müssig, Danube Private Univ. (DPU) (Austria); Bert Müller, Univ. Basel (Switzerland)

The preparation of prosthetic restorations and orthodontics appliances requires three-dimensional data on the patient's dentition. Previously, the dentition was replicated using impressions with dedicated mold materials. The disadvantages of the approach relate to the unfavorable flavor of the impression materials and the human choke impulse. In order to overcome these discomforts, the dentists currently employ scanners, which provide digital impressions of the patient's dentition. With these digital data the dentist simplifies the workflow and can reduce the costs. Many dentists, however, are afraid that the accuracy of the present oral scanners does not reach the precision of the replicas using the well-established, conventional protocol. In the present study, we investigate the accuracy of the intraoral scanner "True Definition Scanner" (3M Espe, Seefeld, Germany) taking advantage of high-resolution tomography. For this purpose, we produced five reference models with constant transversal dimension. We have considered five situations in the front region, which were scanned for three times. The reference models were imaged using the tomography system nanotom® m (GE Sensing & Inspection Technologies, Wunstdorf, Germany). The obtained 15 data sets were rigidly registered to the data of reference to extract parameters such as the mean and maximal deviations in order to characterize the precision of the oral scanners. Preliminary results indicate that the intraoral scanner used in the present study reaches a precision comparable to the conventional protocol.

10391-50, Session PWed

Characterization of a spectroscopic detector for application in x-ray computed tomography

Alex A. Dooraghi, Brian J. Fix, Jerel A. Smith, William D. Brown, Stephen G. Azevedo, Harry E. Martz, Lawrence Livermore National Lab. (United States)

Recent advances in cadmium telluride (CdTe) energy-discriminating pixelated detectors have enabled the possibility of Multi-Spectral X-ray Computed Tomography (MSXCT) to incorporate spectroscopic information into CT. MultiX ME 100 V2 is a CdTe-based spectroscopic x-ray detector array capable of recording energies from 20 to 160 keV in 1.1 keV energy bin increments. Hardware and software have been designed to perform radiographic and computed tomography tasks with this spectroscopic detector. Energy calibration is examined using the end-point energy of a bremsstrahlung spectrum and radioisotope spectral lines. When measuring the spectrum from Am-241 across 500 detector elements, the standard deviation of the peak-location and FWHM measurements are ±0.4 and ±0.6 keV, respectively. As these values are within the energy bin size (1.1 keV), detector elements are consistent with each other. The count rate is characterized, using a nonparalyzable model with a dead time of 64 ± 5 ns. This is consistent with the manufacturer's quoted per detector-element linear-deviation at 2 Mpps (million photons per sec) of 8.9% (typical) and 12% (max). When comparing measured and simulated spectra, a low-energy tail is visible in the measured data due to the spectral response of the detector. If no valid photon detections are expected in the low-energy tail, then a background subtraction may be applied to allow for a possible first-order correction. If photons are expected in the low-energy tail, a detailed model must be implemented. A radiograph of an aluminum step wedge with a maximum height of about 20 mm shows an underestimation of attenuation by about 10% at 60 keV. This error is due to partial energy deposition from higher-energy (> 60 keV) photons into a lower-energy (~60 keV) bin, reducing the apparent attenuation. A radiograph of a PTFE cylinder taken using a bremsstrahlung spectrum from an x-ray voltage of 100 kV filtered by 1.3 mm Cu is reconstructed using Abel inversion. As no counts are expected in the low energy tail, a first order background correction is applied to the spectrum. The measured linear attenuation coefficient (LAC) is within 10% of the expected value in the 60 to 100 keV range. Below 60 keV, low counts in the corrected spectrum and partial energy deposition from incident photons of energy greater than 60 keV into energy bins below 60 keV impact the LAC measurements. This report ends with a demonstration of the tomographic capability of the system. The quantitative understanding of the detector developed in this report will enable further study in evaluating the system for characterization of an object's chemical make-up for industrial and security purposes.

10391-51, Session PWed

Integrated high-throughput tomography experiment control environment

Igor Khokhriakov, Felix Beckmann, Lars Lottermoser, Helmholtz-Zentrum Geesthacht (Germany)

The initial design and implementation of such system was presented in the SPIE publication in 2014 [Proc. SPIE 9212, Developments in X-Ray Tomography IX, 921217]. In this paper an update to the system is presented. The paper will cover the following 4 topics. The first topic simply gives an overview of the system. The second topic presents the way how we integrate different software components to achieve simplicity and flexibility. As it is still in research and design phase we need a possibility to easily adjust the system to our needs introducing new components or removing old ones. The third topic presents a hardware driven tomography experiment design implemented at one of our beamlines. The basic idea is

that a hardware signal is sent to the instrument hardware (camera, shutter etc). This signal is emitted by the controller of the sample axis which defines the moment when the system is ready to capture the next image, i.e. next rotation angle. Finally as our software is in a constant process of evaluation a continuous integration process was implemented to reduce the time cost of redeployment and configuration of new versions.

10391-52, Session PWed

Innervation of the cow's inner ear derived from micro-computed tomography data

Loic Costeur, Bastien Mennecart, Naturhistorisches Museum Basel (Switzerland); Anna Khimchenko, Bert Müller, Georg Schulz, Univ. Basel (Switzerland)

The innervation of the inner ear has been thoroughly investigated in humans as well as in animal models including guinea pig, rabbit, cat, dog, rat, pig, and some monkeys. Ruminant inner ears are still poorly known. Despite the potential interest in phylogenetic reconstructions, the innervation was never investigated. Following earlier work on the ontogeny of the cow's ear (Costeur et al., 2016b), we expand our understanding of this delicate structure by reconstructing the fine innervation pattern of the inner ear of the cow in two ontogenetic stages, at seven months gestation and at an adult age. The micro computed tomography data were obtained using the advanced μCT-system nanotom m with a pixel length of 45 μm, an acceleration voltage of 120 kV and the electron beam current of 200 μA. Since we work on dry skeletal specimens, only the endocast of the innervation inside the petrosal bone was reconstructed up to the internal acoustic meatus. The facial and vestibulocochlear nerves could be reconstructed together with the spiral ganglion canal. The nerves have a fibrous pattern. The ampular and utricular branches of the vestibulocochlear nerve could also be reconstructed. Comparisons to the pattern in pig, another Artiodactyla and the closest animal for which the structure is known will be given. Preliminary observations indicate similar anatomical features known from pig.

L. Costeur, B. Mennecart, B. Müller, G. Schulz, Prenatal growth stages show the development of the ruminant bony labyrinth and petrosal bone, Journal of Anatomy 230 (2017) 347-353.

Sparse reconstruction methods in x-ray CT *(Invited Paper)*

Juan Felipe Perez Juste Abascal, Univ. de Lyon (France) and Univ. Jean Monnet Saint-Etienne (France) and CREATIS (France); Monica Abella, Univ. Carlos III de Madrid (Spain) and Instituto de Investigación Sanitaría Gregorio Marañón (Spain); Cyril Mory, Univ. de Lyon (France) and Univ. Jean Monnet Saint-Etienne (France) and CREATIS (France); Claudia de Molina, Univ. Carlos III de Madrid (Spain) and Instituto de Investigación Sanitaría Gregorio Marañón (Spain); Nicolas Ducros, Institut National des Sciences Appliquées de Lyon (France) and Univ. de Lyon (France) and Univ. Jean Monnet Saint-Etienne (France); Eugenio Marinetto, Univ. Carlos III de Madrid (Spain) and Instituto de Investigación Sanitaría Gregorio Marañón (Spain); Françoise Peyrin, CREATIS (France) and Univ. de Lyon (France) and Univ. Jean Monnet Saint-Etienne (France); Manuel Desco, Univ. Carlos III de Madrid (Spain) and Instituto de Investigación Sanitaría Gregorio Marañón (Spain) and Ctr. de Investigación en Red de Salud Mental (Spain)

Recent progress in X-ray CT is contributing to the advent of new clinical applications. A common challenge for these applications is the need for new image reconstruction methods that meet tight constraints in radiation dose and geometrical limitations in the acquisition. The recent developments in sparse reconstruction methods provide a framework that permit obtaining good quality images from drastically reduced signal-to-noise-ratio and limited-view data.

In this work, we present our contributions in this field. For dynamic studies (3D+Time), we have explored the possibility of extending the exploitation of sparsity to the temporal dimension: a temporal operator based on modelling motion between consecutive temporal points in gated-CT and based on experimental time curves in contrast-enhanced CT. In these cases, we also exploited sparsity by using a prior image estimated from the complete acquired dataset and assessed the effect on image quality of using different sparsity operators. For limited-angle CT, we evaluated the viability of exploiting sparsity on the spatial domain to use a convectional radiology system as a tomograph. For other emerging imaging modalities, such as spectral CT, the image reconstruction problem is nonlinear, so we are exploring new efficient approaches to exploit sparsity for multi-energy CT data.

In conclusion, we review our approaches to challenging CT data reconstruction problems and show results that support the feasibility for new clinical applications.

10391-38, Session 9

Spectral CT data reduction for material classification

Mina Kheirabadi, Wail Mustafa, Technical Univ. of Denmark (Denmark); Mark Lyksborg, Fingerprint Cards (Denmark); Ulrik Lund Olsen, Anders Bjorholm Dahl, Technical Univ. of Denmark (Denmark)

In the recent years, using of detectors which are able to allow imaging of many channels at once has been popular in many applications such as medical and security. They provide higher and more accurate discrimination for chemical component of materials. In this paper, we work with data acquired using MULTIX detectors that can give us the information for 128 different energy beams. It is clear that although the reconstruction of all channels of energy can reduce the number of errors in process of recognition of materials but on the other hand it can also be time consuming in the most of cases. Therefore, to ease the process of reconstruction, we can reduce the channels of energy as long as the large amount of information is not lost. We apply classical multi dimensional scaling for reduction of channels of energy which is followed by reconstruction using an iterative algebraic reconstruction (Kaczmarz method) with a total variation regularization. We will analysis the method for the data included aluminum and four liquids, i.e. water, hydrogen peroxide, sucrose solution, Pentaerythritol tetranitrate. We will show that the materials can be distinguished after reduction of energy channels as well as when we consider all of channels of energy. It can be considered an improvement in Multi-spectral CT reconstruction in term of time.

10391-39, Session 9

Removing ring artifacts from synchrotron radiation-based hard x-ray tomography data

Peter Thalmann, Christos Bikis, Georg Schulz, Univ. Basel (Switzerland); Pierre Paleo, Alessandro Mirone, Alexander Rack, ESRF - The European Synchrotron (France); Bert Müller, Univ. Basel (Switzerland)

Indirect detectors which are frequently used in synchrotron radiation-based micro computed tomography (SRμCT) using hard X-rays give rise to ring artifacts, which interfere with image details and reduce the image quality. Such ring artifacts arise, for example, from improperly working detector elements and defects in the scintillator screens such as scratches or dust particles [1]. We propose a method that corrects such artifacts before the

reconstruction algorithm is applied. The main steps of the pipeline are (i) registration of the reference images with the radiographs, (ii) integration of the flat-field corrected projection over the acquisition angle, (iii) high-pass filtering the integrated projection, (iv) subtraction of filtered data from the flat-field corrected projections. One advantage of the algorithm is that it mainly corrects the pixels affected, in comparison to the ones using wavelet-Fourier [2] or median filtering [3]. Furthermore, since the sinograms are mainly locally corrected, the correction method maintains the three-dimensional smoothness of the reconstructed data. The study includes the removal of ring artifacts from μCT-datasets acquired at ID19 (ESRF, Grenoble, France) in phase-contrast mode [4]. The results corroborate the fact that full and partial ring artifacts are effectively removed from the reconstructed slices while preserving the image details and without inducing any gradient in the tomograms.

10391-40, Session 9

Comparison of different phase retrieval algorithms

Rolf Kaufmann, Mathieu Plamondon, Jürgen Hofmann, EMPA (Switzerland)

X-ray phase contrast imaging techniques are developed for numerous applications today, ranging from biomedical research to security scans. First commercial systems are already on the market. Since the phase cannot be measured directly by a conventional detector an indirect method as to be applied, e.g. by a grating interferometer. A common implementation is the Talbot-Lau interferometer, which also works with polychromatic radiation from an industrial X-ray tube. To have enough sensitivity a phase-stepping approach is applied where one of the gratings is slightly shifted between several acquisitions. From such a phase-stepping series of images, typically 4-10, the phase shift of a sample (=phase of the phase-stepping curve), attenuation (=mean value of the phase-stepping curve) and the scattering coefficient (=amplitude of the phase-stepping curve) are extracted. Three different approaches are compared to do so. Besides the usually applied Fourier coefficient method also a fitting technique and series expansion method are applied and compared with respect to speed, accuracy and mechanical error tolerance.

10391-41, Session 9

Nonlinear problems in fast tomography *(Invited Paper)*

William Lionheart, The Univ. of Manchester (United Kingdom)

In this paper we formulate the non-linear problem of monochromatic CT. Of course polychromatic CT is already non-linear due to beam hardening but the important point we make is that it is non-linear even if monochromatic. We calculate the Frechet derivative of the non-linear method and show that it can be solved by a regularized Newton-Kantarovich method. We will include experimental data from the Bergen gamma tomography system to show that we can get quantitatively better images using the non-linear technique. We also show using a MC model that the effect we observe cannot be attributed to scattering. This work will be presented in a paper under preparation in collaboration with the Bergen group.

Non linear problems are common thought a variety of tomographic methods and a similar approach is often effective. As an illustrative example we touch on our work giving the first non-linear reconstructions of magnetic fields using Neutron spin tomography.

I could modify the talk if necessary. Graham wanted me to emphasise fast tomography but I would like to reflect some of my most recent work. However I do not know the interests of the audience.

10391-42, Session 10

Grating-based tomography applications in biomedical engineering *(Invited Paper)*

Georg Schulz, Univ. Basel (Switzerland)

For the investigation of soft tissues or tissues consisting of soft and hard tissues on the microscopic level, hard X-ray phase tomography has become one of the most suitable imaging techniques. Besides other phase contrast methods grating interferometry has the advantage of higher sensitivity than inline methods and the quantitative results. One disadvantage of the conventional double-grating setup (XDGI) compared to inline methods is the limitation of the spatial resolution. This limitation can be overcome by removing the analyser grating resulting in a single-grating setup (XSGI). In order to verify the performance of XSGI concerning contrast and spatial resolution, a quantitative comparison of XSGI and XDGI tomograms of a human nerve was performed. Both techniques provide sufficient contrast to allow for the distinction of tissue types. The spatial resolution of the two-fold binned data sets of (5.2 ± 0.6) μm and (10.7 ± 0.6) μm, respectively, underlies the performance of XSGI in tomography of soft tissues. Another application for grating-based X-ray phase tomography is the simultaneous visualization of soft and hard tissues of a plaque-containing coronary artery. The simultaneous visualization of both tissues is important for the segmentation of the lumen. The segmented data can be used for flow simulations in order to obtain information about the three-dimensional wall shear stress distribution needed for the optimization of mechano-sensitive nanocontainers used for drug delivery.

10391-43, Session 10

Displaying of the human tooth cementum ultrastructure of archeological teeth by non-invasive and high-resolution imaging techniques to determine age-at-death and stress periods

Gabriela Mani-Caplazi, Georg Schulz, Gerhard Hotz, Univ. Basel (Switzerland); Ursula Wittwer-Backofen, Univ. of Freiburg (Germany); Bert Müller, Univ. Basel (Switzerland)

The tooth cementum annulation (TCA) is used by anthropologists to decipher the age-at-death (Wittwer-Backofen 2012) and stress periods based on the yearly deposited incremental lines (Kagerer & Grupe 2001). The destructive aspect of the TCA, which requests to cut the tooth root in sections to display the incremental lines using transmitting light microscopy can be problematic for archaeological teeth and a non-invasive imaging technique would be preferred. The purpose of this study is to evaluate less or non-invasive high resolution 3D imaging techniques including laboratory μCT scanner nanotom® and synchrotron radiation based μCT (SRμCT) to explore the tooth cementum ultrastructure, display the incremental lines and to assess stress markers. Twelve archaeological teeth of the St. Johann hospital cemetery (1845-1868) have been selected for the μCT experiments. The identified skeletons of this collection are considered a worldwide unique reference series in the anthropological science community considering the high level of documented life history data in the medical files and the additionally collected and verified birth history by genealogists (Hotz & Steinke 2012). Before the SRμCT experiments, the specimens were to be measured using the nanotom® in order to select the teeth and to find interesting areas. The preliminary results demonstrate that the μCT and SRμCT display the cementum nanostructure corresponding to the incremental lines in the transmitting light microscope view. Hence these μCT techniques should allow to assess the age-at-death and stress periods in archeological teeth in a non-invasive fashion and display them in a 3D view improving the accuracy of the assessments.

10391-44, Session 10

High-contrast x-ray microtomography in dental research

Graham R. Davis, David Mills, Queen Mary, Univ. of London (United Kingdom)

X-ray microtomography (XMT) is a well-established technique in dental research. Using this technique, much insight has been gained into the complex morphology of the root canal system and to qualitatively and quantitatively evaluate root canal instrumentation and filling efficacy in extracted teeth; enabling different techniques to be compared. Densitometric information can be used to identify and map demineralized tissue resulting from tooth decay (caries) and again, in extracted teeth, the method can be used to evaluate different methods of excavation. More recently, high contrast XMT is being used to investigate the relationship between external insults to teeth and the pulpal reaction. When such insults occur, fluid may flow through dentinal tubules as a result of cracking or porosity in enamel. Over time, there is an increase in mineralization along the paths of the tubules from the pulp to the damaged region in enamel and this can be visualized using high contrast XMT. The scanner used for this employs time-delay integration to minimize the effects of detector inhomogeneity in order to greatly increase the upper limit on signal-to-noise ratio that can be achieved with long exposure times. When enamel cracks are present in extracted teeth, the presence of these pathways indicates that the cracking occurred prior to extraction. At high contrast, growth lines are occasionally seen in deciduous teeth which may have resulted from periods of maternal illness. Various other anomalies in mineralization resulting from trauma or genetic abnormalities can also be investigated using this technique.

10391-45, Session 10

The inside view of 3D photonic nanostructures

Diana A. Grishina, Univ. Twente (Netherlands); Peter Cloetens, ESRF - The European Synchrotron (France); Cornelis A. M. Harteveld, Univ. Twente (Netherlands); Alexandra Pacureanu, ESRF - The European Synchrotron (France); Pepijn W. H. Pinkse, Ad Lagendijk, Willem L. Vos, Univ. Twente (Netherlands)

In nanofabrication, it is important to characterize the structure of a fabricated sample, since optical properties of photonic structures are defined by their complex internal structure. It is particularly challenging to access the inside of the three-dimensional (3D) samples. X-ray techniques are promising tools for nanophotonics, in view of excellent penetration depth, non-destructive character, and nm spatial resolution. Here we study a 3D Si photonic band gap crystal with a cubic diamond-like structure by X-ray tomography.

Our crystals have an inverse woodpile structure that exhibits a complete 3D band gap. The crystals are made in silicon by CMOS-compatible means. Holotomography was performed at the ESRF (beamline ID-16NI): X-rays (17 keV photon energy) are focused before the sample. We collect 1500 images while rotating the crystal from 0 to 180° at four sample-to-detector-distances in Fresnel regime to cover all spatial frequencies. Phase maps are obtained at every angle, followed by tomographic reconstruction to obtain the 3D electron density distribution. We reconstruct the volume of the complete fabricated 3D photonic crystal and its surrounding with 20 nm resolution in a real space. The close inspection of the reconstructed volume reveals new insights for the fabrication process as well as for the optical properties of the nanophotonic structures. We conclude that 3D X-ray tomography has great potential to solve many future questions on optical metamaterials for much nanophotonic research and applications, including cavity arrays, physically unclonable functions, and precise localization of light emitters as qubits and for enhanced lighting efficiency.

10391-46, Session 10

Recovery of text from locked 17th-century letters

David Mills, Graham R. Davis, Queen Mary, Univ. of London (United Kingdom)

The Brienne letters archive offers a snapshot of life in the 17th century preserved in the undelivered letters of people of Europe. The archive has remained virtually untouched by historians until it was recently rediscovered. The letters are uncensored, unedited, and around 600 of them even remain unopened.

The letters pre-date the invention of the gummed envelope, so they have been folded and manipulated such that they form their own protective carriers. Very few historical letters are available in the un-opened state to investigate this letter locking technique.

It is these unopened letters we are imaging with high contrast X-Ray microtomography with the dual intention of revealing the writing inside without opening the letters and also to study the structue of the letters and their seals to revel metadata about the letter's authors.

Conference 10392: Hard X-Ray, Gamma-Ray, and Neutron Detector Physics XIX

Monday - Wednesday 7 –9 August 2017

Part of Proceedings of SPIE Vol. 10392 Hard X-Ray, Gamma-Ray, and Neutron Detector Physics XIX

10392-1, Session 1

History and current status of strontium iodide scintillators *(Invited Paper)*

Nerine J. Cherepy, Patrick R. Beck, Stephen A. Payne, Erik L. Swanberg, Peter A. Thelin, Scott E. Fisher, Steven L. Hunter, Brian Wihl, Lawrence Livermore National Lab. (United States); Arnold Burger, Fisk Univ. (United States); Kanai S. Shah, Rastgo Hawrami, Radiation Monitoring Devices, Inc. (United States); Lynn A. Boatner, Oak Ridge National Lab. (United States); Michael Momayezi, Bridgeport Instruments, LLC (United States); Kevin T. Stevens, Mark H. Randles, Denys Solodovnikov, Northrop Grumman SYNOPTICS (United States)

Since its discovery in 2008, the Europium-doped Strontium Iodide scintillator, SrI2(Eu), has become commercialized and is available from several companies worldwide. SrI2(Eu) offers high proportional light yield (>80,000 ph/MeV), high effective atomic number (Z=49), and relatively easy growth from melt due to is moderate melting point (5380C). High, uniform, proportional light yield requires single crystals which for uniform solid solutions with the activator concentration, as may be obtained for Cerium in Lanthanum Bromide, LaBr3(Ce) and Europium in Strontium Iodide, SrI2(Eu), in both cases the dopant having matched ionic radii with the host.

Establishment of high quality crystal growth feedstock has been key to decreasing the cost of SrI2(Eu) crystal growth and increasing yield of uncracked boules. Recently, high quality 1.5" and 2" diameter encapsulated crystals have become commercially available for integration of SrI2(Eu) into gamma spectrometers providing high resolution and no intrinsic radioactivity. Light-trapping by the Eu2+ dopant may be addressed by: (1) the use of a physical taper, where the top of the crystal has a slight taper for uniform light collection, and (2) the use of on-the-fly correction of scintillation pulses by digital readout electronics. With the digital correction technique, we have demonstrated reproducible energy resolution of R(662 keV) = 2.9% FWHM for multiple 2.5-4 in3 SrI2(Eu) crystals. Based on the digital readout technology, we have developed a detector prototype with greatly improved radioisotope identification capability compared to NaI(Tl).

10392-2, Session 1

Organic spectroscopic scintillators based on nanoparticles *(Invited Paper)*

Qibing Pei, Univ. of California, Los Angeles (United States)

Spectroscopic gamma-photon detection has widespread applications for research, defense and medical purposes. The dominant materials for the detection have been inorganic semiconductors, scintillation crystals, and plastics that are either prohibitively expensive for wide deployment or cannot produce characteristic gamma photopeak. We report the synthesis of transparent, ultra-high-loading (up to 60 wt%) nanoparticle/polymer nanocomposite monoliths for gamma scintillation. The energy transfer of the high-atomic-number nanoparticles to lower-band-gap organic dyes was studied relative to light yield. One nanocomposite system was demonstrated exhibiting simultaneous enhancements in both light yield and gamma attenuation. Synthesis of transparent monoliths capable of producing 662 keV gamma photopeak will be described.

10392-3, Session 1

Plastic scintillator enhancement through QD

Alan Tam, Mikael Nilsson, Univ. of California, Irvine (United States)

Enhancement of PVT scintillating polymer was observed under ionization radiation by suspension of nano-crystalline quantum dots under Förster-type energy transfer. Plastic polymers has the ability to be modified by loading various kinds of dopant to reinforce scintillation property. By loading scintillating polymer with luminescence nanoparticles, particularly wavelength tunable quantum dot, it is possible to shift the primary scintillation emission to the quantum dot through Förster Resonance Energy Transfer (FRET) and enhance scintillation. Unlike conventional wavelength shifters where energy transfers is done by emission and absorption, FRET is a non-radiative transfer between the donor and acceptor. As we observed, primary emission was shifted from PPO's emission at 360 nm to the oleic acid coated CdS quantum dot's emission at 426 nm under high UV excitation while the transfer effect was absent below an excitation threshold. Scintillation fluorescence of PPO with CdS loading at 0.5 wt% was enhanced by 2 to 5 times depending on the beta and gamma energy. A change in energy spectroscopy was also observed with a strong contrast from beta radio luminescence with presence of an energy partition. Even though QD can be seen as a moderate high Z material the low loading have limited impact as a gamma sensitizer in the polymer with small deviations in the gamma spectrum.

10392-4, Session 1

Design and development of position sensitive detector for hard x-ray using SiPM and new-generation scintillators

Shiv Kumar Goyal, Physical Research Lab. (India); Amisha P. Naik, Nirma Univ. (India); Santosh Vadawale, Mithun N. P. S., Neeraj K. Tiwari, Physical Research Lab. (India); Tanmoy Chattopadhyay, The Pennsylvania State Univ. (United States)

Silicon Photomultiplier (SiPM) is a new development in the field of photon detection and can be described as 2D array of small (hundreds of μm2) avalanche photodiodes. SiPM is a linear amplifier device, where the amount of output charge is linearly proportional to the number of incoming photons, as long as these numbers of incoming photons does not exceed the total number of APDs in detection area. SiPM is an alternate option of using conventional PMTs (Photo Multiplier Tubes), as this offers comparable photon detection efficiency, small size, feasibility of compact array, low cost, low operating voltage and insensitivity to the external magnetic field.

Here, we are developing a hard X - ray imaging detector using Scintillator and SiPM devices. In our experiment, we are using CeBr3 Scintillator crystals of size 25 mm x 25 mm x 5 mm, which is optically coupled to SiPM array of size 6 x 6. These SiPMs are SensL make, surface mount device of total size 4 mm x 4 mm with an active area of 3 mm x 3 mm. We are using this setup in two different modes; 1) Total charge output of all SiPMs added together to get the energy information. 2) In the imaging mode to get the X - Y position of the incoming X - ray. The readout of the SiPM is carried out using IDEAS make ASIC. ASIC has 64 channels independent analog readout for the SiPM with input charge range from -20pC to +55pC.

We will present the preliminary results from the experiment for low energy threshold and the achieved position accuracy. We also provide the comparison using CsI scintillator, readout using same SiPMs.

10392-5, Session 2

Implementation of accelerated crucible rotation (ACRT) in vertical Bridgman growth of CdZnTe *(Invited Paper)*

Kelvin G. Lynn, Washington State Univ. (United States); Jeffery J. Derby, Univ. of Minnesota (United States); Jedidiah J. McCoy, Saketh Kakkireni, Santosh K. Swain, Washington State Univ. (United States); Mia S. Divecha, Univ. of Minnesota (United States)

Modified vertical Bridgman based melt growth techniques have several advantages such as fast growth rates and provision for stoichiometry control, however, issues such as secondary phase particles, inhomogeneous zinc distribution and polycrystallinity are common. These issues originate due to growth instabilities triggered by thermal and compositional fluctuations near the solidification front. This paper will investigate the effect of accelerated crucible rotation in minimizing growth instabilities by promoting favorable flow patterns and melt mixing during CZT growth. A number of ACRT growth experiments with varying acceleration, deceleration and melt stoichiometry were performed. Highly uniform axial zinc distribution within 2% of the intended zinc concentration was obtained over the entire boule length. Solidification from a highly off stoichiometric melt (7.5 weight % excess Te) generally resulted in better carrier transport with resistivity >1010 ohm.cm and µ?e >10-3 cm2/V in planar detectors. In addition, the high excess tellurium growths were reproducibly better in terms of second phase particle size distribution. High single crystal yield was obtained in ACRT growths with growth rates exceeding 2mm/hr from a highly tellurium rich melt by implementing boron nitride crucible.

10392-6, Session 2

Spatial calibration of the CdZnTe hard x-ray detectors for textit{NuSTAR}

Brian W. Grefenstette, California Institute of Technology (United States); Varun Bhalerao, Indian Institute of Technology Bombay (India); Fiona A. Harrison, Kristin K Madsen, Hiromasa Miyasaka, Peter Mao, Vikram R. Rana, California Institute of Technology (United States)

Pixelated Cadmium Zinc Telluride (CdZnTe) detectors are currently flying on the Nuclear Spectroscopic Telescope ARray (NuSTAR) NASA Astrophysics Small Explorer. While the pixel pitch of the detectors is $approx$ 605 mum, we can leverage the detector readout architecture to determine the interaction location of an individual photon to much higher spatial accuracy. The sub-pixel spatial location allows us to finely oversample the point spread function of the optics and reduces imaging artifacts due to pixelation. In this paper we demonstrate how the sub-pixel information is obtained, how the detectors were calibrated, and provide in-orbit performance results.

10392-7, Session 2

Electronic and thermodynamic properties of CdZnTeSe alloys from first-principles calculations: candidate room temperature radiation detector materials

Joel B. Varley, Vincenzo Lordi, Lawrence Livermore National Lab. (United States); Utpal N. Roy, Brookhaven National Lab. (United States); Ralph B. James, Savannah River National Lab. (United States)

Room temperature gamma detectors based on Cadmium Zinc Telluride (Cd1–xZnxTe or CZT) have demonstrated the favorable charge transport properties and technological potential of these alloys. However, difficulties in achieving large, uniform CZT single crystals have limited the widespread adoption of CZT detectors due to higher costs from low yields. One solution is the incorporation of Se into CZT, which has recently been shown to improve the homogeneity and charge collection efficiency of CZT-based detectors by decreasing the concentration of Te precipitates and inclusions and sub-grain boundary networks in the crystals. Despite the promise of these alloys, an understanding of how the Se incorporation influences the electronic properties of CZT is lacking. Here we use hybrid functional calculations to computationally assess the properties of Cd1–xZnxTe1–ySey (CZTS) alloys as a function of composition to improve the development of alloys with favorable electronic properties. Our calculations characterize the band gaps, band edges, and thermodynamic properties of the solid solutions over the entire quaternary space and identify compositions that are candidate alternative alloys to pure CZT.

Prepared by LLNL under Contract DE-AC52-07NA27344 and funded by the U.S. DOE/NNSA Office of Defense Nuclear Nonproliferation R&D.

10392-8, Session 3

Towards the development of a SiPM-based module for the camera of the Schwarzschild-Couder Telescope prototype of the Cherenkov Telescope Array

Giovanni Ambrosi, Michelangelo Ambrosio, Carla Aramo, Istituto Nazionale di Fisica Nucleare (Italy); Elisabetta Bissaldi, Politecnico di Bari (Italy) and Istituto Nazionale di Fisica Nucleare (Italy); Alfonso Boiano, Carmela Bonavolontà, Istituto Nazionale di Fisica Nucleare (Italy); Leonardo Di Venere, Univ. degli Studi di Bari Aldo Moro (Italy) and Istituto Nazionale di Fisica Nucleare (Italy); Emanuele Fiandrini, Univ. degli Studi di Perugia (Italy) and Istituto Nazionale di Fisica Nucleare (Italy); Nicola Giglietto, Politecnico di Bari (Italy) and Istituto Nazionale di Fisica Nucleare (Italy); Francesco Giordano, Univ. degli Studi di Bari Aldo Moro (Italy) and Istituto Nazionale di Fisica Nucleare (Italy); Maria Ionica, Univ. degli Studi di Perugia (Italy); Francesco Licciulli, Istituto Nazionale di Fisica Nucleare (Italy); Serena Loporchio, Univ. degli Studi di Bari Aldo Moro (Italy); Vincenzo Masone, Istituto Nazionale di Fisica Nucleare (Italy); Riccardo Paoletti, Univ. degli Studi di Siena (Italy) and Istituto Nazionale di Fisica Nucleare (Italy); Vasile Postolache, Istituto Nazionale di Fisica Nucleare (Italy); Andrea Rugliancich, Univ. degli Studi di Siena (Italy) and Istituto Nazionale di Fisica Nucleare (Italy); Daniela Simone, Istituto Nazionale di Fisica Nucleare (Italy); Valerio Vagelli, Univ. degli Studi di Perugia (Italy) and Istituto Nazionale di Fisica Nucleare (Italy); Massimo Valentino, Consiglio Nazionale delle Ricerche (Italy) and Istituto Nazionale di Fisica Nucleare (Italy)

The Italian Institute of Nuclear Physics (INFN) is currently involved in the development of a prototype for a camera based on Silicon Photomultipliers (SiPMs) for the Cherenkov Telescope Array (CTA), a new generation of telescopes for ground-based gamma-ray astronomy. In recent years, SiPMs have proven to be highly suitable devices for applications where high sensitivity to low-intensity light and fast responses are required. Among their many advantages are their low operational voltage when compared with classical photomultiplier tubes, mechanical robustness, and increased photo-detection efficiency (PDE). Moreover, due to the possibility of operating them during bright moonlight, SiPMs can therefore considerably increase telescope duty cycle.

Here we present a full characterization of a particular type of SiPM produced in Italy by the Fondazione Bruno Kessler (FBK), which is suitable for Cherenkov light detection in the Near-Ultraviolet (NUV SiPMs). This device is a High-Density (HD) NUV SiPM, based on a micro cell of 30 μm x 30 μm and with an area of 6 mm X 6 mm, providing low levels of dark noise and high PDE peaking in the NUV band. NUV-HD SiPMs will be finally arranged in a matrix of 8x8 single units to become part of the focal plane of the Schwarzschild-Couder Telescope prototype (pSCT) for CTA. An update on recent tests of the front-end electronics based on signal sampling with the TARGET-7 chip will be given as well.

10392-9, Session 3

Anti-coincidence scintillation detector for the device “signal” of the spacecraft Interheliozond

Sergey E. Ulin, Alexander S. Novikov, Alexander E. Shustov, Valery V. Dmitrenko, Ziyaetdin M. Uteshev, Konstantin F. Vlasik, National Research Nuclear Univ. MEPhI (Russian Federation)

The device “Signal” intended for research of solar gamma-ray bursts and gamma-ray flares from the galactic objects is described. The device will be installed on board the spacecraft “Interheliozond”. The scintillation anticoincidence system to reject a charged component of cosmic rays is considered. The research results of the scintillation detector characteristics are shown. Major characteristics of silicon photomultipliers electrical signals, used for registration of scintillation flashes from polyvinyl toluene plates, are presented. Optimal number of silicon photomultipliers sufficient for the scintillation system to obtain maximal registration efficiency of these detectors is given.

10392-10, Session 3

Analysis of the energy gamma-spectrum measured by xenon gamma-spectrometer

Alexander S. Novikov, Sergey E. Ulin, Irina V. Chernysheva, Valery V. Dmitrenko, Konstantin F. Vlasik, Ziyaetdin M. Uteshev, Alexander E. Shustov, National Research Nuclear Univ. MEPhI (Russian Federation)

A Xenon gamma-ray spectrometer intended to measure gamma-ray spectra in the energy range 30 keV - 3 MeV is described. Software, which takes into account characteristics and features of the xenon gamma-ray spectrometer, has been developed for the analysis of gamma-ray spectra. The software “Acquisition and processing of gamma-ray spectra” created with the use of programming language DELPHI into IDE CodeGear ™ RAD Studio 2007 is presented. The program is a set of interactive windows for acquisition, visualization, calibration, processing and analysis of the energy spectra from gamma-ray sources. As a result of processing and analyzing the measured spectra, energies of the detected gamma-lines are determined. In order to identify the radioisotopes corresponding to these gamma-lines, a built-in library of radionuclides is used. The identified radionuclides’ activities are also calculated by means the program. The developed software can be used for processing of gamma-ray spectra obtained with other detectors, if their main characteristics are taken into account.

10392-11, Session 3

High-performance neutron spectrometer for planetary hydrogen

Masayuki Naito, Nobuyuki Hasebe, Hiroshi Nagaoka, Junya Ishii, Daisuke Aoki, Waseda Univ. (Japan); Kyeong J. Kim, Korea Institute of Geoscience & Mineral Resources (Korea, Republic of); José A. Matias Lopes, Univ. de Coimbra (Portugal); Jesús Martínez-Frías, Univ. Complutense de Madrid (Spain)

Neutron spectroscopy is regarded as important technique to obtain elemental information of planets such as average atomic mass and concentration of light elements, especially hydrogen. Moreover, to measure gamma-rays and neutron fluxes in thermal/ epithermal and high energy range are essential to derive elemental composition from gamma-ray flux. In future, small and miniature spacecraft to small planetary bodies such as asteroids and comets are expected. For such missions, the development of compact and light equipment is required. In this study, neutron spectrometer (NS) consisting of boron-loaded plastic scintillator (BLP) and lithium-glass scintillator (LiG) is experimentally and numerically studied. The LiG is sensitive to thermal neutron while BLP separately detects epithermal and fast neutrons by delayed coincidence. In experiments, neutrons emitted from 252Cf were injected toward the NS to test the detector response. Silicon photomultiplier (SiPM) and/or Miniaturized PMT are also tested to read out the signals from the NS. The use of SiPM will miniaturize the NS system. In numerical simulations, neutron fluxes emitted from some types of meteorite parent bodies (C, S, and M-type asteroids) were calculated by Monte Carlo simulations. Hydrogen concentration was also changed in the range of 0-20,000 ppm to confirm the effect to the neutron energy spectrum. The calculated neutron spectra were numerically injected toward the NS to estimate the count rate of BLP and LiG. The NS is found to be very sensitive to the existence of water hydrogen in the planetary surface. The results of experiments and simulations will be presented.

10392-12, Session 3

A pixelated x-ray detector for diffraction imaging at next-generation high-rate FEL sources

Luca Lodola, Istituto Nazionale di Fisica Nucleare (Italy) and Univ. degli Studi di Pavia (Italy); Daniele Comotti, Lorenzo Fabris, Univ. degli Studi di Bergamo (Italy); Marco Grassi, Univ. degli Studi di Pavia (Italy); Lodovico Ratti, Piero Malcovati, Univ. degli Studi di Pavia (Italy) and Istituto Nazionale di Fisica Nucleare (Italy); Massimo Manghisoni, Valerio Re, Gianluca Traversi, Univ. degli Studi di Bergamo (Italy); Carla Vacchi, Univ. degli Studi di Pavia (Italy); Giovanni Batignani, Stefano Bettarini, Francesco Forti, Istituto Nazionale di Fisica Nucleare (Italy) and Univ. di Pisa (Italy); Fabio Morsani, Istituto Nazionale di Fisica Nucleare (Italy); Antonio Paladino, Eugenio Paoloni, Giuliana Rizzo, Istituto Nazionale di Fisica Nucleare (Italy) and Univ. di Pisa (Italy); Gian-Franco Dalla Betta, Roberto Mendicino, Lucio Pancheri, Univ. degli Studi di Trento (Italy) and Trento Institute for Fundamental Physics and Applications (Italy); Giovanni Verzellesi, Univ. degli Studi di Modena e Reggio Emilia (Italy) and Trento Institute for Fundamental Physics and Applications (Italy); Hesong Xu, Univ. degli Studi di Trento (Italy) and Trento Institute for Fundamental Physics and Applications (Italy)

The state of the art of X-ray science is shaped by the use of large accelerator-driven X-ray sources such as synchrotron light sources and X-ray free-electron lasers (FELs), for which appropriate X-ray detectors have to be developed. The extremely high brilliance of these sources compensate for the lack of the Bragg peak amplification mechanism typical of crystal diffraction, so that the diffraction method can be extended to the analysis of small, non-periodic specimens. Also, their ultra-short X-ray pulses provide the needed resolution (<1ps) for the reconstruction of time-dependent processes when assisted by pump-probe techniques. Furthermore, operation at very fast rates (up to 5MHz) is foreseen in the next generation FELs. The PixFEL project aims at developing a multi-layer,

hybrid pixel detector for X-ray diffraction imaging applications, compliant with the challenging specifications set by the FELs in terms of input dynamic range, speed, amplitude resolution, energy range from 1 to 10keV and radiation hardness. The sensor consists of a slim edge silicon pixel detector to minimize the dead area. The front-end chip will result from the vertical integration of two layers, one devoted to the analog front-end and the ADC, the second one to memories used in applications with high X-ray pulse rates. A 65nm CMOS technology has been used to accommodate the needed functions in a pixel pitch of 110um. The characterization of the prototype front-end chip, consisting of 32x32 readout channels, is ongoing and the first measurements gave encouraging results in view of the interconnection with the sensor matrix.

10392-13, Session 4

Plastic scintillators for gamma spectroscopy and neutron radiography *(Invited Paper)*

H. Paul Martinez, Nerine J. Cherepy, Robert D. Sanner, Patrick R. Beck, Stephen A. Payne, Lawrence Livermore National Lab. (United States); Charles R. Hurlbut, Eljen Technology (United States)

Plastic scintillators are widely deployed for ionizing radiation detection, as they can be fabricated in large sizes, for high detection efficiency. However, commercial plastics are limited in use for gamma spectroscopy, since their photopeak is very weak, due to low Z, and they are also limited in use for neutron detection, since proton recoils are indistinguishable from other ionizing radiation absorption events in standard plastics. We are working on scale up and production of transparent plastic scintillators based on polyvinyltoluene (PVT) loaded bismuth metallorganics for gamma spectroscopy. When activated with standard organic fluors, PVT scintillators containing 8 wt% bismuth provide energy resolution of 11% at 662 keV. When Iridium complex fluors are used, we can load plastics up to 20 wt% bismuth, while obtaining energy resolution of 10% at 662 keV. Another formulation, activated with Ir fluors for use as neutron radiography scintillator may be used for high energy neutron radiography.

10392-14, Session 4

Directional gamma detection from the occlusion method and singular value decomposition *(Invited Paper)*

Rusty P. Trainham, National Security Technologies, LLC (United States)

Locating a gamma source can be done by a variety of methods, ranging from rotating shields, to inter-detector shadowing, to Compton and Coded aperture imaging. Directional information is usually available in spectra from detector arrays, but that information is often ignored. Compton data from an array can be exploited to yield precise source locations, but the technique is slow. Processing occlusion, or mutual shadowing, data is less precise, but much faster. Instruments currently implementing an occlusion method tend to focus only on azimuthal angles, but with some modification the technique can be extended to estimate elevation angles as well. We present a generalization of the occlusion method for estimating both azimuth and altitude of a source, and the method involves singular value decomposition. The method works even for ill-chosen detector array geometries, and we show results from several detector systems.

10392-15, Session 4

Applications of very fast inorganic crystal scintillators for future HEP experiments

Ren-Yuan Zhu, California Institute of Technology (United States)

In high energy physics (HEP) and nuclear physics experiments, total absorption electromagnetic calorimeters (ECAL) made of inorganic crystals are known for their superb energy resolution and detection efficiency for photon and electron measurements. A crystal ECAL is thus the choice for those experiments where precision measurements of photons and electrons are crucial for their physics missions. Future HEP experiments at the energy and intensity frontiers require very fast inorganic crystal scintillators to achieve excellent timing resolution at a level of a few tens ps and to face the challenge of unprecedented event rate. Very fast inorganic crystals may also find application for Gigahertz hard X-ray imaging. This paper reports recent progress in application of fast inorganic scintillators in HEP experiments, such as a thin LYSO crystal layer for fast timing for the CMS experiment upgrade at the HL-LHC, and the use of undoped CsI and rare earth doped BaF2 crystals for the Mu2e experiment and its upgrade at Fermilab. Applications of very fast crystal scintillators for Gigahertz hard X-ray imaging for the proposed Marie project at LANL will also be discussed.

10392-16, Session 4

Development of the LunaH-Map miniature neutron spectrometer

Erik B. Johnson, Radiation Monitoring Devices, Inc. (United States); Craig Hardgrove, The Univ. of Arizona (United States); Samuel Vogel, Rebecca Frank, Graham Stoddard, James F. Christian, Radiation Monitoring Devices, Inc. (United States)

There is strong evidence that water-ice is relatively abundant within permanently shadowed lunar surface materials, particularly at the poles. Evidence for water-ice has been observed within the impact plume of the LCROSS mission and is supported by data gathered from the Lunar Exploration Neutron Detector (LEND) and the Lunar Prospector Neutron Spectrometer (LPNS). Albedo neutrons from the Moon are used for detection of hydrogen, where the epi-thermal neutron flux decreases as hydrogen content increases. The origin on the concentration of water within permanently shadowed regions is not completely understood, and the Lunar Polar Hydrogen Mapper (LunaH-Map) mission is designed to provide a high-resolution spatial distribution of the hydrogen content over the southern pole using a highly elliptical, low perilune orbit. The LunaH-Map spacecraft is a 6U cubesat consisting of the Miniature Neutron Spectrometer (Mini-NS). Mini-NS is not collimated, requiring a low altitude to achieve a higher spatial resolution compared to previous missions. To develop a compact neutron detector for epi-thermal neutrons, the Mini-NS comprises of 2-cm thick slabs of CLYC (Cs2LiYCl6), which provide a sensitivity similar to a 10-atm, 5.7-cm diameter He-3 tubes, as used in LPNS. The Mini-NS digital processing electronics can discriminate by shape and height to determine signal (albedo neutrons) from background (cosmic rays). The Mini-NS achieves a total active sensing area of 200 cm2 and is covered with a cadmium sheet to shield against thermal neutrons. A review on the design for space flight and the instrument response with the readout scheme is presented.

Effects of post-growth annealing on the properties of Cd1-xMnxTe crystals

Serhii Solodin, Petro Fochuk, Yuriy Fedkovych Chernivtsi National Univ. (Ukraine); Yevgen Nykonyuk, National Univ. of Water Management and Nature Resources Use (Ukraine); Zinaida Zakharuk, Serhii Dremlyuzhenko, Yuriy

Fedkovych Chernivtsi National Univ. (Ukraine); Aleksey E. Bolotnikov, Brookhaven National Lab. (United States); Ralph B. James, Savannah River National Lab. (United States)

The potential of Cd(Mn)Te solid solutions for fabrication of ?-detectors has been substantially restricted by the presence of high concentrations of point defects and impurities and by the presence of structural defects such as Te inclusions. To reduce the density of Te inclusions, we applied a special post-growth annealing method to the ingots. In this method a heater was moved along the ingot. The temperature of the heater was considerably less then the melting point of the Cd(Mn)Te crystals, but it exceeded the melting point of tellurium. Such a method for post-growth annealing (called «dry zone») leads to the following effects:

- Significant reduction in the density of Te inclusions within the crystals;
- Reduction in the concentration of shallow acceptors A1 (?A≈0.05??); and
- Increase in the degree compensation for acceptors A2(?A=0.17??).

10392-39, Session PMon

Vertical Bridgman growth and characterization of Cd0.95-xMnxZn0.05Te (x=0.20, 0.30) single-crystal ingots

Vasylyna Kopach, Oleh Kopach, Larysa Shcherbak, Petro Fochuk, Yuriy Fedkovych Chernivtsi National Univ. (Ukraine); Aleksey E. Bolotnikov, Brookhaven National Lab. (United States); Ralph B. James, Savannah River National Lab. (United States)

Solid solutions of Cd(Zn)Te are well known as materials for optoelectronics, nonlinear optics, solar cell and radiation detector applications. Substitution of Cd or Zn in the Cd(Zn)Te zinc-blende lattice by the magnetic impurity Mn promises more flexible properties arising from tailoring the alloy's enhanced chemical and structural peculiarities. Thus, quaternary chalcogenides based on Cd(Zn,Mn)Te arouse both scientific and technological interest.

Cd0.95-xMnxZn0.05Te alloys with x=0.20, 0.30 were investigated by differential thermal analysis (DTA) for determining their solid-liquid phase transitions at equilibrium temperature intervals. The heating/cooling rates were 5 and 10 K/min with a melt dwell time of 10, 30 and 60 minutes. Cd0.95-xMnxZn0.05Te (x=0.20, 0.30) single-crystal ingots were grown by the Vertical Bridgman method using the DTA results.

As commonly observed for CdTe and Cd(Zn)Te crystals, Te spherical inclusions (1-20 microns) were seen in these ingots by infrared transmission microscopy. Using current-voltage (I-V) measurements, the resistivity of the samples from each ingot was estimated to be about 105 Ohm•cm). The optical transmission analysis demonstrated that the band-gap values of the investigated ingots increased from 1.74 to 1.88 eV with the increase of the MnTe concentration from 20 to 30 mol. %.

10392-40, Session PMon

Improved pyroelectric x-ray generator for planetary active x-ray spectrometer

Masayuki Naito, Nobuyuki Hasebe, Hiroshi Nagaoka, Yusuke Oshima, Miho Mizone, Eido Shibamura, Haruyoshi Kuno, Waseda Univ. (Japan); Kyeong J. Kim, Korea Institute of Geoscience & Mineral Resources (Korea, Republic of); José A. Matias Lopes, Univ. de Coimbra (Portugal); Jesús Martínez-Frías, Univ. Complutense de Madrid (Spain)

Concentration of elements in planetary surface provides important clues to characterize geochemical restrictions and the geological evolution of the planetary bodies. As future missions, landing/roving on planetary surface are planned in Japan. The active X-ray spectrometer (AXS) , which consists of silicon drift detector, pyroelectric X-ray Generators (PXGs), and common electronics, is developed to measure the elemental composition on planetary surface. The AXS can measure major elements: Mg, Al, Si, Ca, and Fe; submajor elements: Na, K, P, S, Cl, Cr, and Ti. The previous missions such as Chang'E-3, MSL used radioisotopes to excite planetary surface materials. However, it is difficult to use radioisotopes for today's Japanese mission. Then, we adopted the PXG, which is composed by pyroelectiric crystal, peltier device, and metal target. The PXG yields X-rays in low pressure by utilizing spontaneous polarization of the crystal depending on temperature. Its characteristic features are light weight, compact size, and no radioisotopes. To obtain fluorescent X-rays effectively, selection of incident X-ray energy is important. For example, Mo L? line (2.29 keV) excites Si by ~20 times larger efficiency than Cu K? line (8.04 keV). By such a reason, the PXGs with different targets should be loaded on the AXS. In this study, PXGs with Cu and Mo targets are experimentally studied. Experimental configurations such as pressure surrounding the crystal, thickness of the target, distance between target and crystal, and shape of the target are changed to obtain high X-ray intensity. The results of experiments will be presented and discussed.

10392-41, Session PMon

Improved materials process for two promising semiconductors Rb3Bi2Br9 and Cs3Bi2Br9 for room-temperature gamma-ray detector applications

Duck Young Chung, Fang Meng, Mercouri G. Kanatzidis, Argonne National Lab. (United States)

A new class of metal chalco-halide compounds A3M2X9 (A = Rb, Cs; M = Bi, Sb; X = Br, I) was identified as good candidate materials for hard energy radiation detection. Particularly the fundamental physical properties of Rb3Bi2Br9 and Cs3Bi2Br9 well meet the requirements for gamma-ray detector materials with band gap 2.6 eV and 2.7 eV, high density 4.48 and 4.46 g/cm3, and low melting point 550 and 650 oC, respectively. These two compounds initially showed high resistivity near 10^12 ohm?cm but relatively low carrier mobility-lifetime product in 10^-5–10^-6 cm2/V For high responsiveness to the high energy radiation these should be further improved . To achieve high detection performance of these materials we focused on developing synthesis and purification process. By using solution process for synthesis of materials followed by a series of purification process and subsequent crystal growth by the Bridgman and Electro-Dynamic Gradient technique, we obtained highly pure single crystals and characterized. The crystals of Rb3Bi2Br9 and Cs3Bi2Br9 show the improved electrical resistivity and the mobility-lifetime products, in the range of 10^13–10^14 ohm.cm and 10^-4–10^-5 cm2/V, respectively. They also exhibit a strong spectroscopy counting response when exposed to Ag X-ray and a medium intense spectroscopy response to 57Co gamma-ray.

10392-42, Session PMon

Effect of cathode energy spectrum on the depth of interaction correction and anode signal recovery in CZT detectors

Mohan Li, Shiva Abbaszadeh, Univ. of Illinois at Urbana-Champaign (United States)

One electrode configuration frequently used in CZT detector is the cross-strip pattern. It is an efficient way to achieve multiplexing through the electrode pattern and it can achieve high spatial resolution in three dimensions (3-D) for imaging applications such as positron emission tomography. The intersection of the anode and cathode strips defines the x-y localization of photon interactions. The cathode-to-anode (C/A) signal ratio can be used to estimate the position of photon interaction in the z direction. In this work we evaluate the effect of cathode energy spectrum on the corrected depth dependent anode energy signal for a cross-strip

CZT detector. In the design investigated, the anode leverages the small pixel effect and the width of the cathode is comparable to the thickness of the CZT crystal. For converting the ADC counts to energy, 68Ge and 137Cs are used. The cathode energy spectrum is broad and does not have a well-defined peak. Therefore, the energy of the cathodes becomes sensitive to the user-selected ADC-to-keV fitting parameters, which affects the anode energy resolution through depth of interaction correction. The anode energy resolution is studied for a variation of cathode fitting parameters, and a method to automate calibration is investigated to improve the robustness of the calibration process, which is especially important for a system comprised of more than a hundred channels.

10392-43, Session PMon

Silicon grid collimator for CsI:Tl scintillator

Toru Aoki, Kento Tabata, Shizuoka Univ. (Japan); Akifumi Koike, ANSeeN Inc. (Japan); Hidenori Mimura, Junichi Nishizawa, Shizuoka Univ. (Japan)

Si grid type optical separator has been developed by using MEMS process. CsI:Tl was filled into the grid hole by evaporation method. Luminescence of CsI:Tl into the grid substrate was observed. The effect of the wall was confirmed by observing deposition of CsI:Tl into through hole substrate. Verification that photo-diode receive luminescence of CsI:Tl in the grid hole is conducted, and intensity and wavelength controlled by Tl concentration of luminescence is enough value for imaging detector. Measurement of spatial frequency is conduct by using test chart. Because the difference of amount of luminescence between pixels adhered test chart and pixels doesn't adhered was observed, the spatial frequency of the grid substrate filled CsI:Tl is 5.0LP/mm by MTF measurement.

10392-44, Session PMon

Characterization of CdTe x-ray detector with modulative depletion layer

Tsuyoshi Terao, Shizuoka Univ. (Japan); Akifumi Koike, ANSeeN Inc. (Japan); Katsuyuki Takagi, Toru Aoki, Shizuoka Univ. (Japan)

A novel method for realizing X-ray energy discrimination with conventional accumulation-type CdTe flat panel detector (FPD) has been proposed. Since the thickness of depletion layer in a diode detector depends on the bias voltage applied, the sensitivity of the detector to higher energy X-ray can be controlled by modulating the bias voltage. Measurements have been carried out to investigate the carrier transportation characteristics of Schottky CdTe detector at lower bias voltage.

10392-45, Session PMon

The development of a low-cost CsI(Tl)-SiPM detector for radiation monitoring by members of the public

Steven J. Bell, National Physical Lab. (United Kingdom); Craig Duff, Kromek (United Kingdom)

The accident at the Fukushima Daiichi NPP has increased interest amongst members of the public in the measurement and monitoring of radiation. Many simple radiation detectors have been developed and made freely available for public purchase and use; however these devices often lack a metrological underpinning and so their results are difficult to interpret. A collaboration between Kromek and the National Physical Laboratory has been established to develop and metrologically validate a CsI(Tl)-SiPM gamma radiation detector for on-line, geo-tagged radiation monitoring by members of the public. The device under development is based on the hybrid gamma/neutron detector; D3S, which was developed by Kromek for homeland security as a "wearable" networked detector carried by government agencies. The new device will contain a re-designed CsI(Tl)-SiPM gamma spectrometer and bluetooth for communication with the user's smartphone. A website will be developed to allow public sharing of radiation measurements. Presented is an overview of the project aims, details of the device design and a review of measurements made by the existing D3S device. This work is part of the EMPIR Preparedness project funded by EURAMET, BEIS and Kromek.

10392-46, Session PMon

Doping and metallization of the CdTe crystal surface by laser irradiation of the metal substrate through the semiconductor

Volodymyr A. Gnatyuk, V.E. Lashkaryov Institute of Semiconductor Physics (Ukraine); Kateryna Zelenska, Taras Shevchenko National Univ. of Kyiv (Ukraine); Toru Aoki, Shizuoka Univ. (Japan)

In fabrication of diode type CdTe-based X/gamma-ray detectors, a high barrier can be implemented by doping of a surface crystal layer and creation of a p-n junction or formation of a Schottky contact. Laser-assisted techniques have been studied for high resistivity p-like CdTe crystals to develop diode structures with high rectification properties and low leakage current. The key feature of the proposed method is irradiation of a CdTe crystal placed on the polished chemically pure metal (Al or In) plate with nanosecond pulses of the first harmonic (1064 nm) of a YAG:Nd laser. CdTe is transparent for this radiation which is strongly absorbed by only a thin layer of the substrate. Depending on energy density and number of laser pulses, irradiation of the metal through the CdTe causes such extreme conditions (high temperature, stresses, pressure, etc.) in the confined area at the metal-CdTe interface which can provide: (i) doping of the thin CdTe region adjoining to the substrate with Al (In) atoms and formation of a p-n junction; (ii) creation of a Schottky barrier by deposition of a thin Al (In) contact film; (iii) formation of a metal electrode. These technological procedures are realized as a result of laser-induced thermal extension of a thin layer of the substrate, melting of this layer and solubility of CdTe in the liquid metal, melting of both the semiconductor and metal layers near the interface, ablation of the metal with following deposition, respectively. The electrical properties of the formed CdTe-metal diodes are investigated.

10392-47, Session PMon

Challenges in the quantitative optical detection of radiation

Sean Fournier, Jeffrey B. Martin, Richard Harrison, Dora K. Wiemann, Sandia National Labs. (United States)

Modern ultraviolet (UV) cameras, when combined with UV-transmitting lenses/filter arrangements can be used to detect radiation dose in air. Ionizing radiation excites nitrogen molecules in ambient air resulting in decay by the emission of photons. The strongest emissions are in the 337 nm, 357 nm, 316 nm, 391 nm and 380 nm bands of the ultraviolet. This process is referred to as scintillation where roughly 17 photons are emitted per MeV of ionizing radiation deposited in the air. Previous work has proven this phenomenon is detectable using highly-sensitive electronically cooled cameras traditionally used in astronomy for low-background imaging. While the ability to detect the presence of radiation (i.e. qualitative measurement) has been demonstrated, there are several challenges in correlating images to known dose-fields (quantitative measurement). These challenges include: a low signal to background ratio, interferences due to electronic noise and direct radiation interactions with the camera, and a complex source-dependent detection efficiency. Based on measurements of low-level radioactive sources as well as high-level sources at several irradiation facilities at Sandia National Laboratories, researchers are building an understanding of these challenges in an attempt to engineer a system that can be used for quantitatively measuring radiation dose fields. This presentation will describe these efforts and share the lessons learned from several experiments.

10392-48, Session PMon

Characterization of Yb-doped silica optical fibre as real-time dosimeter

Ivan Veronese, Univ. degli Studi di Milano (Italy); Norberto Chiodini, Univ. degli Studi di Milano-Bicocca (Italy); Simone Cialdi, Edoardo D'Ippolito, Univ. degli Studi di Milano (Italy); Mauro Fasoli, Univ. degli Studi di Milano-Bicocca (Italy); Salvatore Gallo, Univ. degli Studi di Milano (Italy); Eleonora Mones, Azienda Ospedaliera Maggiore della Carità (Italy); Anna Vedda, Univ. degli Studi di Milano-Bicocca (Italy); Gianfranco Loi, Azienda Ospedaliera Maggiore della Carità (Italy)

Scintillator dosimeters (SD) have been a research topic by many groups over the last decade. The recent availability of a commercial system (ExradinW1) represents a significant accomplishment. The attractiveness of SD would be furtherly enhanced by a scintillator free from any spectral superposition with the Cherenkov light, so to avoid any sensitive calibration procedure for the stem effect correction. Yb-doped silica optical fibres, thanks to their near-infrared (NIR) emission, proved to be a promising option.

This study aims to characterize the dosimetric properties of Yb-doped fibers in radiotherapy and to compare their resultswith those obtained by various reference dosimeters like micro ion-chambers, the commercial SD, and diodes designed for small field dosimetry.

Yb-doped fibres were prepared by sol–gel. The scintillation was detected with a laboratory-made photon counting system based on an avalanche photodiode, using a long-pass filter at 950 nm. Irradiations were carried out with photons and electron beams generated by a Varian Trilogy accelerator.

The NIR scintillation proved to be unaffected by the stem effect, even in unfavorable large field irradiations. The system showed a satisfactory reproducibility, good sensitivity, linear dose-rate response, independence of the signal (total counts) of dose rate and impinging beam orientation. The results were in good agreement with reference dosimeters in terms of relative dose profiles and output factors.

We thus expect that our results will be of great interest for medical physicists involved in the complex issues of small field dosimetry and in-vivo dose monitoring in the new advanced radiation treatment modalities.

10392-17, Session 5

First report on printed contacts for CdZnTe detectors. *(Invited Paper)*

Arie Ruzin, Artem Brovko, Sergey Marunko, Tel Aviv Univ. (Israel)

This work reports on the first steps toward 3-D printed contacts to CdZnTe detectors. The three-dimensional printing is rapidly gaining new territories. This study is the first attempt to print silver contacts onto Cd1-xZnxTe crystals grown by horizontal Bridgman method. The contact printing technology is very promising since it enables mask-free design and fabrication of various contact configurations. It does not require vacuum deposition systems or chemical processes.

Although the printing process is relatively simple, it is not trivial and requires a review of surface preparation and optimization, as well as in contact annealing. The silver printing is done from a liquid phase of silver nano particles. In this study various surface treatments and post-printing annealing procedures were studies. The printed contacts are compared to evaporated contacts of the same metal.

10392-18, Session 5

Perovskite CsPbBr3 single crystals with improved physical properties for gamma-ray detector *(Invited Paper)*

Duck Young Chung, Fang Meng, Argonne National Lab. (United States); Christos Malliakas, Northwestern Univ. (United States); Gregory A. Bizarri, Tetiana Shalapska, Edith D. Bourret-Courchesne, Lawrence Berkeley National Lab. (United States); Mercouri G. Kanatzidis, Northwestern Univ. (United States); Anton S. Tremsin, Space Sciences Lab. (United States)

CsPbBr3 is a promising candidate for gamma-ray detector applications, as it has direct band gap (2.25 eV), high density (4.85 g/cm3), attenuation coefficient comparable to CZT, and high resistivity ~10^9 ohm?cm. CsPbBr3 exhibits the carrier mobility-lifetime product (??) in the order of 10^-5 - 10^-4 cm2/V, promising enough to further develop for practical applications. The major challenge is its detection performance limited by impurity phases and crystal defects that may act as carrier traps at a deep level of the energy gap. Here, we report new processes for synthesis and purification to obtain highly pure CsPbBr3 with reduced impurities, which improve the crystal quality and physical properties relevant to radiation detection. Compared to the conventional synthetic route which involves high temperature melting of precursors, the solution based route using aqueous HBr or organic solvent/anti-solvent mixture produced higher quality materials. After a series of purification process, large single crystals of CsPbBr3 were grown by the Bridgman and Electro-Dynamic Gradient (EDG) method. The crystals were characterized by optical and spectroscopic studies for crystal quality evaluation, charge transport and photo-response study using X-ray and gamma-ray sources for detection performance assessment, and carrier trap analysis. We report single crystals of CsPbBr3 with significantly improved properties such as reduced defects and low concentration of carrier trap high transmittance, high resistivity ~ 10^11 ohm?cm, and ?? ~ 10^-4 cm2/V. In addition, they exhibit the strong counting response to both Ag X-ray and 57Co gamma-ray irradiation.

10392-19, Session 5

Highly stable thallium bromide devices for long-term room temperature field applications *(Invited Paper)*

Amlan Datta, John Fiala, Piotr Becla, Shariar Motakef, CapeSym, Inc. (United States)

Thallium bromide (TlBr) is a wide bandgap, compound semiconductor with high gamma-ray stopping power and promising physical properties. However, performance degradation and the eventual irreversible failure of TlBr devices can occur rapidly at room temperature, due to "polarization", caused by the electro-migration of Tl+ and Br- ions to the electrical contacts across the device. In the previous studies we extensively explored and reported the defect nucleation and migration phenomena in TlBr devices.

With significantly better surface preparation, non-reactive electrodes, and optimized unique biasing switching schemes we have demonstrated that the room temperature long term performance of the detectors can be improved significantly. We have demonstrated spectroscopic performance of several devices under continuous bias and gamma irradiation for more than a year. This is close to ten times longer than other demonstrated room temperature lifetime for TlBr devices. This was achieved without the Cl-based heterojunctions between the TlBr matrix and the contact metal. Different bias-switching schemes and its effects would be discussed in this paper. These devices are stable within 2% standard deviation of the energy channels, which demonstrates the potential of TlBr detector modules for use in field applications. Effects of ambient atmosphere and applied detector bias on the long-term detector performance will be reported.

High-efficiency and high-sensitivity thermal neutron detectors based on hexagonal BN epilayers

Avisk Maity, Sam Grenadier, Jing Li, Jingyu Lin, Hongxing Jiang, Texas Tech Univ. (United States)

Due to the inherent nature of low flux of fission neutron emission from a potential fissile material and the fact that the neutron flux is inversely proportional to the square of the distance from the source, it is challenging to detect neutron signals at relatively large distances. Large size high efficiency detectors are desired to improve the detector performance and to provide a reasonable count rate. We have successfully synthesized by MOCVD wafer-scale 10B enriched hexagonal boron nitride (h-BN) epilayers with a thickness of about 50 microns [1-3]. We have realized recently vertical photoconductor-like thermal neutron detectors of 1 mm2 in size with 51.4% detection efficiency [1]. We report here the fabrication and characterization of 3 mm x 3 mm h-BN vertical detectors with 50% detection efficiency. The effects of resistivity, dark current density, and the carrier mobility-lifetime products on the device performance were monitored and optimized via MOCVD growth parameters. With improved material quality, the noise related dark counts have been significantly reduced. The work laid the groundwork for realizing large area detectors. Our results indicate that h-BN are highly promising for realizing highly sensitive solid-state thermal neutron detectors with expected advantages resulting from semiconductor technologies, including compact size, light weight, low operating voltage, and low cost.

Neutron detector development for microsatellites *(Invited Paper)*

Julia G. Bodnarik, Dave Hamara, The Univ. of Arizona (United States); Arnold Burger, Fisk Univ. (United States) and Vanderbilt Univ. (United States); Vladimir Buliga, Joanna C. Egner, Michael Groza, Fisk Univ. (United States); Walter M. Harris, The Univ. of Arizona (United States); Liviu Matei, Fisk Univ. (United States); Thomas H. Prettyman, Planetary Science Institute (United States); Keivan G. Stassun, Vanderbilt Univ. (United States) and Fisk Univ. (United States); Ashley C. Stowe, Y-12 National Security Complex (United States)

The 3He supply shortage has spurred scientist to develop alternative neutron detectors for space science applications. One promising new neutron detector is 6LiInSe2, a room temperature semiconductor thermal neutron detector that also detects incident neutrons via scintillation [1]. It is an effective neutron detector due to the high neutron capture cross-section area of 6Li (935 barns). Although the thermal neutron cross section of 6Li is lower that of 3He, the atomic density of 6Li in a solid is higher, resulting in improved neutron absorption due to increased atomic density. This makes 6LiInSe2 a promising candidate for thermal neutron detection in space science applications.

6LiInSe2 has a response to both neutrons and gamma rays [2]. We investigate 6LiInSe2 in scintillation mode in the laboratory to determine this response and see if we can separate thermal neutrons, epithermal neutrons, and gamma rays in the resultant energy spectrum using moderating materials and digital signal processing if necessary. The results from our study will help us determine if 6LiInSe2 is a useful detector for space and planetary science missions.

Cs2LiCeCl6: An intrinsic scintillator for dual gamma and neutron detector applications

Utpal N. Roy, Giuseppe S. Camarda, Yonggang Cui, Rubi Gul, Brookhaven National Lab. (United States); Anwar Hossain, Brookhaven National Lab (United States); Ge Yang, Brookhaven National Lab. (United States); Ralph B. James, Savannah River National Lab. (United States); Steven L. Hunter, Patrick R. Beck, Nerine J. Cherepy, Stephen A. Payne, Lawrence Livermore National Lab. (United States)

Intrinsic materials can offer advantages over doped materials for some important applications. The doped material might suffer from non-uniform distribution of the dopant, such as fine-scale striations and larger scale segregation, which might affect the overall device response, especially for large-volume detectors such as those in demand for homeland security applications for gamma spectroscopy. Cs2LiCeCl6 (CLCC), being an intrinsic scintillator, can be grown in large volume to produce large detectors with good performance, provided the crystals are free from unwanted scattering centers. CLCC belongs to the elpasolite family and the structure is cubic, so large-volume ingots can be grown without the strains resulting from anisotropic thermal expansion coefficients. In this presentation, we will discuss extensive material characterization and device response of CLCC for gamma and thermal neutron detector applications.

10392-24, Session 7

Arrays of position sensitive virtual Frisch-grid detectors *(Invited Paper)*

Aleksey E. Bolotnikov, Giuseppe S. Camarda, Rubi Gul, Gianluigi De Geronimo, Jack Fried, Ge Yang, Anwar Hossain, Brookhaven National Lab. (United States); Luis A. Ocampo Giraldo, Brookhaven National Lab. (United States) and The Pennsylvania State Univ. (United States); Emerson Vernon, Brookhaven National Lab. (United States); Ralph B. James, Savannah River National Lab. (United States)

We present new results from testing a small array of position-sensitive virtual Frisch-grid gamma-ray detectors. Such arrays provide high-detection efficiency, excellent energy and position resolution. They can be used in compact hand-held instruments or in large-area gamma ray imaging cameras. The high granularity position sensing enables these detectors to correct the response non-uniformity caused by crystal defects. This important feature allows one to achieve high detection performance while using standard-grade (unselected) CZT crystals, which is expected to reduce the overall cost of field deployable high-resolution CZT gamma ray detection instruments. Here, we report the results of testing several array prototypes with configurations designed for different applications.

10392-25, Session 7

Bridgman growth of scintillator crystals via neutron imaging and finite-element modeling

Jeffrey J. Derby, Jeffrey H. Peterson, Chang Zhang, Jan Seebeck, Univ. of Minnesota (United States); Anton S. Tremsin, Univ. of California, Berkeley (United States); Didier Perrodin, Gregory A. Bizarri, Edith D. Bourret-Courchesne, Lawrence Berkeley National Lab. (United States); Sven Vogel, Mark A. M. Bourke, Los Alamos National Lab. (United States)

In this presentation, we discuss experiments that employ spallation neutrons to visualize, in situ, the compositional field that is developed during the growth of a mixed halide scintillator crystal via the Bridgman method. These measurements provide, for the very first time, a direct observation of melt crystal growth within a system large enough to display the complex interplay of heat transfer, fluid flow, segregation, and phase change characteristic of an industrially relevant process.

To understand the mechanisms at play during growth, we apply finite element models to predict the macroscopic transport of heat, mass, and momentum along with phase-change phenomena in the crystal growth system observed in these neutron imaging experiments. We discuss how ongoing synergies between modeling and experiment allow for unambiguous interpretation of growth experiments. This is particularly significant, since there is a lack of fundamental understanding of how microstructural defects arise during growth. If we can directly observe these phenomena via imaging and real-time measurements and correlate their behavior with growth conditions provided by the model, we have a path by which we can begin to understand and quantify the responsible mechanisms. Ultimately, the understanding obtained by model and experiment will truly allow the closing of the loop between materials quality, growth conditions, and process development, an undertaking that in the past has relied on empiricism and experience to typically achieve only incremental advances.

Supported by U.S. DOE/NNSA DE-NA0002514 and U.S. DOE/NNSA/DNN R&D (LBNL subcontract AC0205CH11231); no official endorsement should be inferred.

Real-time leakage current monitoring in two-step annealing process

Kihyun Kim, Seokjin Hwang, Hwanseung Yu, Korea Univ. (Korea, Republic of); Aleksey E. Bolotnikov, Brookhaven National Lab. (United States); Ralph B. James, Savannah River National Lab. (United States)

Te secondary phase defect is one of major limiting factor in the performance of CdZnTe(CZT) detectors. We want to get rid of Te secondary phase defects of CZT crystals through post-growth two-step annealing without creating new trapping centers. Two-step annealing (i.e. the first in Cd pressure, the second in Te pressure) demonstrated to be effective in order to preserve the resistivity of detector grade CZT. Leakage current of CZT detector during the two-step annealing was investigated with the help of real-time current monitoring system. First annealing of semi-insulating CZT under Cd pressure at 700/600 C (CZT/Cd) for 24 hours eliminated Te secondary phase defect completely but bring out low resistivity CZT of 2 Ohm cm. For example, second-step annealing of CZT under Te pressure at 550/350 C (CZT/Te) for 240 hours restored its resistivity to 8 x 10^8 ohm cm. In this research, we tried to find out proper annealing condition for restoring CZT's resistivity by using real-time leakage current monitoring system.

Transient current waveforms and electric-field profile in CZT detectors

Rubi Gul, Brookhaven National Lab. (United States) and Idaho State Univ. (United States); Aleksey E. Bolotnikov, Giuseppe S. Camarda, Anwar Hossain, Louis Iocampo, Brookhaven National Lab. (United States); Rene Rodriguez, Idaho State Univ. (United States); Utpal N. Roy, Ge Yang, Brookhaven National Lab. (United States); Ralph B. James, Savannah River National Lab. (United States)

We will present characterization data for the electric field and electrical transport properties of Bridgman- and THM- (travelling heater method) grown CZT detectors by using a transient current technique (TCT). The TCT system has an excellent position resolution and focused beam width; it has been routinely used for detailed study of the transient waveforms and the electric-field profile in II-VI radiation detectors. Four CZT gamma-ray detectors (two planar and two Frisch-grid designs) were characterized along the thickness of the detector extending from the top contact (cathode) to the bottom contact (anode). Transient current waveforms were collected for different applied bias conditions, and they were analyzed to determine the electron charge-carrier mobility and lifetime. In addition the data are used to calculate and plot the internal electric-field profile. The measured electric-field profile shows variations indicating creation of positive space charge induced by the laser illumination. The electric-field analysis indicates that the field strength decreases from the cathode towards the anode, which shows the strong positive space-charge region near the cathode and weaker space charge region towards the anode of the detector. A model based on the transient current waveforms will also be presented.

10392-28, Session 8

Mechanistic study of the accelerated crucible rotation technique (ACRT) applied to vertical Bridgman growth of CZT *(Invited Paper)*

Mia S. Divecha, Univ. of Minnesota (United States); Jedidiah J. McCoy, Saketh Kakkireni, Santosh K. Swain, Kelvin G. Lynn, Washington State Univ. (United States); Jeffrey J. Derby, Univ. of Minnesota (United States)

Current Bridgman crystal growth methods for cadmium zinc telluride (CZT) result in significant second-phase particle populations, the latter of which require lengthy annealing processes to remove. Additionally, spontaneous nucleation of new grains can occur at the solidification interface during growth, reducing the yield of single-crystal material. The application of the Accelerated Crucible Rotation Technique (ACRT) promises to reduce second-phase particles and improve monocrystallinity. However, there is little guidance on how this approach should be applied to the Bridgman growth of CZT.

We are applying a finite-element model for time-dependent flow, heat and mass transfer, and the crystal growth under realistic furnace thermal profiles. We are testing various ACRT strategies and their impact on melt flow and composition, interface morphology, and morphological stability of the growth interface. In this presentation, we summarize our effort to optimize the rotation schedule for ACRT Bridgman growth of CZT. We emphasize the underlying physical mechanisms that are expected to provide better growth conditions for single-crystal CZT with fewer second-phase tellurium inclusions. Comparison with ongoing growth experiments will also be featured.

10392-29, Session 8

Through-Silicon Vias (TSVs) for 3D readout of ASIC for nearly gapless CdZnTe detector arrays

Jaesub Hong, Branden Allen, Jonathan Grindlay, Harvard-Smithsonian Ctr. for Astrophysics (United States); Sankgi Hong, Tezzaron Semiconductor Corp. (United States); Hiromasa Miyasaka, Jill Burnham, California Institute of Technology (United States); Robert Patti, Tezzaron Semiconductor Corp. (United States); Fiona A. Harrison, California Institute of Technology (United States); Scott Barthelmy, NASA Goddard Space Flight Ctr. (United States)

Wirebonds, although proven for space application and perceived necessary for hybrid sensors like CdZnTe detectors, introduce assembly complexity and undesirable gaps between detector units. Thus they poses a serious challenge in building a low cost large area detector. We are developing Through-Silicon Vias (TSVs) to make all connections (both power and data) through ASICs, which will eliminate wirebonds and enable a simple direct bonding between the ASIC and a substrate electronics layer. TSVs also enable a more compact layout of ASIC, which reduces the inactive area of the detector plane, and thus enables nearly gaplessly tilable detector arrays. We demonstrate the first successful TSV implementation on ASICs used for CZT detectors onboard the Nuclear Spectroscopic Telescope Array (NuSTAR) mission. We present the TSV development process, and the performance of CZT detectors using NuSTAR ASICs with TSVs.

10392-30, Session 8

Sub-pixel resolution in pixelated CdZnTe gamma ray detectors with different pixel sizes (0.5 mm to 1.72 mm) using a focused laser beam

Luis A. Ocampo Giraldo, The Pennsylvania State Univ. (United States); Aleksey E. Bolotnikov, Giuseppe S. Camarda, Gianluigi De Geronimo, Rubi Gul, Jack Fried, Anwar Hossain, Brookhaven National Lab. (United States); Kenan Unlu, The Pennsylvania State Univ. (United States); Emerson Vernon, Ge Yang, Brookhaven National Lab. (United States); Ralph B. James, Savannah River National Lab. (United States)

High-resolution position-sensing has been proposed to correct response non-uniformities in Cadmium Zinc Telluride (CZT) gamma ray detectors by virtually subdividing the area into small voxels and equalizing responses from each voxel. 3D pixelated detectors coupled with multichannel readout electronics are the most advanced type of CZT devices offering many options in signal processing and enhancing detector performance. The main hurdle in achieving high sub-pixel position resolution is the relatively low signal induced on the neighboring pixels because of the electrostatic shielding effect caused by the collecting pixel. In addition, to achieve high position sensitivity one should rely on time-correlated transient signals, which means that digitized output signals must be used. Previous results have shown the benefit of using a focused laser beam to study position resolution in 3D pixelated detectors. We present the results of our studies to measure the amplitude of the pixel signals so that these can be used to measure positions of the interaction points. This is done with the processing of digitized correlated time signals measured from several adjacent pixels taking into account rise-time and charge-sharing effects. In these measurements we used a focused pulsed laser to generate a 10-micron beam at one milliwatt (650-nm wavelength) over the detector surface while the collecting pixel was moved in cardinal directions. The results include measurements that present the benefits of combining conventional pixel geometry with digital pulse processing for the best approach in achieving sub-pixel position resolution with different pixel dimensions ranging from 0.5 mm to 1.72 mm.

10392-31, Session 8

Analysis of accelerated crucible rotation technique (ACRT) in the traveling heater method (THM) growth of CZT

Jeffrey H. Peterson, Jeffrey J. Derby, Univ. of Minnesota (United States)

The traveling heater method (THM) has enjoyed particular success for the growth of large, high-quality bulk crystals of cadmium telluride (CdTe) and cadmium zinc telluride (CZT) for radiation detector applications. However, the THM suffers from growth rates that are an order of magnitude slower than competing methods, such as Bridgman growth. Increasing THM growth rates would represent a major advance toward decreasing the very high cost of this material for use in large-volume gamma-ray spectrometers with high energy resolution.

In this presentation, we apply a rigorous, comprehensive computational model that couples phase equilibria with heat and species transfer, fluid mechanics, and interfacial dissolution and growth phenomena to faithfully describe the THM crystal growth process. We explain mechanisms that drive supercooling instabilities that limit THM growth rates. Specifically, we discuss the formation of melt flow structures (lee-wave vortices) near the growth interface that influence lateral transport in the melt and, in turn, promote concentration gradients in excess of the limit for morphological stability. In this presentation, we build on previous work to more carefully analyze the role of the lee-wave vortex in the onset of constitutional supercooling and investigate strategies for mitigation. Specifically, we consider the application of the accelerated crucible rotation technique (ACRT) to disrupt solute transport within the liquid zone that may alleviate constitutional supercooling and allow for faster growth rates.

This work has been supported in part by the National Science Foundation, under DMR-1007885, and no official endorsement should be inferred.

10392-32, Session 9

Recent advances in garnet scintillator gamma spectrometers *(Invited Paper)*

Erik L. Swanberg, Zachary M. Seeley, Patrick R. Beck, Brian Wihl, Nerine J. Cherepy, Stephen A. Payne, Steven L. Hunter, Scott E. Fisher, Peter A. Thelin, Lawrence Livermore National Lab. (United States); Todd Stefanik, Nanocerox, Inc. (United States); Joel Kindem, Cokiya, Inc. (United States)

Gadolinium Garnet transparent ceramics doped with Ce, ((Gd,Y,Ce)3(Ga,Al)5O12), for gamma-ray spectroscopy provide high density, high light yield, high energy resolution , high Z, mechanical robustness, and they are unreactive to air and water. Gadolinium garnet single crystals are costly to grow, due to their high melting points, and suffer from non-uniform light yield, due to Ce segregation. In contrast, transparent polycrystalline ceramic Garnets are never melted, and therefore are less costly to produce

and provide the uniform light yield required to achieve high energy resolution with a scintillator.

GYGAG(Ce) transparent ceramics offer energy resolution as good as R(662 keV) = 3.5%, in a pixelated detector utilizing Silicon photodiode array readout. We have developed a modular handheld detector based on pixelated GYGAG(Ce) on a photodiode array, that offers directional detection for point source detection as well as gamma spectroscopy. Individual modules can be assembled into detectors ranging from pocket-size to large panels, for a range of applications.

Large GYGAG(Ce) transparent ceramics in the 2-5 in3 size range have been fabricated at LLNL. Instrumentation of these ceramics with Silicon photomultipliers (SiPMs) and super bi-alkali PMTs has been explored and energy resolution as good as R(662 keV) = 5% has been obtained. Further improvements with SiPM readout will leverage their high quantum efficiency in the 500-650 nm range where GYGAG(Ce) emits, and implement electronics that minimize the effect of SiPM dark current and capacitance on the pulse height spectra.

This work was performed under the auspices of the U.S. DOE by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344, and has been supported by the US Department of Homeland Security, Domestic Nuclear Detection Office, under competitively awarded IAA HSHQDC-12-X-00149 under Contract No. DE-AC03-76SF00098. LLNL-ABS-724480.

10392-33, Session 9

Crystal growth of CdZnTeSe (CZTS) gamma detectors: a promising alternative to CdZnTe *(Invited Paper)*

Utpal N. Roy, Giuseppe S. Camarda, Yonggang Cui, Rubi Gul, Ge Yang, Anwar Hossain, Brookhaven National Lab. (United States); Ralph B. James, Savannah River National Lab. (United States); Jakub Zázvorka, Václav Dedic, Jan Franc, Charles Univ. in Prague (Czech Republic); Vincenzo Lordi, Joel B. Varley, Lawrence Livermore National Lab. (United States)

Alloying of CdZnTe (CZT) with selenium has been found to be very promising and effective in reducing the overall concentration of secondary phases (Te precipitates/inclusions) and sub-grain boundary networks in the crystals. These two types of defects are the main causes for incomplete charge collection, and hence they affect the yield of high-quality CZT, resulting in a very high cost for large-volume, high-quality detector-grade CZT detectors. The addition of selenium was also found to very effective in increasing the compositional homogeneity along the growth direction of the CdZnTeSe (CZTS) ingots grown by the traveling heater method (THM) technique. The compositional homogeneity along the growth direction can enhance the overall yield of detector-grade CZTS, which should therefore be possible to produce at a lower cost compared to CZT. The electrical properties and detector performance of the CZTS crystals will be presented and discussed.

10392-34, Session 9

Stoichiometry and extended defects in Cd(Zn,Mn)Te and CdTeSe crystals

Anwar Hossain, Aleksey E. Bolotnikov, Giuseppe S. Camarda, Yonggang Cui, Utpal N. Roy, Ge Yang, Brookhaven National Lab. (United States); Ralph B. James, Savannah River National Lab. (United States)

We investigated the elemental distribution and extended defects in CdTe-based crystals with Zn, Mn or Se as the third element in a tertiary compound. The understanding and reduction of these defects in bulk crystals are vital for the manufacturing of high-quality large-volume detectors, as they have detrimental effects on detector performance. In this work, we obtained high spatial resolution X-ray fluorescence maps of the compositional elements, as well as the doping elements to determine elemental distributions along the both growth and radial directions of the crystals. We also used chemical etching and X-ray diffraction and fluorescence techniques to investigate the extended defects in crystals grown by Bridgman and traveling heater methods. We measured the shapes, sizes, and concentrations of these crystal defects to identify their nature. We evaluated areal densities and distributions of the etch pits associated with dislocations and other crystallographic defects using IR transmission microscopy and a scanning electron microscopy (SEM) combined with energy-dispersive x-ray spectroscopy (EDS). We performed a comparative assessment of the properties of different crystals and correlated our detailed data with detector response measurements to understand the influence of the material properties on detector performance.

10392-35, Session 9

Ionizing organic-based nanocomposites for efficient gamma-ray sensor

Narsingh B. Singh, Fow-Sen Choa, Bradley Arnold, Stacey Sova, Christopher Cooper, Jayati Bhavsar, Univ. of Maryland, Baltimore County (United States)

Single crystal based radiation detectors have been developed for semiconductor based radiation sensors. Materials such as cadmium zinc tellurides and its analogs have shown great promise. To reduce the cost a great deal of researches led by Khalil Arshak developed nickel oxide based sensors. But the sensors have low sensitivity. Our studies indicated that thickness and microstructure have pronounced effect on sensitivity. Since the interaction of gamma-ray with composites involves all three interaction processes; photoelectric effect, Compton scattering, and pair production, composites have better chance for enhancing sensitivity. The probability of the photoelectric effect where a gamma ray interacts with an atom resulting in the ejection of an electron from the atom is proportional to the atomic number (Z) of the absorbing element and inversely related to the energy of the gamma ray is most important for low energy gamma rays. In the composites of ionizing organics oxidation effect of unusual oxides changes much faster and hence increases the sensitivity of radiation. We expect that resistivity of the oxide composite will gradually increase following sequential irradiation processes because of the decrease in holes' concentration. In this presentation, we will present the effect of morphology and processing on sensing gamma-ray by oxides - ethylene carbonate composites.

10392-36, Session 10

Deep level analysis of CdZnTeSe radiation detectors: their effect on the internal electric field *(Invited Paper)*

Ge Yang, Utpal N. Roy, Yonggang Cui, Giuseppe S. Camarda, Anwar Hossain, Rubi Gul, Brookhaven National Lab. (United States); Ralph B. James, Savannah River National Lab. (United States)

We studied the defect-related deep levels in CdZnTeSe radiation detectors using low-temperature photoluminescence spectroscopy measurements. The outcomes are compared with the results of Pockels-effect measurements, which are coupled with external stimulation of light at different wavelengths to excite the deep levels. We discuss the correlation between the two measurements in detail. Our efforts help to understand better the effects of deep levels on the internal electric field of CdZnTeSe X- and gamma-ray detectors.

10392-37, Session 10

Three-dimensional mapping and analysis of mid-gap defect distributions in TlBr by a femtosecond two-photon photocurrent microscope

Drew Onken, Sergii Gridin, Kamil B. Ucer, Richard T. Williams, Wake Forest Univ. (United States); Shariar Motakef, Amlan Datta, CapeSym, Inc. (United States)

Thallium bromide is a promising semiconductor for room temperature radiation detection. One of the remaining challenges of this soft material is defects associated with strain. Defect states near mid-gap promote rapid loss of carriers at high densities by Shockley-Read-Hall bimolecular recombination. We describe 3-D mapping of nonlinear photoconductive response using femtosecond pulse trains at 840 nm, somewhat above mid-gap of TlBr. A confocal two-photon microscopy setup with photocurrent detection affords spatial resolution perpendicular to the surface. We report analysis of the irradiance dependence of the induced current as a function of depth in the sample. There are three separate contributions to the second-order current response. First is the intrinsic two-photon absorption of non-defective TlBr. As noted above, there will be a subtractive 2nd-order quenching term proportional to the local density of mid-gap states. Crucially for our technique, the same mid-gap states responsible for nonlinear carrier quenching also constitute a second-order source term causing resonantly enhanced two-photon absorption across the band gap in crystal regions where the mid-gap states are found. At moderately low irradiance, two-photon induced conductivity comes only from defective regions. At high irradiance, one finds normal 2-photon photocurrent from the nondefective regions and diminished response from nonlinear quenching in the defective regions. From such data, the spatial distribution of the defects is directly displayed and the cross section for bimolecular carrier quenching can be extracted. WFU acknowledges support of DNDO-ARI DHS-2014-DN-077-ARI077-04. This support does not constitute an express or implied endorsement on the part of the government.

10393-1, Session 1

Threat detection of liquid explosives and precursors from their x-ray scattering pattern using energy dispersive detector technology

Jan Kehres, Mark Lyksborg, Ulrik Lund Olsen, Technical Univ. of Denmark (Denmark)

After the transatlantic Airplane plot in 2006 the maximum volume of liquids, aerosols and gels (LAG's) in carryon luggage was temporarily limited to 1 Liter, packed in individual bottles of max. 100 ml, until scanner technology emerges capable of identifying liquid threats. One approach to identify liquid threats in presence of complex electronics and without removing them from the luggage is the application of energy dispersive X-ray diffraction (EDXRD) on a by X-ray absorption contrast imaging pre identified object. To investigate the application an energy dispersive laboratory X-ray diffractometer using slit collimation and a CdTe detector has been developed. For the development of robust threat detection algorithms, EDXRD spectra of 11 liquid threats and 46 common LAGS at multiple angles and with limited count statistics, corresponding to realistic acquisition times in scanner applications, were recorded. The measurements were repeated 10 times, yielding a data set of 570 EDXRD patterns. Initial results from testing of threat detection algorithm, trained with the corrected, normalized and merged data acquired at multiple angles and in an energy window between 50 – 100 keV, which has been determined to be realistically usable with the limited count statistics and in presence of complex electronics in realistic luggage arrangements, detection levels as good as > 95 % true positive with < 6 % false positive alarms have been achieved.

10393-2, Session 1

Rapid and accurate detection of uranium in aqueous solutions

Gary Tepper, Brandon Dodd, Virginia Commonwealth Univ. (United States)

Elevated levels of uranium in water can be associated with activities such as uranium mining, enrichment and transport. Currently, water samples must be obtained and transported to a laboratory for analysis in order to determine the concentration of uranium. This costly and time-consuming method is inadequate for defense and security applications. This paper presents a new optical method for fast and accurate measurement of uranium in water. Water samples are circulated through a nanoporous silica gel material where dissolved uranium is accumulated and concentrated. The natural fluorescence of the dissolved uranium compounds is enhanced within the silica gel matrix allowing for rapid and highly sensitive measurement using a simple optical system. Uranium concentration is determined by controlling the flow-rate and measuring the kinetics of the fluorescent output signal.

10393-3, Session 1

Small unmanned aircraft system for remote contour mapping of a nuclear radiation field *(Invited Paper)*

Paul P. Guss, Karen McCall, Russell Malchow, Richard Fischer, Michael Lukens, Mark Adan, Ki Park, Roy Q. Abbott, Michael E. Howard, Eric Wagner, Rusty P. Trainham, Tanushree Luke, National Security Technologies, LLC (United States); Sanjoy Mukhopadhyay, International Atomic Energy Agency (Austria); Paul Oh, Pareshkumar Brahmbratt, Eric Henderson, Univ. of Nevada, Las Vegas (United States); Jinlu Han, Justin Huang, Casey Huang, Astro Flight, Inc. (United States); Jon Daniels, Univ. of Nevada, Las Vegas (United States)

For nuclear disasters involving radioactive contamination, small unmanned aircraft systems (sUASs) equipped with nuclear radiation detection and monitoring capability can be very important tools. Among the advantages of a sUAS are quick deployment, low-altitude flying that enhances sensitivity, wide area coverage, no radiation exposure health safety restriction, and the ability to access highly hazardous or radioactive areas. Additionally, the sUAS can be configured with the nuclear detecting sensor optimized to measure the radiation associated with the event. In this investigation, sUAS platforms were obtained for the installation of sensor payloads for radiation detection and electro-optical systems that were specifically developed for sUAS research, development, and operational testing. The sensor payloads were optimized for the contour mapping of a nuclear radiation field, which will result in a formula for low-cost sUAS platform operations with built-in formation flight control. Additional emphases of the investigation were to develop the relevant contouring algorithms; initiate the sUAS comprehensive testing using the Unmanned Systems, Inc. (USI) Sandstorm platforms and other acquired platforms; and both acquire and optimize the sensors for detection and localization. We demonstrated contour mapping through simulation and validated waypoint detection. We mounted a detector on a sUAS and operated it initially in the counts per second (cps) mode to perform field and flight tests to demonstrate that the equipment was functioning as designed. We performed ground truth measurements to determine the response of the detector as a function of source-to-detector distance. Operation of the radiation detector was tested using different unshielded sources.

10393-4, Session 1

International Radiation Monitoring and Information System (IRMIS)

Sanjoy Mukhopadhyay, Florian Baciu, Jan Stowisek, Gurdeep Saluja, Patrick Kenny, International Atomic Energy Agency (Austria); Franck Albinet, Independent Contractor - GIS & Data Analyst Consultant (France)

This article describes the International Radiation Monitoring Information System (IRMIS) which was developed by the International Atomic Energy Agency (IAEA) with the goal to provide Competent Authorities, the IAEA and other international organizations with a client server based web application to share and visualize large quantities of radiation monitoring data. The data maps the areas of potential impact that can assist countries to take appropriate protective actions in an emergency.

Ever since the Chernobyl nuclear power plant accident in April of 19861 European Community (EC) has worked towards collecting routine environmental radiological monitoring data from national networked monitoring systems. European Radiological Data Exchange Platform (EURDEP) was created in 19952 to that end – to provide radiation monitoring data from most European countries reported in nearly real-time.

During the response operations for the Fukushima Dai-ichi nuclear power plant accident (March 2011) the IAEA Incident and Emergency Centre (IEC) managed, harmonized and shared the large amount of data that was being generated from different organizations. This task underscored the need for a system which allows sharing large volumes of radiation monitoring data in an emergency.

In 2014 EURDEP started the submission of the European radiological data to the International Radiation Monitoring Information System (IRMIS) as a European Regional HUB for IRMIS.

IRMIS supports the implementation of the Convention on Early Notification of a Nuclear Accident by providing a web application for the reporting,

sharing, visualizing and analyzing of large quantities of environmental radiation monitoring data during nuclear or radiological emergencies.

IRMIS is not an early warning system that automatically reports when there are significant deviations in radiation levels or when values are detected above certain levels. However, the configuration of the visualization features offered by IRMIS may help Member States to determine where elevated gamma dose rate measurements during a radiological or nuclear emergency indicate that actions to protect the public are necessary. The data can be used to assist emergency responders determine where and when to take necessary actions to protect the public.

This new web online tool supports the IAEA's Unified System for Information Exchange in Incidents and Emergencies (USIE), an online tool where competent authorities can access information about all emergency situations, ranging from a lost radioactive source to a full-scale nuclear emergency.

10393-5, Session 2

Development and deployment of the Collimated Directional Radiation Detection System *(Invited Paper)*

Amber L. Guckes, National Security Technologies, LLC (United States); Alexander Barzilov, Univ. of Nevada, Las Vegas (United States)

The Collimated Directional Radiation Detection System (CDRDS) is capable of imaging radioactive sources in two dimensions. The detection medium of the CDRDS is a single $Cs_2LiYCl_6:Ce^{3+}$ scintillator enriched in Li-7 (CLYC-7). The CLYC-7 scintillator is surrounded by a heterogeneous ABS plastic and lead (Pb) collimator. These materials make-up a coded aperture inlaid in the collimator. The collimator is rotated 360 degrees by a stepper motor which enables time-encoded imaging of a measured radioactive source.

The measurements of a radioactive source are collected in discrete time steps that correlate to the angular rotation of the collimator. These measurements are collected in 360 degrees and recorded for post-measurement processing. The measurement results, combined with the decoding mask of the coded aperture, are convoluted to create an image of the measured radioactive source.

This collimator design allows for the directional detection of photons and fast neutrons by utilizing only one CLYC-7 scintillator. Directional detection of thermal neutrons can also be performed by utilizing another suitable scintillator. In addition to directional detection capabilities, the CDRDS is also capable of spectroscopy and pulse shape discrimination of photons and fast neutrons.

The CDRDS is portable, robust, and user friendly. This unit is capable of utilizing wireless data transfer for possible radiation mapping and network?centric CONOPS. The CDRDS is tested by performing laboratory directional measurements with various gamma-ray check sources and neutron sources. Field directional measurements are also performed to demonstrate the CDRDS's feasibility for deployment.

10393-6, Session 2

Performance of pulse-shape discriminating plastic scintillation modules using SiPMs for detecting fast neutrons

James F. Christian, Erik B. Johnson, Daniel E. Fernandez, Samuel Vogel, Rebecca Frank, Graham Stoddard, Radiation Monitoring Devices, Inc. (United States); Jorge Pereira, Remco Zegers, National Superconducting Cyclotron Lab. (United States); Christopher J. Stapels, Mathworks (United States)

The development of neutron detection systems is important to make further progress and complement the increased drive to explore very exotic nuclei systems, in particular with very large neutron excesses. Often, such experiments are performed in environments where background (gamma) radiation is high, or where strong magnetic fields are present. Traditional neutron-gamma separation techniques (using liquid scintillators) are expensive and employ photo-multipliers that cannot operate well in significant magnetic fields.

This work describes the development of detector modules, whose quantity accommodates large detector volumes, as well as the characterization of the modules at the National Superconducting Cyclotron Laboratory (NSCL). The approximately 1.8 cm x 1.8 cm x 2.5 cm plastic scintillation detector, coupled to a 1.2 cm x 1.2 cm SiPM, discriminates neutron from gamma events using the shape of the scintillation pulse. The LENDA Digital Data Acquisition System (DDAS) of the NSCL Charge-Exchange Group processed the signals from the detector module. This work compares the signal-to-noise performance of the detector module to a LENDA bar, which is a plastic scintillation material coupled to a PMT. Additionally, we present measurements of the PSD performance for the detector module in the relevant operating environment.

10393-7, Session 2

High-resolution photon spectroscopy with a microwave-multiplexed four-pixel transition edge sensor array

Paul P. Guss, National Security Technologies, LLC (United States); Mike Rabin, Mark Croce, Los Alamos National Lab. (United States); Nathan Hoteling, National Security Technologies, LLC (United States); Sanjoy Mukhopadhyay, International Atomic Energy Agency (Austria)

We demonstrate very high–resolution photon spectroscopy with a microwave-multiplexed 4-pixel transition edge sensor array. The readout circuit consists of superconducting microwave resonators coupled to radio frequency superconducting-quantum-interference devices (RF-SQUIDs) and transduces changes in input current to changes in phase of a microwave signal. We used a flux-ramp modulation to linearize the response and avoid low-frequency noise. The result is a very high-resolution photon spectroscopy with a microwave-multiplexed 4-pixel transition edge sensor (TES) array. We performed and validated a small-scale demonstration and test of all the components of our concept system, which encompassed microcalorimetry, microwave multiplexing, RF-SQUIDs, and software-defined radio (SDR). We shall display data we acquired in the first simultaneous combination of all key innovations in a 4-pixel demonstration, including microcalorimetry, microwave multiplexing, RF-SQUIDs, and SDR. We present the energy spectrum of a gadolinium-153 (153Gd) source we measured using our 4-pixel TES array and the RF-SQUID multiplexer. For each pixel, one can observe the two 97.4 and 103.2 keV photopeaks. We measured the 153Gd photon source with an achieved energy resolution of 70 eV, a full width half maximum (FWHM) of 100 keV, and an equivalent readout system noise of 90 pA/pHz at the TES. This demonstration establishes a path for the readout of cryogenic x-ray and gamma ray sensor arrays with more elements and spectral resolving powers. We believe this project has improved capabilities and substantively advanced the science useful for missions such as nuclear forensics, emergency response, and treaty verification through the explored TES developments.

10393-8, Session 2

Large-area CdTe imaging sensor and its applications *(Invited Paper)*

Tadayuki Takahashi, Shin Watanabe, Institute of Space and Astronautical Science (Japan); Shin'ichiro Takeda, Okinawa Institute of Science and Technology Graduate Univ. (Japan)

No Abstract Available

10393-9, Session 3

X-ray backscatter radiography with lower open fraction coded masks *(Invited Paper)*

Andre M. A. Munoz, Anna Vella, Matthew J. F. Healy, David W. Lane, Cranfield Univ. (United Kingdom); David Lockley, Defence Science and Technology Lab. (United Kingdom)

Single sided radiographic imaging would find great utility for medical, aerospace and security applications. While coded apertures can be used to form such an image from backscattered X-rays they suffer from near field limitations that introduce noise. Several theoretical studies have indicated that for an extended source the image's signal to noise ratio may be optimised by using a low open fraction (<0.5) mask. However, few experimental results have been published for such low open fraction patterns and details of their formulation are often unavailable or are ambiguous. In this paper we address this process for two types of low open fraction mask, the dilute URA the Singer set array. For the dilute URA the procedure for producing multiple 2D array patterns from given 1D binary sequences (Barker codes) is explained. Their point spread functions are calculated and their imaging properties are critically reviewed. These results are then compared to those from the Singer set and experimental exposures are presented for both type of pattern; their prospects for near field imaging are discussed.

10393-10, Session 3

Recent developments in high-speed proton radiography at LANSCE

Johnny Goett, Los Alamos National Lab. (United States)

Two recent developments in Proton Radiography at LANSCE's line C will be discussed.

The new pRAD2 10-frame hybridized focal plane array design offers much improved spatial and charge resolution, higher quantum efficiency, lower noise, and faster repetition rate over the current state of the art, with integration times below 50 ns. Characterization procedures and data, along with notable physics results will be shown.

Preliminary results from a single pixel proton time-of-flight measurement for energy resolved radiography will be presented along with device concepts for a multi-pixel imager. These advances, bringing tighter timing resolution, more frames and improved density resolution will significantly enhance pRad's capabilities for advances in materials and shock physics research.

10393-11, Session 3

New results from sub-3 MeV Compton spectrometer experiments *(Invited Paper)*

Amanda E. Gehring, Michelle A. Espy, Todd J. Haines, Los Alamos National Lab. (United States)

Our team at Los Alamos National Laboratory has successfully employed Compton spectrometers to measure the x-ray spectra of both continuous and flash, intense radiographic sources. In this method, a collimated beam of x-rays incident on a convertor foil ejects Compton electrons. A collimator may be inserted into the entrance of the spectrometer to select the angular acceptance of the forward-scattered electrons, which then enter the magnetic field region of the spectrometer. The position of the electrons at the magnet's focal plane is proportional to the square root of their momentum, allowing the x-ray spectrum to be reconstructed. A new samarium-cobalt spectrometer with an energy range of 50 keV to 4 MeV has been fielded at two facilities. The x-ray generating machines produced intense beams (> 4 rad at 1 m) of photons with spectral endpoints below 3 MeV. Recent experimental results will be presented.

10393-12, Session 3

Modeling charge collection in x-ray imagers

Giovanni Pinaroli, Univ. degli Studi di Udine (Italy) and Elettra-Sincrotrone Trieste S.C.p.A. (Italy); Pierpaolo Palestri, Luca Selmi, Alessandro Pilotto, Univ. degli Studi di Udine (Italy)

Biomedical and advance material research utilizing photons with energy range of some hundreds of eV to some keV, which are generated by high brilliance Light Sources such as new generation Synchrotron and Free Electron Lasers, put certain constrains on the utilized detection technology. Typical requirements in these applications are high frame and photon rates, single-photon counting capability with low probability of false positives, thus large dynamic range, high quantum efficiency, and (multi)-mega-pixels. To meet these requirements different detector strategies have been suggest and some have been implemented recently. Back-thinned, monolithic active pixel sensors (MAPS) based on standard CMOS technology and standard CMOS parameters are promising candidates for these applications. A priori it is important to understand if a generic photo-diode architecture where photo-generated carriers diffusion dominates the charge collection is suited to fulfill all the aforementioned requirements. A thorough simulation-based investigation of field line distribution, charge transportation and collection has been carried out on 3D-model of a generic pixel by utilizing the commercial TCAD tool Sentaurus.

Several aspects were observed in order to analyze the most relevant features of the photo-sensitive area of the sensor. Beside static simulations to determine the electric-field profile under different bias conditions and for different back-biasing strategies, charge collection was analyzed with transient simulations. Since these simulations are very time consuming when applied to 3D structures, we then investigated the possible use of Ramo's theorem to obtain reliable estimate of the trajectories of the generated carriers and of the associated currents at the device terminals.

10393-13, Session 3

A multi-purpose RTSD readout electronics for XRD and photon-counting x-ray imaging

Zhi Deng, Xiaobing Yue, Yuxiang Xing, Yinong Liu, Tsinghua Univ. (China)

RTSDs (Room-Temperature Semiconductor Detector) such as CdTe and CdZnTe have shown great potential power for X-ray detection in wide range of applications from medical imaging to security inspection. However the requirements of energy resolution, counting rate and efficiency are quite different, which bring big challenges not only for the detector technolgies, but also for the readout signal processing electronics.

A multi-purpose RTSD readout electronics was being developed mainly for linear array CdTe detectors and for luggage inspection systems. It can work at different modes, including high energy resolution at relatively low counting rate and high rate photon-counting (~10 Mcps per channel) with reduced energy resolution. Hence it can be used both for XRD (X-Ray Diffraction) and energy resolved photon-counting X-ray imaging. The multi-mode capability was implemented by using programmable digital signal processing. The linear array CdTe detector was firstly readout by a 32-channel analog front-end ASIC, which consisted of a charge sensitive preamplifier and a CR-(RC)^6 shaper with 100 ns peaking time for each channel. Then the analog signal was continuously digitized by commercial fast ADC cards and processed by different digital filters in FPGA. Only the final extracted information will be sent to the computer. Different digital signal processing algorithms will be verified and the test results will be compared and be present in the paper.

10393-14, Session 4

3D-printed coded apertures for x-ray backscatter radiography *(Invited Paper)*

Andre M. A. Munoz, Anna Vella, Matthew J. F. Healy, David W. Lane, Cranfield Univ. (United Kingdom); David Lockley, Defence Science and Technology Lab. (United Kingdom)

Many different mask patterns can be used for X-ray backscatter imaging using coded apertures, which can find application in the medical, industrial and security sectors. While some of these patterns may be considered to have a self-supporting structure, this is not the case for some of the most frequently used patterns such as uniformly redundant arrays or any pattern with a high open fraction. This makes mask construction difficult and usually requires a compromise in its design by drilling holes or adopting a 'no two holes touching' version of the original pattern. In this study this compromise was avoided by 3D printing a support structure that was then filled with a radiopaque material to create the completed mask. The coded masks were manufactered using two different methods, hot cast and cold cast. Hot casting involved casting a bismuth alloy at 80°C into the 3D printed acrylonitrile butadiene styrene mould which produced an absorber with density of 8.6 g cc-1. Cold casting was undertaken at room temperature, when a tungsten/epoxy composite was cast into a 3D printed polylactic acid mould. The cold cast procedure offered a greater density of around 9.5 to 10 g cc-1 and consequently greater X-ray attenuation. It was also found to be much easier to manufacture and more cost effective. A critical review of the manufacturing procedure is presented along with some typical radiographs. In both cases the 3D printing process allowed square apertures to be creating avoiding their approximation by circular holes when conventional drilling is used.

10393-15, Session 4

Leveraging multi-channel detector technology to improve quality metrics for industrial and security applications

Edward S. Jimenez, Kyle R. Thompson, Noelle M. Collins, Srivathsan Koundinyan, Sandia National Labs. (United States)

Sandia National Laboratories has recently developed the capability to acquire multi-channel radiographs for multiple research and development applications in industry and security. This capability allows for the acquisition of x-ray radiographs or sinogram data to be acquired at up to 300 keV with up to 128 channels per pixel. This work will investigate whether multiple quality metrics for computed tomography can actually benefit from binned projection data compared to traditionally acquired grayscale sinogram data. Features and metrics to be evaluated include the ability to distinguish between two di?erent materials with similar absorption properties, interface resolution of juxtaposed materials with wide absorption di?erences, and signal-to-noise for both raw data and reconstructed volumetric data. The impact of this technology to non-destructive evaluation, national security, and industry is wide-ranging and has to potential to improve upon many inspection methods such as dual-energy methods, material identification, object segmentation, and computer vision on radiographs. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DEAC0494AL85000.

10393-16, Session 4

Spectral correction algorithm for multispectral CdTe x-ray detectors

Erik D. Christensen, Niels Bohr Institute (Denmark); Yun Gu, Jan Kehres, Technical Univ. of Denmark (Denmark); Robert Feidenhans'l, European XFEL GmbH (Germany); Ulrik L. Olsen, Technical Univ. of Denmark (Denmark)

Compared to the dual energy scintillator detectors widely used today, pixelated multispectral X-ray detectors show the potential to improve material identification in various radiography and tomography applications used for industrial and security purposes. However, detector effects, such as charge sharing and photon pile up, distort the measured spectra in high flux pixelated multispectral detectors. These effects significantly reduce the detectors' capabilities to be used for material identification, which requires accurate spectral measurements. We have developed a semi analytical computational algorithm for multispectral CdTe X-ray detectors which corrects the measured spectra for severe spectral distortions coursed by the detector. The algorithm is developed for the Multix M100 CdTe X-ray detector, but could potentially be adapted for any pixelated multispectral CdTe detector. The calibration of the algorithm is based on simple attenuation measurements of commercially accessible materials using standard laboratory sources, making the algorithm applicable in any X-ray setup. The validation of the algorithm has been done using experimental data acquired with both standard lab equipment and synchrotron radiation. The experiments show that the algorithm is fast, reliable even at X-ray flux up to 4 Mph/s/pix, and greatly improves the accuracy of the measured X-ray spectra, making the algorithm very useful for both security and industrial applications where multispectral detectors are used.

10393-17, Session 4

Optimization of input parameters to improve big-data computed tomography reconstruction performance

Celia J. Flicker, Edward S. Jimenez, Sandia National Labs. (United States)

This work seeks to develop an autonomous optimization of input computational resource parameters for arbitrary big-data computed tomography (CT) configurations. It is well known that graphics processing units (GPU) have been a boon to many high-performance applications, including CT. The reconstruction task has both colossal computational and data throughput requirements that easily tax high-end GPUs to their limit. For big-data industrial and research applications, the burden is exacerbated through the use of high pixel count detectors (≥ 16 megapixels) and the large number of projections needed to meet Nyquist sampling requirements, resulting in datasets up to terabytes in size. Previous work has shown that the GPU kernels can be optimized to e?ciently handle big-data; however, as this work will show, some sensitivities exist with respect to the tunable input parameters that can exact an exaggerated toll on reconstruction performance. This work will investigate the input parameter space for various relevant and future-sized datasets and will present a calibration approach to optimize reconstruction performance for varying sized detectors, geometries, and graphics processing resources. This work has the potential to dramatically improve many non-destructive evaluation and inspection applications in industry, security, and research where reconstruction rate is the main bottleneck of the resource chain. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DEAC04-94AL85000.

10393-32, Session PWed

The dual-channel ultraviolet/low-light CMOS camera using image fusion technique

Yunsheng Qian, Xiangyu Kong, Xiaoyu Zhou, Xiaodong Tang, Yijun Zhang, Nanjing Univ. of Science and Technology (China)

Ultraviolet(UV) detection technology, as immediate area of research focus, has been adopted in the fields of fingerprint identification, corona detection and exhaust plume detection for its significant value and practical meaning. Low-light(LL) CMOS, which can work in even 10-3 lux, is used in visible light channel. The prominent advantage of the dual-channel UV/LL camera is the fusion of UV and wide dynamic range visible light information, which can enrich image details and help observers locate the UV targets in the complicated background around the clock rapidly. The paper studied on the component structure of ultraviolet ICMOS, imaging driving, the UV/LL images fusion algorithm and the photon counting algorithm. Firstly, the one inch and wide dynamic range CMOS chip with the coupling optical fiber panel are coupled to the ultraviolet image intensifier. The ultraviolet image intensifier adopts Te-Cs photocathode. Secondly, in consideration of the ultraviolet detection demand, the drive circuit of the CMOS chips is designed and the corresponding program based on Verilog language is written. Thirdly, after analysis and comparison of the characteristics of UV image and LL CMOS image, the improved Laplace pyramid fusion algorithm is applied. UV image and LL CMOS image are multiscale decompose, and the features in different frequency layer are chosen from either UV image or LL CMOS image. Weighted average fusion algorithm is also used as a contrast. Finally, the connected components labeling way is utilized for the ultraviolet detection and imaging. At last, the detection experiment of the ultraviolet signal in day and night is carried out, and the test results are given and analyzed.

10393-18, Session 5

Measurement of x-ray spectra using a recent YAP(Ce)-MPPC detector

Eiichi Sato, Yasuyuki Oda, Sohei Yoshida, Satoshi Yamaguchi, Yuichi Sato, Iwate Medical Univ. (Japan); Tomotaka Ishii, Osahiko Hagiwara, Hiroshi Matsukiyo, Toshiyuki Enomoto, Manabu Watanabe, Shinya Kusachi, Toho Univ. (Japan)

To measure X-ray spectra with high count rates, we developed a detector consisting of a cerium-doped yttrium aluminum perovskite [YAP(Ce)] crystal and a recent multipixel photon counter (MPPC). Scintillation photons are detected using the MPPC, and the photocurrents flowing through the MPPC are converted into voltages and amplified using a high-speed current-voltage (I-V) amplifier. The MPPC bias voltage was set to a maximum value at the pre-Geiger mode to perform zero-dark counting. The event-pulse widths were approximately 200 ns, and the X-ray spectra were measured using a multichannel analyzer (MCA) for pulse-height analysis. The photon energy was roughly determined by the four-point calibration using tungsten K photons, iodine K fluorescence, and bremsstrahlung maximum-energy photons. K-series characteristic photons from the tungsten target were observed using a 0.5-mm-diam lead pinhole at a tube voltage of 100 kV. Using the YAP(Ce)-MPPC detector, first-generation dual-energy computed tomography was accomplished using iodine and gadolinium contrast media.

10393-19, Session 5

Analysis of the effect of dielectric interlayer on modulation transfer function of granular x-ray scintillator detector

Hyeon Bo Shim, Jookwon Song, Jae W. Hahn, Yonsei Univ. (Korea, Republic of)

Modeling of visible light propagation through diffusive granular scintillator plate is important to predict optical properties of scintillators such as modulation transfer function (MTF). To estimate the diffusive light propagation, it is necessary to solve the radiative transfer equation (RTE) for photon. Therefore, there are various approaches to get the solution of RTE such as Monte-Carlo method and diffusion equation (DE). Although the most of the scintillators contain dielectric interlayer such as shields or adhesives between plate and detector, DE is not suitable to handle the light propagation in this layer because it ignores the propagation direction at an exit plane of the scintillator.

In this study, we suggest the light transport model for the scintillator with dielectric interlayer. From the RTE solution of homogeneous medium, we calculate the intensity distribution at exit plane under the propagation direction. This intensity, paired with specific point of the detector by refraction, is modulated by the rules of etendue conservation and Fresnel equation. The radiant power of the detector point comes from the product of solid angle of the detector mesh and the corresponding intensity. The point spread function (PSF), equivalent to the radiant power distribution of the detector plane, is calculated by numerical integration along the exit plane and the plate thickness. Finally, we analyze the MTF of the scintillator with different refractive index and layer thickness of the dielectric interlayer. We verify our modeling by comparing with the Monte-Carlo method (LightTools).

Silicon strip photon-counting detectors for breast CT *(Invited Paper)*

William C. Barber, DxRay, Inc. (United States) and Interon AS (Norway); H. Ding, L. Singh, K. Habashi, Univ. of California, Irvine (United States); Nail Malakhov, Gregor Wawrzyniak, Interon AS (Norway); Neal E. Hartsough, DxRay, Inc. (United States); Eirik Næss-Ulseth, Interon AS (Norway); Jan Christopher Wessel, Interon AS (Norway) and DxRay, Inc. (United States); Jan S. Iwanczyk, DxRay, Inc. (United States); Sabee Molloi, Univ. of California, Irvine (United States)

We report on recent imaging experiments using edge illuminated silicon strip detectors for high resolution breast computed tomography (CT). The detector's throughput, energy resolution, and stability have been measured at a dynamic range suitable for breast CT at room temperature. The detectors have an array of pixels with a 0.1 mm pitch and can be tiled in one dimension on a single printed circuit board panel and multiple panels can be stacked in two dimensions. The detectors are have a 6 mm or 10 mm depth in the incident direction providing a dynamic range of up to 45 keV and 65 keV respectively. Each pixel has four energy discriminators with a linear energy response across the entire dynamic range. We have tiled the detectors in one dimension (1D) onto single printed circuit boards creating a 20 cm field of view panel. We have stacked two such 1D panels and measured; an output count rate of up to 100 Mcps/mm2 with a linear response up to 40 Mcps/mm2, an energy resolution of 2 keV full width at half maximum across the entire dynamic range, and a noise floor below 4 keV. Images of phantoms have been obtained under realistic breast CT conditions showing micro-calcification detection at a comparable dose as compared to conventional dual view mammography using a single 1D panel. Our future plans include imaging phantoms and post mortem breast tissue with the goal of demonstrating both micro-calcification detection and superior mass legion detection at a comparable dose as compared to conventional dual view mammography.

Optimized modeling of powder-based x-ray scintillator screen for improved total efficiency by double-layer scintillator design

Jookwon Song, Hyeon Bo Shim, Jae W. Hahn, Yonsei Univ. (Korea, Republic of)

Powder-based flat panel X-ray scintillator screen has been widely used in many medical fields for diagnosis and measurement. For the proper application in medical field, required dominant scintillator performances are total efficiency and resolution. We define total efficiency as a multiplication of conversion efficiency (X-ray to visible light energy) and light collection efficiency (ratio of detected visible light energy to emitted visible light energy). Even though high efficiency is required for low dose exposure to patient and high resolution is preferred to maintain each medical field's functional clinical task, both are in trade-off relation. A variety of powder-based flat panel scintillator designs have been proposed to improve its performance, however, because of the scintillator particle's isotropic radiation characteristics, collection efficiency cannot exceed over 50% within a single layer.

In this study, double-layer scintillator design is suggested for improving total efficiency with using theoretical x-ray absorption model and Mie-scattering-based Monte-Carlo (LightTools) analysis. Optimized scintillator layer design would be proposed with respect to the medical fields' clinical task, since image resolution quality requirement is quite different, individually. With selection of design parameters consisted of particle size and each layer's thickness, total efficiency can be improved with equal conversion efficiency while maintaining sufficient resolution-functionality in particular medical field without special complex fabrication technique. We expect that our double-layer scintillator design can be helpful and useful for the one who are in medical fields and scintillator manufacturers.

10393-23, Session 6

3D position-sensitive scintillation detectors for a high-resolution loco-regional PET imaging system *(Invited Paper)*

David Hsu, David Freese, Derek Innes, Craig S. Levin, Molecular Imaging Instrumentation Lab., Stanford School of Medicine (United States)

We are building a dual-panel positron emission tomography (PET) system prototype that enables focused imaging of local regions of interest of the body with 1 mm3 spatial resolution, The detector panels are built from novel 3D position sensitive scintillation (3DPSS) detectors comprising arrays of 1x1x1 mm3 LYSO scintillation crystal elements coupled to position-sensitive avalanche photodiodes (PSAPD). At the present state of system construction, the measured energy resolution over 98,304 crystal elements coupled to 1,536 PSAPDs is 11.34%, and 76.2% (74,938) of the system LYSO crystal elements are found to have greater than 99% event positioning accuracy. Imaging studies performed with a high-resolution phantom demonstrate resolution of the smallest (1.2 mm diameter) features. Besides enabling 1 mm resolution clinical PET studies, we describe other novel ways we are planning to exploit the 3DPSS detector information.

10393-24, Session 6

Applications of IQID cameras

Ling Han, Brian W. Miller, Harrison H. Barrett, H. Bradford Barber, Lars R. Furenlid, The Univ. of Arizona (United States)

iQID is an ionizing-radiation quantum imaging detector developed in the Center for Gamma-Ray Imaging (CGRI). Originally called BazookaSPECT, iQID was originally used for high-resolution gamma-ray imaging and preclinical single-photon emission computed tomography (SPECT). With the use of a columnar scintillator, an image intensifier, and modern CMOS visible light sensors, iQID cameras features outstanding intrinsic spatial resolution. In recent years, many advances have been achieved that greatly boost sensitivity and FOV of iQID, broadening its utility to include nuclear and particle imaging, preclinical and clinical imaging. This paper presents an overview of the recent advances of iQID technology and its applications in gamma-ray scintigraphy, preclinical SPECT, particle imaging (alpha, neutron, beta, and fission fragment), and autoradiography.

A compact energy-independent CZT-based gamma camera *(Invited Paper)*

Youngho Seo, Univ. of California, San Francisco (United States); Yonggang Cui, Paul O'Connor, Brookhaven National Lab. (United States); Qiu Huang, Shanghai Jiao Tong Univ. (China); Zhi Deng, Yu Chen, Tsinghua Univ. (China); Ralph B. James, Savannah River National Lab. (United States)

Conventional gamma cameras are heavy and occupy large volume for all required hardware components. Direct-conversion solid-state detectors like cadmium zinc telluride (CZT) enable a compact design of gamma camera. In addition, conventional gamma camera requires multiple collimators for different gamma-ray photon energies, and the change of collimators between studies sometimes disrupts the workflow. To ease this inconvenience (i.e., bulkiness and collimator change), we have recently developed a compact, CZT-based, energy-independent gamma camera that requires only one collimator to cover a broad range of photon energies.
In this presentation, we will show our design parameters and system specification as well as simulation studies that support our design principles.

Investigation of a high-sensitivity near-infrared-ray computed tomography scanner

Eiichi Sato, Yasuyuki Oda, Sohei Yoshida, Yuichi Sato, Iwate Medical Univ. (Japan); Tomotaka Ishii, Toho Univ. (Japan); Osahiko Hagiwara, Iwate Medical Univ. (Japan) and Toho Univ. (Japan); Hiroshi Matsukiyo, Toshiyuki Enomoto, Manabu Watanabe, Shinya Kusachi, Toho Univ. (Japan)

To perform biomedical computed tomography (CT) for fundamental studies, we have constructed a first-generation near-infrared-ray (NIR) CT scanner. In the NIR-CT, NIR rays are produced from a light-emitting diode (LED), and the penetrating NIR rays are detected using an NIR phototransistor (PT) in conjunction with a long graphite collimator. The peak wavelengths of the LEDs are 850 and 940 nm. The photocurrents flowing through the PT are converted into voltages using an emitter-follower circuit, and the NIR sensitivity increases with increasing resistance between the emitter and the ground. The output voltages are sent to a personal computer through an analog digital converter. The X-ray projection curves for tomography are obtained by repeated linear scans and rotations of the object. The object rotates on the turn table, and the NIR scanning is conducted in both directions of its movement.

10393-30, Session 8

An integrated circuit readout for TOF-PET detectors for PET/MRI *(Invited Paper)*

Ilaria Sacco, Chen-Ming Chang, Stanford University (United States); Michael Ritzert, Peter Fischer, Heidelberg University (Germany); Craig Levin, Stanford University (United States)

The new generation positron emission tomography (PET) detectors for combined PET/magnetic resonance imaging (MRI) must achieve extremely good timing resolution while also being capable of simultaneous data acquisition in a high power, dynamic electromagnetic environment. SiPM-based detectors are a natural choice for this application, given the high gain and fast response of the SiPMs and their insensitivity to magnetic fields. We present the highly-integrated readout circuit “PETA”, specifically designed for SiPM readout and optimal timing resolution required for high performance TOF-PET. PETA is a bump-bonded chip, with pitch between bumps of 272 μm, suitable for compact detector design. It includes 36 readout channels, available with both single-ended and differential-ended front-ends. The event arrival time and energy are measured and digitized on chip with TDC/ADC circuits. The readout architecture is optimized for coping with high hit rate per channel. Two very compact MR-compatible TOF-PET detector modules based on PETA readout have been constructed and tested. Each is built on a single layer (ceramic and PCB substrate respectively), hosting the SiPM array and the readout electronics on opposite surfaces, and thermally decoupled with efficient integrated cooling. Coincidence measurements have shown coincidence time resolution of 230 ps FWHM using arrays of 2.25x2.25x10 mm3 LYSO crystals coupled to matching SiPMs.

Direct and indirect photon pathway imaging: an information-theoretic perspective

Amit Ashok, Liang-Chih Huang, Eric W. Clarkson, The Univ. of Arizona (United States); Sumanta Pattanaik, Univ. of Central Florida (United States)

Typically, a camera only exploits the direct (line-of-sight) optical signal to infer information about the scene. However, the indirect (non-line-of-sight) optical signal, generated by interaction of ambient illumination with objects outside camera's field of view (FoV) and reflected or scattered into the camera FoV carries information about the extended scene, i.e. beyond the FoV. We use Fisher information and a physics-based ray tracing forward model to quantify the extended scene information embedded in the direct and indirect optical signal incident on the camera aperture. Our analysis uses a prototype "Hallway" scene to gauge the feasibility of indirect imaging (i.e. using non-line-of-sight optical signal) when reflector(s) in the scene range from fully diffuse (i.e. Lambertian surface) to fully specular (i.e. mirror surface). Our analysis indicates that under certain conditions, it is indeed theoretically possible to image objects in a scene that are fully obscured or outside the camera FoV.

Paris-Saclay (France); Gabriel Peyré, Ecole Normale Supérieure (France); Jean-Luc Starck, CEA-Ctr. de SACLAY (France)

Optimal Transport theory enables the definition of a distance across the set of measures on any given space. This Wasserstein distance naturally accounts for geometric warping between measures (including, but not exclusive to, images). We introduce a new, Optimal Transport-based representation learning method in close analogy with the usual Dictionary Learning problem. This approach typically relies on a matrix dot-product between the learned dictionary and the codes making up the new representation. The relationship between atoms and data is thus ultimately linear. By reconstructing our data as Wasserstein barycenters of learned atoms instead, our approach yields a representation making full use of the Wasserstein distance's attractive properties and allowing for non-linear relationships between the dictionary atoms and the datapoints.

We apply our method to the PSF (Point Spread Function) spatial interpolation problem in the context of upcoming cosmological surveys, such as ESA's Euclid mission. Euclid will cover a large area of the sky in order to accurately measure the shape of billions of galaxies. PSF estimation and correction is one of the main sources of systematic errors on those galaxy shape measurements. Because of Euclid's large field of view, the PSF variation can be highly non-linear, while still retaining strong geometrical information, making the use of Optimal Transport distances an attractive prospect. By performing the interpolation within our new representation (that of barycentric weights), we can accurately reconstruct Euclid-like PSFs at any point in the field of view.

10394-15, Session 4

Localization of sound sources in a room by one microphone

Helena Peic Tukuljac, Hervé Lissek, Pierre Vandergheynst, Ecole Polytechnique Fédérale de Lausanne (Switzerland)

In this paper we introduce a method for the estimation of the location of multiple sound sources in a room by using only one microphone. Shape of the room is assumed to be known and the position of the microphone. The design guidelines and the limitations of the sensing matrix are given. The implementation is based on the sparsity in the terms of voxels in a room occupied by a source. What is especially interesting about our solution is the localization of the sound sources not only in the horizontal plane, but in the terms of the 3D coordinates.

Solution relies on the fact that the attenuation in the room transfer function at the resonant frequencies differs among different position in the room.

Once we have the location of the sound sources in a room, we can use it in numerous applications starting from hearing aids, robotics up to the investigation of creating anechoic conditions in a room by active noise removal.

10394-16, Session 4

Limited memory trust-region methods for sparse relaxation

Lasith Adhikari, Univ. of California, Merced (United States); Jennifer B. Erway, Wake Forest Univ. (United States); Omar DeGuchy, Univ. of California, Merced (United States); Shelby Lockhart, Wake Forest Univ. (United States); Marcia F. Roummel, Univ. of California, Merced (United States)

Sensing a sparse signal from underdetermined linear measurements is the main problem of compressed sensing. Sparse recovery is important in a variety of different applications such as medical imaging, photography, face recognition, and network tomography. Basis Pursuit and the Least Absolute Shrinkage and Selection Operator (LASSO) are few popular models for sparse recovery. In this paper, we minimize an objective function with a quadratic data-fidelity term (L2-norm) combined with a sparsity-promoting penalty function (L1-norm). There are various methods in the literature to solve this L2-L1 problem, many of which use a gradient decent-type approach. In our method, we propose to solve the L2-L1 sparse recovery problem by transforming the objective function into an unconstrained

differentiable function and applying a limited-memory trust-region method. Unlike gradient projection-type methods, which use only the current gradient, our method uses gradients from previous iterations to obtain a more accurate Hessian approximation. Moreover, we compute a global solution to the trust-region subproblem using a formula which makes use of an efficient partial spectral decomposition of the Hessian approximation via a QR factorization. Numerical experiments in 1- and 2-dimension show that our proposed approach is competitive with the well-known methods by eliminating spurious solutions and artifacts more effectively.

10394-17, Session 4

Underwater object classification using scattering transform of sonar signals

David Weber, Naoki Saito, Univ. of California, Davis (United States)

We present a novel method for underwater object classification using the Scattering Transform (ST) applied to sonar signals. The ST, developed by Mallat et al., performs consecutive layers of wavelet transforms followed by absolute values. The output from a given layer comes from averaging the wavelet transform with the father wavelet. A path corresponds to choosing different scales at each layer. We add paths until a discriminative measure on the classes, such as the earth mover's distance, is reached. We then use LASSO-based logistic regression to select a small number of these coefficients. We used a synthetic dataset generated using a fast solver for the Helmholtz equations, and real data from a semi-controlled experiments with 14 different objects. Our numerical experiments suggest the effectiveness of the ST compared to the results based on the Fourier transform. This is because the ST has more relevant invariants: It has been shown to be quasi-translation invariant and Lipschitz with respect to a very specific form of diffeomorphism, both in the signal domain. We examine the translation quasi-invariance of the ST on the synthetic dataset with respect to the object domain.

10394-18, Session 4

Non-convex Shannon entropy for photon-limited imaging

Lasith Adhikari, Omar DeGuchy, Marcia F. Roummel, Univ. of California, Merced (United States)

In compressed sensing, we acquire a sparse signal by solving an underdetermined linear system, which is typically penalized by a sparsity promoting penalty term. When the measurements are known to be corrupted by Gaussian noise, this optimization problem is known as the LASSO. However, there are many real-world situations such as astronomy, nuclear medicine, and night vision, where the measurement noise does not follow a Gaussian distribution. For example, in imaging, when a relatively low number of photons hits a camera detector, the imaging process is known to be photon-limited. Then the measurements at the detector are corrupted by Poisson noise and are typically modeled using Poisson noise statistics. There are different sparsity promoting optimization methods that have been employed to solve this photon-limited imaging problem. Recent work in nonconvex optimization has shown that sparse signals can be recovered accurately by minimizing the p-norm ($0 <= p < 1$) regularized negative Poisson log-likelihood function. The typical convex Shannon entropy also has been used in literature for imaging. For example, Skilling et al. maximized the Shannon entropy for image recovery in astronomy. In this paper, we propose to regularize the Poisson log-likelihood by the generalized nonconvex Shannon entropy function for recovering sparse signals. In our approach, the Poisson log-likelihood is approximated by a sequence of quadratic approximations and the non-separable Shannon entropy is approximated using its first-order Taylor series. We explore the effectiveness and efficiency of the proposed method using numerical experiments and compare with more recently proposed methods.

K?means clustering on the space of persistence diagrams

Joshua Mike, Andrew Marchese, The Univ. of Tennessee, Knoxville (United States); Vasileios Maroulas, The Univ. of Tennessee Knoxville (United States)

A recent cohort of research aims to apply topological and geometric theory to data analysis. However, more effort is needed to incorporate statistical ideas and structure to these analysis methods. To this end, we present persistent homology clustering techniques through the perspective of data analysis. These techniques provide insight into the structure of the underlying dynamic and are able to recognize important shape properties such as periodicity, chaos, and multi-stability. Moreover, introducing quantitative structure on the topological data space allows for rigorous understanding of the data's geometry, a powerful tool for scrutinizing the morphology of the inherent dynamic. Additionally, we illustrate the advantages of these techniques and results through examples derived from dynamical systems applications.

Shearlet-based regularization in limited data and sparse tomography

Tatiana A. Bubba, Samuli Siltanen, Matti Lassas, Univ. of Helsinki (Finland)

This paper is invited to the LABATE LAEZZA session.

Over recent years, many novel medical imaging technologies employ sparse or limited sampling of the data space. While the use of sparse data may be motivated by different reasons, such as a lower exposure to X-ray radiation, or the need of a reduced scanning time (e.g., a faster sampling due to fast physiological changes), a common feature for such imaging technologies is the ill-posedness of the image reconstruction problem. The use of traditional CT reconstruction algorithms usually leads to poor reconstructions, which tend to be very unstable to noise.

We propose a novel method of promoting a priori information, that accounts for the missing information in the data, by using shearlets as regularization tool. The designed technique is tested on 2D synthetic and real data.

10394-32, Session 9

Detecting neuronal activity from calcium imaging data using FRI methods

Stephanie Reynolds, Jon Oñativia, Simon R. Schultz, Pier Luigi Dragotti, Imperial College London (United Kingdom)

Two-photon calcium imaging can be used to monitor the activity of thousands of neurons across multiple brain areas at single-cell resolution. To harness the power of this imaging technology, neuroscientists require algorithms to detect from the imaging data the time points at which each neuron was active. We present an algorithm based on Finite Rate of Innovation (FRI) theory to detect neuronal spiking activity from this data. By exploiting the parametric structure of the signal, the activity detection problem can be reduced to the classic FRI problem of reconstructing a stream of Diracs.

10394-33, Session 9

GASPACHO: a generic automatic solver using proximal algorithms for convex huge optimization problems

Bart Goossens, Hiêp Q. Luong, Wilfried Philips, Univ. Gent (Belgium)

Many inverse problems (e.g., demosaicking, deblurring, denoising, image

fusion, HDR synthesis) share various similarities: degradation operators are often modeled by a specific data fitting function while image prior knowledge (e.g., sparsity) is incorporated by additional regularization terms. In this paper, we investigate automatic algorithmic techniques for evaluating proximal operators. These algorithmic techniques also enable efficient calculation of adjoints from linear operators in a general matrix-free setting. In particular, we study the simultaneous-direction method of multipliers (SDMM) and the parallel proximal algorithm (PPXA) solvers and show that the automatically derived implementations are well suited for both single-GPU and multi-GPU processing. We demonstrate this approach for an Electron Microscopy deconvolution problem.

10394-34, Session 9

Adaptive windowing and windowless approaches to estimate dynamic functional brain connectivity

Maziar Yaesoubi, Vince D. Calhoun, The Mind Research Network (United States)

We discuss estimation of dynamic dynamic-connectivity among functional-networks in brain. Commonly used approaches are often based on a locality assumption (e.g. sliding-window) which can miss spontaneous changes due to blurring with local but unrelated changes. We discuss recent approaches to overcome this limitation including 1) a wavelet-space approach, essentially adapting the window to the underlying frequency content and 2) a sparse signal-representation which removes any locality assumption. The latter is especially useful when there is no prior knowledge of the validity of such assumption as in brain-analysis. Results on several large resting-fMRI data sets highlight the potential of these approaches.

10394-35, Session 9

Wavelet scattering transforms and machine learning for many particle systems

Matthew Hirn, Michigan State Univ. (United States)

Computing the energy and forces of many particle systems is a fundamental computational problem in quantum chemistry, materials science, and biochemistry. Machine learning algorithms do not simulate the physical system, but estimate solutions by interpolating values provided by a training set of known examples. However, precise interpolations may require a number of examples that is exponential in the system dimension. Tractable algorithms balance the flexibility of general machine learning architectures versus specific design choices that guarantee the learned model will obey fundamental physical laws. This delicate balance is the subject of an emerging body of research at the interface of machine learning and many particle physics. In this talk we give an overview of the field and discuss in some detail one approach based on wavelet scattering transforms.

De-biasing one-step matrix completion

Yaniv Plan, The Univ. of British Columbia (Canada)

A simple and quick method for matrix completion is to fill in missing entries with zeros, take the low-rank projection of the result, and then rescale, thereby giving an estimate of all entries of the matrix. It is known that (amid noise) the estimate has near-optimal sample complexity. The simplicity and speed of creating this estimate makes it appealing to use as a warm start for other methods. However, a non-uniform sampling pattern can introduce bias, resulting in an unusable estimated matrix. We give a simple, data-dependent method to de-bias, which does not assume any knowledge of an underlying sampling distribution.

On distribution of a product of N Gaussian variables

Martin Kliesch, Univ. of Gda?sk (Poland); Daniel Suess, Zeljka Stojanac, Univ. zu Köln (Germany)

Although the product of N Gaussian variables appears naturally in many applications in probability theory and statistics, the distribution of this random variable has not yet been analyzed for generic $N>2$. It has been known that the probability density function of a product of N Gaussian variables can be expressed in terms of Meijer G-functions. First we show that also the complementary cumulative distribution function (ccdf) of the product of Gaussians can be written in terms of Meijer G-functions. Using the residue theorem and the theory developed for even more general Fox H-functions, we are able to expand the corresponding ccdf into power-log series. Numerically we show that for relatively small values of the argument, the ccdf of product of N Gaussians can be well approximated by the principal terms of the series. This bound becomes tighter, as N becomes larger.

This research is motivated by the reconstruction of rank-1 tensors from overlaps of rank-1 measurement tensors. If the latter are formed by products of vectors with independent standard normal components, the resulting measurements follow the product-of-Gaussians distribution. In ongoing work, we have shown that concentration inequalities for unbounded random variables such as Chernoff's inequality are not sufficient to prove recovery guarantees when the number of measurements scales polynomially.

The scaling limit and dynamics of nonconvex algorithms for low-rank subspace estimation

Chuang Wang, Yue M. Lu, Harvard Univ. (United States)

We analyze, in the high-dimensional limit, the exact dynamics of a family of stochastic algorithms for nonconvex subspace estimation. We show that the time-varying empirical measures of the estimates given by the algorithms will converge weakly to a deterministic "limiting process" in the high-dimensional limit. Moreover, this limiting process can be obtained as the unique solution of a nonlinear PDE, and it provides exact information regarding the asymptotic performance of the algorithms. For example, performance metrics such as the MSE, the cosine similarity and the misclassification rate in sparse support recovery can all be obtained by examining the deterministic limiting process. A steady-state analysis of the nonlinear PDE also reveals interesting phase transition phenomena related to the performance of the algorithm. Although our analysis is asymptotic in nature, numerical simulations show that the theoretical predictions are accurate for moderate signal dimensions.

No Abstract Available.

10394-51, Session 13

2D phaseless super-resolution

Myung Cho, The Univ. of Iowa (United States); Christos Thramboulidis, Massachusetts Institute of Technology (United States); Babak Hassibi, California Institute of Technology (United States); Weiyu Xu, The Univ. of Iowa (United States)

Super-resolution is concerned about recovering a signal in the continuous domain from limited measurement data. For the 1D signals, super-resolution often refers to the line-spectrum estimation problem, where we want to find frequency information in the [0,1) continuous domain from randomly or uniformly sampled time-domain data. Unlike the conventional super-resolution problem, in phaseless super-resolution, we only have magnitude measurements of the continuously-parameterized signals in a transform domain. Optic microscopy is one application where the phaseless super-resolution for 2D signals arise. In this paper, we propose algorithms for performing phaseless super resolution for 2D or higher-dimensional signals, and investigate their performance guarantees.

Noise and outlier tolerance of RobustPhaseMax

Paul Hand, Rice Univ. (United States); Thang Huynh, Univ. of California, San Diego (United States)

In the phase retrieval problem, one attempts to find a vector from phaseless linear measurements. The first method with a recovery guarantee for this problem was the PhaseLift semidefinite program. Unfortunately, this approach is intractable for large problem sizes because it squares the problem's dimensionality. Subsequently, algorithms in the natural parameter space were invented, including Wirtinger Flow and several variants. Despite their convexity, these methods enjoy a recovery guarantee under idealized generic measurements, though the proofs are lengthy and technical. Because of the nonconvexity of these approaches, a careful initialization is often used and analyzed.

Recently, a convex formulation in the natural parameter space, called PhaseMax, was discovered independently by Bahmani and Romberg and by Goldstein and Studer. This formulation is a linear program that can be written provided some initialization that correlates with the true solution. The method provably recovers the exact signal under O(n) Gaussian measurements, and it is provably stable to bounded noise. Because of the structure of PhaseMax, it is susceptible to outliers. For example, if a fixed fraction measurements are arbitrary outliers, it is possible for the feasible set of PhaseMax to be trivial. Consequently, Hand and Voroninski recently introduced an L1 penalized version of PhaseMax called RobustPhaseMax. This version permits provably recovery in the presence of a fixed fraction of arbitrarily corrupted measurements. In the present paper, we empirically show the robustness of RobustPhaseMax to the simultaneous presence of outliers and dense noise under real and complex measurements.

Multiscale space-frequency analysis of functions defined on directed graphs

Harry Sevi, Ecole Normale Supérieure de Lyon (France) and Commissariat à l'Énergie Atomique (France); Gabriel Rilling, Commissariat à l'Énergie Atomique (France); Pierre Borgnat, Ecole Normale Supérieure de Lyon (France)

Over the last decade, numerous graph wavelet transforms have been proposed for functions defined on undirected graphs. Based on the diffusion wavelet framework of Coifman and Maggioni, Mhaskar has recently introduced a multi-scale transform for functions defined on directed graphs by studying the singular value decomposition of the random walk operator. One of the fundamental difficulties in the extension of wavelets to directed graphs is the absence of a suitable definition of frequency. In the undirected graph setting, the notion of frequency can be meaningfully related to the quadratic form associated to the Laplacian matrix. This gives properties similar to a Fourier basis to the eigenbasis of the Laplacian operator. However, in the directed graph case the definition of a Laplacian is not as straightforward and it is unclear how to define a meaningful notion of frequency. Using Diffusion wavelets as a starting point, we make a connection between the eigenvectors/eigenvalues of the Random walk matrix, usually non symmetric, with the directed graph Laplacian investigated by Chung, which is symmetric. That enables us to define a desirable notion of frequency on a directed graph and provide a frequency interpretation for the eigenvectors of the random walk matrix. This paves the way for a generalization of the diffusion wavelet approach based on spectral properties of the random walk operator instead of its singular value decomposition as in Mhaskar's work. The idea is developed to build both an orthogonal and a biorthogonal diffusion wavelet transform for directed graphs.

Semi-parametric, parametric, and possibly sparse models for multivariate long-range dependence

Vladas Pipiras, The Univ. of North Carolina at Chapel Hill (United States); Stefanos Kechagias, SAS Institute Inc. (United States); Changryong Baek, Sungkyunkwan Univ. (Korea, Republic of)

The focus of this talk is on multivariate (vector-valued) time series that exhibit long-range dependence (LRD) and, more specifically, on (semi-) parametric models that account for general phase parameters in the cross spectra of the series at the zero frequency. Several new multivariate LRD time series models are introduced and their estimation is discussed, possibly assuming sparsity of model parameters. Applications to several real time series are also presented.

10394-64, Session 17

Simultaneous sparse reconstruction using copula functions

Joao Mota, Heriot-Watt Univ. (United Kingdom); Evangelos Zimos, Vrije Univ. Brussel (Belgium); Miguel Rodrigues, Univ. College London (United Kingdom); Nikos Deligiannis, Vrije Univ. Brussel (Belgium)

Modern sensing devices often acquire multiple modalities of the same phenomenon, yielding necessarily correlated, but possibly heterogeneous, signals. In this paper, we address the problem of simultaneously reconstructing correlated sparse signals. We adopt the framework of Bayesian compressed sensing, specifically belief propagation, and model correlations between different signals through their sparse coefficients. Our main tool to learn correlations is copula functions, which allow treating dependent signals as if they were independent plus a small correction term. We illustrate the potential of the proposed scheme in simple image processing tasks.

Analytic wavelets for multivariate time series analysis

Irène Gannaz, Institut National des Sciences Appliquées de Lyon (France); Sophie Achard, Ctr. National de la Recherche Scientifique (France); Marianne Clausel, Univ. Grenoble Alpes (France); François Roueff, Télécom ParisTech (France)

Many applications fields deal with multivariate long-memory time series. A challenge is to estimate the long-memory properties together with the coupling between the time series. Wavelets offer well-suited tools and many developments have been proposed in univariate settings. In multivariate framework, some recent works highlighted some good properties. Yet real

wavelets procedures present some limitations.

Phase phenomenons appear in multivariate analysis and real wavelets failed to well identify them. Indeed the presence of phase implies different behaviour of the spectral density for positive and negative frequencies around zero. A perspective is to use analytic wavelets to recover jointly long-memory properties, modulus of long-run covariance between time series and phases. Unfortunately it is impossible to construct exact analytic wavelets. Approximate wavelets Hilbert pairs of Selesnick (2002) fullfilled some of the required properties. The quality of analyticity yet has to be quantified. As an extension of Selesnick (2002)'s work, we present some results about existence and quality of these approximate analytic wavelets.

Change point detection in covariance/ network structures

Yi Yu, Univ. of Bristol (United Kingdom)

In this talk I will talk about change point detection in covariance/network structures with application in resting state fMRI data. The talk will be consist of motivation, methodology, as well as numerical and theoretical results.

10394-71, Session 19

Adaptive synchrosqueezing based on a quilted short-time Fourier transform

Alexander Berrian, Naoki Saito, Univ. of California, Davis (United States)

In recent years, the synchrosqueezing transform (SST) has gained popularity as a method for analyzing signals that can be broken down into multiple components determined by instantaneous amplitudes and phases. The central idea of SST is the usage of a reassignment frequency (RF) mapping to improve the concentration of a base time-frequency representation. One such version of SST, based on the short-time Fourier transform (STFT), enables the sharpening of instantaneous frequency (IF) information derived from the STFT, as well as the separation of amplitude-phase components corresponding to distinct IF curves. However, this SST is limited by the time-frequency resolution of the underlying window function used in the STFT, and may not resolve signals exhibiting diverse time-frequency behaviors with sufficient accuracy. In this work, we develop a framework for an SST based on a "quilted" short-time Fourier transform (SST-QSTFT), which allows adaptation to signal behavior in different time-frequency regions through the use of multiple windows. This motivates us to introduce a new discrete RF mapping for the SST, ensuring computational accuracy for a wider variety of windows. We develop a theoretical framework for the SST-QSTFT in both the continuous and the discrete settings, and describe an algorithm for the automatic selection of optimal windows depending on the region of interest. We also describe the potential usefulness of SST-QSTFT for problems in audio signal processing, and provide a Python implementation of our method.

10394-72, Session 19

Coupling wavelets and non-stationary Gaussian process models for the reconstruction of highly heterogeneous data

Sébastien Marmin, Jean Baccou, Institut de Radioprotection et de Surete Nucleaire (France); Jacques Liandrat, Ecole Centrale Marseille (France) and Institut de Mathématiques de Marseille (France); David Ginsbourger, Idiap Research Institute, Ecole Polytechnique Fédérale de Lausanne (Switzerland) and Univ. Bern (Switzerland)

Prediction of objective functions with highly heterogeneous behavior across the input space have various applications such as uncertainties analysis of complex computer codes. The wavelet transform is widely used to capture local variations in a signal or an image. It informs precisely about locations of breakdowns as well as their local frequencies. However, relying on a regular and dense grid of evaluations, it is expensive in some context.

Gaussian Process (GP) models do not require particular designs of experiments. Covariances determining GPs are usually stationary, but this is irrelevant when objective functions have high variations in subareas. Constructing non-stationary covariances, the non-linear map method estimates a warping of the input space. Classical estimation approaches are parametric and require a large set of evaluations which is often not affordable.

We exploit advantages of wavelets and GP models. The wavelet analysis is used in a new non-parametric method for estimating the warping involved in the non-stationary GP model. Stochastical wavelet transform have been studied for many applications with dense data points (image/sound). The originality of our contribution stands in an efficient coupling between wavelets with a non-stationary GP model for situations with only sparse and irregularly placed data points. We provide an algorithm estimating a warping focusing on high variation regions, and consequently the non-stationary GP can fit the data. Convergence is theoretically and numerically studied. The model estimation is incorporated in a sequential design of experiments. This approach show lower prediction errors compared with different methods on a mechanical case study.

10394-73, Session 19

Affine shear tight frames with two-layer structure

Zhihua Che, Xiaosheng Zhuang, City Univ. of Hong Kong (Hong Kong, China)

In this talk, we present the characterizations, construction, and applications of affine shear tight frames with 2-layer structure. First, affine shear tight frames are directional multiscale representation systems generated through operations of dilations, shears, and translations of bandlimited generating functions. Motivated by the successful applications of tensor product complex tight frames that are able to capture both edge and texture features of images, in this talk, we introduce affine shear systems with 2-layer structure that have generators splitting the frequency region at each scale into inner and outer layers, where the inner layer generators are used to capture edge-like features while the outer layer texture-like features. Second, we provide the characterizations of a sequence of affine shear systems with 2-layer structure to be a sequence of affine shear tight frames with 2-layer structure, based on which, smooth affine shear tight frames with 2-layer structure can be easily designed. Moreover, we show that affine shear tight frames with 2-layer structure naturally induce affine shear filter banks with 2-layer structure. Last but not least, based on the affine shear filter banks with 2-layer structure, we show that digital affine shear transforms can be implemented with low redundancy rate and with near-linear computational complexity (NlogN). Numerical experiments are conducted to demonstrate the advantages of our digital affine shear filter banks with 2-layer structure over many other state-of-the-art frame-based methods in image/video processing.

Conference 10395: Optics and Photonics for Information Processing XI

Monday - Tuesday 7 –8 August 2017

10395-1, Session 1

Real time adaptation of spatial resolution for high resolution space cameras

Ralf Reulke, Andreas Eckardt, Deutsches Zentrum für Luft- und Raumfahrt e.V. (Germany)

We expect commercial high resolution imaging systems, which are able to provide data with 25 cm ground sample distance (GSD) or better in the near future. For selling the data, it is necessary to re-sample it to 30 cm. The situation is similar when swinging out the satellite perpendicular to his flight direction. The GSD is then variable with the angle to Nadir direction. In this paper a method is proposed that the resolution adjusts adaptively according to the requirements.

10395-2, Session 1

Ronchigrams of parabolic concave mirrors by inverse ray tracing

Rigoberto Juarez-Salazar, Ctr. de Investigación y Desarrollo de Tecnología Digital (Mexico); Carlos I. Robledo-Sanchez, Fermin Guerrero-Sanchez, Benemérita Univ. Autónoma de Puebla (Mexico); Victor H. Diaz-Ramirez, Ctr. de Investigación y Desarrollo de Tecnología Digital (Mexico); Antonio Barcelata-Pinzón, Univ. Tecnológica de Puebla (Mexico); Gerardo Diaz-Gonzalez, Univ. Tecnológica de la Mixteca (Mexico)

An algorithm to generate ronchigrams of parabolic concave mirrors is proposed. Unlike the conventional direct ray-tracing method, which generates scattered pixels, the proposed algorithm returns regularly sampled images. This provides full compatibility with further fringe processing tasks such as phase demodulation and wavefront analysis. The theoretical principles of our proposal are explained in detail and the computer code is provided. The advantages of our proposal are highlighted by several experiments and computer simulations.

10395-3, Session 1

Radiometric calibration of digital cameras using neural networks

Michael Grunwald, Martin Schall, Pascal Laube, Georg Umlauf, Matthias O. Franz, Hochschule Konstanz (Germany)

Digital cameras are used in a large variety of scientific and industrial applications. For most applications, the acquired data should represent the real light intensity per pixel as accurately as possible. However, digital cameras are subject to physical, electronic and optical effects that lead to errors and noise in the raw image. Temperature-dependent dark current, read noise, optical vignetting or different sensitivities of individual pixels are examples of such effects. The purpose of radiometric calibration is to improve the quality of the resulting images by reducing the influence of the various types of errors on the measured data and thus improving the quality of the overall application.

In this context, we present a specialized neural network architecture for radiometric calibration of digital cameras. Neural networks are used to learn a temperature- and exposure-dependent mapping from observed gray-scale values to true light intensities for each pixel. In contrast to classical flat-fielding, neural networks have the potential to model nonlinear mappings which allows to accurately capture the temperature dependence of the dark current and to model cameras with nonlinear sensitivities. Both scenarios are highly relevant in industrial applications.

The experimental comparison of our network approach to classical flat-fielding shows a consistently higher reconstruction quality, also for linear cameras. In addition, the calibration is faster than previous machine learning approaches based on Gaussian processes.

10395-4, Session 1

An optimized knife-edge method for on-orbit MTF estimation of optical sensors using powell parameter fitting

Lu Han, Chen Gong, Kun Gao, Zhenyu Zhu, Yue Guo, Beijing Institute of Technology (China)

On-orbit Modulation Transfer Function (MTF) is an important indicator to evaluate the performance of the optical remote sensors in a satellite. There are many methods to estimate MTF, such as pinhole method, slit method and so on. Among them, knife-edge method is quite efficient, easy-to-use and recommended in ISO12233 standard for the whole-frequency MTF curve acquisition. However, the accuracy of the algorithm is affected by Edge Spread Function (ESF) fitting accuracy significantly, which limits the range of application. So in this paper, an optimized knife-edge method using Powell algorithm is proposed to improve the ESF fitting precision. Fermi function model is the most popular ESF fitting model, yet it is vulnerable to the initial values of the parameters. Considering the characteristics of simple and fast convergence, Powell algorithm is applied to fit the accurate parameters adaptively with the insensitivity to the initial parameters. Numerical simulation results reveal the accuracy and robustness of the optimized algorithm under different SNR, edge direction and leaning angles conditions. Experimental results using images of the camera in ZY-3 satellite show that this method is more accurate than the standard knife-edge method of ISO12233 in MTF estimation.

10395-5, Session 2

Generation of arbitrary complex phases by a spatial light modulator in a common path interferometer

Ceciibet Mendoza-Rodriguez, Rafael Rueda Ramos, Carlos I. Robledo-Sanchez, Areli Montes-Pérez, Benemérita Univ. Autónoma de Puebla (Mexico); Rigoberto Juarez-Salazar, Ctr. de Investigación y Desarrollo de Tecnología Digital (Mexico)

A method to generate arbitrary complex phases with a two-aperture common path interferometer is presented. The proposed optical setup is based on a 4f system. A transmissive Spatial Light Modulator generates two windows in the input plane. In the first window, the reference beam, a pattern of straight fringes with controlled phase shifts is displayed. In the second window, the test beam, a fringe pattern with curved fringes is displayed. In the Fourier plane, a mask and a Ronchi grating with an appropriate spatial frequency are fixed for diffraction order filtering and superposition of the reference and test beams, respectively. Preliminary experimental results and potential applications in optical metrology are discussed.

10395-6, Session 2

Complex amplitude modulation with a single phase-only spatial light modulator

Liangcai Cao, Dezhao Kong, Song Zong, Hao Zhang, Guofan Jin, Tsinghua Univ. (China)

Complex amplitude modulation is widely applied in optical information processing, optical communications, and laser engineering. The commercialized devices for complex amplitude spatial light modulator is rather limited till now. Two spatial light modulators could be combined to server as a complex amplitude modulator with a pixel-to-pixel superimposition. Several methods, such as phase-only elements and the double-pixel approach, may avoid a strict alignment for pixel-to-pixel superimposition. In this work, complex amplitude data page is encoded into two phase-only data pages by the vector stochastic decomposition algorithm. The two pages could be encoded as one phase-only page and uploaded in a single phase-only spatial light modulator. The experimental evaluation of our method suggests a simple yet effective solution for the applications of computer generated holography.

10395-7, Session 2

SF-FDTD analysis of a predictive physical model for parallel aligned liquid crystal devices

Andrés Márquez, Jorge Francés, Francisco J. Martínez-Guardiola, Sergi Gallego, Mariela L. Álvarez López, Eva M. Calzado, Inmaculada Pascual, Augusto Beléndez, Univ. de Alicante (Spain)

Recently we demonstrated a novel and simplified model enabling to calculate the voltage dependent retardance provided by parallel aligned liquid crystal devices (PA-LCoS) devices for a very wide range of incidence angles and any wavelength in the visible. To our knowledge it represents the most simplified approach still showing predictive capability. We demonstrated the good agreement between theoretical and experimental results, which enables to calculate and optimize the wavefront modulation capabilities of PA-LCoS devices for most of the photonics applications where these devices are applied to control the amplitude, phase and/or state of polarization (SOP) of light beams. Deeper insight into the physics behind the simplified model is necessary to understand if the parameters in the model are physically meaningful. Since the PA-LCoS is a black-box where we do not have information about the physical parameters of the device, we cannot perform this kind of analysis using the experimental retardance measurements. In this work we develop realistic simulations for the non-linear tilt of the liquid crystal director across the thickness of the liquid crystal layer in the PA devices. For these simulations we develop a rigorous method based on the split-field finite difference time domain (SF-FDTD) technique which provides realistic retardance values. These values are used as the experimental measurements to which the simplified model is fitted. From this analysis we learn that the simplified model is very robust to a large range of tilt angle profiles of the LC director across the cell. We also learn that some of the parameters in the model are physically meaningful, proving a useful reverse-engineering approach to probe into internal characteristics of the PA-LCoS device.

10395-8, Session 2

Particle field diagnose using angular multiplexing volume holography

Yu Zhao, China Academy of Engineering Physics (China)

The problem of particle field diagnosing using holography can be met in many areas. But single frame hologram can only catch one moment of the fast event, which can't reveal the change process of an unrepeatable fast event. For events in different time-scale, different solution should be used. We did this work to record a laser induced particle field in the time-scale of tens of micron seconds. A laser of pulse sequence mode is applied to provide 10 pulses, the energy and time interval of whom is 150mJ and 1?s. Four pockels cells are employed to pick up the last four pulses for holographic recording, the other pulses are controlled to pre-expose the photopolymer based recording material, the pre-exposure can enhance photosensitivity of the photopolymer during the moment of holographic recording. The angular multiplexing technique and volume holography is accepted to avoid shifting the photopolymer between each shot. Another Q-switch YAG laser (pulse energy 100mJ, pulse width 10ns) is applied to produce the fast event. As a result, we successfully caught the motion process of the laser induced particle field. The time interval of each frame is 1?s, the angular range of the four references is 14°, and the diffraction efficiency of each hologram is less than 2%. After a basic analysis, this optical system could catch more holograms through a compact design.

10395-9, Session 2

Design and manufacture of volume phase holographic gratings used in VIS/NIR wavebands

Qijing Mei, Peng Liu, Minxue Tang, Soochow Univ. (China)

Volume phase holographic gratings (VPHGs) recorded in dichromated gelatin (DCG) is a kind of hologram with periodic variation of refraction index. They have the characteristics of high diffraction efficiency, high signal-to-noise ratio, low scattering, with no ghosts, and good wavelength selectivity and angular selectivity. As the VPHGs are widely applied in the fields of holographic display, astronomical spectroscopy, optical communications, etc., the requirements for the diffraction properties of VPHGs are getting higher.

In this paper, reflective and transmission VPHGs with high diffraction efficiency that prospected to be used as components in a light beams combiner in VIS/NIR wavebands are designed by applying Rigorous coupled wave theory. By adjusting the process conditions of grating recording, chemical processing and packaging, a reflective VPHG with a frequency near 5000 lp/mm and Bragg wavelength at 633nm used as one element of the light beams combiner are manufactured. The diffraction efficiency and angular selectivity of the VPHG are tested and compared with the theoretical values. A method for improving the diffraction wave-front of the reflective VPHG is also explored. According to the initial diffraction wave-front measured by Zygo interferometer, it took a considerable amount of polishing on the surface of the glass-substrate of the above reflective VPHG and the diffraction wave aberration of the grating is reduced significantly. The experiment results in this paper will provides a technical support for further manufacturing VPHGs with high diffraction efficiency and wave-front quality.

10395-10, Session 3

On the use of video projectors for three-dimensional scanning

Rigoberto Juarez-Salazar, Victor H. Diaz-Ramirez, Ctr. de Investigación y Desarrollo de Tecnología Digital (Mexico); Carlos I. Robledo-Sanchez, Benemérita Univ. Autónoma de Puebla (Mexico); Gerardo Diaz-Gonzalez, Univ. Tecnologica de la Mixteca (Mexico)

Structured light projection is one of the most useful methods for accurate three-dimensional scanning. Video projectors are typically used as the illumination device. However, because video projectors are not designed for structured light systems, some considerations in the calibration procedure must be taken into account. In this work, we present a simple method for calibration of structured light projection systems with video projectors. The proposed method is applied in a fringe projection application.

10395-11, Session 3

Light output enhancement for a plastic scintillator using nano-fibers

Zhangkai Cheng, Samuel J. Blake, The Univ. of Sydney (Australia) and Ingham Institute (Australia); Philip Vial, Sydney South West Health Service (Australia) and The Univ. of Sydney (Australia) and Ingham Institute (Australia); Steven R. Meikle, The Univ. of Sydney (Australia); Minghui Lui, PerkinElmer, Inc. (United States); Zdenka Kuncic, Shaghik Atakaramians, The Univ. of Sydney (Australia)

Electronic portal imaging devices (EPIDs) are x-ray detector systems conventionally used for medical imaging applications in cancer radiotherapy. To improve upon current EPIDs, our group has developed a novel prototype EPID for simultaneous imaging and dose verification that utilises an array of plastic scintillating fibers in place of the standard copper and gadolinium oxysulfide phosphor components [1].

While our prototype EPID exhibits the tissue equivalent response needed for dose verification relative to commercial EPIDs, it suffers from reduced optical output. One contributing factor is the reduced optical coupling due to an air gap between the fiber array and the underlying photodetector. Here we investigate the effect of a layer of polystyrene nano-fibers placed at the end interface of the scintillator array on light extraction efficiency using finite element modelling. We demonstrate that when the nano-fiber diameter is on the order of optical wavelengths (670 nm) and the separation between the fibers is 150-200 nm, overall light extraction enhancement exceeding 10% is possible.

This enhancement stems from two effects: Bragg diffraction arising from the periodic arrangement of the fibers and whispering gallery modes formed at the cross-section of the fiber due to Mie resonances. We show that the nano-fibers increase the transmittance above the critical angle. Moreover, we demonstrate that the light extraction efficiency strongly depends on the polarization of the incident light (s- and p-polarizations), as well as the diameter and periodicity of the nano-fibers.

10395-12, Session 3

Development spectroellipsometric technology for the diagnosis of aquatic environments

Ferdenant A. Mkrtchyan, Vladimir V. Kovalev, Kotel'nikov Institute of Radio Engineering and Electronics of Russian Academy of Sciences (Russian Federation)

Spectroellipsometry methods used for non-destructive investigation of chemical and physical properties of solids and liquids. These methods are based on detection of optical polarization effects arising from the reflection or distortion of a light wave in the interaction with the analyte. In solid state physics spectroellipsometry allows simultaneous measurement of amplitude and phase characteristics of the test sample and accurately determine both film thickness and optical constants of the film material. In the diagnosis of liquids are given the opportunity to assess the concentration of dissolved and suspended chemicals, as well as to determine the spots of pollutants of the water surface. There are several major trends in modern ellipsomery. This spectroellipsometry polarization rotating elements with a photoelastic modulators speed and dividing the radiation beam reflected from the sample to multiple channels with different polarization states and several photodetectors. In V.A. Kotelnikov's Institute of Radioengiheering and Electronics, RAS developed spectroellipsometer a method with the binary modulation of the polarization state, based on the elemental base polarization optics for measurements in a wide spectral range and non-moving polarization elements. This approach provides spectral image of the test sample in a specific spectral range, which enables using mathematical techniques to evaluate the chemical and physical characteristics of this sample. In essence, it is necessary to solve the inverse problem of multi-channel.

In this paper, we propose a new method of ellipsometry measurements - ellipsometry with the binary modulation of the polarization state (BMPS), wherein the sample is alternately directed light with two polarization states and analyzes the signal to the photodetector. The work also explores the possibility of creating and using multi-channel LED spectroellipsometer based on ellipsometry method BMPS completely overlying a relatively broad spectral range 350-810 nm. In developed spectroellipsometer BMPS with no moving polarizing elements combined with high sensitivity, stability and measurement speed.

" The reported study was partially supported by RFBR, research project No. 17-07-00467".

10395-13, Session 3

Optical frequency comb generator using FWM for modern WDM system design

Abel Sanchez-Nieves, Escuela Superior de Ingeniería Mecánica y Eléctrica (Mexico); Ivan A. Aldaya-Garde, Univ. Estadual de Campinas (Brazil); Mauro A. Enciso Aguilar, Ctr. de Educación Continua (Mexico); Abraham Sierra-Calderon, Jose A. Alvarez-Chavez, Ctr. de Investigación e Innovación Tecnológica (Mexico)

Due to the high demand for bandwidth around the world, it is necessary to design optical communications systems with high capacity in addition to being low in cost. Wavelength Division Multiplexing systems are a good choice for such demands. Within WDM systems, Optical frequency comb generator is a technology that produces densely and equally spaced multiple optical subcarrier channels with the use of a minimum number of devices, offering bit rates from gigabits to even a few terabits per second. In this work, a novel optical frequency comb generator using Four Wave Mixing (FWM) for modern WDM systems is presented. The optical frequency comb generator is composed by a continuous wave (CW) laser at 1550.21 nm, a Mach-Zehnder modulator (MZM) fed by a sinusoidal signal at 12.5 GHz, an amplifier with 20 dB gain and a piece of 1.2 km highly nonlinear fiber (HNLF). The result is the generation of six subcarriers with 25 GHz spacing, spectral flatness of 0.71 dBm and transmission rate per subcarrier of 100 Gbps. Full design and characterization results will be included in the presentation.

10395-14, Session 3

A novel symmetric 40 Gbps RZ-DPSK-based colorless WDM-PON

Aftab Hussain, Swedish College of Engineering and Technology (Pakistan)

In this paper a novel Transmission approach regarding generation of simultaneous transmission of 40 Gbps RZ-DPSK data signal is simulated for both downstream & upstream directions. An OCS scheme is utilized for generation of second order dual side-band optical carrier by quadrupling a 50GHz clock-frequency with a 10GHz LN-MZM. The lower side second order band is used to generate an RZ-DPSK data signal at the OLT. At the receiving end 20 km apart, the higher side second order un-modulated band, coupled with the downlink transmitted signal is separated and used for uplink transportations of 40Gbps data in RZ-DPSK format. The proposed architecture eliminated the need of use of a pulse carver at either transmission ends. The proposed solution also eliminated the requirement of using a power splitting at the ONU. The proposed DWDM-PON architecture is seemed to be highly robust, cost effective as well as future proof design.

10395-15, Session 4

Restoration of degraded images using stereo vision

Jose Enrique Hernandez-Beltran, Victor H. Diaz-Ramirez, Ctr. de Investigación y Desarrollo de Tecnología Digital (Mexico)

Image restoration consists in retrieving an original image by processing a captured image of a scene which is degraded by noise or blurring. Commonly restoration algorithms utilize a single monocular image of the observed scene by assuming a known degradation model. In this approach, valuable information of the three dimensional scene is discarded. This work presents the design of a locally-adaptive algorithm for image restoration by employing a stereo camera. The proposed algorithm utilizes information of a three-dimensional scene as well as local image statistics to improve the quality of a single restored image by processing pairs of stereo images. Computer simulations results obtained with the proposed algorithm in terms of objective metrics are analyzed and discussed by processing stereo images degraded by noise and blurring.

10395-16, Session 4

Modeling apparent color for visual evaluation of camouflage fabrics

Scott Ramsey, Troy Mayo, Andrew Shabaev, Samuel G. Lambrakos, U.S. Naval Research Lab. (United States)

As the U.S. Navy, Army, and Special Operations Forces progress towards fielding more advanced uniforms with multi-colored and highly detailed camouflage patterning, additional test methodologies are necessary in evaluating color in these types of camouflage textiles. The apparent color is the combination of all visible wavelengths (380-760 nm) of light reflected from large (≥1m^2) fabric sample sizes for a given standoff distance (10-25ft). Camouflage patterns lose resolution with increasing standoff distance, and eventually all colors within the pattern appear monotone (the "apparent color" of the pattern). This paper presents an apparent color prediction model that can be used for evaluation of camouflage fabrics.

10395-17, Session 4

Restoration of motion blurred images

Leopoldo N. Gaxiola, Rigoberto Juarez-Salazar, Victor H. Diaz-Ramirez, Ctr. de Investigación y Desarrollo de Tecnología Digital (Mexico)

Motion blur estimation is a challenging problem in image restoration. Image degradation occurs due to various reasons like camera defocussing, atmospheric turbulence, and camera or object motion, among others. Satellite imaging, medical imaging, surveillance and target tracking are examples in where automatic motion blur estimation is required. In this work, we present a method to estimate linear uniform motion blur in an observed scene. The proposed approach is based on the spectrum of the blurred image to estimate the degradation parameters. The performance of the proposed method is evaluated in synthetic and real-life images. The obtained results are characterized in terms of accuracy of linear uniform motion blur estimation using objective metrics.

10395-18, Session 4

Computational reduction of the image sets required in conventional phase shifting methods applied to digital photoelasticity

Juan Carlos Briñez de León, Alejandro Restrepo Martínez, John W. Branch Bedoya, Univ. Nacional de Colombia Sede Medellín (Colombia)

In photoelasticity studies, phase shifting methods are highlighted for determining the principal stress directions, and principal stress differences. Notwithstanding, they require sets of images, whose acquisition process involves several rotations of the optical instruments, which makes complex their application.

Reducing the quantity of images represents an opportunity to decrease the time in the acquisition stage, and avoid errors introduced by the optic misalignment caused when the instruments are rotated.

In this paper, a conventional six phase shifting method is modified for evaluating the stress field using less images. Here, the light intensities that emerge from the optical arrangement are rescaled computationally to adjust the fringe patterns to the top and bottom values into the gray scale. There, the black color corresponds to the background light, and the white is the maximum transmitted light. With this process, the intensity equations for three of the phase shifted are expressed in function of the other three. This implicates that three of the images required by the method can be generated computationally from three acquired previously. The rest of the phase shifting process is performed according to traditional methods.

Our method is evaluated in synthetic images generated for the analytical model of a disk under diametric compression.

The results show that the new proposal evaluates the stress information with similar performance than the conventional method, using only a half of the images. This method can be useful for the industrial inspection area in which the image acquisition time is important into the process.

10395-19, Session 4

An adaptive template-matched filtering approach for object segmentation in real-life scenes

Kenia Picos Espinoza, CETYS Univ. Baja California (Mexico) and Ctr. de Investigación y Desarrollo de Tecnología Digital (Mexico); Victor H. Diaz-Ramirez, Ctr. de Investigación y Desarrollo de Tecnología Digital (Mexico)

Object segmentation is a basic task in computer vision that is required to assist several image processing applications such as object extraction, boundary detection, image retrieval, and target tracking for surveillance. Generally, the quality of image segmentation affects the overall performance of these systems. This work uses template matching filters in order to detect a target of interest within a scene. The system employs an adaptive strategy for the generation of space-variant filters which take into account several versions of the target and local statistical properties of the input scene. Template-matching filters has demonstrated that are able to yield a high performance in target recognition applications, given in terms of efficiency of target detection and accuracy in location estimation of the target in cluttered and noisy scenes. Moreover, the proposed method considers the geometric modifications of the target while is moving through a video sequence. The detection accuracy of the matched filter brings the location of the target of interest.

Furthermore, for the case of object segmentation, we implement an adaptive filtering procedure according to the geometrical changes of the target for the estimation of its current support region. The estimated location coordinates are used to compute the support area covered by the target. Then, a watershed segmentation technique is implemented in each frame using the estimated location in order to extract the area of the target from the remaining information of the scene. Experimental tests carried out in a video sequence show that the proposed system yields high detection accuracy, and object segmentation efficiency in real-life scenes.

10395-22, Session PMon

An improved silhouette for human pose estimation

Anthony H. Hawes, Khan M. Iftekharuddin, Old Dominion Univ. (United States)

We propose is a novel method of handling self-occlusion in human pose estimation (HPE) that exploits the dynamic range of a single image to infer the relative positions of limbs under self-occlusion. Specifically, self-occlusions in which the occluded parts are similar in appearance to the background are discussed. Errors caused by self-occlusion cause several modern human pose estimation methods to mis-identify body parts, complicating pose estimation algorithms. Techniques such as contour migration resolve ambiguity for rigid objects, however, require a database of known objects and are not suited for handling self-occlusion with non-rigid, deformable objects. More advanced methods of fitting 3D models to 2D silhouettes could be improved with knowledge of occluded limbs. While more effective algorithms exist for depth images, self-occlusion in 2D images remains a challenge. Our method is motivated by the variable aperture behavior of the human vision processing system: when viewing darker parts of a scene, our iris opens to allow more light, which gives humans more effective dynamic range compared to a single camera image. This method can be used to 1) help solve the inherent ambiguity of pose resulting from fitting a 3D human body model to a 2D silhouette obtained from background substitution, and 2) help initialize pose estimation algorithms. An intelligent edge detection algorithm based on the above principle can be used to provide an input superior to the silhouette for human pose estimation algorithms, which represents an essential step for model-based action recognition methods.

10395-36, Session PMon

Spectrum refinement and correction for laser Doppler velocimeter

Qiucheng Gong, Xiaoming Nie, Jian Zhou, National Univ. of Defense Technology (China)

In this paper, frequency spectrum refinement and frequency spectrum correction method for Doppler signal was proposed separately. Basic principle of frequency spectrum refinement and frequency spectrum correction algorithm was expounded. Spectrum simulation of different frequency ideal sinusoidal signal and real time Doppler signal were studied based on these theories. Theoretical analyses and experimental results demonstrated that, the Goertzel refinement algorithm has the least computing amount and the quickest computing speed; the ratio correction algorithm for frequency correction has simple correction formula, less computing amount and higher correction accuracy. Distinguishability of frequency spectrum can be improved by frequency spectrum refinement and correction technology, which is practical useful in frequency spectrum analyzing laser Doppler velocimeter.

10395-37, Session PMon

Influence of fiber-optic system of transmission of analyzed signals to spread function of diffraction grating spectral device

Vasily Kazakov, Oleg D. Moskaletz, Saint-Petersburg State Univ. of Aerospace Instrumentation (Russian Federation)

Fiber-optic system of transmission of analyzed signal is considered, which allow to transmit signals from optical sources with either impossible or undesirable contact. Diffraction grating spectral device is considered as investigated system. Moreover, the diffraction grating operates with transmitted light, not reflected. Influence of optical fiber is manifested in the distortion of the wave front incident on the spectral device. Front distortion leads to a broadening of the spread function of the device in all diffraction orders, and as a consequence, to a deterioration in resolution of the device. Under the complex spread function a reaction to the homogeneous plane monochromatic wave which clearly communicates the input-output of spectral device is understood. Accounting of fiber-optic system influence is made by introducing a fictitious transparency located directly in front of the diffraction grating.

Investigation of the influence of fiber-optic system to the spread function of the diffraction grating spectral device is made in two ways:

1. Mathematical model describing the influence of a single-mode optical fiber to a spread function of the diffraction grating spectral device is proposed. On the basis of the proposed model computer simulations of the analyzed signal transmission from the end of the optical fiber to the result of photodetection is performed. The calculations are performed for a single-mode optical fiber with a core diameter of 8 microns.

2. Experimental laboratory set up of the diffraction grating spectral device with a fiber optic transmission system is created.

Theoretical calculations are compared with the results of experimental studies.

10395-38, Session PMon

Acousto-optic modulator as an element of signal processing systems of radio and optical diapasons

Vasilisa Romashova, Oleg D. Moskaletz, Saint-Petersburg State Univ. of Aerospace Instrumentation (Russian Federation); Dmitriy Moskaletz, Saint Petersburg Electrotechnical Univ. “LETI” (Russian Federation)

Acousto-optic modulator is a device for input dynamic signals in the optical computing devices, which perform spectrum analysis of signals and calculate correlation functions of the signals.

The important characteristic of the acousto-optic modulator is a transparency function, which determines the quality of acousto-optic systems of information processing. Transparency function is determined by the acoustic wave, which propagating through the medium of acousto-optic interaction. In the idealized case, the action of acousto-optical devices is considered in the approximation of the acoustic wave in the form of acoustic column(parallelepiped form). The linearity of the input signal (linearization of the transparency function) was considered only for rarely used modes of diffraction of the Raman – Nath.

In real conditions it’s necessary to consider diffraction divergence of the acoustic column and the linearization of the transparency function of acousto-optic modulator in the General case of diffraction. In represented research is performed analysis of the diffraction divergence in the dissipative medium and application of methods of nonlinear functional analysis (the formula of finite increments of the Frechet derivative) for purposes of linearizing of transparency function.

The criterion of distinction of the diffracted field taken the increase in the radius of inertia of a plane figure, which describing a one-dimensional diffraction from the radius of inertia of the rectangle, which describing an undiffracted field.

Computer simulation of the diffraction pattern is realized by the method of calculation of the Fresnel integrals in Matlab software

10395-39, Session PMon

An edge detection method with boundary reserved based on non-subsampled contourlet transform for remote sensing imagery

Zizheng Hua, chen gong, Kun Gao, Yan Lu, su chen, Beijing

Institute of Technology (China); Yanqin Jia, Southwest Jiaotong Univ. (China)

During space reconnaissance applications, edge detection from remote sensing imagery plays an important role in the target recognition processing. However, traditional edge detection methods usually only utilize the high-frequency information in one image. Since low-frequency elements may be aliasing with high-frequency parts, the edges extracted may be unconnected under complex topography, different objects and imaging conditions. This paper proposes a novel image edge detection method based on Non-Subsampled Contourlet Transform (NSCT) to keep the object boundary continuously. It transforms the image into Contourlet domain in both high-frequency and low-frequency sub-bands respectively. Depending on the feature of flexible directivity reservation of an image during NSCT, the further edge extraction consists of 3 steps: firstly, the elements of the high-frequency coefficient matrix in Contourlet domain are filtered with high values left using adaptive thresholds. Then the low-frequency edge information is extracted via Canny operator from the low-frequency sub-band information. Finally, to achieve a more consistent edge image, the low-frequency edge image is achieved according to the low-frequency matrix and adopted to compensate the high-frequency image with the isolated noise points eliminated as well. The numerical simulation and practical test results show the higher effectiveness and robustness of the proposed algorithm when comparing with the classical edge detectors, such as Sobel operator, Canny operator, Log operator and Prewitt operator, etc.

Security analysis of the first random phase mask in double random phase encryption

Lingfei Zhang, Thomas J. Naughton, National Univ. of Ireland, Maynooth (Ireland)

Double random phase encoding is one of the most studied techniques in optical encryption. It encrypts an input image to stationary white noise using two statistically independent random phase masks. When the input image is an amplitude image, the first mask is not required for decryption, and this has led to a preponderance in the literature to consider only the second mask (the Fourier plane mask) in security analysis. However, the first mask must also be kept secret because knowing the first mask and a plaintext-ciphertext pair allows one to directly solve for the second mask.

Any error in one's knowledge of the first mask leads to an imperfect estimation of the second mask. In this paper, we examine how the errors propagated to the second mask are amplified when decrypting previously unseen encrypted images. In particular, we find that with even 5% error in the first phase mask the decrypted images are completely unrecognisable (white noise).

The obvious approach to improve the quality of the first phase mask is to consider phase retrieval (given that the mask is already so close to the correct key). However, its convergence can slow considerably after the initial iterations. In this context, we introduce a greedy algorithm to improve the estimation of the first encryption key in order to better recover the second encryption key. We compare how accurately each of the phase retrieval and greedy approaches quantify the security implications of an attacker estimating the first phase mask.

10395-42, Session PMon

Imaging simulation for three-FOV daytime star sensors based on ray tracing

Feng Wu, Xifang Zhu, Ruxi Xiang, Xiaoyan Jiang, Qingquan Xu, Gong Chen, Tao Wu, Changzhou Institute of Technology (China)

Daytime star sensors provide accurate navigation information to air vehicles flying near the ground all day and all night. In order to resist the strong background irradiation disturbance in the atmosphere environment, daytime star sensors are made up of multiple star cameras working in the infrared band. They are called star sensors with multiple fields of view(FOV) and have become an important developing direction of modern star sensors. Huge amounts of star maps are demanded during the daytime star sensors development. Imaging simulation using computer programming is a shortcut to produce star maps efficiently. In this paper, an imaging simulation method of the three-FOV daytime star sensor is proposed. The structure of the three-FOV daytime star sensor is analyzed. Its working principle is introduced. Then, the simulation framework is designed which contains observed star catalog, observed star calculating module, ray tracing module and image output module. The observed star catalog is created after 2MASS (the Two Micron All-Sky Survey)star catalog is studied and processed. Procedures of tracing rays going through the optical systems of the three-FOV daytime star sensors made up of spherical or aspherical optical surfaces are described in detail. Then simulation star maps are output by calculating the pixel energy on the image plane. Finally, simulation experiments are implemented. Simulation star maps are compared with those produced by Sky chart. Observed stars in the maps are identified by applying Pentagram star pattern identification algorithm. Their results prove that the proposed imaging simulation method of the three-FOV daytime star sensor is satisfactory and appropriate.

Optical-microstructures for read-only holograms

Joo Yeon Kim, Electronics and Telecommunications Research Institute (Korea, Republic of); Seung-Yeol Lee, Kyungpook National Univ. (Korea, Republic of); Yong-Hae Kim, Sanghoon Cheon, Seong-Mok Cho, Hojun Ryu, Tae-Youb Kim, Electronics and Telecommunications Research Institute (Korea, Republic of)

In recent years, optical micro-structures have become more important to be developed as optical components for security and authentication applications. The fabrication of these optical micro-structures, the compute-based holograms (CGHs) generating diffraction patterns in a space are attractive technology due to its difficulty in counterfeit. However, in order to generate certain images based on CGHs, it is challenge because of requiring a huge amount of calculation even for binary holograms.

Therefore, the consideration in terms of "mass-production" with an appreciate time and cost-efficient, replication technology is introduced in this work.

The developed binary CGHs generated by SiO_2 patterns on a transparent substrate were transferred onto polymeric layers, and their optical properties will be presented.

Rapid and high-throughput microalgae monitoring platform based on lens-free shadow imaging technology

Dongmin Seo, Sanghoon Shin, Korea Univ. (Korea, Republic of); Sangwoo Oh, Korea Research Institute of Ships and Ocean Engineering (Korea, Republic of); Kiyoung Ann, Euijin Han, Korea Univ. (Korea, Republic of); Moonjin Lee, Korea Research Institute of Ships and Ocean Engineering (Korea, Republic of); Sungkyu Seo, Korea Univ. Sejong Campus (Korea, Republic of)

Microalgae have been employed and studied by various research fields including alternative energy, environmental science, pharmaceutics, or toxicology. Most of studies for microalgae analyzed them by counting the cells, determining the byproducts, or dissolving the cells to check internal materials. However, those analytical methods to date are extremely labor intensive and time consuming or require specialists and expensive equipment. In this study, we propose a rapid and high-throughput

microalgae monitoring platform based on LSIT, which utilizes the changes of diffraction or shadow patterns of micro-objects to count, differentiate, check viability, or evaluate other critical characteristics within a low-cost and compact platform mainly composed of light emitting diode (LED) light source and a complementary metal oxide semiconductor (CMOS) image sensor. In this platform, since the diffraction pattern changes sensitively to the change of an microalgae in shape and size, the change of growth state of the microalgae could be determined by analyzing the diffraction pattern in real time and by single cell basis. Dunaliella tertiolecta is an oval-shaped microalgae in healthy state (live) that turns into a circle shape (cyst) when exposed to stress, eventually losing its original shape (dead) and turning into a dead cell, and its small biological change was successfully quantified and determined by newly developed shadow parameters. Within this platform, automatic counting and analyzing of microalgae were performed with a single digital image rapidly and simultaneously for hundreds of the cells in real time. Therefore, this platform holds great promise in various research fields related with microalgae.

Polarization characteristic pulse electromagnetic signals

Valentina Akperova, Oleg D. Moskaletz, Saint-Petersburg State Univ. of Aerospace Instrumentation (Russian Federation)

Polarization state is one of the important characteristics of signals in radio and optical ranges, and essentially influences on these signals receiving and processing. Propagation of electromagnetic signals is accompanied by polarization distortions; analysis of these distortions was performed in this paper. Vector models of electromagnetic signals and their polarization spectra is the basis of fulfilled research. Vector models and the polarization spectra of electromagnetic signals were introduced on the basis of Fourier integrals. These vector models and the polarization spectra are considered as a generalization of the spectra of scalar signals and as the most common characteristic of electromagnetic signal. All other characteristics of vector signal, including polarization properties, can be found from these vector models and polarization spectra.

The investigation techniques are based on the representation of polarization characteristics in the form Jones vector and the properties of propagation medium and reception system, which change polarization state are described by Jones matrices. Jones matrix, reflecting the properties of propagation medium is frequency dependent. This matrix is presented in form of matrix series, that allows in simplified form to consider polarization distortions with necessary degree of accuracy. On the base of Jones matrices formalism from polarization spectra following correlation functions: cross-correlation function between orthogonal components, cross-correlation function between received and referenced components, and autocorrelation function of every received component were derived.

Optic fields transformation in acousto-optical signal processing systems

Aleksei Orlov, Oleg D. Moskaletz, Saint-Petersburg State Univ. of Aerospace Instrumentation (Russian Federation)

Major topic of our researches is optic fields transformation in the acousto-optical devices designed for spectral-correlation processing of radio signals based on generalized scheme, which includes an optical coherent Fourier-processor, dynamic and static transparents, which allows to input dynamic and static signals in optical coherent Fourier-processor, and a photodetector with photo-detector processing module. As a dynamic transparents we may use an acousto-optic modulators.

Transparents are making possible spatial and spatially-temporal modulation of laser radiation and can be characterized by the transmission functions. These transmission functions are represented in the form of two components: an unit and an additional modulating summand, which can be described in the case of dynamic transparent by a nonlinear representation of the acoustic wave. This wave propagates in the acousto-optical interaction medium. Linearity requirement of the processed dynamic signal inputting in the optical system can be satisfied by the linearization of additional modulating summand in the context of approximation of nonlinear operator by the formula of finite increments.

The distribution of laser light modulated by one, two and three transparents was investigated in the rear focal plane of optical coherent Fourier processor.

Photodetection and postdetector processing is considered both in the context of correlation functions receiving and radio signals spectrum analysis. The expressions for the correlation functions of cross-correlation of two radio signals and the correlation function with a fixed reference signal were obtained. The relation, expressing the radio signal energy spectrum estimation, was given.

Diffractive lenses in biocompatible photopolymers using LCoS

Sergi Gallego, Roberto Fernández, Víctor Navarro-Fuster, Manuel Ortuño, Andrés Máquez, Cristian Neipp, Augusto Beléndez, Inmaculada Pascual, Univ. de Alicante (Spain)

The improving of the technology related to the Spatial Light Modulators (SLM), which can be used to modulate the wavefront of a light beam in many different applications in Optics and Photonics, has widespread their use in many new ways. In particular, the continue miniaturization of the pixel size let them be used as a master for Diffractive Optical Elements (DOE) recording applications. One of these displays is the parallel-addressed liquid crystal on silicon (PA-LCoS) microdisplay, which offers easily the possibility of phase-only modulation without coupled amplitude modulation, but can be use also as an amplitude master just rotating the angles of two polarizers. Together with the DOEs, the optic recording material is also one of the crucial components in the system. Photoresist has been used classically for this purpose. Recently some works provide results of the incorporation of photopolymers, initially used for holographic recording, to fabricate DOEs. Among photopolymers, polyvinil alcohol/acrylamide (PVA/AA) materials have been studied firstly due to the accurate control of their optical properties and the ease of fabrication. Nevertheless, this kind of photopolymer presents a high level of toxicity due mainly to the monomer, acrylamide. In this sense, we made efforts to search alternative “green” photopolymers, one of these is called “Biophotopol”. This material presents good optical properties; nevertheless, it has two principal drawbacks: its refractive index modulation is lower than for the PVA/AA one and the dye used presents very low absorption at 532 nm. In order to solve these problems for recording spherical diffractive lenses, in the present work we have explored different possibilities. On the first place, we have modified the fabrication technique of the solid layer to achieve thicker samples, on the second place we have introduce a biocompatible crosslinker monomer. These two actions provide us a higher value of the phase modulation capability. On the third place we have modified the dye to record DOE’s with the wavelength of 532 nm and obtain a direct comparison with the results obtained with PVA/AA materials.

Laser radiation scattering by the cement in the process of setting and hardening

Peter P. Maksimyak, Mykhaylo P. Gorsky, Andrew P. Maksimyak, Yuriy Fedkovych Chernivtsi National Univ. (Ukraine)

Optical methods of concrete hydration diagnostics have a great potential. In this work we simulated the dynamics of intensity fluctuations in the process of coherent light scattering by the cement during its setting and hardening. Simulation was compared with experimental data.

Modeling of this process using transfer theory and Mie scattering indicatrix is impossible as they don't carry any information about scattered radiation phase. Strict modeling of this process is possible only with analytical theory of multiple scattering using. At present moment, there is an exact solution of this problem for a medium consisting of a set of spheres of equal radius, which is not suitable for our case.

The results show that the presented computer model of cement setting and hardening satisfactorily describes the initial stage of cement minerals hydration with calcium hydroxide formation in the interval 0 - 50 minutes, and the tobermoryth crystals formation and merging in the interval 0 - 300 min, when cement hardening finishes and cement stone begins to gain strength. The stage of further strengthening in the interval 300 - 600 minutes is worse described by this model, because it is not considered the possibility of solid porous structure formation. In addition, on the course of time dependence of speckle field fluctuations intensity of scattered radiation also effects the real shape of scattering particles, which in the framework of this model is not considered. Experimental studies show the optical examination perspectives of the process of cement setting and hardening and also good correlation with theoretical modeling.

Phase-depth mapping in structured light field: analysis and application

Zewei Cai, Xiaoli Liu, Dingnan Deng, Xiang Peng, Shenzhen Univ. (China)

In the previous work, we proposed a method of structured light field combining the light field imaging with the structured illumination. In the structured light field, every ray carries not only the direction information but also the depth-modulated phase information, so that multidirectional depth estimation can be performed for high-dynamic-range 3D imaging. However, the projection axis was implicitly assumed to be perpendicular to the reference plane to obtain the mapping relationship between the phase and the depth. In this paper, we relaxed the implicit condition that the projection axis was not perpendicular to the reference plane, and then derived a universal phase-depth mapping in the structured light field, of which the previous mapping relationship was one special case. Based on this universal mapping relationship, nonlinear model used two coefficients and linear model used single coefficient were proposed. Each ray in the structured light field has its corresponding mapping coefficients that can maps the phase to the depth independently. Real and simulated experiments were implemented to compare the two models in different ranges of depth. Through error analysis, we found that the precision of the nonlinear model could keep consistent in a large range of depth. Consequently, the nonlinear model within a large range of depth was recommended to realize depth estimation, as demonstrated in our final experiment of the multidirectional scene reconstruction.

Spectral analysis of a secure chaotic free space optical communication system

Marc M. Sepantaie, Nader M. Namazi, Amir M. Sepantaie, The Catholic Univ. of America (United States)

This paper aims to study the impact of Free Space Optical (FSO) channel on a transmitted chaotic signal infused by a random binary message [1, 2]. In particular, it examines and corroborates the numerical solution by analytical analysis of the chaotic communication system utilizing the autocorrelation function and power spectral density approach in the presence of multiplicative noise. The autocorrelation function of the multiplicative scintillation noise has been modeled by an exponential function as reported in [3]. Moreover, the transmitted chaotic signal was modeled by a telegraph signal as presented in [4].

The approach taken here renders the additive noise in the FSO channel as negligible, effectively employing the linear system concept to analyze the influence of the scintillation noise on the transmitted chaotic waveform. Consequently, the multiplicative term (scintillation noise) in the received signal can be converted to an additive term with respect to the received signal using a linear portion of the logarithmic operation. The subsequent signal, which consists of two additive terms was then passed through two cascaded Haar filters where a decision can be made using a static threshold to detect the original transmitted random binary message. Simulation experiments were performed in Matlab to validate the theoretical approach.

Aerosol detection using Lidar-based atmospheric profiling

Mohamed I. Elbakary, Old Dominion Univ. (United States); Hossam M. Abdelghaffar, Virginia Polytechnic Institute and State Univ. (United States); Kwasi Afrifa, Old Dominion Univ. (United States); Hesham A. Rakha, Virginia Polytechnic Institute and State Univ. (United States); Mecit Cetin, Khan M. Iftekharuddin, Old Dominion Univ. (United States)

A compact light detection and ranging (LiDAR) is a system that provides aerosols profile measurements by identifying the aerosol scattering ratio as function of the altitude. The aerosol scattering ratios are used to obtain multiple aerosol intensive ratio parameters known as backscatter color ratio, depolarization ratio, and lidar ratio. The aerosol ratio parameters are known to vary with aerosol type, size, and shape. In this paper, we employed lidar measurements to detect the potential source of the aerosol around the campus of Old Dominion University. The lidar ratio and the color ratio are retrieved from collected data. To find the source of aerosol in the measurements, a tracking algorithm is employed to track the concentration of that pollution in the data. The results show that the source of soot pollution in the area of study is Hampton Blvd, a major street, in the area of the campus where the diesel trucks travel between the ports in the city of Norfolk.

Phase demodulation for digital fringe projection profilometry: a review

Juana Martinez Laguna, Rigoberto Juarez-Salazar, Victor H. Diaz-Ramirez, Ctr. de Investigación y Desarrollo de Tecnología Digital (Mexico)

Phase demodulation is an essential image processing stage required by digital fringe projection profilometers. Currently, several approaches for phase demodulation have been proposed. In this work, a comprehensive review of the most successful phase demodulation methods useful for digital fringe projection profilometry is presented. This survey covers fringe pattern normalization, extraction of wrapped phase, and phase unwrapping. Experimental results obtained with a laboratory fringe projection system are analyzed and discussed. The accuracy of the reconstructed surfaces is measured by comparing with the digitized surfaces obtained by a commercial profilometer device.

Polarimetric and diffractive evaluation of 3.74 micron pixel-size LCoS in the telecommunications C-band

Mi Wang, Huawei Technologies Duesseldorf GmbH (Germany); Francisco J. Martínez-Guardiola, Andrés Márquez, Univ. de Alicante (Spain); Yabin Ye, Huawei Technologies Duesseldorf GmbH (Germany); Liangjia Zong, Huawei Technologies Co., Ltd. (China); Inmaculada Pascual, Augusto Beléndez, Univ. de Alicante (Spain)

Liquid-crystal on Silicon (LCoS) microdisplays are one of the competing technologies to implement reconfigurable optical interconnects and more specifically wavelength selective switches (WSS) for optical telecommunications. These systems are the current promising solution for further increasing the traffic capacity in fiber networks. In order to increase the spatial bandwidth and resolution, last generation LCoS have decreased pixel size to values smaller than 4 microns, while increasing the number of pixel elements to more than 4 megapixels. This increases the port count number, thus enabling a superior manageable interconnection capacity bandwidth. However, for the LCoS to be applied in the telecommunication C-band (1.55 micron wavelength) the liquid-crystal layer needs to be significantly thicker than when used in the visible spectrum. The large ratio between the thickness with respect to the pixel size introduces important vicinity problems between neighbouring pixels due to the fringing-field and other cross-talk related phenomena. In the present work we proceed with an experimental evaluation of a 3.74 micron pixel size parallel-aligned LCoS (PA-LCoS) device. We evaluate its performance with well established techniques already applied to larger pixel size PA-LCoS microdisplays in the visible. We analyse with time-average Stokes polarimetry the retardance and its flicker magnitude as a function of voltage, and the existence of residual or induced twist of the LC director. Since the device performs as a beam steering device, diffraction efficiency evaluation is also fulfilled. Discussion of various trade-offs to optimize the performance for the range of steering angles is eventually done.

Quantification of absolute blood velocity using LDA

Mariya A. Borozdova, Ivan Fedosov, Valery Tuchin, Saratov State Univ. (Russian Federation)

Abstract: We developed a novel type of laser Doppler anemometer (LDA) to measure absolute velocity of blood flow in superficial arterioles and venules. The instrument uses two laser beams to probe flow velocity and it is capable for measurement of velocity component perpendicular to its optical axis. Confocal detector with pinhole field filtering allows for registration of singly scattered light for measurements of velocity of blood in superficial vessels . When probing a blood vessel in a direction perpendicular to its axis, the result of velocity measurements almost does not depend on the small variations of angle of incidence. We propose novel method of signal processing to minimize the effect of undesirable light scattering on Doppler frequency shift estimation based on subtraction of low frequency components

10395-56, Session PMon

Research on characteristic of scattered light in laser Doppler velocimeter

Xiaoming Nie, Qiucheng Gong, Jian Zhou, National Univ of Defense Technology (China)

This paper introduced the principle of reference-beam laser Doppler velocimeter, analyzed the relationship between laser Doppler signal and the diameter of spot in theory, and investigated the effect of spot for laser Doppler signal, the polarization characteristic of scattered light and its intensity distribution. The result of theory and experiment showed that, first, the intensity of laser Doppler signal is proportional to the diameter of detector, and is inversely proportional to the diameter of spot, second, the scattered light is centrally distributed to the direction which follows the law of reflection, and the intensity of scattered light is related to coarseness of measured object, and the last, the signal is composed of linear polarization and natural light, and the rougher measured object is, the more seriously polarized light degenerate.

Classification of cognitive systems dedicated to data sharing

Lidia Dominika Ogiela, Marek R. Ogiela, AGH Univ. of Science and Technology (Poland)

In this paper will be presented classification of new cognitive information systems dedicated to cryptographic data splitting and sharing processes. Cognitive processes of semantic data analysis and interpretation, will be used to describe new classes of intelligent information and vision systems. In addition, cryptographic data splitting algorithms and linguistic threshold schemes will be used to improve processes of secure and efficient information management with application of such cognitive systems. The utility of the proposed cognitive sharing procedures and distributed data sharing algorithms will be also presented. A few possible application of cognitive approaches for visual information management and encryption will be also described.

10395-20, Session 5

Unassisted reduction and segmentation of large hyperspectral image datasets

Leanna N. Ergin, John F. Turner II, Cleveland State Univ. (United States)

The information density in hyperspectral data is not uniform across the spectral and spatial dimensions, and the overall information sparsity is often high. While these non-uniformities underpin the sought-after image contrast, high sparsity generates unnecessarily long acquisition and data processing times. Conventional reduction techniques like those based on principal components analysis (PCA) sacrifice the contributions of minority pixel populations while retaining those representing a greater portion of the overall variability. The effect is that some regions in the reconstructed images achieve a higher degree of recovery than other locations, making it difficult to assess the meaning or relevance of the minority pixels, even when this information would reveal important sample defects or spectral inhomogeneities. In the work presented here, we introduce a novel user-unassisted data reduction and image segmentation method called reduction of spectral images (ROSI). The aim of ROSI is to achieve a threshold information density in the spectral dimension for all image pixels. The result effectively segments the image in a manner that provides rapid image contrast that is comparable to traditionally classified images, but does so without a priori information. In addition, ROSI results are suitable for subsequent data analysis enabling ROSI to be performed alone or as a preprocessing data reduction step. A full description of ROSI is presented along with results from both model and real hyperspectral data, and its performance is compared quantitatively to several conventional data reduction methods.

10395-21, Session 5

Visual environment recognition for robot path planning using template matched filters

Ulises Orozco-Rosas, Kenia Picos Espinoza, CETYS Univ. Baja California (Mexico); Victor H. Diaz-Ramirez, Oscar Montiel, Roberto Sepulveda, Ctr. de Investigación y Desarrollo de Tecnología Digital (Mexico)

Computer vision is an important task in robotics applications. Nowadays, there is a demand for autonomous mobile robots in various fields of application, such as driver assistance in automotive industry, logistics and transport of industrial materials, and object tracking for military applications. For robotics applications, the precise interaction with the environment is crucial to accomplish their tasks, in which is frequently changing or unforeseen. This work addresses the problem of environment recognition for path planning and robot navigation. We propose a computer vision system in order to sense a cluttered environment. This work includes template matching filtering approach for accurate obstacle detection and feasible path recognition. The autonomous mobile robot will have to interact with the environment and avoid collisions with obstacles, following the path planned to achieve its established mission. To achieve a smooth mobile robot navigation, an integration of a physics-based technique known as potential field functions is employed. Due to the robot, can move from the start to the goal by taking a single path between multiple possible ways, we use evolutionary computation in order to find an optimal path. Computer simulation results are presented and discussed in terms of accuracy of the recognition system, effectiveness of navigation, and computational efficiency.

Dynamic vehicle guidance by B-spline curves

Rigoberto Juarez-Salazar, Victor H. Diaz-Ramirez, Ctr. de Investigación y Desarrollo de Tecnología Digital (Mexico); Edgar Hernandez-Garcia, Jose Ramiro-Ramiro, Marcos A. Alvarez-Trejo, Instituto Tecnológico Superior de Zacapoaxtla (Mexico)

Path planning for autonomous vehicles is a challenging computer vision problem. In this work, we propose an algorithm to generate dynamically a smooth path for trajectory guidance of an autonomous vehicle. For this, we use B-spline curves and the perspective-distorted images obtained from an onboard camera. The theoretical principles of the algorithm are presented in detail. Preliminary results obtained with an experimental prototype are shown.

10395-24, Session 5

Road mark recognition using HOG-SVM and correlation

Ayman Alfalou, Yousri Ouerhani, C. Brosseau, ISEN Brest (France)

We present an innovative approach for identification and localization of road marks by making use of the VIAPIX® module [1,2]. In the identification step of this scheme, a perspective transform of the image is performed to get a global view of the road. Then, color segmentation is realized to keep only white color objects. Base on the calibration of the VIAPIX® module, the length and width of each detected object are evaluated. Next, a classification of the detected objects is performed using the correlation method [3]. Each road mark is detected and compared to a set of reference objects of a data base. To evaluate the degree of similarity between them, the peak-to-correlation energy (PCE) criterion is taken [3]. Such step of our scheme allows us to avoid considering detected objects with low PCE values. Additionally, other objects treated as false alarms are suppressed via the support vector machine (SVM) classifier [4] based on gradient histograms (HoG) [5]. In the localization step, the distance between road marks and the operating camera determined by Vincenty's approach [6] yields the GPS coordinates.

Optical beam classification using deep learning: a comparison with rule and feature based classification

Md. Zahangir Alom, Univ. of Dayton (United States); Abdul A. S. Awwal, Roger R. Lowe-Webb, Lawrence Livermore National Lab. (United States); Tarek M. Taha, Univ. of Dayton (United States)

Deep Learning methods are becoming popular because of its state-of-the-art performance in image classification tasks. In this paper, we explore laser beam image classification using a novel deep learning approach. The National Ignition Facility (NIF) is the world's largest, most energetic laser which has nearly 40,000 optics that precisely guide, reflect, amplify and focus 192 laser beams onto a fusion target. NIF utilizes four petawatt lasers called the Advanced Radiographic Capability (ARC) to produce backlighting X-ray illumination to capture implosion dynamics of NIF experiments with picoseconds temporal resolution. In the current operational configuration, four independent short-pulse ARC beams are created and combined in a split-beam configuration in each of two NIF Apertures at the entry of the pre-amplifier. The sub-aperture beams then propagate through the NIF beam-path up to the ARC compressor. Each ARC beamlet is separately compressed with a dedicated set of four gratings and recombined as sub-apertures for transport to the parabola vessel where the beams will be focused using parabolic mirrors and pointed to the target. Small angular errors in the compressor gratings can cause the pointing of the sub-aperture beams to diverge from one-another and prevent accurate alignment through the transport section between the compressor and parabolic mirrors. This is an off-normal condition that must be detected and corrected. The goal of the off-normal check is to determine whether the ARC beamlets are sufficiently overlapped into a merged single-spot or diverged into two distinct spots. Thus, the objective of the current task is to explore the use of Convolutional Neural Network (CNN) for beam classification. The recognition results are compared with other approaches such as Deep Neural Network (DNN) and Support Vector Machine (SVM). The experiment results show around 96% classification accuracy using CNN that the CNN approach provides comparable recognition results compared to the present feature based off-normal detection. The misclassified results are further studied to explain the differences and discover any discrepancies or inconsistencies in current classification. The feature based solution is designed to capture the expertise of a human Physicist in classifying the images.

Short summary: The ARC beam is used to generate high energy X-rays for temporally recording the implosion dynamics of a NIF target. As an off-normal condition, we must determine if the beam has two or multiple spots instead of a single spot. Convolutional Neural Network (CNN), Deep Neural Network (DNN) and Support Vector Machine (SVM) are used.

Cognitive approaches for patterns analysis and security applications

Marek R. Ogiela, Lidia D. Ogiela, AGH Univ. of Science and Technology (Poland)

New generation information systems and security solutions are developing rapidly due to the application of the latest achievements in cognitive technologies, and biologically-inspired computational approaches. What are especially important in creation of such systems are techniques used for securing strategic or classified data, and allowing its intelligent transmission and management in distributed infrastructures or in the Cloud.

There is no doubt that all such technologies will become more important in the near future, as a result of the very dynamic development of new generation information systems dedicated for ubiquitous computing in cyberspace or ambient world.

In this paper will be presented new opportunities for developing innovative solutions for semantic pattern classification and visual cryptography, which will based on cognitive and bio-inspired approaches. Such techniques can be used for evaluation of the meaning of analyzed patterns or encrypted information, and involved such meaning into the classification task or encryption process. It also allows using some crypto-biometric solutions to extend personalized cryptography methodologies based on visual pattern analysis.

In particular application of cognitive information systems for semantic analysis of different patterns will be presented, and also a novel application of such systems for visual secret sharing will be described. Visual shares for divided information can be created based on threshold procedure, which may be dependent on personal abilities to recognize some image details visible on divided images.

A study of multiple correct keys and heuristic attacks in optical encryption

Lingfei Zhang, Thomas J. Naughton, National Univ. of Ireland, Maynooth (Ireland)

The strength of optical image encryption techniques, such as double random phase encoding, has been routinely measured using statistical and heuristic attacks. The most common attack scenario is a known-plaintext attack in which an attacker tries to infer the Fourier plane encryption phase key from a 'plaintext' input and 'ciphertext' encrypted image pair. For intensity-encoded inputs, it is well known that there are multiple perfect keys in the keyspace. This was previously considered an advantage to an attacker because finding any one of the keys or approximate solutions were sufficient. However, we propose that this is the reason for the well-documented performance limitations of heuristic attacks. For a small sample of inputs, we have observed that a class of heuristic attack performs suboptimally when its keyspace contains multiple equivalent solutions. We propose that a solution to the problem of underperforming heuristic attacks might be achieved by transforming the keyspace so that it contains only one correct solution. We illustrate this by introducing special circumstances that restrict the keyspace to one solution while keeping the size of the keyspace the same. We use the heuristic-based simulated annealing algorithm in a known-plaintext attack. In our limited tests, the performance of the heuristic attack is significantly improved. In particular, the accuracy of the heuristic-estimated decryption key far exceeds that found with any other simulated annealing attack when measured in terms of decrypting any subsequent decrypted images that were encrypted with the same key.

10395-28, Session 6

Performance evaluation of the multiple-image optical compression and encryption (MIOCE) method by increasing target images number

Ayman Alfalou, M. Aldossari, C. Brosseau, ISEN Brest (France)

In our earlier study [Opt. Express 22, 22349-22368 (2014)], we proposed and validated a compression and encryption mothed that simultaneous compress and encrypt closely resembling images. This multiple-image optical compression and encryption (MIOCE) method is based on a special fusion of the different target images spectra together in the spectral domain. To assess the capacity of the MIOCE method, we now evaluate and determine the influence of target images number on the MIOCE method. This analysis allows us to evaluate the performance limitation of this method. To achieve this goal, we use a new criterion based on root-mean-square (RMS) [Opt. Lett. 35, 1914-1916 (2010)] and compression ratio to determine the spectral plane area. Then, these different spectral areas are merged in a single spectrum plane. By choosing specific areas, we can compress together 38 images instead of 26 using the classical MIOCE method. The quality of reconstructed image is evaluated by making use of the mean-square-error criterion (MSE).

A low-light-level video recursive filtering technology based on the three-dimensional coefficients

Rongguo Fu, Shu Feng, Tianyu Shen, Hao Luo, Yifang Wei, Nanjing Univ. of Science and Technology (China); Qi Yang, Institute of Electric Science of Shanxi Province (China)

Low light level video is an important method of observation under low illumination condition, but the SNR of low light level video is low, the effect of observation is poor, so the noise reduction processing must be carried out. Low light level video noise mainly includes Gauss noise, Poisson noise, impulse noise, fixed pattern noise and dark current noise. In order to remove the noise in low-light-level video effectively, improve the quality of low-light-level video. This paper presents an improved time domain recursive filtering algorithm with three dimensional filtering coefficients.This algorithm makes use of the correlation between the temporal domain of the video sequence. In the video sequences, the proposed algorithm adaptively adjusts the local window filtering coefficients in space and time by motion estimation techniques,for the different pixel points of the same frame of the image, the different weighted coefficients are used.It can reduce the image tail, and ensure the noise reduction effect well. Before the noise reduction,,a pretreatment based on Boxfilter is used to reduce the complexity of the algorithm and improve the speed of the it. In order to enhance the visual effect of low-light-level video, an image enhancement algorithm based on guided image filter is used to enhance the edge of the video details. The results of experiment show that the hybrid algorithm can remove the noise of the low-light-level video effectively, enhance the edge feature and heighten the visual effects of video.

Fast automated 3D modeling of building interiors

Avideh Zakhor, Univ. of California, Berkeley (United States)

In this talk, I will present a mapping and visualization platform for 3D modeling and documentation of indoor environments. Unlike existing mobile mapping systems with wheels, our proposed hardware acquisition devices are human wearable and hence must compensate for complex human gait. Furthermore, lack of GPS in indoor environments precludes us from applying existing outdoor mapping techniques indoors. We propose two distinct hardware systems to accomplish this task. The first one is an ambulatory backpack system equipped with a suite of sensors worn by an operator walking at normal speeds in and out of rooms inside a building in a continuous walk through. The second one is a handheld system carried by a human operator as s/he waives it at walls while walking inside the building. Both systems share a common software pipeline that results in 3D point clouds, texture mapped surface reconstructed 3D models, 3D architectural models and floor plans, and web based virtual navigation with tagging, annotation, and dimension measurement capability. We also describe a visual analytic platform that can be used to automatically recognize energy relevant assets such as windows, lights, and computers. The same walkthrough that generates 3D model can also be used to collect building sensor fingerprints which can later be used in a mobile app to locate building occupants, for example by first responders in emergency situations. I will describe some of the challenges in design and implementation of this platform and outline a number of open technical problems.

Adaptive noise filtering of sinusoidal signals with unknown nonlinear phase

Rigoberto Juarez-Salazar, Victor H. Diaz-Ramirez, Ctr. de Investigación y Desarrollo de Tecnología Digital (Mexico)

A self-tuning filter for noise rejection useful for sinusoidal signals is proposed. Unlike the conventional sine fitting methods, no a priori knowledge of the encoded phase distribution is assumed. For this, an analytical model with two parameters (the amplitude of the sinusoid and the standard deviation of the noise) is used. The estimated standard deviation is used for adaptively tuning the noise filter. The results show the feasibility of the proposal for fringe pattern normalization.

10395-32, Session 7

Ultra-high-speed multiframe imaging with all-optical information shutters

Guanghua Chen, China Academy of Engineering Physics (China)

We have developed a multiframe imaging system with both ultra-high temporal resolution and diffraction lim-ited spatial resolution based on all-optical information shutter (AOIS). An AOIS consists of a signal beam and a strobe beam. The signal beam is a train of laser pulses which carry the movie information of the object, and the strobe beam is a single reference laser pulse. Using ultra-short pulse laser and multiple Mach-Zehnder interfer-ometer cavities, a group of AOIS were built and all-optical multiframe imaging was realized. The AOIS is not applied to control the energy transmission of light but to switch the optical information related to the specific process. By the AOIS, the multiframe images can be captured with interval of fs~ns. Moreover, the AOIS will not decrease the image resolution until the diffraction limit is reached. Experimentally, the ultra-fast physical processes such as air breakdown by intense laser radiation and laser ablation of Al foil were observed by the all-optical multiframe imaging system. The results of laser driven air experiments showed “point breakdown” and “serial breakdown” phenomenon induced by laser focusing in the air. In the diagnostics of laser driven Al foil, ultra-fast “jet” with apparent velocity of exceeding 9000 km/s were observed. These results confirmed that this method is effective for the ultra-high temporal and spatial resolution diagnosis of ultra-fast phenomenon.

10395-33, Session 7

Experimental demonstration of OFDM/OQAM transmission with DFT-based channel estimation for visible laser light communication system

Jing He, Jin Shi, Rui Deng, Lin Chen, Hunan Univ. (China)

Recently, visible light communication(VLC) based on light-emitting diodes (LEDs) is considered as a candidate technology for fifth-generation (5G) communications, VLC is free of electromagnetic interference and it can simplify the integration of VLC into heterogeneous wireless networks. Due to the data rates of VLC system limited by the low pumping efficiency, small output power and narrow modulation bandwidth, visible laser light communication(VLLC) system with laser diode(LD) has paid more attention. In addition, orthogonal frequency division multiplexing/offset quadrature amplitude modulation (OFDM/OQAM) is currently attracting attention in optical communications. Due to the non-requirement of CP and time-frequency domain well-localized pulse shapes, it can achieve high spectral efficiency. Moreover, OFDM/OQAM has lower out of-band power leakage so that it increases the system robustness against inter-carrier interference (ICI) and frequency offset.

In this paper, a Discrete Fourier Transform (DFT)-based channel estimation scheme combined with the interference approximation method (IAM) is proposed and experimentally demonstrated for VLLC OFDM/OQAM system. The performance of VLLC OFDM/OQAM system with and without DFT-based channel estimation is investigated. Moreover, the proposed DFT-based channel estimation scheme and the intra-symbol frequency-domain averaging (ISFA)-based method are also compared for the VLLC OFDM/OQAM system. The experimental results show that, the performance of EVM using the DFT-based channel estimation scheme is improved about 3dB compared with the conventional IAM method. In addition, the DFT-based channel estimation scheme can resist the channel noise effectively than that of the ISFA-based method.

10395-34, Session 7

The least-squares algorithm for interferograms with random phase shifts

Zhongsheng Zhai, Hubei Univ. of Technology (China)

Phase-shifting interferometry (PSI) is a useful technique in surface shape measurements with the advantages of non-contact, non-destruction, high accuracy and high resolution. The measurement correctness is relied on the extraction accuracy of initial phase. In traditional PSI, the phase shift between each interferogram is expected to keep constant. However, because of the influence of nonlinear phase shifter, mechanical vibration or air turbulence, there are some unavoidable phase shift errors. Therefore, the accuracy of the initial phase and phase-shifts is important but often difficult to be guaranteed.

In this paper, we propose a general least-squares algorithm to extract the parameters of interferograms: the initial phase, the background intensity and the modulation amplitude. It is a non-iterative algorithm, and it is also suitable for non-uniform phase shifts conditions. We express the phase-shift fringe patterns with the intensity of pixel index. With the rule of LS, we deduced the solution progress by extending the partial derivatives. With a single calculation, the parameter of the initial phase, the background intensity and the modulation amplitude can be extracted, and the solutions for the parameters are analytical. Numerical simulations and optical experiments are given to demonstrate the performance of the presented method, and the results show that the proposed method is rapid, effectively and accurate.The proposed method can accurately and rapidly present the solution of parameters of interferograms. Moreover, it is offer a way to solve the parameters of signal with sine feature in other domain.

10395-51, Session 7

Research on active polarization-based target detection on sea surface

Dongming Lu, Guohua Gu, Lixiang Geng, Jiang Xu, Nanjing Univ. of Science and Technology (China)

Under the sea-sky background, the optical characteristics of vessel target are influenced by many factors, such as atmospheric scattering, water reflecting, and the surface properties of the target, which blocks the objects being observed and discriminated. Since the polarization image contains abundant information of the object, the detecting ability of imaging system would be improved via observing the polarization features of this object. The active polarized imaging method is adopted, in which two beams of light with orthogonal polarization state are used to illuminate the target alternatively. While in the detecting part, two-channel CCD cameras are set in parallel, which are also fitted with orthogonal polarizer to acquire polarized images. Once the polarized data of various angle is collected, objects with different optical properties could be discriminated by the means of retrieval of the material's optical parameters. The PFR (Polarization Fresnel Reflection Coefficient) varies as the incident angle of the active polarized light changes which are demonstrated by the experimental results. Therefore by obtaining the PFR data at various angles could help to distinguish different material, which could enhance the discriminative ability. Since the PFR diversity of metallic material from the water, the proposed method could increase detection probability of vessel target under the sea-sky background.

Conference 10396: Applications of Digital Image Processing XL

Monday - Thursday 7 –10 August 2017

Part of Proceedings of SPIE Vol. 10396 Applications of Digital Image Processing XL

10396-2, Session 1

Joint denoising, demosaicing, and chromatic aberration correction for UHD video

Ljubomir Jovanov, Wilfried Philips, Univ. Gent (Belgium); Klaas Jan Damstra, Frank Ellenbroek, Grass Valley Nederland B.V. (Netherlands)

High-resolution video capture is crucial for numerous applications such as surveillance, security, industrial inspection, medical imaging and digital entertainment. In the last two decades, we are witnessing a dramatic increase of the spatial resolution and the maximal frame rate of video capturing devices.

In order to achieve further resolution increase, numerous challenges will be facing us. Due to the reduced size of the pixel, the amount of light also reduces, leading to the increased noise level. Moreover, the reduced pixel size makes the lens imprecisions more pronounced, which especially applies to chromatic aberrations. Even in the case when high quality lenses are used some chromatic aberration artefacts will remain. Next, noise level additionally increases due to the higher frame rates. To reduce the complexity and the price of the camera, one sensor captures all three colors, by relying on Color Filter Arrays. In order to obtain full resolution color image, missing color components have to be interpolated, i.e. demosaiced, which is more challenging than in the case of lower resolution, due to the increased noise and aberrations.

In this paper, we propose a new method, which jointly performs chromatic aberration correction, denoising and demosaicing. By jointly performing the reduction of all artefacts, we are reducing the overall complexity of the system and the introduction of new artefacts. In order to reduce possible flicker we also perform temporal video enhancement. We evaluate the proposed method on a number of publicly available UHD sequences and on sequences recorded in our studio.

10396-3, Session 1

A hardware architecture for real-time shadow removal in high-contrast video

Pablo Verdugo, Jorge E. Pezoa Nunez, Miguel Figueroa, Univ. de Concepción (Chile)

Broadcasting an outdoor sport event at daytime is a challenging task due to the high contrast present between areas in shadow and light within the same scene. Commercial cameras typically do not handle the high dynamic range of these scenes well, resulting in broadcast streams with very little shadow detail. We propose a hardware architecture for real-time shadow removal in high-resolution video, which reduces the effect mentioned above and improves shadow detail. The algorithm operates only on the shadow portions of each video frame, thus improving the results and producing more realistic images than algorithms that operate on the entire frame, such as simplified Retinex and histogram shifting. The architecture receives an input in the RGB color space, transforms it into the YUV space, and uses color information from both spaces to produce a mask of the shadow areas present in the image. The mask is then filtered using a connected components algorithm to eliminate false positives and negatives. The hardware uses pixel information at the edges of the mask to estimate the illumination ratio between light and shadow in the image, which is then used to correct the shadow area. Our prototype simultaneously processes up to seven video streams of 1920x1080 pixels at 60 frames per second on a Xilinx Kintex-7 XC7K325T FPGA.

10396-4, Session 1

High quality image recovery

Xiteng Liu, QualVisual Technology (Canada)

We introduce a new computing method for extracting essential data elements from data sets or data sources without loss of information. The full data sets may be recovered from the essential elements. Both extraction and recovery can be accomplished in real time. The invertible operations build a new type of equivalence between data sets and their subsets. This equivalence changes traditional concepts and methodologies in mathematics, data science and data processing engineering. The new method makes revolutionary improvement in technical performance than existing methods. It may greatly improve efficiency in data acquisition, compression and visualization, especially in resolution scalable applications. It may be extensively applied to image and video technologies, medical imaging, remote sensing, wireless communication and many other fields. Demo software and testing data are downloadable at http://qualvisual.net.

10396-5, Session 1

Image quality assessment for determining efficacy and limitations of image processing methods

Chris M. Ward, Joshua D. Harguess, Shibin Parameswaran, SPAWAR Systems Ctr. Pacific (United States)

Traditional metrics for evaluating the efficacy of image processing techniques do not lend themselves to understanding the capabilities and limitations of modern image processing methods - particularly those enabled by deep learning. When applying image processing in engineering solutions, a scientist or engineer has a need to justify their design decisions with clear metrics. By applying blind/referenceless image spatial quality (BRISQUE) and Structural SIMilarity (SSIM) index scores to images before and after image processing, we can quantify quality improvements in a meaningful way and determine the lowest recoverable image quality for a given method.

10396-6, Session 1

The role of optical flow in automated quality assessment of full-motion video

Joshua D. Harguess, Scott Shafer, SPAWAR Systems Ctr. Pacific (United States)

In real-world video data, such as that taken of full-motion-video (FMV) from unmanned vehicles, surveillance systems, and other sources, various corruptions to the raw data is inevitable. This can be due to the image acquisition process, noise, distortion, and compression artifacts, among other sources of error. However, we desire methods to analyze the quality of the video to determine whether the underlying content of the corrupted video can be analyzed by humans or machines and to what extent. Previous approaches have shown that motion estimation, or optical flow, can be an important cue in automating this video quality assessment. However, there are many different optical flow algorithms in the literature, each with their own advantages and disadvantages. We examine the effect of the choice of optical flow algorithm (including baseline and state-of-the-art), on motion-based automated video quality assessment algorithms using two standard optical flow databases.

10396-7, Session 2

Prediction of HDR quality by combining perceptually transformed display measurements with machine learning

Anustup Choudhury, Suzanne Farrell, Robin Atkins, Scott J. Daly, Dolby Labs., Inc. (United States)

We present an approach to predict overall HDR display quality as a function of key HDR display parameters. We first performed subjective experiments on a high quality HDR display (Pulsar) that explored five key HDR display parameters: maximum luminance, minimum luminance, color gamut, bit-depth and local contrast (backlight resolution). Subjects rated overall quality for different combinations of these display parameters: maximum luminance from 100 to 4000 nits; color gamut areas of BT. R. 709 and DCI-P3; minimum luminance from 0.005 to 0.1 nits; bit-depths from 7 to 12 bits; and backlight resolution ranging from the Pulsar's full backlight resolution to global dimming.

We explored two models – a physical model solely based on physically measured display characteristics and a perceptual model that transforms physical parameters using human vision system models. For the perceptual model, we use a family of metrics based on a recently published color volume model (ICtCp), which consists of the PQ luminance nonlinearity (ST2084) and LMS-based opponent color, as well as an estimate of the display point spread function.

To predict overall visual quality, we apply linear regression and other machine learning techniques such as SVM and RBF networks. We use RMSE and Pearson/Spearman correlation coefficients to quantify performance. We found that the perceptual model is better at predicting subjective quality than the physical model and that SVM is better at prediction than linear regression. We studied the significance and contribution of each display parameter. In addition, we found that combined parameters such as contrast do not improve prediction. Alternate perceptual models were also evaluated and we found that models based on PQ non-linearity are the best at prediction.

10396-8, Session 2

Low complexity reference frame selection in QTBT structure for JVET future video coding

Sang-hyo Park, Tianyu Dong, Euee S. Jang, Hanyang Univ. (Korea, Republic of)

In this paper, we propose a reference frame search method for JVET future video codec (FVC) that employs the quadtree plus binary tree (QTBT) structure. Among many new technologies proposed in FVC, QTBT poses a significant challenge since it contains the structural change of coding tree unit from HEVC. To reduce the encoding complexity of FVC with QTBT structure, we investigated some redundancy in motion estimation process—particularly, the reference frame search. In this paper, we present a method that effectively restricts the reference frame search range of general motion estimation as well as of affine motion estimation, exploiting the dependence within QTBT structure. The proposed method minimizes the maximum of the reference frame search ranges per each coding unit (CU) based on the prediction information of parents node. To be specific, the prediction direction and the index of reference frame of parent node were used. In addition, the proposed method utilizes the information of binary tree depth and of temporal layer to prevent undesired coding loss. The experimental results showed that the proposed method decreased the encoding time of motion estimation by 34% on average in comparison with joint exploration test model (JEM) 3.0, maintaining a reasonable coding efficiency (less than a 0.3% BD-rate loss).

10396-9, Session 2

Performance analysis of the AV1 video codec on 360 video coding

Adeel Abbas, Sandeep Doshi, GoPro, Inc. (United States); Pankaj Topiwala, Wei Dai, Madhu Krishnan, FastVDO Inc. (United States)

In this paper, we present performance evaluation of the AV1 codec from Alliance for Open Media (AOM) for virtual reality (VR) content. AV1 is a new codec which promises to offer compression efficiency beyond HEVC and VP9, with the benefit of being open and royalty free. From our experiments, AV1 achieves average bitrate savings of about X% compared to HEVC reference software HM.

10396-10, Session 2

Viewport analysis for omnidirectional videos

Adeel Abbas, Sandeep Doshi, GoPro, Inc. (United States); Pankaj Topiwala, Wei Dai, Madhu Krishnan, FastVDO Inc. (United States)

In this paper, we analyze viewport size considerations for Omnidirectional videos. As viewport size increases, rectilinear projection suffers from notable distortions along the edges of viewport. We attempt to classify and propose ways to correct some of these distortions. We present some results from subjective quality analysis to demonstrate effectiveness of the proposed scheme.

10396-11, Session 3

Verification testing of the HEVC screen content coding extensions

Gary J. Sullivan, Microsoft Corp. (United States); Vittorio A. Baroncini, GBTech (Italy); Rajan L. Joshi, Qualcomm Inc. (United States); Shan Liu, MediaTek USA Inc. (United States); Jizheng Xu, Microsoft Research Asia (China); Haoping Yu, Huawei Technologies Co., Ltd. (United States); Xiaoyu Xiu, InterDigital Communications, Inc. (United States)

This paper presents a verification test of the compression capability of the recently developed Screen Content Coding (SCC) extensions of the High Efficiency Video Coding (HEVC) standard. Formal subjective testing was conducted, and the results verify a major benefit in compression capability for the SCC extensions.

10396-12, Session 3

JPEG XS-based frame buffer compression inside HEVC for power-aware video compression

Alexandre Willème, Antonin Descampe, Univ. Catholique de Louvain (Belgium); Gaël Rouvroy, Pascal Pellegrin, intoPIX s.a. (Belgium); Benoît M. Macq, Univ. Catholique de Louvain (Belgium)

With the emergence of Ultra-High Definition video, reference frame buffers (FBs) inside HEVC-like encoders and decoders have to sustain huge bandwidth. The power consumed by these external memory accesses accounts for a significant share of the codec's total consumption. This paper

describes a solution to significantly decrease the FB's bandwidth, making HEVC encoder more suitable for use in power-aware applications. The proposed prototype consists in integrating an embedded lightweight, low-latency and visually lossless codec at the FB interface inside HEVC in order to store each reference frame as several compressed bitstreams. As opposed to previous works, our solution compresses large picture areas (ranging from a CTU to a frame stripe) independently in order to better exploit the spatial redundancy found in the reference frame. This work investigates two data reuse schemes namely Level-C and Level-D. Our approach is made possible thanks to simplified motion estimation mechanisms further reducing the FB's bandwidth and inducing very low quality degradation. In this work, we integrated JPEG XS, the upcoming standard for lightweight low-latency video compression, inside HEVC. In practice, the proposed implementation is based on HM 16.8 and on XSM 1.0 (JPEG XS Test Model). Through this paper, the architecture of our HEVC with JPEG XS-based frame buffer compression is described. Then its performance is compared to HM encoder. Compared to previous works, our prototype provides significant external memory bandwidth reduction. Depending on the reuse scheme, one can expect bandwidth and FB size reduction ranging from 50% to 83.3% without significant quality degradation.

10396-13, Session 3

Comparison and enhancements of JVET, AV1, and HEVC codecs

Pankaj Topiwala, Wei Dai, FastVDO Inc. (United States)

A brief comparative analysis of recent modern codecs is provided, covering HEVC, AV1, and JVET. Summary results for performance analysis are included. We also explore enhancements of current codecs, especially AV1. Our enhancements are in the areas of high performance image coding, coding of HDR content, and for 360 degree video.

10396-14, Session 3

Advanced single-stream HDR coding with SDR backward compatibility

Pankaj Topiwala, FastVDO Inc. (United States)

High dynamic range and wide color gamut (HDR/WCG, or briefly HDR) video is the current pinnacle of video transmission formats, and is already in use in streaming services such as Amazon and Netflix. Several formats for transmitting HDR content are currently in the market, including a standard called HDR10 (or PQ10), as well as proprietary technology called Dolby Vision. Neither of these formats offer what we called backward compatibility... the ability to render an SDR video straight from the bitstream, as well as to recreate an HDR by using embedded metadata. This paper presents an advanced approach that offers backward compatibility to SDR, yet has performance advantages over the current HDR10 approach.

10396-15, Session 3

Novel inter and intra prediction tools under consideration for the emerging AV1 video codec

Urvang B. Joshi, Debargha Mukherjee, Jingning Han, Yue Chen, Sarah Parker, Hui Su, Angie Chiang, Yaowu Xu, Google (United States); Zoe Liu, Google (United States); Yunqing Wang, Jim Bankoski, Google (United States)

Google has been developing new coding tools starting from VP9 as the baseline since early 2015, with a target to release a next generation codec by the end of 2017. Initially the plan was to release a successor codec to VP9, called VP10, but subsequently with the launch of the consortium called Alliance for Open Media, the efforts on VP10 merged into AV1 - the formal name of the first codec from the consortium.

As part of this effort, several new coding tools have been developed and already integrated into the Av1 codebase. In this paper we provide an overview of the new tools that aid prediction of pixel blocks. Specifically, we will describe the following: new block partition structures; a tool for ranking candidate motion vectors for available references; expanded intra prediction tools - including recursive filter intra prediction, extended directional prediction as well as new intra prediction modes; overlapped block motion compensation modes - including causal and non-causal; compound prediction modes - including wedge and smooth predictors - that combine two inter predictors as well as one inter and one intra predictor; expanded interpolation filter sets for inter prediction; warped motion modes including global and locally adaptive ones.

Results are presented on standard test sets to show up to 15% BDRATE reduction.

10396-16, Session 3

Novel intra prediction modes for AV1 codec

Ariel Shleifer, Ofer Hadar, Ben-Gurion Univ. of the Negev (Israel)

As the demand for high quality video data has been permanently increasing, the need and scope for compression has also been increasing due to increased spatial correlation of pixels within a high quality video frame. One basic feature that utilizes the spatial correlation of pixels for video compression is Intra prediction, which determines the compression efficiency of codec. Intra prediction enables significant reduction of the Intra frame (I frame) size and, therefore, contributes to efficient exploitation of bandwidth. In a recent work presenting video codec comparisonit was shown that the coding efficiency of VP9 is inferior to that of H.265/MPEG-HEVC. One possible reason for this result is that the HEVC's Intra prediction algorithm uses as many as 35 directions for prediction, while VP9 uses only 9 directions including the TM prediction mode. Therefore, there is high motivation to improve the Intra prediction scheme with new, original and proprietary algorithms that will enhance the total performance of the Google future codec and reduce the gap between its performance and that of HEVC. In this work, instead of using different angles for predictions, we introduce four unconventional intra-prediction modes for the AV1 codec and a new intra prediction concept called Intra prediction standard routes (IPSR).

Furthermore, we implement a new scanning method for inter/intra prediction in order to maximize the correlation and to reduce the sent data.

The following modes were developed and tested in the AV1 new platform:

Weighted CALIC (WCALIC), Intra-Prediction using System of Linear Equations (ISLE), Prediction of Discrete Cosine Transformations (PrDCT) Coefficients and Reverse Least Power of Three (RLPT).

10396-17, Session 3

Display of high dynamic range images under varying viewing conditions

Tim Borer, British Broadcasting Corp. (United Kingdom)

Recent demonstrations of high dynamic range (HDR) television have demonstrated that superb images are possible. With the emergence of an HDR television production standard (ITU Recommendation BT.2100) last year, HDR television production is poised to take off. Some programmes have already been made in HDR. However research to date has focused on image display only under "dark" viewing conditions. HDR television will need to be displayed at varying brightness and under varying illumination (for example to view sport in daytime or on mobile devices). We know, from common practice with conventional TV, that the rendering intent (gamma) should change under brighter conditions, although this is poorly quantified. For HDR the need to render images under varying conditions is all the more acute.

This paper seeks to explore the issues surrounding image display under

varying conditions. It presents results of the relationship between viewing conditions and the visibility of quantisation ("banding" artefacts). It also describes how visual adaptation is affected by display brightness, screen size and viewing distance, and surround illumination. Existing experimental results are presented and extended to try to quantify these effects. Using these results it is shown how HDR images may be displayed so that they are perceptually equivalent under different viewing conditions. In this way the consistency of HDR image reproduction should be improved, thereby better maintaining "creative intent" in television.

10396-18, Session 3

Spherical rotation orientation indication for HEVC and JEM coding of 360 degree video

Jill M. Boyce, Qian Xu, Intel Corp. (United States)

Omnidirectional (or "360 degree") video, representing a panoramic view of a spherical 360º x 180º scene, can be encoded using conventional video compression standards, once it has been projection mapped to a 2D rectangular format. When viewed with virtual reality devices such as head mounted displays, 360 degree video can provide an immersive experience, where users can dynamically change their viewport of the omnidirectional video. Because a much larger region of video is coded than is viewed, high resolution is required, leading to a large bitrate. Efficient compression of 360 degree video is thus highly desirable to facilitate storage and transmission.

Equirectangular projection is the most common format currently used for mapping 360 degree video to a rectangular representation using the HEVC standard, or the JEM under development by the JVET. However, video in the top and bottom regions of the image, corresponding to the "north pole" and "south pole" of the spherical representation, is significantly warped. Conventional HEVC codecs do not efficiently encode these regions. In this paper and in JCTVC-Z0025/JVET-E0075, we propose to perform spherical rotation of the input video prior to HEVC/JEM encoding in order to improve the coding efficiency, and to signal in an SEI message parameters that describe the inverse rotation process recommended to be applied following HEVC/JEM decoding, prior to display.

An encoder algorithm is presented that automatically determines pan, tilt, and roll spherical rotation parameters that can improve coding efficiency for some video sequences. For the Chairlift sequence, after a rotation of (0, 12, 79) degrees has been applied, 17.8% bitrate gain (using the WS-PSNR end-to-end metric) using HM16.14 and 12.3% gain using JEM 4.1, and an average gain of 2.9% for HM16.14 and 2.3% for JEM 4.1 for the full test set using the common test conditions described in JVET-D1030.

An SEI message has been adopted for a future edition of HEVC, as described in JCTVC-Z0051, to indicate the presence of equirectangular projection format omnidirectional video. Portions of our JCTVC-Z0025 contribution were incorporated into this SEI message, to accomplish the proposed spherical rotation operation.

10396-19, Session 3

Complexity and performance tradeoff for next generation video coding standard development

Elena A. Alshina, SAMSUNG Electro-Mechanics (Korea, Republic of)

New international standards for video coding come roughly once in 10 years. Typical requirement for the new standard is twice better compression efficiency compared to the predecessor. Unfortunately, each new video codec also increase implementation cost and power consumption a lot. This paper present analysis of performance and complexity for several key tools in HEVC standard and tools included into Joint Exploration Model which is used for potential of future video coding standard study. Suggestions and recommendation form industry on future video codec standardization are discussed.

10396-20, Session 3

Optimal design of encoding profiles for ABR streaming

Yuriy A. Reznik, Karl O. Lillevold, Abhijith Jagannath, Justin Greer, Manish Rao, Brightcove, Inc. (United States)

We discuss a problem of optimal design of encoding profiles for adaptive bitrate (ABR) streaming applications.

We show, that under certain conditions and optimization targets, this problem becomes equivalent to the problem of quantization of random variable, which in this case is bandwidth of a communication channel between streaming server and the client. But using such reduction to a known information-theoretic problem, we immediately arrive at class of algorithms for solving this problem optimally. We illustrate effectiveness of our approach by examples of optimal encoding ladders designed for different networks and reproduction devices.

Specific techniques and models utilized in this paper include:

- modeling of SSIM-rate functions for modern video codecs (H.264, HEVC) and different content

- adaptation of SSIM (by using scaling & CSF-filteing) to account for different resolutions and reproduction settins

- SSIM - MOS scale mapping

- CDF models of typical communication networks (wireless, cable, WiFi, etc)

- algorithms for solving quantization problem (Lloyd-Max algorithms, analytic solutions, etc)

10396-120, Session 3

Performance comparison of AV1, JEM, VP9, and HEVC encoders

Dan Grois, Tung Nguyen, Detlev Marpe, Fraunhofer-Institut für Nachrichtentechnik Heinrich-Hertz-Institut (Germany)

This work presents a performance evaluation of the current status of two distinct lines of development in future video coding technology: the so-called AV1 video codec of the industry-driven Alliance for Open Media (AOM) and the Joint Exploration Test Model (JEM), as developed and studied by the Joint Video Exploration Team (JVET) on Future Video Coding of ITU-T VCEG and ISO/IEC MPEG. As a reference, our study also includes reference encoders of the respective starting points of development, as given by the first encoder release of AV1/VP9 for the AOM-driven technology, and the HM reference encoder of the HEVC standard for the JVET activities. For a large variety of video sources ranging from UHD over HD to 360° video content, the compression capability of the different video coding technology has been evaluated by using a Random Access scenario along with the JVET common test conditions. As an outcome of our study, it was observed that the latest AV1 release achieved average bit-rate savings of around 12% relative to VP9 at the expense of a factor of 46 in encoder run-time. On the other hand, the latest JEM release provides an average bit-rate saving of around 28% relative to HM with a factor of approximately 10 in encoder run-time. When directly comparing AV1 and JEM for static quantization parameter settings, AV1 produces an average bit-rate overhead of more than 95% relative to JEM at the same objective reconstruction quality and a factor of approximately 1.5 in encoder run-time. Even when operated in a two-pass rate control mode, AV1 shows a significantly inferior compression performance relative to that of the one-pass JEM encoder for a static quantization configuration.

Dynamic frame resizing with convolutional neural network in video codec

Jaehwan Kim, Youngo Park, Kwang Pyo Choi, Jong-Seok Lee, Sunyoung Jeon, Jeong-Hoon Park, SAMSUNG

Electronics Co., Ltd. (Korea, Republic of)

In the past, video codecs such as vc-1 and H.263 used a technique to encode reduced-resolution video and restore original resolution from the decoder for improvement of coding efficiency. The techniques of vc-1 and H.263 Annex Q are called dynamic frame resizing and reduced-resolution update mode, respectively. However, these techniques have not been widely used due to limited performance improvements that operate well only under specific conditions. In this paper, video frame resizing (reduced/restore) technique based on machine learning is proposed for improvement of coding efficiency. The proposed method does not show limited performance improvements in specific conditions like the existing techniques, but shows improved subjective performance over all the high resolution videos which are dominantly consumed recently. In order to assess subjective quality of the proposed method, Video Multi-method Assessment Fusion (VMAF) which showed high reliability among many subjective measurement tools was used as subjective metric. Moreover, to assess general performance, diverse bitrates are tested. Experimental results showed that BD-rate based on VMAF was improved by about 30% compare to conventional HEVC. Especially, VMAF values were significantly improved in low bitrate. Also, when the method is subjectively tested, it had better subjective visual quality in similar bit rate.

Variable block Harris-based-features image watermarking

Issam J. Dagher, Univ. of Balamand (Lebanon)

Feature-based image watermarking schemes have gained important attention. Existing schemes have shown robustness against noise and geometrical attacks.

This paper proposes an improved feature-based watermarking algorithm. Robust feature points are detected using the Harris Detector. In the embedding stage, sequences are placed into regions located around feature points. The sequences used are PN, Gold and decimal. In the extraction process, image features are re-allocated using the same detector. Each feature point is used as a center of an N x N region. This region is moved horizontally and vertically within its neighboring pixels. Each move should be registered in a matrix as a correlation value of this region with the initial sequence. This procedure is repeated for all feature points till we find all the watermarked regions. The maximum correlation obtained will determine the center of the watermarked region. The proposed algorithm is compared to other feature-based watermarking schemes. Different variety of tests showed that this algorithm is more robust against noise and geometric attacks for grayscale images.

A multi-scale segmentation algorithm for high resolution remote sensing images

Tingting Zhou, Lingjia Gu, Ruizhi Ren, Jilin Univ. (China)

In recent decades, with the rapid development of remote sensing technology, high resolution remote sensing images have been widely used in various fields due to their characteristics, such as rich spectral information and complex texture information. As a key step in the feature extraction, multi-scale image segmentation algorithm has been a hotspot currently. Traditional statistical region merging methods only consider spectral similarities but ignore the phenomenon that the same spectrums may represent different objects. Pixels' similarities rather than regions' are taken into account for traditional merging methods. That might lead to an over-merging problem for the regions with high regional and low pixel differences located in the fuzzy boundary. A multi-scale segmentation algorithm based on dynamic statistical region merging with texture information (DSRMT) for high resolution remote sensing images is proposed in this paper. In this algorithm, the segmental scale is controlled by an adjustable parameter Q. Meanwhile, the similarity function is redefined to guarantee that the most similar regions are merged each time. In addition, the texture information is introduced with the increasing of merging region area. Therefore, the algorithm is adjusted to apply for multi-band images easily. The experimental results demonstrated that the multi-scale segmentation algorithm based on DSRMT is more efficient and accurate for image segmentation of high resolution remote sensing.

Automated extraction of complex shape buildings from high resolution imagery

Qiong Cao, Lingjia Gu, Ruizhi Ren, Tingting Zhou, Jilin Univ. (China)

Building extraction from the remote sensing imagery is one of the major application fields of remote sensing techniques since 1970s. In particular, high resolution satellites have practical significance in exploiting automatic, intelligent, accurate building extraction methods. Most methods are appropriate for rectangular building with regular shape, which cannot extract irregular building structures including arc lines. To address these problems, an extraction method for complex shape building is proposed in this paper. Considering that the high-resolution imagery can provide extensive information, including spectral and spatial information, building properties are analyzed. Subsequently, the decision tree for building information extraction is constructed by the analysis results. Finally, other features, such as Soil Adjusted Vegetation Index ?SAVI?, Normalized Difference Water Index (NDWI), texture analysis and morphological filtering are used to reduce interference from false information. The advantage of the proposed method is that it is applied to non-rectangular building extraction, not just the rectangular building.

In order to validate the proposed method, a comparative study is performed between the supervised method by the support vector machine (SVM) classification and the proposed method. The results demonstrate that the proposed method can achieve satisfactory correctness rates for complex shape buildings, and give better results than the supervised method.

Blind image quality evaluation using the conditional histogram patterns of divisive normalization transform coefficients

Ying Chu, Shenzhen Univ. (China); Xuanqin Mou, Xi'an Jiaotong Univ. (China); Hengyong Yu, Univ. of Massachusetts Lowell (United States)

The performance of traditional machine learning based blind image quality assessment (BIQA) methods is sensitive to the contents of training samples, and it is easily influenced by the learning strategies. In this project, a novel blind image quality evaluation frame is presented to overcome the aforementioned drawbacks. Without complicated training and learning processes, the proposed method utilizes a clustering method to generate image quality code book. The idea comes from a property that image quality could be reflected by the degree of statistical independence among neighboring divisive normalization transform (DNT) coefficients. Specifically, it is observed that the patterns of combined conditional histograms among spatially adjacent DNT coefficients in degraded images could be used to represent image quality. Therefore, a high dimensional feature vector is constructed by using the conditional histogram patterns, and the code book is clustered and generated by combining the extracted feature vectors from sample database and the corresponding subjective score levels. Then, the distances between the image feature vectors and the code words are calculated and interpolated to construct the objective image quality score. Experiments are performed based on up to date databases (e.g. LIVE, CSIQ, TID2013 and CID 2013). The results show that the proposed metric outperforms the current no training BIQA methods for most cases. In cross database experiments, the proposed method is comparable to those metrics based on support vector machine. This implies that it is feasible and effective to evaluate image quality blindly by constructing code book through clustering image pattern of conditional histograms among adjacent DNT coefficients.

An effective road extraction algorithm from high resolution remote sensing images

Yushan Zhang, Tingfa Xu, Beijing Institute of Technology (China); Tingting Zhou, Jilin Univ. (China)

Satellite remote sensing technology has become one of the most effective methods for land surface monitoring in recent years, due to its advantages such as short period, large scale and rich information. Meanwhile, road extraction is an important field in the applications of high resolution remote sensing images. An intelligent and automatic road extraction algorithm with high precision has great significance for transportation, road network updating and urban planning.The fuzzy c-means (FCM) clustering segmentation algorithms have been used in road extraction, but the traditional algorithms did not consider spatial information. An improved fuzzy C-means clustering algorithm combined with spatial information is proposed in this paper, which is proved to be effective for noisy image segmentation. Firstly, the image is segmented using the improved FCM algorithm. Based on the segmentation result, the center lines of the roads are extracted by the ridgeline tracking algorithm and then connected by the tensor voting algorithm. By using the characteristics of both sides of the road, the roads are reconstructed by shifting the center lines at final. The experimental results demonstrated that the improved fuzzy C-means clustering algorithm is more accurate for road extraction from high resolution remote sensing images. The problem of centerline fracture in the process of road extraction is effectively solved using the tensor voting algorithm. Meanwhile, the loss of the integrity of the road caused by obstacles is greatly compensated through the road reconstruction result using the centerline characteristic.

Investigation of methods for construct a system of optical sensors for measure relative orientation of industrial robots for monitoring of the technosphere objects

Andrey V. Petrochenko, Igor A. Konyakhin, ITMO Univ. (Russian Federation)

Purpose: Developing of the methods of relative orientation of industrial robots and construction of three-dimensional scenes areas of interest using optical sensors. Results: Developed the method of construction of the relative orientation of industrial robots to meet the challenges of reconstruction of three-dimensional mapping and image-set received from the optical sensors. The basis of this technique is the problem of finding the solution of the global position of each industrial robot on the relative orientation of each of them. The global position of the industrial robot characterized by a matrix of rotation and transfer vector in a coordinate system (adopted as a global). As a result of the global positioning possible to solve the major problems of vision such as detection, tracking and classification of objects of the space in which these systems and robots operate. Practical significance: Continuous qualitative monitoring of technosphere objects.

Siamese convolutional networks for tracking the lumbar spine

Yuan Liu, Nanjing Univ. of Science and Technology (China)

Deep learning models have demonstrated great success in various computer vision tasks such as image classification and object tracking. However, tracking the lumbar spine by digitalized video fluoroscopic imaging (DVFI), which can quantitatively analyze the motion mode of spine to diagnose lumbar instability, has not yet been widely applied in clinic due to the lack of steady and robust tracking method. In this paper, we propose a novel visual tracking algorithm of the lumbar vertebra motion based on a siamese convolutional neural network(CNN) model. We train a full-convolutional neural network offline to learn generic image features. The siamese network is trained to learn a similarity function that compares the labeled target in the first frame with the candidate patches in the current frame. And the similarity function returns a high score if the two images depict the same object. Once learned, the similarity function is used to track a previously unseen object without any adapting online. In the current frame, our tracker is performed by evaluating the candidate rotated patches sampled around the previous frame target position and presents a rotated bounding box to locate the predicted target precisely. Experiments indicate that the proposed tracking method can detect the lumbar vertebra steadily and robustly. Especially for images with low contrast and background clutter, the presented tracker can still achieve good tracking performance. Further, the proposed algorithm operates at real-time speed and achieves state-of-the-art performance in the online tracking benchmark (OTB) data set.

Research on node extraction based on line feature

Xiaofeng Li, Sheng Chen, Weimin Li, Yuhai Zhang, Univ. of Science and Technology of China (China)

This paper is based on the FAST observatory fund project, whose panel surface is required to detect. The panel image is obtained by the camera and the panel nodes are extracted by the digital image processing method, finally ,the three-dimensional coordinates of the nodes are reconstructed to obtain the surface shape of the panel. The extraction of the relevant data information in the image, such as the intersection of two straight lines, which is a very important part in the machine vision learning, directly affects the quality of the experimental data. Based on the analysis of a large number of corner detection methods, the following detection method is proposed: first of all, the image down sampling and binaryzation are operated through the basic methods of digital image processing; secondly, Canny operator is used to detect the image to extract the best edge data; then, according to the corresponding threshold, the straight line data in the image is obtained by the cumulative version of the Hough transform, and duplicate removal and merging operations are carried out on the extracted straight lines to obtain optimized lines. Then on the basis of the relevant mathematical equations, the intersection of the lines optimized are solved; merging the near intersections according to the relevant threshold, the original matching results are obtained. Finally, through the experimental verification, the operation on the specified ROI region can achieve better experimental results, and achieve the optimal extraction of points.

An efficient algorithm for coplanar feature points matching in binocular vision photogrammetry

Weimin Li, Siyu Shan, Yuhai Zhang, Gang Liu, Sheng Chen, Univ. of Science and Technology of China (China); Xiaofeng Li, Univ of Science and Technology of China (China)

Feature points matching, an important branch of machine vision, are frequently used in three-dimensional reconstruction, photogrammetry, camera calibration, object recognition and so on. In the system of binocular stereo vision, the prerequisite for three-dimensional reconstruction is the proper treatment of the feature point matching of images in the left and right cameras. Correct feature point matching functions as the groundwork to get accurate three-dimensional metric information. To solve the problem that feature points matching in the binocular vision measurement of plane workpiece, an efficient matching algorithm for coplanar feature points is presented in this paper. Firstly, the method utilize the existing algorithm

used for detection and recognition to obtain the high-precision center coordinates of the circular target. Then the proposed algorithm make use of the epipolar geometry to calculate the correlation values between the points in the left and right camera images. Next, sort these values and their corresponding points could obtain the initial matching sets. Finally, according to the above ordered sets, the presented method do correct the mismatching relationship of the initial matching sets to achieve the best matching which based on the reprojection errors of points and the plane constraint. Experimental results show that the mismatch can be eliminated effectively by the method, and the proposed algorithm is efficient, robust and high enough in accuracy. Compared with existing calibration methods, the proposed method is effective and simple to solve the above-mentioned problem.

Real-time heartrate measurement for multi-people using compressive tracking

Ling Liu, Yuejin Zhao, Ming Liu, Lingqin Kong, Liquan Dong, Feilong Ma, Zhi Cai, Zongguang Pang, Yachu Zhang, Peng Hua, Ruifeng Yuan, Beijing Institute of Technology (China)

The rise of aging population has created a demand for inexpensive, unobtrusive, automated healthcare solutions. Image PhotoPlethysmoGraphy(IPPG) aids in the development of these solutions by allowing for the extraction of physiological signals from video data. However, the main deficiencies of the recent IPPG methods are non-automated, non-real-time and susceptible to motion artifacts(MA).To date, few works have studied this problem. In this paper, a real-time heart rate(HR) detection method for multiple subjects simultaneously is proposed, which consists of getting multiple subjects' facial video automatically through a Webcam, detecting the region of interest (ROI) in the video and reducing the false detection rate by our improved Adaboost algorithm, reducing the MA by our improved compress tracking algorithm, signal preprocessing for denoising and multi-threads for higher detection speed. For comparison, HR was measured simultaneously using an medical pulse oximetry device for every subject during all sessions. Experimental results on a data set of 30 subjects show that the max average absolute error of heart rate estimation is less than 8 beats per minute (BPM), and processing speed of every frame has almost reached real-time:the experiments with video recordings of ten subjects under the condition of the pixel resolution of 600? 800 pixels show that the average HR detection time of 10 subjects was about 17 frames per second (fps).

Vision-based mobile robot navigation through deep convolutional neural networks and end-to-end learning

Yachu Zhang, Yuejin Zhao, Ming Liu, Liquan Dong, Mei Hui, Lingqin Kong, Xiaohua Liu, Beijing Institute of Technology (China)

In contrast to humans, who use only visual information for navigation, many mobile robots use laser scanners and ultrasonic sensors along with vision cameras to navigate. This work proposes a vision-based robot control algorithm based on deep convolutional neural networks. We create a large 15-layer convolutional neural network learning system and achieve the advanced recognition performance. Our system is trained from end to end to map raw input images to direction in supervised mode. The images of data sets are collected in a wide variety of weather conditions and lighting conditions. Besides, the data sets are augmented by adding Gaussian noise and Salt-and-pepper noise to avoid over-fitting. The algorithm is verified by two experiments, which are line tracking and obstacle avoidance. The line tracking experiment is proceeded in order to track the desired path which is composed of straight and curved lines. The goal of obstacle avoidance experiment is to avoid the obstacles indoor. Finally, we get 3.29% error rate on the training set and 5.1% error rate on the test set in the line tracking experiment, 1.8% error rate on the training set and less than 5% error rate on the test set in the obstacle avoidance experiment. During the actual test, the robot can follow the runway centerline outdoor and avoid the obstacle in the room accurately. The result confirm the effectiveness of the algorithm and our improvement in the network structure and train parameters.

A locally adaptive algorithm for shadow correction in color images

Victor Karnaukhov, Vitaly Kober, Institute for Information Transmission Problems (Russian Federation)

Correction of color images distorted by nonuniform illumination usually uses the following degradation model: a part of the scene close to a directed light source is illuminated much brighter than the rest of the scene. A serious problem often arises in the case of nonuniform illumination of 3D objects of the scene; that is, extended heavily shadowed regions with a small area of transition from light to shadow are appeared in captured images. In this presentation, a locally-adaptive algorithm for correction of shadow regions in color images is proposed. The algorithm consists of segmentation of shadow areas with rank-order statistics followed by correction of nonuniform illumination with human visual perception approach. The performance of the proposed algorithm is compared to that of common algorithms for correction of color images distorted by nonuniform illumination and contained shadow regions.

Tracking of multiple objects with time-adjustable composite correlation filters

Alexey Ruchay, Chelyabinsk State Univ. (Russian Federation); Vitaly Kober, Ctr. de Investigación Científica y de Educación Superior de Ensenada B.C. (Mexico); Ilya Chernoskulov, Chelyabinsk State Univ. (Russian Federation)

An algorithm for tracking of multiple objects in video based on time-adjustable adaptive composite correlation filtering is proposed. The object is selected at the beginning of the algorithm. For each frame a bank of composite correlation filters are designed in such a manner to provide invariance to pose, occlusion, clutter, and illumination changes. The filters are synthesized with the help of an iterative algorithm, which optimizes discrimination capability for each object. The filter is adapted to the objects changes online using information of current and past scene frames. Results obtained with the proposed algorithm using real-life scenes, are presented and compared with those obtained with state-of-the-art tracking methods in terms of detection efficiency, tracking accuracy, and speed of processing.

Fast perceptual image hash based on cascade algorithm

Alexey Ruchay, Chelyabinsk State Univ. (Russian Federation); Vitaly Kober, Ctr. de Investigación Científica y de Educación Superior de Ensenada B.C. (Mexico); Evgeniya Evtushenko, Chelyabinsk State Univ. (Russian Federation)

In this presentation, we propose a perceptual image hash algorithm, which can be applied in image authentication, retrieval, and indexing. Image perceptual hash uses for image retrieval in sense of human perception against distortions caused by compression, noise, common signal processing and geometrical modifications. The main disadvantage of perceptual hash

is high time expenses. In the proposed cascade algorithm of image retrieval initializes with short hashes, and then a full hash is applied to the processed results. Computer simulation results show that the proposed hash algorithm yields a good performance in terms of robustness, discriminability, and time expenses.

Removal of impulse noise clusters from color images with local order statistics

Alexey Ruchay, Chelyabinsk State Univ. (Russian Federation); Vitaly Kober, Ctr. de Investigación Científica y de Educación Superior de Ensenada B.C. (Mexico)

This paper proposes a novel algorithm for restoring images corrupted with clusters of impulse noise. The noise clusters often occur when the probability of impulse noise is very high. The proposed noise removal algorithm consists of detection of bulky impulse noise in three color channels with local order statistics followed by removal of the detected clusters by means of vector median filtering. With the help of computer simulation we show that the proposed algorithm is able to effectively remove clustered impulse noise. The performance of the proposed algorithm is compared in terms of image restoration metrics with that of common successful algorithms.

10396-79, Session PMon

Impulsive noise removal from color video with morphological filtering

Alexey Ruchay, Chelyabinsk State Univ. (Russian Federation); Vitaly Kober, Ctr. de Investigación Científica y de Educación Superior de Ensenada B.C. (Mexico)

This paper deals with impulse noise removal from color video. The proposed noise removal algorithm employs a switching filtering for denoising of color video; that is, detection of corrupted pixels by means of a novel morphological filtering followed by removal of the detected pixels on the base of estimation of uncorrupted pixels in the previous scenes. With the help of computer simulation we show that the proposed algorithm is able to well remove impulse noise in color video. The performance of the proposed algorithm is compared in terms of image restoration metrics with that of common successful algorithms.

Application of white-light phase-shifting interferometry in white-light scanning interferometry

Yujing Wu, Yunsheng Qian, Nanjing Univ. of Science and Technology (China)

White–light scanning interferometry (WLSI) is an important technique, which has the advantages of high precision and noncontact testing, to measure surface profile when a test object contains discontinuous structures or microstructures. A series of algorithms is used to detect the peak position of a coherence envelope, which can estimate the profile. Phase-shifting interferometry (PSI) has a high precision. However, PSI suffers from phase-ambiguity problems, which limit the height difference between two adjacent data points to ?/4, where ? is the wavelength of the light. On the other hand, the coherence envelope techniques have a large dynamic range but are less precise. So a method that combines phase-shifting and coherence-peak-sensing techniques will provide the advantages of both, i.e., high precision and a large dynamic range. In this paper, an overlapping averaging four-bucket algorithm, which can eliminate phase shift errors caused by PZT in a large extent, is proposed to determine both the best-focus frame position and the fractional phase from the best-focus frame of the correlogram obtained from vertical scanning. Then a wavefront unwrapping algorithm is utilized to remove 2? phase ambiguities. Simulation and experimental results are presented to demonstrate the validity fo the proposed method.

Edge detection for optical synthetic aperture based on deep neural network

Wenjie Tan, Mei Hui, Ming Liu, Lingqin Kong, Liquan Dong, Yuejin Zhao, Beijing Institute of Technology (China) and Beijing Key Lab. of Precision Photoelectric Measuring Instrument and Technology (China)

Synthetic aperture optics systems can meet the demands of the next-generation space telescopes being lighter, larger and foldable. However, the boundaries of segmented aperture systems are much more complex than that of the whole aperture. More edge regions mean more imaging edge pixels, which are often mixed and discretized. In order to achieve high-resolution imaging, it is necessary to identify the gaps between the sub-apertures and the edges of the projected fringes. In this work, we introduced the algorithm of Deep Neural Network into the edge detection of optical synthetic aperture imaging. According to the detection needs, we constructed image sets by experiments and simulations. Based on MatConvNet, a toolbox of MATLAB, we ran the neural network, trained it on training image set and tested its performance on validation set. The training was stopped when the test error on validation set stopped declining. As an input image is given, each intra-neighbor area around the pixel is taken into the network, and scanned pixel by pixel with the trained multi-hidden layers. The network outputs make a judgment on whether the center of the input block is on edge of fringes. We experimented with various pre-processing and post-processing techniques to reveal their influence on edge detection performance. Compared with the traditional algorithms or their improvements, our method makes decision on a much larger intra-neighbor, and is more global and comprehensive. Experiments on more than 2,000 images are also given to prove that our method outperforms classical algorithms in optical images-based edge detection.

Accurate generation of the 3D map of environment with a RGB-D camera

Jose A. González-Fraga, Univ. Autónoma de Baja California (Mexico); Vitaly Kober, Ctr. de Investigación Científica y de Educación Superior de Ensenada B.C. (Mexico); Victor H. Diaz-Ramirez, Ctr. de Investigación y Desarrollo de Tecnología Digital-IPN (Mexico); Everardo Gutiérrez López, Omar Alvarez-Xochihua, Univ. Autónoma de Baja California (Mexico)

Simultaneous Localization and Mapping (SLAM) is one of the most fundamental problems in the field of robotics. The goal of a SLAM system is to determine the position of a moving camera in its environment, and at the same time, to construct a map representation of the explored workspace. With the development of RGB-D sensors, a new alternative for generation of 3D maps is appeared, because visual features are not robust enough in some situations. Thus, feature detectors and descriptors used in SLAM significantly affect the system performance. In this work, we propose a robust method for searching and selecting the minimum number of keypoints and keyframes to perform correct feature correspondences and to track the keypoints. The selected points and frames are utilized for generation of the 3D map of indoor environment with a help of the ICP algorithm. For tracking of the keypoints, we use composite correlation filters with adjustable training sets depending on appearance of indoor environment as well as relative position and perspective from the camera to environment components. The tracking algorithm is scale-invariant because it utilizes the depth information from RGB-D camera. The performance of

the proposed system is evaluated in terms of accuracy, robustness, and processing time and compared with classical RGB-D SLAM systems.

Veterinary software application for comparison of thermograms for pathology evaluation

Gita Pant, Scott E. Umbaugh, Rohini Dahal, Norsang Lama, Southern Illinois Univ. Edwardsville (United States); Dominic J. Marino, Joseph Sackman, Long Island Veterinary Specialists (United States)

The bilaterally symmetry property in mammals can be used to detect pathologies where body parts on both sides can be compared. For any pathological disorder, thermal patterns differ compared to the normal body parts. A software application for veterinary clinics is under development to input two thermograms of body parts on both sides, one normal and the other unknown, and the application compares them on the basis of extracted features and appropriate similarity and difference measures and outputs the likelihood of pathology. Previous research has been used to determine the appropriate image processing, feature extraction and comparison metrics to be used. The comparison metrics used are the vector inner product, Tanimoto, Euclidean, city block, Minkowski and maximum value metric. Also, results from experiments with comparison tests are used to derive a potential threshold values which will separate normal from abnormal images for a specific pathology. In the first phase, the anterior cruciate ligament (ACL) pathology in dogs was considered and comparison tests were performed on 20 random leg pairs based upon texture, histogram and spectral features which suggested any thermogram variation below 50% of Euclidean distance is normal and above 50% is abnormal. Further experiments are ongoing with larger image datasets, and pathologies, new features and comparison metric evaluation for determination of more accurate threshold values to separate normal and abnormal images.

Haze removal method based on decomposition

Xifang Zhu, Ruxi Xiang, Feng Wu, Qingquan Xu, Xiaoyan Jiang, Chunyu Zhao, Changzhou Institute of Technology (China)

In order to obtain a clear image with free haze, a new removing haze method is proposed, which effectively reconstructs the reflected image. Firstly, the image decomposed is easily formed by the monochrome atmospheric scattering model, and then it is decomposed two layers where one layer is smoother than the other by the constrained regularized total variance method .Thus the decomposition problem can be formulated as a constrained quadratic programming optimization problem, and the optimized solution of the layer contained more details can be obtained by effectively combining the Bregman method with half quadratic minimization method. Finally, the color of the reflectance image is adaptively adjusted according to the white balance theory. Compared with some existing methods, our experimental results show that the proposed method can effectively remove the haze from the bad weather condition and improve the image quality such as the contrast, sharpness and color.

Texture analysis integrated to infrared light sources for identifying high fringe concentrations in digital photoelasticity

Hermes Fandiño Toro, Univ. Nacional de Colombia Sede Medellín (Colombia) and Instituto Tecnológico Metropolitano (Colombia); Juan Carlos Briñez de León, Alejandro Restrepo Martínez, John W. Branch Bedoya, Univ. Nacional de Colombia Sede Medellín (Colombia)

Digital photoelasticity allows to obtain the whole stress field of a birefringent sample undergone to mechanical loads. This technique provides stress information by processing fringe patterns observed in phase images, captured using optical arrangements named polariscopes. Such patterns are a function of the material optical coefficient, the sample thickness, the principal stress difference, and the wavelength. Thus, photoelasticity images vary with the material type, the applied load and the light source.

The polariscopes require a light source, polarizers and phase retarders, and a specific variant --phase shifting-- is a standard technique to implement the digital photoelasticity. However, images of phase shifting photoelasticity often show inconsistencies and phase wrappings, being a challenge to get the stress field. On the other hand, high stress concentrations points normally produce zones with high fringe densities, which affects isochromatic maps and phase unwrapping process.

In this work, we perform simulations of the diametral compression of birefringent discs in phase shifting photoelasticity. We evaluate the relevance of texture operators for recognizing regions with high fringe concentrations in photoelasticity images, when the wavelength of the light source change from visible to far infrared. Our results show that extending photoelasticity to the far infrared could help to reconstruct stress fields. Furthermore, we show that texture descriptors could be useful for dealing with difficulties associated to the phase-wrapping of the stress field in the visible spectrum, due to high fringe concentrations.

Robot path planning algorithm based on symbolic tags in dynamic environment

Aleksandr Vokhmintcev, Andrey Melnikov, Aleksandr Kozko, Chelyabinsk State Univ. (Russian Federation)

Methods for solving the task of simultaneous localization and mapping (SLAM) do not account for information about semantic properties of investigated unknown environment. On the other hand, when building three-dimensional models of the virtual world, approaches based on the semantic labeling of investigated environment gained currency. Under a semantic marker a three-dimensional object in investigated space is meant, which can be detected based on methods of image recognition and object classification. The main focus of the research in this project will be aimed at developing new methods of deriving information about semantic properties of a 3D dynamic environment based on the depth and color of an analyzed scene, and on the use of this information for robot path planning on a dynamic scene. A new method of the “subtle” detection and classification of objects on images will be developed in the project, which employs the enthropic-optimal randomization of parameters of models of observed objects in conditions of uncertainty. Also, an algorithm will be developed of the search for the global minimum of the functional of the quality of detection and classification, which is based on Monte Carlo batch iterations and which permits obtaining probabilistic evaluations of accuracy through an analysis of real computational trajectories.

Application of speckle-field images processing for concrete hardening diagnostics

Mykhaylo P. Gorsky, Peter P. Maksimyak, Yuriy Fedkovych Chernivtsi National Univ. (Ukraine)

This paper is devoted to processing of speckle field images dynamics during coherent light scattering by the cement surface in the process of hydration (hardening). Currently, optical methods aren't used in industry to determine concrete hardening stages. Traditional method for hardening diagnostics is mechanical Vicat apparatus, which has been used as referrer in our research. Coherent light scattering on concrete produces complex speckle-field which is changing during cement hardening. We tried to use these changes to determine concrete hardening stages. Experimentally obtained set of speckle-field images, were processed by different methods including Fourier transform, Wavelet analysis, statistical moments and deviation calculation. Results of each analysis were evaluated in order to select best image processing approach. Deviation method has been selected like most accurate and less resource consuming one. It allows fast and accurate determining of concrete hardening stages by optical method. Optical method allows "remote" and "not destructive" diagnostics in compare with Vicat apparatus.

Transform extension for block-based hybrid video codec with decoupling transform sizes from prediction sizes and coding sizes

Jing Chen, Peking Univ. Shenzhen Graduate School (China)

In the block-based hybrid video coding framework, transforms are applied to the residual signal resulting from prediction. So we note that transform block sizes must be equal or smaller than prediction block sizes. Recent video coding techniques have allowed for decoupling of transform and prediction block structures. Such as in high efficient video coding (HEVC), transform block may overlap multiple prediction blocks with strict restrictions. Therefore in this paper, we propose an extension to the transform process in video coding. In our proposed method, transforms are operated not only within prediction blocks or coding blocks, but also span some prediction blocks or coding blocks which are in the same basic largest coding block (In H.264/AVC is macroblock, in HEVC is coding tree block and so on) and adjacent with each other. It's apparent in our method we will have to consider for boundary transition effects since the number of prediction blocks the extension transform span has increased largely. Overlapped block motion compensation (OBMC) has been verified effective to reduce blocking artifacts and thus can be used to improve the efficiency of large block transform. According to our experiment in some popular video coding platforms, we obtain consistent coding performance gains.

A new cloud detection method based on CNN and SVM joint algorithm

Zhicheng Yu, China Academy of Space Technology (China)

Terrain information is difficult to obtain due to cloud cover, these regions will become blind in remote sensing images, which led to the remote sensing images can not play their due value. So we need to use some detection technology to detect the cloud in remote sensing images to avoid a lot of useless images captured by the satellite wastes a large amount of storage unit and transmission bandwidth.

In this paper, based on a delicate high-resolution earth observation satellite in synchronous orbit, I combined the CNN(convolutional neural network) with SVM(support vector machine) for cloud detection, and finally present a new algorithm which can be realized in remote sensing satellite video processing system to statistic the cloud coverage ratio in orbit. The new algorithm uses the deep learning algorithm to automatically abstract the effective features, and after that SVM classifier is used to recognize the thick cloud. The most important is that the CNN network is simple enough so that it can be realized in embedded system like Zynq platform . Final results show that this algorithm is much more accurate than traditional cloud detection such as threshold method or SVM.

Robot mapping algorithm based on Kalman filtering and symbolic tags

Aleksandr Vokhmintcev, Tatiana Botova, Ilya Sochenkov, Chelyabinsk State Univ. (Russian Federation); Anastasia S. Sochenkova, RUDN Univ. (Russian Federation); Artyom Makovetskii, Chelyabinsk State Univ. (Russian Federation)

In the present project, a new method will be proposed of determining the dynamic position of a robot in a relative coordinate system based on Kalman filtering, on a history of camera positions and on the robot's movements, on symbolic tags. At each step, we can determine the displacement of the robot and predict its new position. On the other hand, we can single out the location of special signs from a new frame and calculate the position of the robot relative to them. Based on the difference between these two evaluations of the position of the robot, probabilities/weights for all special signs may be updated and the robot's poses and movement trajectory adjusted. In order to solve this problem, an approach based on Extended Kalman Filter will be employed, and on the orientation in an environment on the basis of symbolic tags. The Kalman filter enables one to obtain accurate and continuously updated evaluations of the position of a mobile robot based on a time series of inaccurate measurements of its location. To obtain an evaluation of a state vector during the robot's movement according to a series of noisy measurements and symbolic labels, it is necessary to present a model of this process in the form of a matrix equation of corresponding type. In order to track the robot's reiterated passage of one and the same place, it is necessary to carry out, at each step, the matching of the robot's position and state with the previous steps (the problem of "loop closure").

An efficient point-to-plane registration algorithm for affine transformations

Artyom Makovetskii, Sergei Voronin, Chelyabinsk State Univ. (Russian Federation); Vitaly Kober, Ctr. de Investigación Científica y de Educación Superior de Ensenada B.C. (Mexico); Dmitrii Tihonkih, Chelyabinsk State Univ. (Russian Federation)

The problem of aligning of 3D point data is the known registration task. The most popular registration algorithm is the Iterative Closest Point (ICP) algorithm. The traditional ICP algorithm is a fast and accurate approach for rigid registration between two point clouds but it is unable to handle affine case. Recently, extensions of the ICP algorithm for composition of scaling, rotation, and translation have been proposed. A generalized ICP version for an arbitrary affine transformation also was suggested. These methods work with point-to-point approach. There is still no closed-form solution to the point-to-plane case for orthogonal transformations. In this presentation, a new iterative algorithm for registration of point clouds based on the point-to-plane ICP algorithm with affine transformations is proposed. At each iteration, a closed-form solution to the affine transformation is derived. This approach allows us to get a precise solution for transformations such as rotation, translation, and scaling. With the help of computer simulation, the proposed algorithm is compared with common registration algorithms.

A generalized Condat's algorithm of 1D total variation regularization

Artyom Makovetskii, Sergei Voronin, Chelyabinsk State Univ. (Russian Federation); Vitaly Kober, Ctr. de Investigación Científica y de Educación Superior de Ensenada B.C. (Mexico)

Denoising has numerous applications in communications, control, machine learning, and many other fields of engineering and science. A common way to solve the problem utilizes the total variation (TV) regularization. Many efficient numerical algorithms have been developed for solving the TV regularization problem. Condat described a fast direct algorithm to compute the processed 1D signal. It is appropriate for real-time processing of incoming stream of data. Also there exists a direct algorithm with a linear time for 1D TV denoising referred to as the taut string algorithm. The Condat's algorithm is based on a dual problem to the 1D TV regularization. In this presentation, we propose a variant of the Condat's algorithm based on the direct 1D TV regularization problem. The usage of the Condat algorithm with the taut string approach leads to a clear geometric description of the extremal function. Moreover, the Condat's algorithm for some functions yields the quadratic complexity, while the performance of the proposed algorithm in terms of complexity is much better. Computer simulation results are provided to illustrate the performance of the proposed algorithm for restoration of degraded signals.

Convolutional neural networks for face recognition

Ilya Sochenkov, Chelyabinsk State Univ. (Russian Federation) and RUDN Univ. (Russian Federation); Anastasiia S. Sochenkova, RUDN Univ. (Russian Federation); Artyom Makovetskii, Andrey Melnikov, Chelyabinsk State Univ. (Russian Federation)

Computer vision tasks are remaining very important for the last couple of years. One of the most complicated problems in computer vision is face recognition that could be used in security systems to provide safety and to identify person among the others. There is a variety of different approaches to solve this task, but there is still no universal solution that would give adequate results in some cases. Current paper presents following approach. Firstly, we extract an area containing face, then we use Canny edge detector. On the next stage we use convolutional neural networks (CNN) to finally solve face recognition and person identification task. This paper also contains analysis of obtained results. Furthermore there is additionally presented comparison of the described method performance to using CNN without Canny edge detection.

System of multifunctional Jones matrix tomography of phase anisotropy in diagnostics of endometriosis

Alexander Ushenko, Vladimir Ushenko, Yuriy Fedkovych Chernivtsi National Univ. (Ukraine)

Historically, the optical methods of biological objects diagnostic may be divided into three groups. The spectrophotometric methods, which are based on analysis of spatial or time changes of radiation field intensity, scattered by biological tissues. Polarizing methods are based on usage of coherency matrix of complex amplitude. The correlation methods are based on the analysis of the correlation degree of the parallel polarization components of the light fluctuation at different points of object field.

For the complex azimuthally-stable analysis of polarizationally heterogeneous laser radiation fields a new approach was suggested, based on the generalization of coherence matrix by the polarization Jones matrix.

The theoretical background of azimuthally stable method Jones matrix mapping of histological sections of biopsy of uterine neck on the basis of spatial-frequency selection of the mechanisms of linear and circular birefringence is presented. The comparative results of measuring the coordinate distributions of complex degree of mutual anisotropy formed by polycrystalline networks of blood plasma layers of donors (group 1) and patients with endometriosis (group 2). The values and ranges of change of the statistical (moments of the 1st - 4th order) parameters of complex degree of mutual anisotropy coordinate distributions are studied. The objective criteria of diagnostics of the pathology and differentiation of its severity degree are determined.

The obtained results enable to state a rather high level of accuracy of azimuthally stable Jones matrix tomography.

Azimuthally invariant Mueller-matrix mapping of biological optically anisotropic network

Olexander V. Dubolazov, Alexander Ushenko, Yuriy Fedkovych Chernivtsi National Univ. (Ukraine)

Biological tissues and fluids represent structurally inhomogeneous media with absorption. To describe interactions of polarized light with such complex systems the most general approaches based on Mueller-matrix formalism are required. Nowadays in biological and medical investigations many practical techniques based on measurement and analysis of Mueller matrices of investigated samples are used. In addition, laser polarimetry techniques require further development and generalization.

Firstly, not all elements of Mueller matrix prove to be convenient for characterizing biological samples. The reason of this is the azimuthally dependence of the majority of matrix elements – generally 12 of 16 elements change at rotation of the sample around the probing axis. Secondly, the spectrum of mechanisms of optical anisotropy of biological layers is not confined to linear birefringence only. Taking into consideration the impact of other mechanisms – circular birefringence, as well as linear and circular dichroism – is topical in the aspect of enlarging the range of diagnostic techniques.

The model of Mueller-matrix description of mechanisms of optical anisotropy typical for polycrystalline films of blood - optical activity, birefringence, as well as linear and circular dichroism - is suggested. Within the statistical analysis of such distributions the objective criteria of differentiation of films of blood from the healthy patients and patients with breast cancer. From the point of view of probative medicine the operational characteristics (sensitivity, specificity and accuracy) of the method of Mueller-matrix reconstruction of optical anisotropy parameters were found.

Polarization-interference mapping of biological fluids polycrystalline films in differentiation of weak changes of optical anisotropy

Olexander V. Dubolazov, Alexander Ushenko, Yuriy Fedkovych Chernivtsi National Univ. (Ukraine)

Powered theoretical justification of method of polarization-interference mapping of optically thin polycrystalline films of human body fluids.

Investigated coordinate distribution of local contrast value of interference distributions of inhomogeneous polarization-microscopic images of polycrystalline films of human joints synovial fluid.

Within the statistical (statistical moments 1st - 4th order), correlation

(dispersion and kurtosis, describing autocorrelation function) and fractal (dispersion that characterizes the logarithmic dependence of power spectra) approaches set objective criteria of distributions of local contrast values.

The possibility of differentiation of weak optical anisotropy changes of synovial fluid films of patients with varying severity of the pathology of the knee joints.

A comparative study of accuracy of this method and traditional method of polarization mapping.

Methods and means of 3D diffuse Mueller-matrix tomography of depolarizing optically anisotropic biological layers

Olexander V. Dubolazov, Alexander Ushenko, Yuriy Fedkovych Chernivtsi National Univ. (Ukraine)

This work contains the results:

1) Mueller-matrix description of phase anisotropy model of polycrystalline biological layers with linear and circular birefringence.

2) Justification of theoretical principles and experimental techniques of obtaining 3D distribution of Muller-matrix elements of biological layers.

3) Approval of 3D Mueller-matrix mapping methods of three-dimensional polycrystalline structure of biological layers.

4) Experimentally investigated statistical (statistical moments 1st - 4th order) correlation (autocorrelation function) and fractal (logarithmic dependence of power spectra) structure of Mueller-matrix images distribution of histological sections of biological tissues and polycrystalline films of biological fluids.

Feature recognition of metal salt spray corrosion based on color spaces statistics analysis

Liqun Ma, Zhi Zou, Changcheng Institute of Metrology & Measurement (China)

Corrosion region and feature extraction is the key step of evaluating the metal material surface corrosion level. The color digital Images contains certain corrosion information. In this paper, we investigate a method on extracting the corrosion region and feature which is based on multi-color space feature analyzing and region growing. The object that we research is high strength alloy steel corrosion samples acquired from accelerating salt spray corrosion test. Through this method, 2 types corrosion can be extracted and recognized.

For the first type corrosion, the multi-color space statistics is applied. The working process of the extraction strategy is summarized as shown in figure 1. (1)Transform the image color RGB space to other spaces including HSV and YCbCr. Then analyze the histogram of each channel of each color space and calculate the statistics of each channel, the statistics include certain moments of the image such as skewness and kurtosis. Through analyzing these moments, choose the proper channel of image to process and extract. (2) A segmentation using Otsu threshold to process the single channel images from the last step.

For the second type corrosion which is mainly dim and surround by the first type corrosion, using the multi-color space statistics to choose the proper space and channel then segmenting would get some extra wrong regions, we using the region growing to amend and optimize the extraction which summarized as shown in figure 2. (1) Based on the image saturation mutation caused by procedure of the corrosion generation, we choose the local maximum in saturation channel as the initial pixels which are on the boundary between two type corrosion. (2) Use the initial pixels to execute the region growing algorithm, if any region from the extra regions hits the initial 8-neighbour, refresh the initial pixels to initial region, do the iterative refreshing until the initial region would not grow any more. Thus, the metal material salt spray corrosion which has strongly color mutation can be recognized. Through processing several sample color images of alloy steel, it is proved that the feature and region extracted by this procedure has more accuracy and the corrosion degree is quantifiable and the precision of discriminating the corrosion is improved. Fig 1 shows some results of this research.

New opportunities of differential diagnosis of biological tissues polycrystalline structure using methods of Stokes correlometry mapping of polarization inhomogeneous images

Olexander V. Dubolazov, Yuriy Fedkovych Chernivtsi National Univ. (Ukraine)

A new method of Stokes correlometry evaluation of polarization-inhomogeneous images of optically anisotropic biological tissues histological sections of different morphological structure and physiological state was developed.

Algorithms and analytical description of experimental determination of the coordinate value distribution module and the phase of “two-point” Stokes vector parameters were determined.

Within statistic, correlation and fractal analysis was investigated the possibility of differential diagnosis of weak optical anisotropy changes in tissues and internal organs of healthy and with diabetes rats.

The research showed excellent precision (more than 90 percent) of differential diagnosis changes of optical anisotropy of internal tissues by rat using Stokes correlometry.

Fuzzy logic for cognitive impairment prediction in structural imaging

Annarita Fanizzi, I.R.R.C.C.S. Oncologico di Bari (Italy); Nicola Amoroso, Univ. degli Studi di Bari (Italy) and Istituto Nazionale di Fisica Nucleare (Italy); Roberto Bellotti, Univ. degli Studi di Bari Aldo Moro (Italy) and Istituto Nazionale di Fisica Nucleare (Italy); Sabina Tangaro, Istituto Nazionale di Fisica Nucleare (Italy)

BBrain atrophy is a well-known biomarker for cognitive impairment related to several brain diseases, such as Multiple Sclerosis and Alzheimer’s Disease. Hippocampal atrophy is a well known biomarker for the Alzheimer’s disease (AD) progression state. We propose a novel methodology to drive features selection into prediction of conversion to brain disease. We define significant fuzzy classes of the hippocampal volume segmented by means of Hippocampal Unified Multi-Atlas-Networks (HUMAN). The proposed methodology is accurate, robust and can find a wide range of applications.

Resolution analysis of archive films for the purpose of their optimal digitization and distribution

Karel Fliegel, Stanislav Vítek, Petr Páta, Czech Technical Univ. in Prague (Czech Republic); Jiri Myslík, Josef Pecák, Marek Jícha, Film and TV School of Academy of Performing Arts in Prague (Czech Republic)

With recent high demand for ultra-high-definition (UHD) content to be screened in high-end digital movie theaters but also in the home environment, film archives full of high-quality movies are in the scope of UHD content providers. Movies captured with the traditional film technology represent virtually unlimited source of UHD content. The goal to maintain complete image information is also related to the choice of scanning resolution. It might seem that scanning the film material in the highest possible resolution of the modern film scanners is the right choice. The information content of the film material is however limited, and various degradations moreover lead to its further reduction. Scanning and mainly exporting the content in the highest image resolution is therefore often unnecessary and uneconomical. In other cases, the highest possible resolution for digitization is inevitable if we want to preserve fine details and film grain structure. This paper deals with the information content analysis of archive film records. The theoretical limit in captured scene information and factors which make the final real resolution lower are discussed. Methods are proposed to determine the information content of the film material based on the analysis of its digitized image data. These procedures will allow determining the optimum resolution for scanning, followed by recommendations for optimal resolution for archiving or distribution of digitized video content intended for various display devices. Obtained results are illustrated using real examples of digitized film content and performance evaluation of the proposed techniques using this content is presented.

An efficient direct method for image registration of flat objects

Dmitry Nikolaev, Artyom Makovetskii, Sergei Voronin, Chelyabinsk State Univ. (Russian Federation)

Image alignment of rigid surfaces is a rapidly developing area of research and has many practical applications. Alignment methods can be roughly divided into two types: feature-based methods and direct methods. Known SURF and SIFT algorithms are examples of the feature-based methods. Direct methods refer to those that exploit the pixel intensities without resorting to image features and image-based deformations are general direct method to align images of deformable objects in 3D space. Nevertheless, it is not good for the registration of images of 3D rigid objects since the underlying structure cannot be directly evaluated. In the article we propose a model that is suitable for image alignment of rigid flat objects under various illumination models. The brightness consistency assumptions used for reconstruction of optimal geometrical transformation. Computer simulation results are provided to illustrate the performance of the proposed algorithm for computing of an accordance between pixels of two images.

Smoothing of astronomical images with Poisson distribution

Zuzana Krbcová, Univ. of Chemistry and Technology Prague (Czech Republic); Jaromir Kukal, Czech Technical Univ. in Prague (Czech Republic); Jan ?vihlík, Univ. of Chemistry and Technology Prague (Czech Republic); Karel Fliegel, Czech Technical Univ. in Prague (Czech Republic)

Images obtained from an astronomical digital camera are of integer nature as event counters in every pixel of its image sensor. The quality of the captured images is influenced mostly by the camera characteristics and photon noise caused by natural random fluctuation of observed light. We suppose the image pixel intensity as a mean value of the signal with Poisson distribution. The application of maximum likelihood method with image gradient regularization leads to variational task in continuous and discrete formulations. This variational task has only one unique solution on which the novel numerical method of image smoothing is based. The performance of the proposed smoothing procedure is tested using real images obtained from the digital camera in Meteor Automatic Imager and Analyzer (MAIA).

A modified iterative closest point algorithm for noisy data

Dmitrii Tihonkih, Artyom Makovetskii, Aleksei Voronin, Chelyabinsk State Univ. (Russian Federation)

The ICP (Iterative Closest Point) algorithm has become the dominant method for aligning three dimensional models based purely on the geometry, of the points clouds. ICP starts with two clouds and an initial guess for their relative rigid-body or affine transform, and iteratively refines the transform by repeatedly generating pairs of corresponding points on the clouds and minimizing an error metric. The first step of the ICP algorithm is the selection of some set of points in one or both clouds. This paper proposes a new method of a realization of the selection step. We suppose that the values of the point coordinates are noisy by an additive noise. The cloud is divided into the smaller clouds by the smart approach. For each obtained subcloud is used RANSAC algorithm for finding the mean point. This step allows reduce the noise influence to the result. The set of obtained points is a new cloud. We get two new clouds with smaller quantity of points. For the new clouds are applied the matching ICP step based on the a previously described geometric similarity method. With the help of computer simulation, the proposed method is compared with common algorithms for the ICP matching step.

10396-105, Session PMon

Estimation of Poisson noise characteristics in wavelet domain

Jan ?vihlík, Univ. of Chemistry and Technology Prague (Czech Republic); Karel Fliegel, Czech Technical Univ. in Prague (Czech Republic); Jaromír Kukal, Zuzana Krbcová, Univ. of Chemistry and Technology Prague (Czech Republic)

This paper deals with modeling of astronomical images in the wavelet domain.

We consider astronomical light images contaminated by dark current which is modeled by Poisson random process. Dark frame image maps the thermally generated charge of the CCD sensor. In this paper, we solve the problem of linear filtering of the Poisson random variable. At first, the noise analysis of images obtained from the astronomical camera is performed. It allows estimating parameters of the Poisson probability mass function in every pixel of the acquired dark frame. Then the resulting distributions of the wavelet coefficients can be found. If the distributions of the coefficients are identified, then the denoising algorithm can be applied. The performance of the Bayesian approach is compared with the application of the Anscombe transform followed by denoising algorithm designed for the additive Gaussian noise.

Discrete Fourier transform limitations regarding the MTF measurement of optoelectronic imaging systems

Oleg A. Perezyabov, ITMO Univ. (Russian Federation); Aleksandr V. Ilinski, S.I. Vavilov State Optical Institute (Russian Federation); Nadezhda K. Maltseva, ITMO Univ. (Russian Federation)

An important characteristic of every optoelectronic imaging system that determines its image final quality is resolution. This characteristic can be precisely determined using modulation transfer function (MTF).

The advantages of using MTF as the main characteristic to measure imaging system resolution are: the ability to measure the quality of the image

directly and quantitatively; objectivity and flexibility of the measurement (minimal influence of the human factor); the ability to measure the quality of the combined systems.

All the existing resolution measurement methods can be subdivided into several groups by the type of the pattern used: method using groups of bands of equal width or sinusoids of different frequencies; random target method; slanted edge pattern method.

Fourier Transform which decomposes a function of time (a signal) into the frequencies is used in all of this methods as MTF describes spatial frequency response of the imaging system.

Fast Fourier transform (FFT) is one of the most widespread algorithms of discrete Fourier transform (DFT) which is used to determine the MTF of an imaging system. Despite the fact this algorithm is much faster than the usual Fourier transform, it has some drawbacks. Speaking of finite signals, the DFT algorithm can be mistaken at the frequencies range next to Nyquist frequency.

Such behavior of MTF obtained by the FFT, can be explained by a small number of counts of some sine waves — components of the Fourier image.

The aim of the paper is to research the Fourier transform and FFT differences regarding the MTF measurement.

Efficient encryption of image data in video sequences using discrete orthogonal moments

José Saúl Rivera López, Univ. Politécnica de Tulancingo (Mexico); César Joel Camacho Bello, Univ. Tecnológica de Tulancingo (Mexico)

Currently, new techniques have been implemented to provide data security, confidentiality, integrity and authentication. Orthogonal moments can be used for the watermark in small binary images. In this work we use this principle to encrypt a grayscale image in a video sequence. To validate our approach, we present a comparative analysis using different families of discrete orthogonal moments in terms of accuracy. Finally, results and conclusions are presented.

High speed camera recording in the service of research of dependences between kinetics of eye pupil parameters and blood pulsation

Marta A. Szmigiel, Henryk T. Kasprzak, Wroclaw Univ. of Science and Technology (Poland)

The basis for the implementation of this study is high speed video recording of the pupil of human eye. With a use of optimum magnification it was possible to register images which accurately show the edge of the eye pupil. Synchronously with the pupil image the blood pulsation was recorded with the use of the oximeter - both with the frequency of 200Hz.

This study shows measurement and numerical analysis of variability of the eye pupil geometry in time, as well as its correlations with blood pulsation. Volunteers were asked to abstain from blinking while fixating their vision on a bright point. The head of the patient was stabilized in a rigid head rest. Number of video sequences of the pupil image for every subject were recorded. Each single image from a sequence was numerically processed. The contour of the pupil was detected and approximated with the best fitted ellipse. Selected geometrical parameters of the ellipse (area, lengths of both semiaxes, eccentricity, orientation angle of the axis, ellipse center) were calculated and processed. The main idea was to observe, how the parameters were changed in time and if there was any dependency between pupil parameters and blood pulsation signal. Spectral analysis of time variability of all calculated parameters was determined, as well as correlation and coherence analysis between pairs of those signals.

The relation between the retinal image quality and the refractive index of defects arising in IOL: numerical analysis

Malwina Geniusz, Wroclaw Univ. of Science and Technology (Poland)

The best treatment for cataract patients, which allows to restore sharp vision is implanting an artificial intraocular lens (IOL). The image quality of the lens has a significant impact on the quality of patient's vision. After a long residence in the eye time of the implant various defects appear in the artificial lenses. The defects generated in the IOL have different refractive indices. For example, glistening phenomenon is based on light scattering on the oval microvacuoles filled with a aqueous humor, whose refractive index value is about 1.34. Calcium deposits are another example of lens defects and can be characterized by the refractive index 1.63. In the presented studies it was calculated how the difference between the refractive indices of the defect and the refractive index of the material, from which the lens is made ($\Delta n= |nm-nd|$), affects the quality of image.

The OpticStudio Professional program (from Radiant Zemax, LLC) was used for the construction of the numerical model of the eye with an artificial lens and to calculate the characteristics of the retinal image. Retinal image quality was described in such characteristics as Point Spread Function (PSF) and the Optical Transfer Function with amplitude and phase.

The results show a strong correlation between the refractive indices difference and retinal image quality.

Analysis of image reconstruction artifacts in structured illumination microscopy

Jakub Pospíšil, Czech Technical Univ. in Prague (Czech Republic); Tomáš Lukeš, Czech Technical Univ. in Prague (Czech Republic) and Ecole Polytechnique Fédérale de Lausanne (Switzerland); Karel Fliegel, Miloš Klíma, Czech Technical Univ. in Prague (Czech Republic); Guy M. Hagen, Univ. of Colorado at Colorado Springs (United States)

Structured Illumination Microscopy (SIM) is a super-resolution technique which enables to enhance the resolution of optical microscopes beyond the diffraction limit. The final super-resolution image quality strongly depends on the performance of SIM image reconstruction. Standard SIM methods require precise knowledge of the illumination pattern and assume the sample to be stationary during the acquisition of illumination patterned images. In the case of imaging live cells, the movements of the cell result in the occurrence of image reconstruction artifacts. To reduce this kind of artifacts the short acquisition time is needed. However, short exposure time causes low signal to noise ratio (SNR). Moreover, a drift of the specimen may distort the illumination pattern properties in each image. This issue together with the low SNR makes the estimation of reconstruction parameters a challenging task. Inaccurate assessment of spatial frequency, phase shift or orientation of the illumination pattern leads to incorrect separation and shift of spectral components in Fourier space. This results in unwanted image reconstruction artifacts and hampers the resolution enhancement in practice. In this paper, we analyze possible artifacts in super-resolution images reconstructed using different SIM techniques. An overview of typical image reconstruction artifact types is presented. A metric is proposed for the quantitative evaluation of these artifacts in reconstructed images, which allows for performance comparison of different SIM reconstruction methods. Distinguishing image artifacts from newly resolved sample features is essential for future SIM applications in cell biology.

FPGA implementation of image dehazing algorithm for real time applications

Rahul Kumar, Brajesh Kumar Kaushik, Indian Institute of Technology Roorkee (India)

Weather degradation such as haze, fog, mist, etc. severely reduces the effective range of the visual surveillance. This degradation is a spatially varying phenomena, which makes this problem non trivial. Dehazing is an essential preprocessing stage in applications such as long range imaging, border security, intelligent transportation system, etc. However, these applications require low latency of the preprocessing block. In this work, single image dark channel prior algorithm is modified and implemented for fast processing with comparable visual quality of the restored images/video. Although conventional single image dark channel prior algorithm is computationally expensive, it yields impressive results. Moreover, a two stage image dehazing architecture is introduced, wherein, dark channel and airlight are estimated in the first stage. Transmission map and intensity restoration are computed in the next stage. The algorithm is implemented using Xilinx Vivado software and validated with Xilinx zc702 development board, which contains an Artix7 equivalent FPGA and ARM Cortex-A9 dual core processor. Additionally, HDMI interface has been incorporated for video feed and display purposes. The results show that the dehazing algorithm attains 29 frames per second for the image resolution of 1920x1080 which is suitable for real time applications. It utilizes only 17% of the available resources.

Radiometric calibration of wide-field camera system with an application in astronomy

Stanislav Vítek, Czech Technical Univ. in Prague (Czech Republic)

Camera response function (CRF) is widely used for the description of a relationship between scene radiance and image brightness. Most common application of CRF is High Dynamic Range (HDR) reconstruction of the radiance maps of imaged scenes from a set of frames with different exposures. CRF may be obtained by precise measurement of the digital camera, for example using a uniformly illuminated chart containing patches of known reflectance. However, this process is quite complicated and can be performed only under laboratory conditions. Numerous papers showed that set of differently exposed images of the same scene contain enough information to recover response using images themselves. The main goal of this work is to provide the comprehensive overview of CRF estimation algorithms. These algorithms, typically designed for multimedia data, are unfortunately quite useless with astronomical image data, mostly due to their nature - noise with a priori unknown statistical distribution, motion blur due to long exposures, and the shape of stellar objects close to point spread function (PSF) of the imaging system. Therefore, we propose an optimization of selected methods to use in the astronomical imaging application. An important part of this contribution is the description of CRF utilization in a non-linear camera system with the space-variant impulse response, used for detection and monitoring of faint meteor showers.

Robust parameterization of time-frequency characteristics for recognition of musical genres of Mexican culture

Osvaldo Gerardo Perez Rosas, Ctr. de Investigación y Desarrollo de Tecnología Digital (Mexico); Luis Alejandro Maldonado Cano, Ctr. de Investigación y Desarrollo de Tecnología Digital (Mexico); Mario Lopez Rodriguez, Ctr. de Investigación y Desarrollo de Tecnología Digital-IPN (Mexico); Laura Mariel Amaya Reyes, Ctr. de Investigación y Desarrollo de Tecnología Digital-IPN (Mexico); Elizabeth Cano Martinez, Ctr. de Investigación y Desarrollo de Tecnología Digital (Mexico); Mireya Sarai García Vazquez, Ctr. de Investigación y Desarrollo de Tecnología Digital-IPN (Mexico); Alejandro Álvaro Ramírez Acosta, MIRAL R&D&I (United States)

The automatic identification and classification of musical genres based on the sound similarities to form musical textures, it is a very active investigation area. In this context it has been created recognition systems of musical genres, formed by time-frequency characteristics extraction methods and by classification methods. The selection of this methods are important for a good development in the recognition systems. In this article they are proposed the Mel-Frequency Cepstral Coefficients (MFCC) methods as a characteristic extractor and Support Vector Machines (SVM) as a classifier for our system. The stablished parameters of the MFCC method in the system by our time-frequency analysis, represents the gamma of Mexican culture musical genres in this article. For the precision of a classification system of musical genres it is necessary that the descriptors represent the correct spectrum of each gender; to achieve this we must realize a correct parametrization of the MFCC like the one we present in this article. With the system developed we get satisfactory detection results, where the least identification percentage of musical genres was 66.67% and the one with the most precision was 100%.

Recognition of uncorrelated characters in maritime environment

Chris M. Ward, SPAWAR Systems Ctr. Pacific (United States)

Text detection and recognition in the wild present challenges where traditional Optical Character Recognition (OCR) methods fail: extreme skew, noise, target motion, and egomotion. Moreover, maritime environments present their own unique challenges in the analysis of motion imagery: haze, occlusion, high noise levels, poor ground truth, and moving targets. Much of the data under analysis consists of strings of non-correlated characters: Serial Numbers, Hull Identification Numbers, Vessel Names – algorithms that rely on fixed-typeface sets, dictionaries, and predictive language are not sufficiently robust in these conditions. Therefore, recognition must be accomplished on a character by character basis, under extreme optical conditions, with marginal sensor technology. This paper presents a methodology for identifying scene text in maritime environments using Text-Like Object Detection, Text-Object Tracking, Super Resolution Enhancement, and Convolutional Neural Networks (CNNs) for character classification.

Text detection in natural scenes with phase congruency approach

Julia Diaz-Escobar, Vitaly Kober, Ctr. de Investigación Científica y de Educación Superior de Ensenada B.C. (Mexico)

In recent years, the importance of text detection in imagery has been increasing due to the great number of applications developed for mobile devices, such as document classification, image retrieval, language translator, assisting visually impaired, and augmented reality.

Text detection is one of the first stages of character recognition task. The fundamental goal is to determine whether or not there is text in a given image. Although text detection seems to be a simple task, it becomes complicated when backgrounds are complex, different types of fonts and sizes are presented or when captured conditions are not controlled (changes

of illumination, resolution, alignment).

To solve the problem, in this work a method for text detection in natural scenes is proposed. The method is based on the Phase Congruency approach, obtained via Scale-Space Monogenic Signal framework. The proposed method is robust to illumination, resolution and noise degradation, as well as geometrical distortions (rotations, scales and shearing). Finally, in order to verify the performance of the proposed scheme, experimental results are presented using a real natural scene dataset.

Enhancing user experience by using multi-sensor data fusion to predict phone's Illumination

Asmaa H. A. Al-Marhoubi, Higher College of Technology (Oman)

The movement of a phone in an environment with different illumination changes makes the illumination prediction challenging. The ambient light sensor takes a time to modify the illumination of the screen based on the environment it is placed in. This causes an unsatisfactory user experience and delays in adjustment of the screen illumination. In this research, a method is proposed for enhancing the prediction of illumination using accelerometer, gyroscope and speed measurement technique. The speed of the phone is identified using Sum-of-Sine parameters along with the accelerometer and gyroscope sensors. The illumination is then fused with them to present more accurate illumination values for the ALS based on the movement of the phone. An investigation is made during the movement of the user in different lighting environments. This enhances the user experience and improves the screen brightness precision. The accuracy has given an R-Square value of up to 0.97.

Global stereo matching algorithm based on disparity range estimation

Jing Li, Hong Zhao, Xi'an Jiaotong Univ. (China); Feifei Gu, Shenzhen Institutes of Advanced Technology (China)

The global stereo matching algorithms is of high accuracy for the estimation of disparity map, but the time-consuming in the disparity optimization still faces a curse, especially for the image pairs with high resolution and large baseline setting. To improve the computational efficiency of the global algorithms, a disparity range estimation scheme for the global stereo matching is proposed to estimate the disparity map of rectified stereo images in this paper. The projective geometry in a parallel binocular stereo vision is investigated to reveal a ratio relationship between the disparity values at each pixel in the rectified stereo images with different baselines, which can be used to quickly obtain a referenced disparity map in a large baseline setting estimated by that in the small one. Then, the drastically reduced disparity ranges at each pixel under a large baseline setting can be determined by the referenced disparity map. Furthermore, the disparity range estimation scheme is introduced into the graph cuts (GC) with expansion moves to estimate the precise disparity map, which can greatly save the cost of computing without loss of accuracy in the stereo matching, especially for the dense global stereo matching, compared to the traditional algorithm. Experimental results with the Middlebury stereo datasets are presented to demonstrate the validity and efficiency of the proposed algorithm.

The error model of the handheld target in Target-based Vision Measurement System (T-VMS)

Yueyang Ma, Hong Zhao, Xi'an Jiaotong Univ. (China); Feifei Gu, Shenzhen Institutes of Advanced Technology (China); Meiqi Fang, Hehui Geng, Kejia Li, Xi'an Jiaotong Univ. (China)

The handheld Target-based Vision Measurement System (T-VMS) is advantageous in measuring inaccessible areas such as deep holes, occlusion regions, and internal surfaces that cannot be captured directly by traditional cameras. The handheld target performs the role of intermediary in the measurement process. The feature points mounted on the face of the handheld target can be positioned by two cameras, so the probe fixed at the bottom of the handheld target can be located by known spatial relations. The said process is called the calibration of the handheld target. Extracting feature points and establishing handheld target coordinate system, as essential part of the calibration of the handheld target, however, introduce extraction errors and handheld target coordinate system position errors, which degrades the positioning precision of the T-VMS. Therefore, in order to evaluate the handheld target' influence on the accuracy of visual measuring system in the process of measurement, we first analyzed the accuracy of the visual measurement system under some certain extrinsic parameters and established the corresponding precision model. We then studied the main error sources introduced by the handheld target during the measurement process: the extraction errors of feature points and the position errors of handheld target coordinate system, and quantified corresponding errors under some certain extrinsic parameters. Finally, we discussed the influence of the said errors on the measurement results under system precision model. We applied the precision model in an actual T-VMS to confirm its feasibility and effectiveness, and found that it indeed estimates the errors introduced by the handheld target effectively.

Multiscale imaging of collagen

Michael Pinkert, Zachary J Simmons, University of Wisconsin-Madison (United States); Brittany L Woods, Appalachian State University (United States); Adib Keikhosravi, Bing Dai, Timothy J Hall, Jeremy Rogers, Paul Campagnola, Kevin Eliceiri, University of Wisconsin-Madison (United States)

Changes in tissue collagen organization accompany many major diseases, including a number of cancer types. Measuring this organization can give important clinically relevant information. The LINK multimodality imaging system integrates Second Harmonic Generation Microscopy, High-Frequency Ultrasound, Enhanced Backscattering Spectroscopy, and Optical Coherence Tomography onto a single platform. These four modalities are sensitive to different properties of collagen and operate across different spatial scales, with resolutions ranging from below the optical diffraction limit to the tissue mesoscale at tens of microns.

10396-21, Session 4

JPEG XS: a new standard for visually lossless low-latency lightweight image compression

Antonin Descampe, intoPIX s.a. (Belgium); Joachim Keinert, Fraunhofer-Institut für Integrierte Schaltungen (IIS) (Germany); Thomas Richter, Univ. Stuttgart (Germany); Siegfried Fößel, Fraunhofer-Institut für

Integrierte Schaltungen (IIS) (Germany); Gaël Rouvroy, intoPIX s.a. (Belgium)

JPEG XS is an upcoming standard from the JPEG Committee (formally known as ISO/IEC SC29 WG1). It aims to provide an interoperable visually lossless low-latency lightweight codec for a wide range of applications including mezzanine compression in broadcast and Pro-AV markets. This requires optimal support of a wide range of implementation technologies such as FPGAs, CPU and GPUs. Targeted use cases are professional video links, IP transport, Ethernet transport, real-time video storage, video memory buffers, and omnidirectional video capture and rendering. In addition to the evaluation of the visual transparency of the selected technologies, a detailed analysis of the hardware and software complexity as well as the latency has been done to make sure that the new codec meets the requirements of the above-mentioned use cases. In particular, the end-to-end latency has been constrained to a maximum of 32 lines. Concerning the hardware complexity, neither encoder nor decoder should require more than 50% of an FPGA similar to Xilinx Artix 7 or 25% of an FPGA similar to Altera Cyclon 5. This process resulted in a coding scheme made of an optional color transform, a wavelet transform, the entropy coding of the highest magnitude level of groups of coefficients, and the raw inclusion of the truncated wavelet coefficients. This paper presents the details of the standardization process, a technical description of the future standard, and the latest performance evaluation results. Finally, it also gives insight on the upcoming profiles and extensions that will soon be investigated.

10396-22, Session 4

Overview of the JPEG XS objective evaluation procedures

Alexandre Willème, Univ. Catholique de Louvain (Belgium); Thomas Richter, Univ. Stuttgart (Germany); Chris Rosewarne, Canon Information Systems Research Australia Pty. Ltd. (Australia); Benoît M. Macq, Univ. Catholique de Louvain (Belgium)

JPEG XS is an initiative conducted by the JPEG Committee, formally known as ISO/IEC SC29 WG1 group that aims at standardizing a low-latency, lightweight and visually lossless video compression scheme. This codec is intended to be used in applications where image sequences are usually transmitted or stored in uncompressed form such as in live production (through SDI or IP transport), display links, or frame buffers. It provides compression ratios ranging from 2:1 to 6:1 and therefore allows for significant bandwidth and power reduction. Through this paper, the objective quality assessment procedures conducted as part of the JPEG XS initiative are described. First, the focus is put on the objective part of the experiments that lead to the technology selection during the 73th WG1 meeting in late 2016. This assessment consists in PSNR measurements after a single and multiple compression decompression cycles at various compression ratios. After this assessment phase, two proposals among six candidates that answered the Call For Proposals were selected and merged to form the first JPEG XS test model (XSM). Eventually, this paper describes the core experiments that have been conducted so far on XSM. These experiments are intended to evaluate its performance in more challenging scenarios (insertion of picture overlay, robustness to frame edition), assess the impact of the different algorithmic choices, and measure its performance with the HDR VDP metric.

10396-23, Session 4

New procedures to evaluate visually lossless compression for display systems and mezzanine networks

Dale Stolitzka, SAMSUNG Electronics Co., Ltd. (United States); Tim Bruylants, Vrije Univ. Brussel (Belgium)

Visually lossless image coding in isochronous display streaming or plesiochronous networks reduces link complexity and power consumption and increases available link bandwidth. A new set of codecs developed within the last four years promise a new level of coding quality, but require new techniques that are sufficiently sensitive to the small artifacts or color variations induced by this new breed of codecs. This paper begins with a summary of the new ISO/IEC 29170-2, a procedure for evaluation of lossless coding and reports the new work by JPEG to extend the procedure in two important ways: for new high dynamic range (HDR) content and for evaluating the differences between still images, panning images and image sequences.

The ISO/IEC 29170-2 international standard relies on selecting and processing relevant images through a well-defined process chain for subjective, forced-choice psychophysical experiments. The procedure sets an acceptable quality level to one just noticeable difference. Traditional image and video coding evaluation techniques, such as, those used for television evaluation [Rec. ITU-R BT.500] have not proven sufficiently sensitive to the small artifacts or color variations induced by this new breed of codecs. In 2015, JPEG received new requirements to expand evaluation of visually lossless coding for high dynamic range images, slowly moving images, i.e., panning, and image sequences. The amended ISO/IEC 29170-2 procedures promise to be highly useful for the new content in television and cinema mezzanine networks.

The new amendments of this procedure are expected to pass their final ballots and should be published later this year.

10396-24, Session 4

JPEG XS call for proposals subjective evaluations

David McNally, Ecole Polytechnique Fédérale de Lausanne (Switzerland); Tim Bruylants, Vrije Univ. Brussel (Belgium) and IMEC (Belgium); Alexandre Willème, Univ. Catholique de Louvain (Belgium); Peter Schelkens, Vrije Univ. Brussel (Belgium) and IMEC (Belgium); Touradj Ebrahimi, Ecole Polytechnique Fédérale de Lausanne (Switzerland); Benoît M. Macq, Univ. Catholique de Louvain (Belgium)

This paper presents the details of how responses to JPEG XS call proposals were subjectively evaluated and how the content was selected and the evaluation methodologies were carried. It also details new interpretations that had to be brought to AIC-2 specifications in order to make JPEG XS evaluations more optimal. Results obtained are then presented together with a description of the statistical analyses that were carried out.

10396-25, Session 4

High-speed low-complexity video coding with EDiCTius: a DCT coding proposal for JPEG XS

Thomas Richter, Univ. Stuttgart (Germany); Joachim Keinert, Siegfried Fößel, Fraunhofer-Institut für Integrierte Schaltungen (IIS) (Germany)

In its 71th meeting, the JPEG committee issued a call for low complexity, high speed image coding, designed to address the needs of low-cost video-over-ip applications. As an answer to this call, Fraunhofer IIS and the Computing Center of the University of Stuttgart jointly developed an embedded DCT image codec requiring only minimal resources while maximizing throughput on FPGA and GPU implementations.

Objective and subjective tests performed for the 73rd meeting confirmed its excellent performance and suitability for its purpose, and it was selected as one of the two key contributions for the development of a joined test model. In this paper, its authors describe the design principles of the codec, provide a high-level overview of the encoder and decoder chain and provide evaluation results on the test corpus selected by the JPEG committee.

10396-26, Session 4

On a parallel rate control method for JPEG2000

Miguel Ángel Martínez del Amor, Volker Bruns, Heiko Sparenberg, Fraunhofer-Institut für Integrierte Schaltungen (IIS) (Germany)

Since the introduction of JPEG2000, several rate control methods have been proposed. Among them, post-compression rate-distortion optimization (PCRD-Opt) is the most widely used. The approach followed by this method is to first compress the entire image, and subsequently, optimally truncate the set of generated bit streams according to the maximum target bit rate constraint. The literature proposes various strategies on how to estimate ahead of time where a block will get truncated in order to stop the execution prematurely and save time. However, none of them have been defined bearing in mind a parallel implementation.

Today, multi-core and many-core architectures are becoming popular for JPEG2000. Therefore, in this paper, we analyze how some techniques for efficient rate control can be deployed in GPUs. In order to do that, the design of our GPU-based codec is extended, allowing to stop the process at a given truncation point. This extension also harnesses a higher level of parallelism on the GPU, leading to an average of 40% of speedup with 2K pictures and 60% with 4K. In a second step, three selected rate control methods are adapted and implemented in our parallel encoder. A comparison is then carried out, and used to select the best candidate to be deployed in a GPU encoder, which gave an extra 30% of speed-up in those situations where it was really employed.

10396-27, Session 4

Lossless medical image compression through lightweight binary arithmetic coding

Joan Bartrina Rapesta, Univ. Autònoma de Barcelona (Spain); Victor Sanchez, The Univ. of Warwick (United Kingdom); Joan Serra Sagrsità, Univ. Autònoma de Barcelona (Spain); Michael W. Marcellin, The Univ. of Arizona (United States); Francesc Aulí Llinàs, Ian Blanes, Univ. Autònoma de Barcelona (Spain)

A lightweight arithmetic coder is proposed for lossless compression of medical imagery. Context definition uses causal data from previous slices (components) and bitplanes, an inexpensive yet efficient approach. To further reduce the computational cost, a binary arithmetic coder with fixed-length codewords is adopted, thus avoiding the normalization procedure common in most implementations, and the probability of each context is estimated through bitwise operations. Experimental results are provided for several medical images and compared against state-of-the-art coding techniques, yielding improvements between 0.12 and 0.45 bps.

10396-28, Session 4

FBCOT: a fast block coding option for JPEG2000

David S. Taubman, Aous Naman, Reji Mathew, The Univ. of New South Wales (Australia)

Based on the EBCOT algorithm, JPEG2000 finds application in many fields, including high performance scientific, geospatial and video coding applications. Beyond digital cinema, JPEG2000 is also attractive as a mezzanine format for content delivery and for low-latency video communication. The main obstacle in some applications is the relatively high computational complexity of the block coder, especially at high bit-rates.

We propose a drop-in replacement for the JPEG2000 block coding algorithm, achieving much higher encoding and decoding throughputs, with only modest loss in coding effiency (typically < 0.5dB). High throughput derives from a vertical (all bit-planes at once) coding sequence, together with carefully optimized, vectorizable coding tools and multiple forward/backward growing bit-streams for each block, which enhance concurrency. The algorithm provides only limited quality/SNR scalability, but offers truly reversible transcoding to/from any standard JPEG2000 block bit-stream. Transcoding may be performed on a block-by-block basis, leading to interesting applications in which lightweight encoding and/or decoding is coupled with incremental communication via the fully scalable EBCOT algorithm.

The proposed FAST block coder can be used with EBCOT's post-compression RD-opimization methodology, allowing a target compressed bit-rate to be achieved even at low latencies, leading to the name FBCOT (Fast Block Coding with Optimized Truncation). We explain how FBCOT manages precise rate control in a complexity constrained low latency coding environment, with encoding and decoding throughputs well below 10 clock cycles per sample (each core) on a modern i7 CPU, at high bit rates such as 4bpp.

10396-29, Session 4

Advanced display stream compression for mobile applications

Natan Jacobson, Vijayaraghavan Thirumalai, Rajan L. Joshi, James Goel, Qualcomm Inc. (United States)

Digital displays are ubiquitous in our lives, and the display properties are constantly improving to provide a better viewing experience. These improvements include increased display resolution, high bit depth, and high refresh rate which enable new experiences such as 4K/8K, high dynamic range (HDR) and virtual reality (VR). Each of these display improvements brings a significant increase on the required transmission bandwidth, such that transmission may not be possible over existing display transmission links. To address this problem, we propose Advanced Display Stream Compression (ADSC), a novel fixed-rate intra-only codec supporting compression rates of 4:1 and beyond while maintaining visually lossless image quality. The ADSC codec is lightweight and is intended to be implemented in hardware (ASIC/FPGA) for real-time operation. The proposed ADSC is versatile, supporting both RGB and YCbCr input color formats with 4:4:4, 4:2:2, and 4:2:0 chroma subsampling and bit depths ranging from 8 to 16 bits/component. The ADSC codec therefore offers a cost-effective solution to enable new applications over existing display links – such as 4K/60 for mobile displays over DSI, 8K/120 for VR applications, and beyond.

10396-30, Session 5

A novel projection for omnidirectional video

Adeel Abbas, Sandeep Doshi, GoPro, Inc. (United States)

Omnidirectional video processing and compression techniques involve projection mapping of spherical data to 2D surface. There are a number of projections available e.g. Equirectangular, Cube Map and Segmented Sphere, and each projection offers multitude of frame packing arrangements. The best projection lies closer to sphere, with lower number of pixels contributing to geometric distortions. Additionally we want to minimize number of faces because face discontinuities present new challenges for encoders. In this paper, we present a new projection that attempts to address some of the limitations of existing projections. Our projection lies very close to the sphere, has small number of faces and offers practical advantages compared to existing projections. We have also tested performance of this projection with HM and found BD-rate gain up to X%.

10396-31, Session 5

Geometry padding for intra prediction in 360 video coding

Philippe Hanhart, Yuwen He, Yan Ye, InterDigital Communications, Inc. (United States)

This paper presents a new reference sample derivation method for intra prediction in 360-degree video coding. Unlike the conventional reference sample derivation method for 2D video coding, which uses the samples located directly above and on the left of the current block, the proposed method considers the spherical nature of 360-degree video when deriving reference samples located outside the current face to which the block belongs, and derives reference samples that are geometric neighbors on the sphere. The proposed reference sample derivation method was implemented in the Joint Exploration Model 3.0 (JEM-3.0) for the cubemap projection format. Simulation results for all intra configuration show that, when compared with the conventional reference sample derivation method, the proposed method gives on average luma BD-rate reduction of 0.3% in terms of the spherical PSNR (SPSNR), SPSNR weighted by latitude access frequency (L-SPSNR), and weighted spherical PSNR (WS-PSNR) metrics.

10396-32, Session 5

Segment scheduling method for reducing 360° video streaming latency

Yong He, InterDigital Communications, Inc. (United States); Srinivas Gudumasu, Aricent Technologies (India); Eduardo Asbun, Yan Ye, InterDigital Communications, Inc. (United States)

360° video is a rapidly growing new format emerging in the media industry enabled by the growing availability of VR devices. It is able to provide the viewer with a very new sense of presence and immersion. Comparing to the conventional rectilinear video (2D or 3D), 360° video poses a new and difficult set of engineering challenges on video processing and delivery. Enabling comfort and immersive user experience requires extreme high video quality and very low latency, while the large video size poses an impediment to delivering 360° video in a quality manner at scale.

Majority of 360° video applications and services available at present encode the entire 360° video into a standard compliant stream for progressive downloading or adaptive streaming. Delivering entire 360° video to the clients allows low-latency rendering (the client has access to the entirety of the 360° video content and can choose to render the portion he or she desire to see without further constraint). From the server's perspective, the same streams can support multiple users with possibly different viewports. On the down side, however, because the entire 360° video has to be encoded in high quality, e.g. 4K@60fps or even 8K@60fps, the coded video size would be tremendously high, incurring high transmission bandwidth when the video is delivered. At the client side, much of this high bandwidth consumption during delivery, as well as the power consumed to decode the video, will be wasted, because the user only watches a small portion (i.e., viewport) of the entire picture.

To solve these problems, tile based or layer based viewport adaptive streaming methods with essential signaling become common approaches to reduce the bandwidth utilization and power consumption and present high quality content to the users with low rendering latency. The tile-based viewport adaptive streaming approach divides a 360 video projection frame into a number of motion constrained tiles. Each tile can be independently encoded into multiple quality level representations. During streaming, the client may request tile segment that corresponds to the current viewing orientation at high quality, and request tiles that do not correspond to the current viewing orientation at low quality. This allows the client to utilize the available bandwidth efficiently and accommodate abrupt viewport changes with low rendering latency. In another layer-based approach, state-of-art scalable video coding standard called the Scalable High Efficiency Video Coding (SHVC) standard may be used to code the 360 video. SHVC encodes a video into a number of layers representing different qualities and/or resolutions: a base layer (BL) and one or more enhancement layers (EL), each incrementally enhancing the quality of the lower layers. With layer-based approach, the entire 360 video can be encoded into a low quality representation as base, and each individual viewport can be separately encoded at high quality levels as enhancement layers. In this approach, the client may request base representation to obtain the whole spherical video. Then, based on the current viewing orientation, an enhancement layer corresponding to the particular viewport can be requested and then overlaid on top of the base quality frame for rendering.

The conventional video streaming scheduling method can be deployed for viewport adaptive 360 video delivery, but it may increase the latency when switching between different viewports due to the segment length and head orientation detection. The start of video segments defines the random access point. Therefore, when a longer segment length is used, it takes a longer time to switch among different target viewports from low quality to high quality, as the next random access point is farther away. An early head orientation detection method to determine the corresponding viewport segment request may not be effective, since the user's head orientation may keep changing before rendering. It is ideal to have minimum segment length, such as one frame, in order to reduce the latency, but the video coding efficiency will drop significantly. An efficient segment scheduling scheme is critical to reducing the viewport switch latency and improve the orientation detection accuracy for 360° video delivery.

A dual buffer segment scheduling method is proposed to reduce the latency when switching between different viewports. In this approach the base buffer holds all lower quality tile segments and the viewport buffer stores the particular high quality viewport segments depending on the latest head orientation detection. The client can always request low quality tiles to fill the base buffer and request high quality tile(s) near to the playback time to improve the viewport prediction accuracy. The number of high quality tiles being requested depends on the available bandwidth and the number of tile(s) within the target viewport. The simulation results verify that the proposed tile based viewport adaptive streaming with dual buffer segment scheduling algorithm is able to utilize the bandwidth more efficiently. As a result, a more consistent high quality 360° video content viewing experience can be presented to the user.

10396-33, Session 5

An ROI multi-resolution compression method for 3D-HEVC

Chunli Ti, Yudong Guan, Guodong Xu, Yidan Teng, Xinyuan Miao, Harbin Institute of Technology (China)

3D High Efficiency Video Coding (3D-HEVC) provides a significant potential on increasing the compression ratio of multi-view RGB-D videos. However?the bit rate still rises dramatically with the improvement of the video resolution, which will bring challenges to the transmission network, especially the mobile network. This paper propose an ROI multi-resolution compression method for 3D-HEVC to better preserve the information in ROI on condition of limited bandwidth. This is realized primarily through ROI extraction and compression multi-resolution preprocessed video as alternative data according to the network conditions. At first, the semantic contours are detected by the modified structured forests to restrain the color textures inside objects. The ROI is then determined utilizing the contour neighbourhood along with the face region, foreground and the central area of the scene. Secondly, the RGB-D videos are divided into slices and compressed via 3D-HEVC under different resolutions for selection by the audiences and applications. Afterwards, the low-resolution videos are directly up-sampled via Laplace transformation and used to replace the non-ROI areas of the high-resolution videos. Finally, the ROI multi-resolution compressed slices are obtained by compressing the ROI preprocessed videos with 3D-HEVC. The temporal and special details of non-ROI are reduced in the low-resolution videos, so the ROI will be better preserved by the encoder automatically. Experiments indicate that the proposed method can keep the key high-frequency information with subjective significance while the bit rate is reduced.

10396-34, Session 5

Key factors for a high quality VR experience

Mary-Luc Champel, Technicolor S.A. (France)

For many years, Virtual Reality has been presented as a very promising technology which could deliver a truly new experience to users but until recently such promise was mostly met by the video game industry using computer Graphics images and with quite confidential success. With the recent invasion of VR headsets, the media & entertainment industry is now investigating the possibility to offer a video based VR 360 experience while using traditional production and delivery workflows. Whether such VR content is consumed on a head-mounted display, a tablet, a phone or a TV, there is no doubt that the immersion of the user within an audio video content offers a unique and never seen before experience. Nevertheless, there is a substantial risk that VR 360 could have the same fate as 3DTV if it cannot offer more than just being the next fad. The present paper aims at presenting the various quality factors that we believe need to be offered in a VR 360 content in order to ensure a high quality VR experience. More specifically, this paper will focus on the main three VR quality pillars: visual, audio and immersion.

10396-35, Session 5

Wider angle viewports for omnidirectional video

Adeel Abbas, Sandeep Doshi, GoPro, Inc. (United States)

Virtual Reality or 360-degree images and video often require one to extract a sub-region portion of video/image data (also called viewport) for rendering purposes. One of the most common method to extract viewport from omnidirectional video involves projecting video data in rectilinear projection. Rectilinear projection works for smaller FOV viewports e.g. 60°x60°, but as soon as FOV of viewport starts to increase, the corners of the viewport experience “stretching”. This is due to the geometric distortions introduced from projecting spherical data rectilinearly. In this paper, we present an alternate approach to creating viewports that overcomes some of the limitations of rectilinear viewports.

10396-36, Session 5

Depth map estimation using multiple captured images

José Luis López Martínez, Univ. Autónoma de Yucatán (Mexico); Vitaly Kober, Ctr. de Investigación Científica y de Educación Superior de Ensenada B.C. (Mexico); Joel Antonio Trejo Sánchez, Ctr. de Investigación en Matemáticas, A.C., CONACyT (Mexico)

The depth map of a scene has many applications like robot navigation, computer vision, 3D reconstruction, etc. In this presentation, we propose a novel algorithm of the depth map generation of a scene using three cameras. The proposed system utilizes a slight displacement between the cameras. The algorithm of the depth map estimation is based on optimization of an objective function. The proposed method yields a good accuracy of the map estimation, and it is robust to noisy data. The performance of the proposed method is compared with that of common depth map estimation algorithms in terms of accuracy.

10396-37, Session 5

Discontinuity minimization for omnidirectional video projections

Vladyslav S. Zakharchenko, SAMSUNG Electronics Co., Ltd. (Korea, Republic of); Elena A. Alshina, SAMSUNG Electro-Mechanics (Korea, Republic of)

Omnidirectional video processing, compression and rendering is actively and rapidly developed topic. Quality measurement is key part of development process. Several quality metrics for 360 video content are considered by MPEG and VCEG during international standardization. Adequacy of those metrics and suggestions on test methodology are discussed in this paper from view point of company actively working on 360 video market.

10396-38, Session 5

Measuring quality of omnidirectional high dynamic range content

Anne-Flore Perrin, Ecole Polytechnique Fédérale de Lausanne (Switzerland); Cambodge Bist, Institut de recherche technologique B-Com (France); Touradj Ebrahimi, Ecole Polytechnique Fédérale de Lausanne (Switzerland)

Although HDR content processing coding and quality assessment have been largely addressed in the last few years, little to no work has been concentrating on how to assess quality in HDR for 360 or omnidirectional content. This paper is a first address to answer to various questions in this direction. As a minimum, a new data set for 360 HDR content is proposed and a new methodology is designed to assess subjective quality of HDR 360 content when it is displayed on SDR HMD after applying various tone mapping operators. The results are then analyzed and conclusions are drawn.

10396-39, Session 5

True 3D digital holographic tomography for virtual reality applications

Alexander Downham, Ujitha A. Abeywickrema, Partha P. Banerjee, Univ. of Dayton (United States)

In our previous work, a spring has been reconstructed using digital holographic tomography by recording the holograms with a ‘on-axis’ system, while the object is rotated about a single axis. The recorded holograms are processed through MATLAB® using the multiplicative technique. In this work ‘off-axis’ Mach-Zehnder system is used to record holograms of each side of a die, by rotating the object along the x and y axes. Then the holograms of all six sides of the die are imported and reconstructed in MATLAB® using Fresnel techniques. Then the depth information of each side of the die is obtained by using phase unwrapping techniques. The unwrapped depth information is then converted into a n?3 array, which is then converted into a Point Cloud image. Finally, the true 3D image is constructed using Point Cloud image processing techniques. Once the true 3D image is constructed, the next step is to export the finale image into the Microsoft HoloLens. The HoloLens uses two holographic waveguides in a stereoscopic setting to generate a 3D image. The image can then be manipulated using hand gestures to rotate, zoom in and zoom out from the object. The HoloLens also, enables the user to spatially map their surroundings, which provided a virtual mesh for the true 3D image to use as an anchor point. With the use of the Microsoft HoloLens, the true 3D image is viewed in virtual reality while still containing the depth information, which is difficult to see with current virtual reality techniques used today.

10396-40, Session 6

Forming intermediate spatial resolution of microscopy images for continuous zooming on multi-resolution processing system

Evan Hutomo Eka Putranto, Tomohiro Suzuki, Shin Usuki, Kenjiro Takai Miura, Shizuoka Univ. (Japan)

Magnification is the main purpose of the microscope which uses to enlarging spatial area of the object appearance without make it physically large. There a many type and method that used by microscope to establish magnification. However, different acquisition on the same object which is done by different microscope might raise a problem to bring a better zooming transition. Hence, we propose a quasi-optical zooming transition by forming intermediate spatial resolution microscopy image using multi-resolution image processing and magnification of two kind physical microscope, optical microscope (OM) and scan electron microscope (SEM). In order to form quasi-optical zooming transition with multi-resolution images, it will involve three steps. The first, image con- formation, performing an image registration between the OM and SEM image which has the same magnification unit. We perform image correction one image with 100X maximum magnification on OM and image with 100X minimum magnification of the SEM and merge it. The second, forming intermediate multi-resolution image between the objective lens magnification that we used on both OM and SEM. The set of physical magnification both of microscope are S ={1X, 100X, 1000X}. We filled the magnification gap between 1X and 100X, 100X and 1000X with integer value of magnification from generated intermediate multi-resolution images. The third, perform a continuous image transition between all of generated spatial image.

Hough transform for microcalcification detection in digital mammograms

Annarita Fanizzi, I.R.C.C.S. Istituto Tumori “Giovanni Paolo II” (Italy); Teresa M. A. Basile, Univ. degli Studi di Bari Aldo Moro (Italy); Ubaldo Bottigli, Univ. degli Studi di Siena (Italy); Rosalba Dentamaro, Vittorio Didonna, I.R.C.C.S. Istituto Tumori “Giovanni Paolo II” (Italy); Alfonso Fausto, Azienda Ospedaliera Univ. Senese (Italy); Raffaella Massafra, I.R.C.C.S. Istituto Tumori “Giovanni Paolo II” (Italy); Marco Moschetta, Univ. degli Studi di Bari Aldo Moro (Italy); Liliana Losurdo, Pasquale Tamborra, I.R.C.C.S. Istituto Tumori “Giovanni Paolo II” (Italy); Sonia Tangaro, Istituto Nazionale di Fisica Nucleare (Italy); Roberto Bellotti, Univ. degli Studi di Bari Aldo Moro (Italy) and Istituto Nazionale di Fisica Nucleare (Italy); Daniele La Forgia, I.R.C.C.S. Istituto Tumori “Giovanni Paolo II” (Italy)

Many screening programs use mammography as principal diagnostic tool for detecting breast cancer at a very early stage. Despite the efficacy of the mammograms in highlighting breast diseases, the detection of some lesions is still doubtless for radiologists. In particular, the extremely minute and elongated salt-like particles of microcalcifications are sometimes no larger than 0.1 mm and represent approximately half of all cancer detected by means of mammograms. Hence the need for automatic tools able to support radiologists in their work. Here, we propose a computer assisted diagnostic tool to support radiologists in identifying microcalcifications in full (native) digital mammographic images. The proposed CAD system consists of a pre-processing step, that improves contrast and reduces noise by applying Sobel edge detection algorithm and Gaussian filter, followed by a microcalcification detection step performed by exploiting the circular Hough transform. The procedure performance was tested on 200 images coming from the Breast Cancer Digital Repository (BCDR), a publicly available database. The automatically detected (clusters of) microcalcifications were evaluated by skilled radiologists which asses the validity of the correctly identified ROIs as well as the system error in case of missed microcalcifications. The system performance was evaluated in terms of sensitivity and False Positives per images (FPi) rate resulting comparable to the state of the art approaches. The proposed model was able to accurately predict the micro-calcification clusters obtaining performances (sensibility = 92.03% and FPi rate = 3.74) which favorably compare to other state-of-the-art approaches.

10396-42, Session 6

Smartphone assisted microscopy for automated quantification of ER, PR, and Ki-67 molecular markers

Suman Tewary, Chandan Chakraborty, Indian Institute of Technology Kharagpur (India); Indu Arun, Rosina Ahmed, Sanjoy Chatterjee, Tata Medical Ctr. (India)

In cancer progression, alteration of molecular expression at tissue level is evaluated by Immunohistochemical (IHC) markers. Hormone receptors such as estrogen receptor (ER) and progesterone receptor (PR), and proliferative marker Ki-67 plays critical role in deciding future therapy of breast cancer patients. The routine pathological evaluation involves the staining of tissue with IHC markers followed by manual counting of positively (brown in color) and negatively (blue in color) stained cells in the tissue slide. The manual evaluation is tedious, time consuming and prone to inter-observer variability which may lead to errors in diagnostic and prognostic evaluation. Available digital image analyzers are not affordable for pathological centers, when most of these centers cannot even afford the facility for digital pathology and depends on manual observation by expert pathologists. In view of this, the presented work aims to develop smartphone assisted microscopic image analyzer. The separation of hematoxylin and diaminobenzidine (DAB) stains followed by quantification of positively and negatively stained cells are performed on smartphone. The application also provides different color balancing algorithms for the ease of user under various illumination conditions. The aim is to quantify the stained cells for population score and proliferation index generation which will assist the clinicians for automated report generation. The developed application is compared with the state-of-the-art web based software ImmunoRatio for a quantitative comparison and the results are promising. With the smartphone assisted IHC image analysis, cancer prognostic evaluation process would become faster, accurate and repeatable.

10396-44, Session 6

A multi-layer description of Parkinson’s disease

Marianna La Rocca, Nicola Amoroso, Roberto Bellotti, Univ. degli Studi di Bari Aldo Moro (Italy); Sabina Tangaro, Istituto Nazionale di Fisica Nucleare (Italy)

Magnetic resonance imaging (MRI) along with complex network is currently one of the most widely adopted techniques for detection of structural changes in neurological diseases, such as Parkinson’s Disease (PD). In this paper, we present a digital image processing study, within the multi-layer network framework, combining more classifiers to evaluate the informative power of the MRI features, for the discrimination of normal controls (NC) and PD subjects. We define a network for each MRI scan; the nodes are the sub-volumes (patches) the images are divided into and the links are defined using the Pearson’s pairwise correlation between patches. We obtain a multi-layer network whose topological features are used to feed a supervised multi-level random forest classifier which exploits this base of knowledge for accurate classification. Method evaluation has been carried out using T1 MRI scans of 356 individuals, including 177 PD subjects and 177 normal controls from the Parkinson’s Progression Markers Initiative (PPMI) database. The experimental results demonstrate that the features obtained from multiplex networks are able to accurately describe PD patterns and that a privileged scale for studying PD disease exists. In particular, this

method gives a comprehensive overview of brain regions statistically affected by the disease, an additional value to the presented study.

10396-45, Session 6

Machine learning for the assessment of Alzheimer's disease through DTI

Eufemia Lella, Nicola Amoroso, Roberto Bellotti, Univ. degli Studi di Bari Aldo Moro (Italy); Domenico Diacono, Istituto Nazionale di Fisica Nucleare (Italy); Tommaso Maggipinto, Univ. degli Studi di Bari Aldo Moro (Italy); Alfonso Monaco, Sabina Tangaro, Istituto Nazionale di Fisica Nucleare (Italy)

Digital imaging techniques have found several medical applications in the development of computer aided detection systems, especially in neuroimaging. Recent advances in Diffusion Tensor Imaging (DTI) aim to discover biological markers for the early diagnosis of Alzheimer's Disease (AD), one of the most widespread neurodegenerative disorders. We explore here how different supervised classification models provide a robust support to the diagnosis of AD patients. We use DTI measures, assessing the structural integrity of white matter (WM) fiber tracts, to reveal patterns of disrupted brain connectivity. In particular, we provide a voxel-wise measure of fractional anisotropy (FA) and mean diffusivity (MD), thus identifying the regions of the brain mostly affected by neurodegeneration, and then computing statistical and intensity features to feed supervised classification algorithms. In particular, we evaluate the accuracy of discrimination of AD patients from healthy controls (HC) with a dataset of 80 subjects (40 HC, 40 AD), from the Alzheimer's Disease Neurodegenerative Initiative (ADNI). In this study, we compare three state-of-the-art classification models: Random Forests, Naive Bayes and Support Vector Machines (SVMs). We use a repeated five-fold cross validation framework with nested feature selection to perform a fair comparison between these algorithms and evaluate the information content they provide. Results show that AD patterns are well localized within the brain, thus DTI features can support the AD diagnosis.

10396-46, Session 6

Association between MRI structural features and cognitive measures in multiple sclerosis

Nicola Amoroso, Univ degli Studi di Bari Aldo Moro (Italy) and Istituto Nazionale di Fisica Nucleare (Italy); Roberto Bellotti, Istituto Nazionale di Fisica Nucleare (Italy) and Univ. degli Studi di Bari Aldo Moro (Italy); Alfonso Monaco, Istituto Nazionale di Fisica Nucleare (Italy); Maria Liguori, Consiglio Nazionale delle Ricerche (Italy); L. Margari, Univ. degli Studi di Bari Aldo Moro (Italy); Marta Simone, Univ degli Studi di Bari Aldo Moro (Italy); R.G. Viterbo, Univ. degli Studi di Bari Aldo Moro (Italy); Sabina Tangaro, Istituto Nazionale di Fisica Nucleare (Italy)

Multiple sclerosis (MS) is an inflammatory and demyelinating disease associated with neurodegenerative processes that lead to brain structural changes. Magnetic Resonance Imaging (MRI) is generally used for diagnosis and follow-up in MS patients, however the conventional MRI measures (e.g. new or enlarging T2-weighted lesions, T1-weighted gadolinium-enhancing lesions) have often failed as surrogate markers of both physical and cognitive dysfunctions. Cognitive dysfunction is one of the most remarkable features of MS, and particularly in pediatric onset MS (POMS), the percentage of patients with cognitive deficit range from 30 to 80%. In order to investigate the association between cognitive measures and brain morphometry, in this work we present a fully automated pipeline for processing and analyzing MRI brain scans. Relevant anatomical structures are segmented with FreeSurfer; besides, statistical features are computed. Thus, we describe the data referred to 19 patients with POMS (mean age at MRI: 15.5 ± 2.7 years) with a set of 182 structural features. We perform an exhaustive investigation of association between single features and cognitive measurements, and exploring different abilities like the verbal and visuo-spatial learning, expressive language and complex attention. Different regression models and parameter configurations are explored to assess the robustness of the results, in particular Generalized Linear Models, Bayes Regression, Random Forests, Support Vector Regression and Artificial Neural Networks are discussed.

10396-47, Session 6

Brain's tumor image proccessing using shearlet transform

Luis Cadena, Univ. de las Fuerzas Armadas-ESPE (Ecuador) and Siberian State Aerospace Univ. (Russian Federation); Franklin Cadena, Colegio Juan Suarez Chacon (Ecuador); Nikolai D. Espinosa Ortiz, Univ. de las Fuerzas Armadas-ESPE (Ecuador); Anna Korneeva, Alexey Kruglyakov, Alexander Legalov, Siberian Federal Univ. (Russian Federation); Alexey Romanenko, Novosibirsk State Univ. (Russian Federation); Alexander Zotin, Siberian State Aerospace Univ. (Russian Federation)

Brain tumor detection is well known research area for medical and computer scientists. In last decades there has been much research done on tumor detection, segmentation, & classification. Medical imaging plays a central role in the diagnosis of brain tumors and nowadays uses methods non-invasive, high-resolution techniques, especially magnetic resonance imaging and computed tomography scans. Edge detection is a fundamental tool in image processing, particularly in the areas of feature detection and feature extraction, which aim at identifying points in a digital image at which the image has discontinuities.

Shearlets is the most successful frameworks for the efficient representation of multidimensional data, capturing edges and other anisotropic features which frequently dominate multidimensional phenomena.

The paper proposes an improved brain tumor detection method by automatically detecting tumor location in MR images, its features are extracted by new shearlet transform.

10396-48, Session 6

Demyelinating disease and cerebral ischemia: detection algorithm through MRI

Darwin P. Castillo Malla, Univ. Técnica Particular de Loja (Ecuador); René Samaniego, Hospital UTPL (Ecuador); María José Rodríguez-Álvarez, Univ. Politècnica de València (Spain)

This work presents the development of an algorithm for automatic detection of demyelinating lesions and cerebral ischemia through magnetic resonance images, which have contributed in paramount importance in the diagnosis of brain diseases [1]. The sequences of images to be used are T1, T2, and FLAIR.

Brain demyelination lesions occur due to damage of the myelin layer of nerve fibers; and therefore this deterioration is the cause of serious pathologies such as multiple sclerosis (MS) [2], leukodystrophy, disseminated acute encephalomyelitis. Cerebral or cerebrovascular ischemia is the interruption of the blood supply to the brain, thus interrupting; the flow of oxygen and nutrients needed to maintain the functioning of brain cells [3]. The algorithm developed allows the differentiation between these lesions.

10396-49, Session 6

Breast thermograms analysis in the search of temperature gradients linked with breast injuries

Osmond Abraham Zermeño Loreto, Carina Toxqui Quitl, Univ. Politécnica de Tulancingo (Mexico); Eber E. Orozco Guillen, Univ. Politécnica de Sinaloa (Mexico); Alfonso Padilla Vivanco, Univ. Politécnica de Tulancingo (Mexico)

Infrared thermography is a technique that allows us to measure the body temperature and represents it in an image without the need to have contact with the person. However the automatic calibration of the devices causes that the same color means a different temperature in each measuring, this increases the difficulty of manual analysis of these images. With digital image processing techniques based on edge detection and temperature thresholding, it is possible to highlight those areas of interest that have a temperature gradient that can be caused by breast injuries. Also, a statistical analysis of the region of interest is carried out to characterize and classify it through neural networks.

10396-50, Session 7

Weighted bi-prediction for light field image coding

Caroline Conti, Instituto de Telecomunicações (Portugal) and Instituto Univ. de Lisboa (Portugal); Paulo Nunes, Luís Ducla Soares, Instituto de Telecomunicações (Portugal) and Instituto Universitário de Lisboa (ISCTE-IUL) (Portugal)

Light field imaging based on a single-tier camera equipped with a microlens array – also known as integral, holoscopic, and plenoptic imaging – has currently risen up as a practical and prospective approach for future visual applications and services. However, successfully deploying actual light field imaging applications and services will require developing adequate coding solutions in order to efficiently handle the massive amount of data involved in these systems. In this context, self-similarity compensated prediction is a non-local spatial prediction scheme based on block matching that has been shown to achieve high efficiency for HEVC-based light field image coding1,2. As previously shown by the authors, this is possible by simply averaging two predictor blocks that are jointly estimated from a causal search window in the current frame itself, referred to as self-similarity bi-prediction. However, theoretical analyses for motion compensated bi-prediction (e.g., in Girod3) have suggested that it is still possible to achieve further rate-distortion performance improvements by adaptively estimating the weighting coefficients of the predictor blocks.

Therefore, this paper presents a comprehensive analysis of the rate-distortion performance for HEVC-based light field image coding when using different sets of weighting coefficients for self-similarity bi-prediction. Based on this analysis, an adaptive algorithm is proposed for estimating optimized weighting coefficients for each coding block. References:

A new framework for interactive quality assessment with application to light field coding

Irene Viola, Touradj Ebrahimi, Ecole Polytechnique Fédérale de Lausanne (Switzerland)

The paper describes a follow up and extended version of an interactive quality assessment approach to analyse user experience in interactive environments and provides enough information in order to make decisions either on the degree of impact of new tools or comparisons between different approaches aiming at the same objectives. The framework will be illustrated in the context of evaluation of codecs for light field image and video coding with analysis of results and as a by product the conclusions about which light field image coding are suitable to efficiently compress such data.

10396-52, Session 7

Liborg: a lidar-based robot for efficient 3D mapping

Michiel Vlaminck, Hiêp Q. Luong, Wilfried Philips, Univ. Gent (Belgium)

In this work we present a spatial mapping and localization system that is able to acquire 3D models in real-time by means of lidar data. To this end we mounted a Velodyne Lidar Puck (VLP-16) on a robot controlled by a Raspberry Pi to serve as an independent acquisition platform. The novelty of this work is in the way we organize the huge amount of data by using efficient multi-resolution maps based on octrees. The paper explains in which ways the proposed data structure can be exploited to speed up the estimation of the current pose of the robot. First, the known spatial relationship of the points in the map enables efficient nearest neighbor queries which on its turn facilitates correspondence estimation between newly acquired points and the current map. Second, an initial guess of the current pose can be estimated using a lower resolution representation of the scene, which can be refined using a higher resolution, yielding another speed-up. The paper further discusses how the octree serves as a compact representation of the scene that is useful to compress the 3D model for potentially streaming the data to a server or other device. Finally, we explain how the system facilitates the detection of changes in the environment and how it is easily updatable making it perfectly suitable for highly dynamic environments. An experimental study was conducted with our mobile acquisition platform and a thorough evaluation was done on both processing time, accuracy and memory usage.

10396-53, Session 7

On the performance of metrics to predict quality in point cloud representations

Evangelos Alexiou, David McNally, Touradj Ebrahimi, Ecole Polytechnique Fédérale de Lausanne (Switzerland)

This paper proposes a new approach to subjectively assess quality of point

cloud content and evaluates performance of state of the art point cloud objective metrics to predict the subjective quality of such content. The paper includes a rigorous methodology to generate various distortions, to display point cloud content, to run subjective protocols and to validate the results.

10396-54, Session 7

A new similarity measure for complex amplitude holographic data

Ayyoub Ahar, Tobias Birnbaum, Vrije Univ. Brussel (Belgium) and IMEC (Belgium); Christian Jäh, Loughborough Univ. (United Kingdom); Peter Schelkens, Vrije Univ. Brussel (Belgium) and IMEC (Belgium)

Simultaneous with rapid developments in the field of Digital Holography, new utilities for related data processing topics like perceptual quality assessment and data compression are highly desired. An efficient algorithm for perceptual quality prediction of holographic data, should be able to effectively analyze the recorded interferogram (the complex wavefield) and predict the perceived quality of the reconstructed object ideally without performing the reconstruction process. Such algorithms primarily require an efficient measure to compare the complex valued distorted holograms with the reference. To do so, one may use the conventional similarity measures defined for real valued data to separately evaluate the real and imaginary parts of holograms. However, that would discard any correlation between the two parts. Currently, Euclidean distance based error measures like Mean Squared Error (MSE) are widely utilized for measuring the dissimilarity of holograms since it is possible to apply them directly on complex data, even though MSE is not bounded and, most importantly, lacks local interpretability. In this research, a new versatile similarity measure specifically designed for complex values and adapted for holographic data will be presented.

This new measure benefits from nice mathematical properties like boundedness to [0;1], relative error weighting based on the magnitudes of the signals, steerable similarity between original and negative phase; symmetry with respect to ordering of the arguments and the regularity of at least a continuous function. We will also present a performance evaluation between the new measure and the MSE for analyzing a set of computer generated holograms.

10396-55, Session 7

Computer-generated holographic near-eye display system based on LCoS phase only modulator

Peng Sun, Fei Fei, Shengqian Chang, Siman Zhang, Ting Xie, Huaye Li, Liu Siqi, Wang Chang, Zhenrong Zheng, Zhejiang Univ. (China)

Augmented reality (AR) technology has been applied in various industries, such as large-scale manufacturing, national defense?healthcare, movie and mass media and so on. An important way to realize AR display is using computer-generated hologram (CGH), which is accompanied by large redundancy and heavy computing defects. In this paper, a fast calculation algorithm is given to improve the image resolution and reduce the speckle noise by multiplying the object light with virtual convergence light. Holograms are the complex far-field diffraction patterns of the desired objects and by this algorithm accurate holograms can be obtained without the need of iteration. 2D dynamic and 3D AR display with wide field of view (FOV) and high resolution are obtained utilizing this algorithm with LCoS. The undesired zero-order diffracted light is also eliminated easily with a digital raster after reconstructed image is shifted. The experimental results show that the FOV is broadened to 35 degree and refresh frequency of 2D dynamic display achieves 24 fps. This algorithm is effective and efficient, and is a promising method in practical applications.

10396-56, Session 8

A neighborhood vector PCA method for small defect target detection

Zhengzhou Wang, Xi'an Jiaotong Univ. (China); Bingliang Hu, Xi'an Institute of Optics and Precision Mechanics, CAS (China)

The LCM (Local Contrast Method) has many advantages in detecting the large defect targets of the optical component. However, it often suffers from low performance when the defect target is located in local bright region, which reduce the accuracy of defect detection. In this study, we proposed a new neighborhood vector PCA (NVPCA) method for small defect target detection. The main idea is that each pixel and its 8 neighborhoods of damage image are considered as a column vector to participate in matrix operations, a 9 dimensional data cube is reconstructed by all vectors of each pixel, and the main information of the data cube is concentrated in the first dimension being the PCA transform. When the NVPCA image is processed by LCM again, there is a great effect on the image enhancement. After extracting the feature of enhancing image, the important statistical information of each defect target, including coordinate, size, area, energy integral, can be obtained. Because the defect targets are segmented by the region growing method, rather than traditional methods of global threshold segmentation, this method has excellent precision in detecting small defect target with size of 1 pixel, and can detect the defect targets located in local bright region.

10396-59, Session 8

3D+T motion analysis with nanosensors

Jean-Pierre Leduc, Reliance Core Consulting (United States)

This paper addresses the problem of motion analysis performed in a digital signal sampled on an irregular grid spread in 3-dimensional space and time (3D+T). Practically, this analysis as described here can be performed on different kinds of fields for a large variety of applications with a ``smart dust'' composed of nanosensors. Applications relevant for this problem can be found in medicine, earth science, military, and neurophysiology.

A general setting of this problem can be described as follows. A source system is actively releasing nanosensors that shall spread randomly in the field. Once released, each nanosensor emits at its own fixed pace a signal which corresponds some physical variable measured in the field. The sampled signal is a digital number corresponding to a magnitude, and potentially a direction (real or complex number). Each nanosensor is supposed to have a limited lifetime given by a Poisson-exponential distribution after release. The source is supposed to diffuse nanosensors in the field as long as the experiment is carried on. Several antennas are located as an array around the perimeter of the measurement field to capture and transmit the signals to a central station where a computer processes the analysis.

At the central station, raw incoming data is processed in a two steps. The first step is data reconciliation. The second step is motion sensing and analysis. Motion analysis, as referred here for digital signals, proceeds through consecutive steps of detection, parameter estimation and tracking.

The data reconciliation consists in using the raw data captured from the different directional antennas to reconstitute the actual signal in 3D+T as sampled on a random grid. A computer will perform multiple triangulations for each received sample in order to derive triples made of parameter, spatial location and time. At this stage, an algorithm can track and determine the path of each nanosensor in the field until inactivation since each sensor is transmitting at a constant but slightly different pace. This motion analysis may be sufficient or would stop at this stage in cases where the nanosensors are just able and limited to sending their own signature.

The motion sensing analysis step can be considered as a so-called inverse problem where a physical model is inferred to estimate the parameters of interest. In this case, the model is classical mechanics on some given geometry. In classical mechanics, motion is ruled by a Lie group called the Galilei group. The Galilei group enables to perform motion parameter

estimation through the use of group representations. Additional parameters to motion can be added to end up with the following set of parameter of interest: spatial translation, dilation and orientation, and temporal translation. This extended Galilei group has representations in the space-time Hilbert space. Those representations have properties of unitarity, irreducibility and square-integrability that enable the existence of admissible continuous wavelets fit for motion analysis in 3D space and time. It is well-known that the Shannon sampling theory can be generalized to uniform sampling and that Fourier transform has generalized versions computing uniformly sampled frequency values from an unevenly sampled signal to enable convolution computations. Parameter estimation is performed as wavelet-based match filters minimizing the mean-square error with a steepest descent algorithm.

To conclude, the technique of motion analysis described in this paper is quite general, applicable to a smart dust setting and has the advantage to be suitable to neural networks and deep learning applications.

10396-60, Session 8

Low-complexity object detection with deep convolutional neural network for embedded system

Subarna Tripathi, Univ. of California, San Diego (United States); Gökçe Dane, Qualcomm Inc. (United States); Byeongkeun Kang, Truong Nguyen, Univ. of California, San Diego (United States)

In this work, we study low-complexity convolutional neural networks for embedded vision applications.

It is well-known that consolidation of an embedded system for CNN-based object detection is more challenging due to computation and memory requirement comparing with problems like image classification.

We design and develop an end-to-end TensorFlow-based fully-convolutional deep neural network for generic object detection task inspired by one of the fastest framework YOLO.

The proposed model predicts the localization of every object by regressing coordinates of the corresponding bounding box as in YOLO. Hence, the detection is not bounded by minimum object size in principle.

However, our detection layer is fully-convolutional unlike YOLO, where the penultimate layer and the final detection layer is fully-connected. The proposed network is optimized for modified weighted-L2 loss while exploiting the domain knowledge of dominant objects.

As a use case, we choose face detection and train the proposed model on images containing varying number of faces of different sizes. Our TensorFlow-Slim based network can predict up to 147 faces of different sizes and poses in a single frame. We evaluate the face detection performance on publicly available FDDB dataset. Our experimental results show that the proposed method achieves comparative accuracy comparing with state-of-the-art CNN-based face detection methods, while reducing the model size by 3x and memory-BW by 3-4x comparing with YOLO. Thus the proposed model becomes amenable for embedded implementations, and is generic to be extended to any number of categories of objects.

10396-61, Session 8

An embedded system for face classification in infrared video using sparse representations

Antonio Saavedra, Jorge E. Pezoa Nunez, Univ. de Concepción (Chile); Payman Zarkesh-Ha, The Univ. of New Mexico (United States); Miguel Figueroa, Univ. de Concepción (Chile)

We propose a platform for robust face recognition in infrared images using compressive sensing. In line with compressive sensing theory, the classification problem is solved within a sparse representation framework, where test images are represented as a linear combination of the training set. Because the training set constitutes an overcomplete dictionary, we identify new images by finding their sparsest representation based on the training set, using standard l1-minimization algorithms. Unlike conventional face-recognition algorithms, we perform feature extraction using random projections with a precomputed binary matrix, as proposed in the compressive sensing literature. This random sampling reduces the effects of image noise and various occlusions such as facial hair, eyeglasses and disguises, which are notoriously challenging in infrared images. Thus, the performance of our framework is robust to these noise and occlusion factors, reaching on average an accuracy of almost 90% using the UCHThermalFace database. For comparison, a combination of Ahonen's algorithm and linear discriminant analysis reaches 80% accuracy on the same data. We implemented a high-performance embedded digital system for face recognition using this framework, where the computation of the sparse representation of the images using the Orthogonal Matching Pursuit algorithm is performed by dedicated hardware using a deeply pipelined architecture on an FPGA, and the rest is executed in software in an embedded processor on the same chip.

10396-62, Session 8

BDVC (Bimodal Database of Violent Content): a database of violent audio and video

Jose L. Rivera, Mario Humberto Mijes Cruz, Ctr. de Investigación y Desarrollo de Tecnología Digital-IPN (Mexico); Abraham Montoya Obeso, Luis Rodriguez Espejo, Manuel Antonio Rodriguez Vazquez, Mireya García, Ctr. de Investigación y Desarrollo de Tecnología Digital-IPN (Mexico); Alejandro Álvaro Ramírez Acosta, MIRAL R&D&I (United States)

Nowadays there is a trend towards the use of unimodal databases for multimedia content description, organization and retrieval applications of a single type of content like text, voice and images, instead bimodal databases allow to associate semantically two different types of content like audio-video, image-text, among others. The generation of a bimodal database of audio-video implies the creation of a connection between the multimedia content through the semantic relation that associates the actions of both types of information. This paper describes in detail the used characteristics and methodology for the creation of the bimodal database of violent content; the semantic relationship is stablished by the proposed concepts that describe the audiovisual information. The use of bimodal databases in applications related to the audiovisual content processing allows an increase in the semantic performance only and only if these applications process both type of content. This bimodal database counts with 580 audiovisual annotated segments, with a duration of 28 minutes, divided in 41 classes. Bimodal databases are a tool in the generation of applications for the semantic web.

10397-1, Session 1

Modeling and measuring charge sharing in hard x-ray imagers using HEXITEC CdTe detectors

Daniel F. Ryan, Steven D. Christe, Albert Y. Shih, Andrew Inglis, Wayne H. Baumgartner, NASA Goddard Space Flight Ctr. (United States); Matthew D. Wilson, Paul Seller, STFC Rutherford Appleton Lab. (United Kingdom); Jessica A. Gaskin, NASA Marshall Space Flight Ctr. (United States)

There is an increasing demand for fine-resolution X-ray spectroscopic imaging to help better understand high-energy solar and astrophysical processes. Such observations require a new breed of solid-state hard X-ray (HXR) detectors. Small independent pixels are needed to sub-sample the point-spread function (PSF) of the X-ray optics in addition to rapid read-outs to provide fast timing or, in the case of solar observations, handle high count rates produced by solar flares. The Rutherford Appleton Laboratory (RAL) has developed the HEXITEC (High Energy X-ray Imaging Technology) ASIC, an 80x80 array of independent 1mm-thick 250-micron CdTe pixels sensitive down to ~3keV and with a full-frame read-out rate of 10kHz. HEXITEC's pixel size is well matched to the few-arcsecond FWHM provided by current HXR focusing optics. However, such small pixels increase the probability of charge-sharing, i.e. a single X-ray depositing its energy over multiple pixels. Charge-sharing can reduce the spectral and imaging performance of pixelated detectors but, if correctly understood, can be mitigated or even utilized, e.g. for obtaining sub-pixel resolution. NASA's Goddard and Marshall Space Flight Centers have been collaborating with RAL to measure and model charge-sharing in HEXITEC. A previous model of a single HEXITEC pixel's response to incident X-rays has been extended to a 2D multi-pixel model which includes diffusion of the charge cloud among neighboring pixels. This paper describes the model and compares it to observations. The results help us understand how spectral imaging of astrophysical sources is affected by charge-sharing and how to correct for it.

10397-2, Session 1

Developing monolithic CMOS detectors as x-ray imaging spectrometers

Almus T. Kenter, Thomas M. Gauron, Ralph P. Kraft, Stephen M. Amato, Harvard-Smithsonian Ctr. for Astrophysics (United States)

The Smithsonian Astrophysical Observatory (SAO) in collaboration with SRI has been developing monolithic CMOS detectors and associated camera and processing electronics optimized for x-ray astronomy. The goal of this multi-year program has been to produce CMOS x-ray imaging spectrometers that are Fano noise limited over the 0.1-10keV energy band while providing: radiation ``hardness'', high levels of integration, and very high read rates.

The latest detectors known as Big Minimal IIIs have been fabricated, back thinned, and are in the process of x-ray testing. These new detectors are fabricated on 9micron epitaxial silicon and have a 1k by 1k format. They incorporate 16 micron pitch, 6TPPD high "gain" (sensitivity) pixels. The devices incorporate a row-at-a-time analog CDS. The high sensitivity pixels have demonstrated read noise < 3 e rms.

Associated FPGA based camera and x-ray processing algorithms have been developed to clock the devices and to extract only those pixels with x-ray photon charge. The resulting x-ray data represents a great decrease in data volume.

Monolithic devices such as these, would be ideal candidate detectors for the focal planes of Solar, planetary and other space-borne x-ray astronomy missions. The high through-put, low noise and excellent low energy response, provide high dynamic range and good time resolution

We present details of our camera design and device performance with particular emphasis on those aspects of interest to single photon counting x-ray astronomy. These features include read noise, x-ray spectral response and quantum efficiency.

10397-3, Session 1

Recent x-ray hybrid CMOS detector developments and measurements

Sam Hull, Abe Falcone, David Burrows, Mitchell Wages, Tanmoy Chattopadhyay, Maria McQuaide, Evan Bray, The Pennsylvania State Univ. (United States); David Schendt, The Pennsylvania State Univ, (United States)

The Penn State x-ray detector lab, in collaboration with Teledyne Imaging Sensors (TIS), have progressed their efforts to improve soft x-ray Hybrid CMOS detector (HCD) technology on multiple fronts. In order to meet the demands of future high-throughput x-ray observatories, detectors with fast readout and small pixel sizes are being developed. Hybrid CMOS detectors were already capable of fast readout rates and they have now been scaled down to a 12.5 micron pixel pitch. We will report characteristics on these new small pixel HCDs that include in-pixel CDS circuitry and CTIA amplifiers for reducing crosstalk. In addition, PSU and TIS are developing a new large-scale array Speedster-EXD device. The original 64x64 pixel Speedster-EXD prototype used comparators in each pixel to enable the exclusive readout of pixels containing charge, while skipping the readout of pixels with no measurable signal. This event driven readout mode allows for order of magnitude higher effective readout rates and will now be implemented in a full sized device. Finally, PSU is involved in a sounding rocket mission that is slated to fly in 2018 with an off-plane grating array and an H2RG x-ray HCD. This H2RG includes a 36 micron pitch absorber array bonded to an 18 micron ROIC for reduced pixel crosstalk. We will report on the planned detector configuration for this rocket, which will increase the NASA technology readiness level of x-ray HCDs to TRL 9.

10397-4, Session 2

Kyoto's event-driven x-ray astronomical SOI pixel sensor

Takeshi Go Tsuru, Hideki Hayashi, Katsuhiro Tachibana, Makoto Itou, Shunichi Ohmura, Hideaki Matsumura, Hiroyuki Uchida, Takaaki Tanaka, Kyoto Univ. (Japan); Shinya Nakashima, Institute of Space and Astronautical Science (Japan); Yasuo Arai, Ikuo Kurachi, High Energy Accelerator Research Organization, KEK (Japan); Koji Mori, Ayaki Takeda, Yusuke Nishioka, Nobuaki Takebayashi, Shoma Yokoyama, Univ. of Miyazaki (Japan); Takayoshi Kohmura, Kouki Tamasawa, Yusuke Ozawa, Tadashi Sato, Tokyo Univ. of Science (Japan); Shoji Kawahito, Keiichiro Kagawa, Keita Yasutomi, Hiroki Kamehama, Sumeet Shrestha, Shizuoka Univ. (Japan)

We have been developing monolithic active pixel sensors, X-ray SOIPIXs based on a Silicon-On-Insulator (SOI) CMOS technology for future X-ray astronomy satellites (eg. Tsuru et al. 2014, Proc. SPIE, 9144, 914412 7pp., arXiv:1408.4556). Immediate readout of only the pixels hit by X-rays is available by an event trigger output function implemented in each pixel with its high time resolution of ~10 usec (event-driven readout). It allows us to do fast timing observation and also reduce non-X-ray background dominating at high X-ray energy band above 5-10 keV by adopting an anti-coincidence technique. We propose the X-ray SOIPIXs as a soft X-ray sensors of wide-band hybrid X-ray imagers of a next Japanese mission, FORCE (Focusing

On Relativistic universe and Cosmic Evolution), which is characterized by broadband (1-80 keV) X-ray imaging spectroscopy with high angular resolution (<15"), reaching to about 10 times the sensitivity compared to previous missions above 10 keV (See Mori et al. 2016, Proc. SPIE, 9905, id. 990510 10pp.). In this presentation, we report followings subjects. We here report (1) X-ray performances of newly fabricated 3-side buttable back-illumination devices with the size of 22mm x 14mm, (2) the source of dark current and its reduction, (3) the optimum device structure for low readout noise and high charge collection efficiency by using double SOI wafer, (4) dead layer thickness of back-illumination devices, (5) and future development plans.

10397-5, Session 2

Characterizing subpixel spatial resolution of a hybrid CMOS detector

Evan Bray, The Pennsylvania State Univ. (United States)

The detection of X-rays is a unique process relative to other wavelengths, and allows for some novel features that increase the scientific yield of a single observation. Unlike other photon energies, X-rays liberate a large number of electrons from the silicon absorber array of the detector. This number is usually on the order of several hundred to a thousand for moderate-energy X-rays. These electrons tend to diffuse outward into what is referred to as the electron cloud. This cloud can then be picked up by several pixels, forming a specific pattern based on the exact incident location. By performing a "mesh experiment", I have determined the responsivity of our hybrid CMOS detectors with subpixel resolution.

This test involved placing a thin mesh with precisely spaced holes directly over the detector and exposing it to a nearly parallel X-ray beam. The holes are spaced 144 ?m apart and have a diameter of 4 ?m, which is less than the 36 ?m pixel pitch of our detector. By limiting where the X-rays can strike the pixels with the mesh grid, it was possible to characterize the exact shape of these electron clouds through the resulting events seen on the detector. Since the shape of the electron cloud is known, we could then determine the exact location of the incident X-rays on the detector with subpixel resolution.

10397-6, Session 2

Overview of high-efficiency and low-noise solid-state detectors for future missions including the Habitable Exoplanet Imaging Mission and the Large UV/Optical/Infrared (LUVOIR) Surveyor

Shouleh Nikzad, Jet Propulsion Lab. (United States)

In preparation for the National Research Council's next Decadal Survey for Astrophysics, NASA is developing concepts for four flagship missions, including the Habitable Exoplanet Imaging Mission (HabEx) and the Large Ultraviolet/Optical/Infrared Survey Mission (LUVOIR). Science and Technology Definition Teams (STDT) have embarked on formulating the objectives, developing instrument designs and defining requirements and technology gaps.

These missions will depend on high performance detector arrays that will meet the exacting instruments' requirements and will be available affordably and with high yield. STDTs and the associated technology working groups have been identifying relevant detector technologies, their state of development, and plans for further development. In developing these matrices, they have been identifying technology gaps.

This talk focuses on potential solid state detector options and briefly reviews their performance and state of readiness. Silicon detectors as well as detectors using III-V and II-VI based IR, and III-N materials will be briefly discussed in terms of key performance metrics: detection spectral range, signal to noise performance, photon counting ability, pixel count, noise, quantum efficiency, TRL, and scalability in their production.

10397-7, Session 3

The VUV instrument SPICE for Solar Orbiter: performance ground testing

Martin E. Caldwell, Nigel Morris, Mark Anderson, Carmen Pastor, Davide Bruzzi, Samuel Tustain, Chris Howe, Jenny Davenne, Timothy Grundy, Roisin Speight, Paul Eccleston, Sunil D. Sidher, Alessandra Giunta, STFC Rutherford Appleton Lab. (United Kingdom); Douglas K. Griffin, Univ. of New South Wales (Australia); Anne Philippon, Frédéric Auchère, Donald M. Hassler, Institut d'Astrophysique Spatiale (France); Udo H. Schuehle, Stefan Meining, Max-Planck-Institut für Sonnensystemforschung (Germany); Joseph M. Davila, William T. Thompson, NASA Goddard Space Flight Ctr. (United States); Buddy Walls, P. Phelan, Greg Dunn, Southwest Research Institute (United States); Manfred Gyo, Physikalisch-Meteorologisches Observatorium Davos (Switzerland); Grant J. Munro, William Holmes, Peter Doyle, ESR Technology Ltd. (United Kingdom); Roman M. Klein, Thomas Reichel, Physikalisch-Technische Bundesanstalt (Germany)

SPICE (Spectral Imaging of Coronal Environment) is an imaging spectrometer operating at vacuum ultraviolet (VUV) wavelengths, 70.4 – 79.0 nm and 97.3 - 104.9 nm. It is a facility instrument on the Solar Orbiter mission, which carries 10 science instruments in all, to make observations of the Sun's atmosphere and heliosphere, at close proximity to the Sun, i.e. to 0.28 A.U. at perihelion. SPICE's role is to make VUV measurements of plasma in the solar atmosphere. SPICE is designed to achieve spectral imaging at spectral resolution ~1500, spatial resolution of several arcsec, and two-dimensional FOV of 11 x16arcmins. The many constraints on the instrument design imposed by the mission requirements, in particular the harsh thermal environment, prevent the imaging performance from exceeding those of previous instruments, but by being closer to the sun there is a gain in spatial resolution. The design constraints lead to some novel features in the design, which needed be proven by ground test programs. These include a dichroic solar-transmitting primary mirror to dump the solar heat, a high in-flight temperature (60deg.C) and gradients in the optics box, and a bespoke variable-line-spacing grating to minimise the number of reflective components used. The tests culminate in the system-level test of VUV imaging performance and pointing stability. We will describe how our dedicated facility with heritage from previous solar instruments, is used to make these tests, and show the results, firstly on the Engineering Model of the optics unit, and more recently on the Flight Model.

10397-10, Session 3

Photon counting type imaging spectrometer for solar soft x-rays

Noriyuki Narukage, National Astronomical Observatory of Japan (Japan); Shin-nosuke Ishikawa, Tomoko Kawate, Japan Aerospace Exploration Agency (Japan); Taro Sakao, Institute of Space and Astronautical Science (Japan); Lindsay Glesener, Univ. of Minnesota, Twin Cities (United States); Sasha Courtade, Space Sciences Lab. (United States); Säm Krucker, Univ. of California, Berkeley (United States) and Fachhochschule NordWestschweiz (Switzerland); Steven Christe, NASA Goddard Space Flight Ctr. (United States)

The imaging spectroscopic observations for solar soft X-rays are expected to provide us novel and valuable information about the plasma activity in the solar corona, e.g., particle acceleration, heating, shock, etc. However, this type of observations has not been performed yet with enough energy, spatial, and temporal resolutions. In this situation, we plan to realize the

imaging spectroscopic observations for solar soft X-rays with a high speed soft X-ray camera and grazing incidence mirrors. Our developing camera consists of a back-illuminated CMOS sensor. This censor has a sensitivity to soft X-rays (0.5 keV - 10 keV), and can perform continuous exposures of 1,000 frame per second for the imaging area of 1k x 100 pixels. We will mount this camera on the FOXSI-3 sounding rocket that is planned to be launched in the summer of 2018. By the combination of our camera and the X-ray mirror on the FOXSI, we can achieve an energy resolution of 0.2 keV, a spatial resolution of ~5 arcsec (1 arcsec sampling), and the temporal resolution of ~10 seconds in an energy range of 0.5 keV - 10 keV. In this presentation, we will explain the science goal, the instrumental design, and the developments of the solar soft X-ray imaging spectrometer.

10397-11, Session 4

Calibration of the hard x-ray detectors for the FOXSI solar sounding rocket

Subramania Athiray, Univ, of Minnesota (United States); Lindsay Glesener, Univ. of Minnesota, Twin Cities (United States); Sam Krucker, Univ. of California, Berkeley (United States) and Fachhochschule NordWestschweiz (Switzerland); Sasha Courtade, Univ. of California, Berkeley (United States); Steven D. Christe, NASA Goddard Space Flight Ctr. (United States); Shin-nosuke Ishikawa, Institute of Space and Astronautical Science (Japan); Tadayuki Takahashi, Shin Watanabe, Institute of Space and Astronautical Science (Japan) and The Univ. of Tokyo (Japan); Juan Camilo Buitrago Casas, Space Sciences Lab. (United States); Juliana Vievering, Sophie Musset, Kendra Bergstedt, Keith Goetz, Steven Monson, Univ. of Minnesota (United States)

The Focusing Optics X-ray Solar Imager (FOXSI) sounding rocket experiment conducts direct imaging and spectral observation of the Sun in hard X-rays, in the energy range 4 to 20 keV. These high-sensitivity observations are used to study particle acceleration and coronal heating. FOXSI is designed with seven grazing incidence optics modules that focus X-rays onto seven focal plane detectors kept at a 2m distance. FOXSI-1 was flown with seven Double-sided Si Strip Detectors (DSSD), and two of them were replaced with CdTe detectors for FOXSI-2. The upcoming FOXSI-3 flight will carry DSSD and CdTe detectors with upgraded optics for enhanced sensitivity. The detectors are calibrated using various radioactive sources. The detector's spectral response matrix was constructed using a Gaussian approximation with a spread (sigma) that accounts for the energy resolution of the detector. Spectroscopic studies of FOXSI flight data suggest that the inclusion of lower energy X-rays could better constrain the spectral modeling to yield a more precise temperature estimation of the hot plasma. This motivates us to carry out an improved calibration to better understand the finer-order effects on the spectral response, especially at lower energies. Here we report our attempts for improved calibration of FOXSI detectors using experiments and Monte-Carlo simulations.

10397-12, Session 4

Strontium Iodide Radiation Instrumentation (SIRI)

Lee Mitchell, Bernard Phlips, U.S. Naval Research Lab. (United States); Emily Jackson, National Research Council (United States); Neil Johnson, Praxis Inc. (United States)

The SIRI instrument was designed to test the performance of new gamma-ray detector technology for space-based astrophysical and military applications. This new technology offers improved energy resolution, lower power consumption and reduced size compared to similar systems. SIRI consists of europium-doped strontium iodide (SrI2:Eu) scintillator technology with improved energy resolution, 3% at 662 keV compare to 7% at 662 keV of traditional sodium iodide and was developed for terrestrial-based weapons of mass destruction (WMD) detection. The objective of SIRI's one year mission is to space qualify SrI2:Eu detector and silicon photomultiplier technology, study the internal activation of the SrI2:Eu material, and measure the performance of the SiPM readouts. The combined detector and readout measure the gamma-ray spectrum over the energy range of 0.04 - 8 MeV. The harsh radiation environment of space can present a challenge to new technology, often only developed for terrestrial uses. The SIRI mission payoff is a space-qualified compact, high-sensitivity gamma-ray spectrometer with improved energy resolution relative to previous sensors. Scientific applications in solar physics and astrophysics include flares, Gamma Ray Bursts, novae, supernovae, and the synthesis of the elements. DoD and security applications are also possible. Construction of the SIRI instrument has been completed, and it is currently awaiting integration onto the spacecraft. The expected launch date is November 2017. This presentation will discuss the design details, mission CONOPS, and expected science return of the SIRI spectrometer.

10397-13, Session 4

Modeling contamination migration on the Chandra X-ray Observatory: IV

Stephen L. O'Dell, NASA Marshall Space Flight Ctr. (United States); Douglas A. Swartz, Universities Space Research Association (United States); Neil W. Tice, Massachusetts Institute of Technology (United States); Paul P. Plucinsky, Smithsonian Astrophysical Observatory (United States); Herman Marshall, Massachusetts Institute of Technology (United States); Akos Bogdan, Smithsonian Astrophysical Observatory (United States); Catherine E. Grant, Massachusetts Institute of Technology (United States); Allyn F. Tennant, NASA Marshall Space Flight Ctr. (United States); Matthew T. Dahmer, Northrop Grumman (United States)

During its first 18 years of operation, the cold (about -60°C) optical blocking filter of the Advanced CCD Imaging Spectrometer (ACIS), aboard the Chandra X-ray Observatory, has accumulated a growing layer of molecular contamination, which attenuates low-energy x rays. Over the past five years or so, the accumulation rate, spatial distribution, and composition of the contamination have changed. This evolution has motivated further analysis of contamination migration within and near the ACIS cavity, in part to evaluate potential bake-out scenarios intended to reduce the level of contamination. This paper, the fourth on this topic, reports the results of recent contamination-migration simulations and their relevance to a decision whether to bake-out the ACIS instrument.

10397-14, Session 4

An update to the Chandra ACIS contamination model

Herman Marshall, Massachusetts Institute of Technology (United States); Akos Bogdan, Harvard-Smithsonian Ctr. for Astrophysics (United States); Paul P. Plucinsky, Smithsonian Astrophysical Observatory (United States)

We detail the steps used to arrive at a new release of the contamination correction file for use in Chandra ACIS data analysis. The update now reconciles a long-standing tension between imaging and grating spectral data. The update starts with fixing the O-K and F-K edge optical depths according to high spectral resolution LETG/ACIS spectra. Temporal and spatial models of the O-K and F-K variation are derived solely from LETG/ACIS data. Direct ACIS observations of galaxy clusters are then used to determine the C opacity above 0.5 keV after accounting for O-K and F-K opacity. The ACIS data are used to derive the spatial and temporal variation simultaneously. Finally, the C-K opacity dependence on energy was adjusted

near the K edge to obtain better agreement with LETG/ACIS-S spectra of blazars. The model was then tested against ACIS measurements of soft X-ray lines from the supernova remnant 1E 0102.2-7219, checking for temporal and spatial improvement when compared to the previous release.

10397-15, Session 4

The evaluation of the Hitomi (Astro-H)/ SXS spare beryllium window in 3.8-30 keV

Akio Hoshino, Yuki Yoshida, Shunji Kitamoto, Rikkyo Univ. (Japan); Ryuichi Fujimoto, Kanazawa Univ. (Japan); Noriko Y. Yamasaki, Institute of Space and Astronautical Science (Japan); Toshiaki Ina, Tomoya Uruga, Japan Synchrotron Radiation Research Institute (Japan); Megan E. Eckart, Maurice A. Leutenegger, NASA Goddard Space Flight Ctr. (United States)

During the Hitomi (Astro-H) commissioning observations the SXS dewar gate valve (GV) remained closed to protect the instrument from initial spacecraft outgassing. As a result, the optical path of the observations included the Be window installed on the GV. Both x-ray fluorescence (XRF) analysis and x-ray transmission measurements were performed in June 2016 on the flight-spare Be window which is from the same lot as the flight material at SPring-8 in Japan. The beamline operating range is 3.8– 30 keV. We used a beam spot size of 1 mm x 0.2mm to measure two positions on the Be window, at the center of the window and at one position 6.5 mm off-center. We used simultaneous transmission measurements of standard materials for energy calibration. The transmission data clearly showed Fe and Ni K-edges, plus a marginal detection of the Mn K- edge. We found that our transmission data was best fit using the following components; Be: 261.86pm 0.01mum, Cr:3nm(fixed), Mn:3.81pm0.05nm, Fe:10.83pm0.05nm, Ni:16.48pm0.03nm, Cu:5nm (fixed) The effective area is reduced 1$%$ at the Fe K-edge. The amount of contaminated materials are comparable to the values of the spec sheet. The surface transmission is constrained with $sigma=0.11%$ of the unbiased standard deviation. We also investigated additional measurement in the lower energy range at KEK-PF in Japan.

10397-16, Session 5

The gas pixel detector on board the IXPE mission

Carmelo Sgrò, Istituto Nazionale di Fisica Nucleare (Italy)

The Imaging X-ray Polarimetry Explorer (IXPE) has been selected by NASA to be the next mission dedicated to X-ray polarimetry. It is based on a Gas Pixel Detector that is able to add polarization measurement to imaging and spectroscopy, and will be placed at the focus of a conventional X-ray optics. The detector exploits the photoelectric effect in gas and a finely segmented ASIC as a collecting anode. In this talk I will describe the experimental technique and the details of the detector concept. I will than go through the detail of the detector construction and operation, the performance in laboratory tests and expected behavior in orbit at the focus of the IXPE telescope.

10397-17, Session 5

Calibrating IXPE from ground to space

Fabio Muleri for the IXPE team, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy)

The Imaging X-ray Polarimetry Explorer (IXPE) will be the next SMEX mission launched by NASA in 2020 in collaboration with the Italian Space Agency (ASI). IXPE will perform groundbreaking measurements of imaging polarization in X-rays for a number of different classes of sources with three identical telescopes, finally (re)opening a window in the high energy Universe after more than 40 years since the first pioneering results. The unprecedented sensitivity of IXPE to polarization poses peculiar requirements on the payload calibration, e.g. the use of polarized and completely unpolarized radiation, both on ground and in orbit. In this talk, we will present the IXPE calibration plan, describing both calibrations which will be performed on the detectors at INAF-IAPS in Rome (Italy) and the calibration on the mirror and detector assemblies which will be carried out at Marshall Space Flight Center in Huntsville, Alabama. In flight calibrations, performed with calibrations sources mounted on a filter wheel in front of each detector or with observations of well-characterized astrophysical sources, will be presented as well.

10397-18, Session 5

Imaging as a tool for the characterization of the gas pixel detector photoelectric polarimeter

Sergio Fabiani, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy)

The Gas Pixel Detector (GPD) is an X-ray polarimeter exploiting the photoelectric effect both to measure polarization and to obtain the image of astrophysical sources. This detector is on board the IXPE (Imaging X-ray Polarimetry Explorer) mission selected by NASA in the framework of the Explorer program for a launch in 2020. We report on the imaging capability of the GPD as a tool to perform a full detector characterization. X-ray photons are absorbed in a 1 cm thick gas cell and the absorption points are calculated by means of the analysis of the statistical momenta of the photoelectron ionization tracks. Imaging can be a useful tool to study the properties of gas diffusion and charge recombination along the drift if the image of the strip produced by an inclined X-ray beam is studied. The capability of track reconstruction can be studied along the depth of the drift because at each depth corresponds a position in the image plane along the strip. We report on the results of this measurement performed with the He 20% - DME 80 % filled detector foreseen on board the IXPE mission.

10397-19, Session 5

IXPE: The Imaging X-ray Polarimetry Explorer

Paolo Soffitta, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy)

IXPE, the Imaging X-ray Polarimetry Explorer, has been selected as a NASA SMEX mission to be flown at the end of 2020. It will perform polarimetry resolved in energy, in time and in angle as a break-through in High Energy Astrophysics.

IXPE will 're-open', after 40 years, a window in X-ray astronomy adding two more observables to the usual ones. It will directly measure the geometrical parameters of many different classes of sources eventually breaking possible degeneracies. The probed angular scales (30") are indeed larger than Chandra but nevertheless capable of producing the first X-ray polarization maps of extended objects with scientifically relevant sensitivity.

It will allow for mapping the magnetic fields in Pulsar Wind Nebualae and Super-Nova Remnants at the acceleration sites of 10-100 TeV electrons.

Finally it will probe vacuum birefringence effects in systems with magnetic fields far larger than those reachable with experiments on-Earth.

The payload of IXPE consists of three identical telescopes with mirrors provided by MSFC/NASA.

The focal plane is provided by ASI with the responsibility of the instrument by IAPS/INAF that includes the detector units with responsibility of INFN. ASI also provides, in kind, the Malindi Ground Station. The Mission Operation Center is at LASP while the Science Operation Center is at MSFC.

The operations phase lasts at least two years. All the data including those related to polarization will be made available soon to the general user.

In this paper we present the mission and the timelines its payload and we discuss few exemplary astrophysical targets.

10397-20, Session 6

The optomechanical design of the REDSoX sounding rocket experiment

Mark D. Egan, Timothy Hellickson, MIT Kavli Institute for Astrophysics and Space Research (United States); Herman Marshall, Massachusetts Institute of Technology (United States)

The Rocket Experiment Demonstration of a Soft X-ray Polarimeter (REDSoX) is an instrument proposed for launch on a Black Brant IX sounding rocket to carry out the first x-ray polarization measurement of an extragalactic source below 1 keV. The REDSoX instrument will consist of 4 major subsystems: the grazing incident optics, the grating assembly, the detector package with integrated polarizers, and the optical bench to which all components mount. The conventional, replicated nested shell mirror assembly houses a star tracker in the core and is protected prior to launch and upon descent/landing by a non-hermetic door assembly. Just past the x-ray optics there is a unique, staircase-like grating assembly attached to the space-frame optical bench organized in 3 sections with 120deg symmetry. The driving design challenge of this CAT-grating based assembly is the multiple-plane mounting: while minimizing obscuration by the support structure we need to provide a rigid frame that allows safe handling of the individual grating cells. The pattern of the grating assembly is matched on the focal plane by the location of the 3 polarizing laterally grated multi-layer mirrors (LGMLs) and the detectors, with a central detector that is used in 0th order for fine-tuning of the pointing. The central detector is shielded from optical light by an optical bandpass filter (OBF), while the other 3 are fully open but facing sideways and illuminated via the LGMLs oriented 45 degrees to the optical axis. The LGMLs work in concert with the gratings to produce a highly reflective and efficiently polarizing reflector, and the 120deg clocking allows for disentangling the 3 Stokes parameters. The sideways facing spectral detectors are baffled against direct and scattered light, and along with the on-axis CCD they are mounted in a small cooled vacuum enclosure at the end of the optical bench. The focal plane utilizes three titanium flexures that lift the focal plane and thermally isolate the detectors. The focal plane is passively cooled by LN2 before launch, and a gate valve to avoid condensation and contamination seals the vacuum volume. Trim heaters set the ideal CCD operating temperature. In this paper we present the opto-mechanical design derived from the mission requirements, including structures and initial thermal- and vibration analysis. We discuss the stress-free thermo-optical mounts, mechanisms, and the thermal management/control system.

10397-21, Session 6

The rocket experiment demonstration of a soft x-ray polarimeter

Herman Marshall, Norbert Schulz, Ralf K. Heilmann, Massachusetts Institute of Technology (United States); Brian Ramsey, NASA Marshall Space Flight Ctr. (United States); Sarah Heine, Massachusetts Institute of Technology (United States); Mark D. Egan, MIT Kavli Institute for Astrophysics and Space Research (United States); Timothy Hellickson, Massachusetts Institute of Technology (United States)

The Rocket Experiment Demonstration of a Soft X-ray Polarimeter (REDSoX Polarimeter) is a sounding rocket instrument that can make the first measurement of the linear X-ray polarization of an extragalactic source in the 0.2-0.8 keV band as low as 10%. We employ multilayer-coated mirrors as Bragg reflectors at the Brewster angle. By matching the dispersion of a spectrometer using replicated optics from MSFC and critical angle transmission gratings from MIT to three laterally graded multilayer mirrors (LGMLs), we achieve polarization modulation factors over 90%. We present a novel arrangement of gratings, designed optimally for the purpose of polarimetry with a converging beam. The entrance aperture is divided into six equal sectors; pairs of blazed gratings from opposite sectors are oriented to disperse to the same LGML. The LGML position angles are 120 degrees to each other. CCD detectors then measure the intensities of the dispersed spectra after reflection and polarizing by the LGMLs, giving the three Stokes parameters needed to determine the source polarization.

A current APRA grant is funding further development to improve the LGMLs. Sample gratings for the project have been fabricated at MIT and the development team continues to improve them under separate funding. Our technological approach is the basis for a possible orbital mission.

This work was supported in part by NASA grant NNX17AE11G to develop the design for a soft X-ray polarimeter.

10397-22, Session 6

Preparations for the Advanced Scintillator Compton Telescope (ASCOT) balloon flight

Tejaswita Sharma, Peter Bloser, Jason Legere, Christopher M. Bancroft, Mark McConnell, James M. Ryan, Alex M. Wright, The Univ. of New Hampshire (United States)

We describe our ongoing work to develop a new medium-energy gamma-ray Compton telescope using advanced scintillator materials combined with silicon photomultiplier readouts and fly it on a scientific balloon. There is a need in high-energy astronomy for a medium-energy gamma-ray mission covering the energy range from approximately 0.4 - 20 MeV to follow the success of the COMPTEL instrument on CGRO. We believe that directly building on the legacy of COMPTEL, using relatively robust, low-cost, off-the-shelf technologies, is the most promising path for such a mission. Fortunately, high-performance scintillators, such as Cerium Bromide ($CeBr_3$) and p-terphenyl, and compact readout devices, such as silicon photomultipliers (SiPMs), are already commercially available and capable of meeting this need. We are now constructing an Advanced Scintillator Compton Telescope (ASCOT) with SiPM readout, with the goal of imaging the Crab Nebula at MeV energies from a high-altitude balloon flight. We expect a ~4-sigma detection at ~1 MeV in a single transit. We present calibration results of the detector modules, and updated simulations of the balloon instrument sensitivity. If successful, this project will demonstrate that the energy, timing, and position resolution of this technology are sufficient to achieve an order of magnitude improvement in sensitivity in the medium-energy gamma-ray band, were it to be applied to a ~1 cubic meter instrument on a long-duration balloon or Explorer platform.

10397-23, Session 6

ximpol: a new x-ray polarimetry observation-simulation and analysis framework

Nicola Omodei, Stanford Univ. (United States) and MIT Kavli Institute for Astrophysics and Space Research (United States); Luca Baldini, Istituto Nazionale di Fisica Nucleare (Italy) and Univ. di Pisa (Italy); Niccolò Di Lalla, Melissa Pesce-Rollins, Istituto Nazionale di Fisica Nucleare (Italy)

We present a new simulation framework, ximpol, based on the Python programming language and the Scipy stack, specifically developed for X-ray polarimetric applications. ximpol is not tied to any specific mission or instrument design and is meant to produce fast and yet realistic observation-simulations, given as basic inputs: (i) an arbitrary source model including morphological, temporal, spectral and polarimetric information, and (ii) the response functions of the detector under study, i.e., the effective area, the energy dispersion, the point-spread function and the modulation factor. The format of the response files is OGIP compliant, and the framework has the capability of producing output files that can be directly fed into the standard visualization and analysis tools used by the X-ray community, including XSPEC---which make it a useful tool not only

for simulating physical systems, but also to develop and test end-to-end analysis chains.

In this contribution we will give an overview of the basic architecture of the software and present a few physically interesting case studies.

10397-24, Session 7

Development of digital system for the wide-field x-ray imaging detector aboard Kanazawa-SAT3

Yasuaki Kagawa, Daisuke Yonetoku, Tatsuya Sawano, Kanazawa Univ. (Japan); Tatehiro Mihara, RIKEN (Japan); Hirokazu Ikeda, Atsushi Harayama, Institute of Space and Astronautical Science (Japan); Makoto Arimoto, Waseda Univ. (Japan); Kazuki Yoshida, Masao Ina, Kaichi Ota, Yuki Minami, Kanazawa Univ. (Japan)

We are planning to launch a micro satellite, named KANAZAWA-SAT3, for a localization of gravitational wave sources with X-ray transients, for example short gamma-ray bursts originated from coalescence of neutron star-neutron star binaries and/or neutron star-black hole binaries. This satellite is designed to be a 50 cm cube and 50 kg class and going to be launched at the end of FY2018. Now we are developing a prototype model of wide field X-ray imaging detector aboard the satellite which covers the energy range of 1-20 keV with more than 1 str field of view.

This detector is composed of 1-dimensional coded aperture mask with tungsten and silicon strip detectors (SSDs) as X-ray imaging detector. The electric signals are read out by multi-channel ASICs controlled by FPGAs. In general, X-ray sky images are obtained by calculating the cross correlation function between the mask pattern and the detected X-ray intensity pattern. This pattern matching calculation with CPU is so easy but takes a lot of time because of many strips. Therefore, we newly designed a high speed X-ray imaging processor on FPGAs. This processor is able to make a 512 + 512 image (not 2-dimension but 2 set of 1-dimension) within 4 milliseconds at 8 MHz digital clock. Additionally we are developing a imaging trigger algorithm, which judges where X-ray came from and detect dim and long lasting X-ray transients from the X-ray sky images.

Using these systems, we also performed X-ray imaging experiments with six meter beamline in our laboratory, and confirmed the localization accuracy of 15 arcminutes. In our presentation, we report overview of the detector development, especially focusing on digital FPGA system, and show some results of X-ray imaging experiments.

10397-25, Session 7

The survey and time-domain astrophysical research explorer (STAR-X)

William W. Zhang, NASA Goddard Space Flight Ctr. (United States)

STAR-X was proposed in December 2016 as a MIDEX mission for launch in 2023. It is an X-ray telescope with the following characteristics: (1) large field of view; (2) excellent uniform PSF in the entire FOV; and (3) large effective area. STAR-X will catch and study transients, including those resulting from mergers of compact objects, supernova explosions, tidal disruptions, and gamma ray bursts. STAR-X will also conduct surveys to study the growth of compact objects, including stellar mass black holes in the Milky Way and nearby galaxies as well as distant, high-redshift supermassive black holes. The capabilities of STAR-X also enable the study of hot, low surface brightness diffuse emission from galaxy clusters and supernova remnants. STAR-X is facilitated by a spacecraft bus capable of autonomous and fast slewing to targets of opportunity. In this paper we will describe the STAR-X mission design, technology, and major science objectives and its synergy with other major observatories in the 2020s, including eROSITA, JWST, WFIRST, and Athena.

10397-26, Session 7

Performance of a double tilted-Rowland-spectrometer on ARCUS

Hans Moritz Günther, Massachusetts Institute of Technology (United States); The ARCUS Collaboration, Smithsonian Astrophysical Observatory (United States)

Spectroscopy of soft X-rays is an extremely powerful tool to understand the physics of the hot plasma in the universe but in many cases, such as kinematic properties of stellar emission lines or weak absorption features we have reached the limits of current instrumentation. Critical-angle transmission (CAT) gratings blaze the dispersed spectra into high orders and also offer a high throughput.

We present detailed ray-traces for the ARCUS mission, which promises an effective area > 0.5m^2 in the soft X-rays. It uses four modules of Athena-like silicon pore optics. Each module spans an azimuth of about 30 degrees and thus offers a point-spread function that is significantly narrower in one dimension than a full mirror would provide. The four channels are split into two pairs, where each pair has its own optical axis. For each pair, CAT gratings are arranged on a tilted Rowland torus and the two separate tori are positioned to overlap in such a way that the dispersed spectra from both pairs can be imaged onto a common set of CCD detectors, while at the same time keeping the requirement of the spectroscopic focus.

Our ray-traces show that a set of 16 CCDs is sufficient to cover both zeroths orders and over 90% of the dispersed signal. We study the impact of misalignment, finite size of components, off-axis sources, and spacecraft jitter on the spectral resolution and effective area and prove that the design achieves R > 3000 even in the presence of these non-ideal effects.

10397-27, Session 7

Arcus: Exploring the formation and evolution of clusters, galaxies, and stars

Randall K. Smith, Harvard-Smithsonian Ctr. for Astrophysics (United States)

The Large Scale Structure (LSS) of the Universe grew via the gravitational collapse of dark matter, but the visible components that trace the LSS–galaxies, groups and clusters–have a more complex history. Their baryons experience shock heating, radiative cooling and feedback from black holes and star formation, which leave faint signatures of hot (T~10^5-10^8 K), metal-enriched gas in the interstellar and intergalactic media (ISM and IGM). While recent Planck and X-ray studies support this scenario, no current mission possesses the instrumentation necessary to provide direct observational evidence for these "missing baryons." Arcus, a proposed MIDEX mission, leverages recent advances in critical-angle transmission (CAT) gratings and silicon pore optics (SPOs), using CCDs with strong Suzaku heritage and electronics based on the Swift mission; both the spacecraft and mission operations reuse highly successful designs. To be launched in 2023, Arcus will be the only observatory capable of studying, in detail, the hot galactic and intergalactic gas–the dominant baryonic component in the present-day Universe and ultimate reservoir of entropy, metals and the output from cosmic feedback. Its superior soft X-ray sensitivity will complement the forthcoming post-Hitomi and Athena calorimeters, which will have comparably high spectral resolution above 2 keV but poorer spectral resolution than XMM or Chandra in the Arcus bandpass.

10397-28, Session 7

The water recovery x-ray rocket (WRX-R)

Drew M. Miles, The Pennsylvania State Univ. (United States)

The Water Recovery X-ray Rocket (WRX-R) is a diffuse soft X-ray spectrometer that will launch on a sounding rocket from the Kwajalein Atoll. WRX-R has a field of view of >10 deg2 and will observe the Vela supernova remnant. A mechanical collimator, state-of-the-art off-plane reflection grating array and hybrid CMOS detector will allow WRX to achieve the most highly-resolved spectrum of the Vela SNR ever recorded. We present here an introduction to the instrument, the expected science return, and an update on the state of the payload as we work towards launch.

10397-29, Session 8

Lynx mission concept status

Jessica A. Gaskin, NASA Marshall Space Flight Ctr. (United States)

The Lynx Mission is a concept under study for prioritization in the 2020 Astrophysics Decadal Survey. Orders of magnitude increase in sensitivity over Chandra, Lynx will examine the first black holes and their galaxies, will map the large-scale structure and galactic halos, and shed new light on the environments of young stars and their planetary systems. This talk will present the concept development status and will highlight the optics and science instrument suite that will enable the next great X-Ray Observatory.

10397-30, Session 8

Conceptual design of the SMART dosimeter

Erik B. Johnson, Sam Vogel, Rebecca Frank, Graham Stoddard, Radiation Monitoring Devices, Inc. (United States); Alonzo Vera, COSMIAC (United States); David Alexander, David Alexander LLC (United States); James F. Christian, COSMIAC (United States)

Active dosimeters for astronauts and space weather monitors are critical tools for mitigating radiation induced health issues or system failure on capital equipment. Commercial spaceflight, deep space flight, and satellites require smarter, smaller, and lower power dosimeters. There are a number of instruments with flight heritage, yet as identified in NASA's roadmaps, these technologies do not lend themselves to a viable solution for active dosimetry for an astronaut, particularly for deep space missions. For future missions, nano- and micro-satellites will require compact instruments that will accurately assess the radiation hazard without consuming major resources on the spacecraft. RMD has developed the methods for growing an advanced scintillation material called phenylcarbazole, which provides pulse shape discrimination between protons and electrons. When used in combination with an anti-coincidence detector system, an assessment of the dose from charged ions and neutral particles can be determined. This is valuable as damage on a system (such as silicon or tissue) is dependent on the particle species. Using this crystal with readout electronics developed in partnership with COSMIAC at the University of New Mexico, the design of the Small Mixed field Autonomous Radiation Tracker (SMART) Dosimeter consists of a low-power analog to digital conversion scheme with low-power digital signal processing algorithms, which are to be implemented within a compact system on a chip, such as the Xilinx Zynq series. A review of the conceptual design is presented.

10397-31, Session 8

First results of Athena WFI prototype detectors

Wolfgang Treberspurg, Johannes Müller-Seidlitz, Robert Andritschke, Günter Hauser, Valentin Emberger, Annika Behrens, Norbert Meidinger, Max-Planck-Institut für extraterrestrische Physik (Germany)

The ATHENA observatory was selected as the second large-class mission in ESA Cosmic Vision 2015-2025, scheduled to be launch in 2028. To enable detailed explorations of the hot and energetic universe, two complementary focal-plane instruments are coupled to a high-performance X-ray telescope. One of these is the WFI (wide field imager). It features an unprecedented survey power by combining a large field of view of 40x40 arcmin2 with an excellent count rate capability (≥ 1 Crab). The large field of view is covered by four large arrays of monolithic 512x512 pixels sensors, while a second focal plane detector with fast readout enables observations of bright point sources. The energy resolution will be below 170 eV FWHM at 7 keV until the end of the nominal mission, with a readout time between 2.5 µs and 10 µs per sensor row.

This performance will be achieved with DEPFET (DEpleted P-channel FET) active pixel sensors. Each pixel contains a p-channel field effect transistor, which is integrated onto a fully depleted silicon bulk and provides a first amplification of the signal in the pixel itself. This is realized by creating an electrical potential minimum below the transistor gate in order to collect charge, generated inside the silicon bulk and modulate the channel conductivity.

To identify a detector concept, which optimally fulfils the scientific requirements, different variants of DEPFET sensors concerning the geometry and technology were implemented on a prototype production. Different concepts were studied and evaluated on small scale devices of 64x64 pixels with respect to the requirements of the WFI. Furthermore different readout mode were studied, in preparation of a fast operation of large detector devices.

10397-32, Session 8

The wide-field imager instrument for Athena

Norbert Meidinger, Kirpal Nandra, Markus Plattner, Arne Rau, Max-Planck-Institut für extraterrestrische Physik (Germany)

The WFI (Wide Field Imager) instrument is planned to be one of two complementary focal plane cameras on ESA's next X-ray observatory Athena. It combines unprecedented survey power through its large field of view of 40 arcmin x 40 arcmin together with excellent count-rate capability (≥ 1 Crab). High energy, spatial and time resolution are accomplished by the development of detectors using DEPFET active pixel sensors and custom-made control and readout ASICs. The large detector comprises 1024 x 1024 pixels and shall be operated with a frame rate of 200/s, whereas the high count-rate capable detector is planned to show a time resolution of 80 µs resulting in a throughput of more than 80% and a pile-up of less than 1% for an 1 Crab source intensity.

Prototypes of such detectors have been developed for the Athena project and tested. This included the development of electronics for operation of the detectors. In front of the camera head with the detectors is a filter wheel mounted which houses an ultra-thin optical blocking filter with a size of 16 cm x 16 cm.

Further subsystems of the instrument are the detector electronics and the instrument control and power distribution units.

We present the status of Athena's Wide Field Imager instrument including an outlook to the main future activities.

10397-33, Session 8

Updates on experimental grazing angle soft proton scattering

Sebastian Diebold, Sarah Hanschke, Emanuele Perinati, Eberhard Karls Univ. Tübingen (Germany); Randall K. Smith, Harvard-Smithsonian Ctr. for Astrophysics (United States); Christopher Tenzer, Andrea Santangelo, Josef Jochum, Eberhard Karls Univ. Tübingen (Germany)

Astronomical X-ray observatories are exposed to various kinds of orbital radiation that has the potential to compromise observations and to degrade the performance of the instruments. Particularly the soft proton component with energies below 10 MeV poses a major source for observational background and particle-induced damages in solid-state detectors. In-orbit experience has proven that soft protons are funneled much more efficient through Wolter-type X-ray optics than expected from simulations. In order to improve and validate simulations and, therefore, to enable a more realistic assessment of the soft proton flux near the focal plane of future X-ray telescopes, a series of grazing angle scattering experiments is being conducted at the University of Tübingen. In this contribution, the latest improvements of the experimental setup as well as preliminary results of the azimuthal scattering distribution on different targets are presented.

10397-8, Session PMon

An improved version of the Shadow Position Sensor readout electronics on board the ESA PROBA-3 Mission

Vladimiro Noce, Mauro Focardi, INAF - Osservatorio Astrofisico di Arcetri (Italy); Steve Buckley, SensL Technologies Ltd. (Ireland); François Denis, Ctr. Spatial de Liège (Belgium); Kevin O'Neill, SensL Technologies Ltd. (Ireland); Alessandro Bemporad, INAF - Osservatorio Astronomico di Torino (Italy); Silvano Fineschi, INAF - Osservatorio Astrofisico di Torino (Italy); Maurizio Pancrazzi, Federico Landini, Cristian Baccani, INAF - Osservatorio Astrofisico di Arcetri (Italy); Gerardo Capobianco, INAF - Osservatorio Astrofisico di Torino (Italy); Davide Loreggia, INAF - Osservatorio Astronomico di Torino (Italy); Marta Casti, INAF - Osservatorio Astrofisico di Torino (Italy); Marco Romoli, INAF - Osservatorio Astrofisico di Arcetri (Italy); Giuseppe Massone, Gianalfredo Nicolini, INAF - Osservatorio Astrofisico di Torino (Italy); Cédric Thizy, Ctr. Spatial de Liège (Belgium); Idriss Mechmech, Ctr. Spatial de Liège (Belgium); Etienne Renotte, Ctr. Spatial de Liège (Belgium)

PROBA3 is an ESA mission that consists of two satellites: the OSC (Occulter Spacecraft) and the CSC (Coronagraph Spacecraft) that will fly together in a rigid configuration. The two spacecraft will form together a giant (about 150 m) coronagraph instrument in space that will allow to study the solar corona closer to the limb than has ever before been achieved (1.02 Rsun). At the same time the mission will demonstrate the feasibility of precision formation-flying (FF) techniques.

The AOCS (Attitude and Orbit Control System) will keep the relative position of the two spacecraft with an unprecedented accuracy of 50 ?m transversal and 1 mm longitudinal ultimately relying on SPS (Shadow Position Sensor): a set of silicon photomultipliers (SiPM) that measures the light in the penumbra around the instrument opening and compares the readout to the expected illumination profile.

This paper presents the recent improvements adopted in the SPS electronics design that derive from the lessons learned during the first tests performed on the Evaluation Board and on the Development Model, the first two manufactured breadboards. The electronic amplification chain has been accurately reconsidered introducing e.g. precision components, a more stable voltage reference and reducing the dependency from temperature variations. Differential mode communication with the "external world" has been implemented as well as a system letting to operate contemporarily the two independent chains, either in the nominal and in the redundant case.

10397-9, Session PMon

Test plan for the PROBA3/ASPIICS scaled model measurement campaign

Federico Landini, INAF - Osservatorio Astrofisico di Arcetri (Italy); Cristian Baccani, Univ. degli Studi di Firenze (Italy); Sébastien Vives, Lab. d'Astrophysique de Marseille (France); Silvano Fineschi, INAF - Osservatorio Astrofisico di Torino (Italy); Marco Romoli, Univ. degli Studi di Firenze (Italy); Gerardo Capobianco, Giuseppe Massone, Marta Casti, INAF - Osservatorio Astrofisico di Torino (Italy); Alessandro Bemporad, INAF - Osservatorio Astronomico di Torino (Italy); Mauro Focardi, INAF - Osservatorio Astrofisico di Arcetri (Italy); Maurizio Pancrazzi, Univ. degli Studi di Firenze (Italy); Davide Loreggia, INAF - Osservatorio Astrofisico di Torino (Italy); Vladimiro Noce, INAF - Osservatorio Astrofisico di Arcetri (Italy); Alain Jody Corso, CNR-IFN Padova (Italy); Cédric Thizy, Etienne Renotte, Ctr. Spatial de Liège (Belgium)

PROBA3/ASPIICS (Association of Spacecraft for Polarimetric and Imaging Investigation of the Corona of the Sun) is the first formation flight solar coronagraph, scheduled by ESA for a launch and currently in phase C/D.

It is constituted by two spacecraft (one hosting the occulter, diameter 142 cm, and one with the telescope) separated by 144 m, kept in strict alignment by means of complex active and metrology custom systems.

The stray light analysis, which is always one the most critical work packages for a solar coronagraph, has been only theoretically investigated so far due to the difficulty of replicating the actual size system in a clean laboratory environment.

The light diffracted by the external occulter is the worst offender for the stray light level on the instrument focal plane, thus there is strong interest for scaling at least the occultation system of the coronagraph and test it in front of a solar simulator in order to experimentally validate the expected theoretical performance..

The theory for scaling the occulter, the occulter-pupil distance and the source dimension has been developed and a scaled model is being manufactured. A test campaign is going to be conducted at the OPSys facility in Torino in front of a solar simulator (conveniently scaled).

This work accounts for the description of the scaled model laboratory set-up and of the test plan.

10397-47, Session PMon

Transmission measurement of the spare Beryllium window of the SXS onboard the Hitomi satellite in 2.0-12 keV with KEK-PF

Yuki Yoshida, Akio Hoshino, Shunji Kitamoto, Jyuri Sugimoto, Ryouta Ishii, Yuki Ohgi, Sayaka Sato, S. Nukamori, Rikkyo Univ. (Japan); Ryuichi Fujimoto, Kanazawa Univ. (Japan); Noriko Y. Yamasaki, Institute of Space and Astronautical Science (Japan); Toshiaki Ina, Japan Synchrotron Radiation Research Institute (Japan); Tomoya Uruga, Japan Synchrotron Radiation Research Institute (Japan)

The Soft X-ray Spectrometer (SXS) onboard the Hitomi (ASTRO-H) satellite observed several celestial objects. All the observations were performed before the gave-vale(GV) opening and through the Be window installed on the GV. However, the Be window was not well calibrated before launching. Therefore, we measured the transmission of a spare Be window, which is from the same lot as the flight material. The measurements were preformed with BL01B1 for 3.8-30 keV range in SPring-8, and BL11B for 2.0-4.5 keV range and BL7C for 4.0-12 keV range in KEK-PF. The details of the SPring-8 experiment are reported as a separate paper. In this paper, we report the results of the KEK-PF experiment. With the BL7C, we measured five points of the Be window. Their estimated thicknesses are consistent with each other in 0.035% in the standard deviation. We detected absorption edges by Fe-K, Ni-K and Mn-K and four edge like features at 6057 eV, 6915 eV, 7590 eV and 9193 eV, which were interpreted as Bragg reflections by Be crystal. These are consistent with the results of the SPring-8 measurement. The edge-like feature at 8790 eV was detected only by KEK-PF experiment. The Be thickness obtained by experiment in range of 2.0-4.5 keV with BL-11C is also consistent with the results of the BL-7C and SPring-8 experiments.

10397-48, Session PMon

Semi-automated high-efficiency reflectivity chamber for vacuum UV measurements

James H. Wiley, Brian T. Fleming, Arika Egan, Univ. of Colorado Boulder (United States)

This paper presents the design and theory of operation for a semi-automated reflectivity chamber for ultraviolet optimized optics. A graphical user interface designed in LabVIEW controls the stages, interfaces with the detector system, takes semi-autonomous measurements, and monitors the system in case of error. Samples and an optical photodiode sit on an optics plate mounted to a rotation stage in the middle of the vacuum chamber. The optics plate rotates the samples and diode between an incident and reflected position to measure the absolute reflectivity of the samples at wavelengths limited by the monochromator operational bandpass of 70 nm to 550 nm. A fine steering tip-tilt motor on a collimating parabolic mirror enables beam steering for detector peak-ups. This chamber is designed to take measurements rapidly and with minimal oversight, increasing lab efficiency for high cadence and high accuracy vacuum UV reflectivity measurements.

10397-49, Session PMon

EXACT: The experiment for characterization and timing cubesat

Trevor Knuth, Univ. of Minnesota (United States); Lindsay Glesener, Univ. of Minnesota, Twin Cities (United States); Demoz Gebre-Egziabher, Univ. of Minnesota, Twin Cities (United States); Ryan Vogt, Hannah Weiher, Joel Runnels, Kale Hedstrom, Tim Kukowski, Maxwell Yurs, Kendra Bergstedt, Cynthia Cattell, Jeffrey Chaffin, Richard Linares, Gjerda RhodeHumphries, Univ. of Minnesota (United States)

The Experiment for X-ray Characterization and Timing (EXACT) mission will be a CubeSat based hard X-ray spectrometer used for measuring solar flares with high time precision. Solar flares and the related coronal mass ejections affect space weather and the near-Earth environment. EXACT can study the hard X-rays generated by the Sun in the declining phase of Solar Cycle 24 in order to probe electron acceleration in solar eruptive events while also serving as a precursor to future hard X-ray spectrometers that could monitor the Sun continuously.

EXACT will be a 3U CubeSat with 1U dedicated to a detector and 2U dedicated to avionics. The detector used will have a surface area of roughly 60 square cm. This allows for a large collecting area despite the spacecraft's small overall size. The detector, named the Gamma-Ray Incidence Detector (GRID), is a thallium-doped cesium iodide scintillator.

10397-50, Session PMon

The third flight of the Colorado high-resolution echelle stellar spectrograph (CHESS): improvements, calibrations, and preliminary results

Nicholas Kruczek, Lab. for Atmospheric and Space Physics (United States); Kevin C. France, Keri Hoadley, Nicholas Nell, Robert Kane, Brian T. Fleming, Univ. of Colorado Boulder (United States)

In this proceeding, we describe the scientific motivation and technical development of the Colorado High-resolution Echelle Stellar Spectrograph (CHESS), focusing on the hardware advancements and testing of components for the third launch of the payload (CHESS-3). CHESS is a far ultraviolet rocket-borne instrument designed to study the atomic-to-molecular transitions within translucent cloud regions in the interstellar medium. CHESS is an objective echelle spectrograph, which uses a mechanically-ruled echelle and a powered (f/12.4) cross-dispersing grating, and is designed to achieve a resolving power R > 100,000 over the band pass ?? 1000 - 1600 Å. Results from final efficiency and reflectivity measurements for the optical components of CHESS-3 are presented. CHESS-3 utilizes a 40mm-diameter cross-strip anode readout microchannel plate detector fabricated by Sensor Sciences LLC, to achieve high spatial resolution with high global count rate capabilities (~1 MHz). We present pre-flight laboratory spectra and calibration results, including wavelength solution and resolving power of the instrument. In support of the fourth launch of CHESS (CHESS-4), the CHESS-3 payload includes a photomultiplier tube, which will confirm the alignment of the CHESS-4 detector. An important role of sounding rocket experiments is the testing and verification of space-flight for experimental technologies. CHESS-4 will demonstrate a delta-doped CCD, assembled in collaboration with the Microdevices Laboratory at JPL and Arizona State University. CHESS-3 was scheduled to launch on 14 June 2017 aboard NASA/CU sounding rocket mission 36.323 UG. We present initial flight results for the CHESS-3 observation of the ? Sco? sightline.

10397-51, Session PMon

On-ground characterization of the IXPE polarization angle knowledge

Yuri Evangelista, INAF - Istituto di Astrofisica e Planetologia Spaziali (Italy)

The Imaging X-ray Polarimetry Explorer (IXPE) has been recently selected for development as part of NASA's Small Explorer program (SMEX), with a launch date in 2020.

IXPE is developed in a collaboration between NASA and the Italian Space Agency (ASI), and will perform groundbreaking measurements of imaging polarization in X-rays for a number of different classes of sources including isolated and accreting neutron stars, pulsar wind nebulae, stellar and supermassive black holes.

Combining 30-arcseond (HPD) grazing-incidence X-ray optics with the polarization-sensitive gas pixel detectors (GPDs) IXPE will provide two-orders of magnitude improvement in sensitivity over past flown instruments.

The IXPE requested precision on the measurement of the polarization angle (goal of 12') poses strict constraints

on the detector unit (DU) mechanical design and requires a specifically developed metrological procedure to meet the scientific performance.

In this paper we describe the design solutions that will be implemented in the DU flight models as well as a step-by-step metrology procedure that will ensure the fulfilment of the scientific requirement.

10397-52, Session PMon

The Marshall Grazing Incidence X-ray Spectrometer

Ken Kobayashi, Amy R. Winebarger, Sabrina Savage, NASA Marshall Space Flight Ctr. (United States); Patrick Champey, The Univ. of Alabama in Huntsville (United States); Peter N. Cheimets, Edward Hertz, Leon Golub, Smithsonian Astrophysical Observatory (United States); Brian Ramsey, ?Jaganathan Ranganathan, NASA Marshall Space Flight Ctr. (United States); Vanessa Marquez, Ryan Allured, Theodore Parker, Smithsonian Astrophysical Observatory (United States); Ralf K. Heilmann, Mark L. Schattenburg, Massachusetts Institute of Technology (United States)

The Marshall Grazing Incidence X-ray Spectrometer (MaGIXS) is a NASA sounding rocket instrument designed to obtain spatially resolved soft X-ray spectra of the Solar atmosphere in the 6-24 Å (0.5 - 2.0 keV) range. The instrument consists of a single shell Wolter Type-I telescope, a slit, and a spectrometer comprising a matched pair of grazing incidence parabolic mirrors and a planar varied-line space diffraction grating. The instrument is designed to achieve a 50 milli-Angstrom spectral resolution and 5 arcsecond spatial resolution along a 4-arcminute long slit, and launch is planned for 2018. We report on the status and our approaches for fabrication and alignment for this novel optical system. The telescope and spectrometer mirrors are replicated nickel shells, and are currently being fabricated at the NASA Marshall Space Flight Center. The diffraction grating is currently under development by the Massachusetts Institute of Technology (MIT); because of the strong line spacing variation across the grating, it will be fabricated through e-beam lithography.

10397-53, Session PMon

ART-XC/SRG: Joint calibration of mirror modules and x-ray detectors

Alexey Tkachenko, Mikhail N. Pavlinsky, Vasily Levin, Valeriy V. Akimov, Aleksandr Krivchenko, Alexey Rotin, Maria M. Kuznetsova, Igor Y. Lapshov, Alexander Yaskovich, Vladimir Alexandrovich Oleynikov, Space Research Institute (Russian Federation); Mikhail V. Gubarev, Brian Ramsey, NASA Marshall Space Flight Ctr. (United States)

The Astronomical Roentgen Telescope – X-ray Concentrator (ART-XC) is a hard x-ray instrument with energy response 6–30 keV that will to be launched on board of the Spectrum Roentgen Gamma (SRG) Mission. The ART-XC consists of seven co-aligned mirror modules coupled with seven focal plane CdTe double-sided strip detectors. The mirror modules had been fabricated and calibrated at the NASA Marshall Space Flight Center (MSFC). The Russian Space Research Institute (IKI) has been developed and tested the X-ray detectors. The joint x-ray calibration of the mirror modules and focal plane detectors was carried out at the IKI test facility. Details of the calibration procedure and an overview of the results will be presented.

10397-54, Session PMon

Characterization of the UV detector of Solar Orbiter/METIS

Michela C. Uslenghi, INAF - IASF Milano (Italy); Udo H. Schühle, Luca Teriaca, Max-Planck-Institut für Sonnensystemforschung (Germany)

METIS, one of the instruments of the ESA mission Solar Orbiter (to be launched in October 2018), is a coronograph able to perform broadband polarization imaging in the visible range (580-640 nm), and narrow band imaging in UV (HI Lyman-? 121.6nm) .

The detector of the UV channel is an intensified camera, based on a Star-1000 rad-hard CMOS APS coupled via a 2:1 fiber optic taper to a single stage Microchannel Plate intensifier, sealed with an entrance MgF2 window and provided with an opaque KBr photocathode. The qualification model and the flight UVDA (UV Detector Assembly) have been characterized and calibrated in the UV range using the Physikalisch-Technische Bundesanstalt (PTB) beamline at the BESSY-II synchrotron.

We present the description of the test setup and the results of the measurements carried out, which include:

- Spectral calibration in the range 115-300 nm
- Linearity of the response vs flux at 121.6 nm
- Linearity of the response vs exposure time
- Characterization of the gain vs intensifier voltages
- Response uniformity at 121.6 nm

10397-34, Session 9

Life testing of ALD-GCA MCPs: recent results

Mark A. Popecki, Christopher A. Craven, Till Cremer, William A. Worstell, Michael J. Minot, Bernhard W. Adams, Michael R. Foley, Alexey Lyashenko, Justin L. Bond, Michael E. Stochaj, Incom, Inc. (United States); Camden Ertley, Oswald H. W. Siegmund, Space Sciences Lab. (United States); Jeffrey W. Elam, Anil U. Mane, Argonne National Lab. (United States)

Microchannel plates have been made by combining glass capillary substrates with thin films. The films impart the resistance and secondary electron emission (SEE) properties of the MCP. This approach permits separate choices for the type of glass, the MCP resistance and the SEE material. For example, the glass may be chosen to provide mechanical strength, a high open area ratio, or a low potassium-40 concentration to minimize dark rates. The resistive film composition may be tuned to provide the desired resistance, depending on the power budget and anticipated count rate. Finally, the SEE material may be chosen by balancing requirements for gain, long term stability of gain with extracted charge, and tolerance to air exposure.

Microchannel plates have been fabricated by Incom Inc., in collaboration with Argonne National Laboratory and UC Berkeley. Glass substrates with microchannel diameters of 10 and 20 microns have been used, typically with a length to diameter ratio of 60:1. Thin films for resistance and SEE are applied using Atomic Layer Deposition (ALD). The ALD technique provides a film with uniform thickness throughout the high aspect ratio microchannels. MCPs have been made in sizes up to 8"x8". This three-component method for manufacturing MCPs also makes non-planar, curved MCPs possible.

Life testing results will be presented for 10 and 20 micron, 60:1 l/d ratio MCPs, with an aluminum oxide SEE film and two types of glass substrates. Results will include measurements of resistance, dark count rates, gain, and pulse height distributions as a function of extracted charge.

10397-35, Session 9

ALD-microchannel plates for cryogenic applications

Till Cremer, Bernhard W. Adams, Melvin Aviles, Justin L. Bond, Christopher A. Craven, Michael R. Foley, Alexey Lyashenko, Michael J. Minot, Mark A. Popecki, Michael E. Stochaj, William A. Worstell, Incom, Inc. (United States); Jeffrey W. Elam, Anil U. Mane, Argonne National Lab. (United States); Oswald H. W. Siegmund, Camden Ertley, Univ. of California, Berkeley (United States)

Atomic layer deposition (ALD) has enabled the development of a new technology for fabricating microchannel plates (MCPs) with improved performance that offer transformative benefits to a wide variety of applications. Incom uses a "hollow-core" process for fabricating glass capillary array (GCA) plates consisting of millions of micrometer-sized glass microchannels fused together in a regular pattern. The resistive and secondary electron emissive (SEE) functions necessary for electron amplification are applied to the GCA microchannels by ALD, which – in contrast to conventional MCP manufacturing– enables independent tuning of both resistance and SEE to maximize and customize MCP performance.

Incom is currently developing MCPs that operate at cryogenic temperatures and across wide temperature ranges. The resistive layers in both, conventional and ALD-MCPs, exhibit semiconductor-like behavior and therefore a negative thermal coefficient of resistance (TCR): when the MCP is cooled, the resistance increases, and when heated, the resistance drops. Consequently, the resistance of each MCP must be tailored for the intended operating temperature. This sensitivity to temperature changes presents a challenge for many terrestrial and space based applications.

The resistivity of the ALD-nanocomposite material can be tuned over a wide range. The material's (thermo-) electrical properties depend on film thickness, composition, nanostructure, and the chemical nature of the dielectric and metal components. We show how the structure-property relationships developed in this work can be used to design MCPs that operate reliably at cryogenic temperatures. We also present data on how the resistive material's TCR characteristics can be improved to enable MCPs operating across wider temperature ranges than currently possible.

10397-36, Session 9

Epitaxial deposition of high-efficiency GaN photocathodes on microchannel plates using lattice-matched metallic buffers

Amir Dabiran, Sara Rothwell, Stephenie Tandean, Robert J. Jorgenson, Lightwave Photonics, Inc. (United States); Anton S. TRemsin, Oswald H. W. Siegmund, Univ. of California, Berkeley (United States)

Negative electron affinity (NEA) semiconductor photocathodes are commonly used in combination with electron multipliers, such as microchannel plates (MCPs), to fabricate sensitive phototubes. In recent years, there have been significant improvements in the performance of these detectors by enhancing quantum efficiency (QE), and by advances in MCPs and readout techniques. In particular, robust GaN-based photocathodes have shown very high QE (> 80% in deep UV), for operation in opaque mode (front side illuminated). However, the QE values are much smaller for semitransparent (backside illuminated) GaN photocathodes, which are used in conjunction with MCP stacks in typical phototubes. Substantial improvements in QE, as well as spatial and temporal resolutions, for these detectors are expected if the high quality photocathode film can be directly deposited on the MCP surface. Previous attempts to deposit opaque p-type GaN cathodes on different MCP substrates have not resulted in high QE photoemission due to the much lower quality of GaN on these MCPs as compared to GaN grown on typical sapphire substrates. In this presentation, we will show performance of high quality p-doped GaN photocathodes deposited on standard MCPs using a lattice-matched transition metal-nitride buffer layer, all deposited by a low-temperature magnetron sputtering epitaxy (MSE) technique. In addition to a suitable buffer layer for epitaxial growth of GaN, the highly conductive transition metal-nitride layer acts as both the MCP electrode and as a blanket back-contact to improve the lateral conductivity of the thin p-GaN film in order to avoid charging effects away from periphery metal contacts.

Microchannel plate detector technology potential for LUVOIR and HabEx

Oswald H. W. Siegmund, Space Sciences Lab. (United States); Eric R. Schindhelm, Southwest Research Institute (United States); Camden Ertley, Space Sciences Lab. (United States); Brian T. Fleming, Kevin C. France, Univ. of Colorado Boulder (United States); Walter M. Harris, The Univ. of Arizona (United States); Alex Harwit, Ball Aerospace & Technologies Corp. (United States); Stephan R. McCandliss, Johns Hopkins Univ. (United States); John V. Vallerga, Space Sciences Lab. (United States)

Microchannel plate (MCP) detectors have been the workhorse detector of choice for ultraviolet (UV) instruments onboard many NASA missions. MCP UV detectors have many advantages, including high spatial resolution (<20 um), photon counting, radiation hardness, large formats (up to 20 cm), and ability for curved surfaces. We summarize the current state of the main component technologies; MCP substrates, photocathodes and anode/readout systems. Borosilicate glass microcapillary arrays with atomic layer deposition combine extremely low backgrounds, high strength, and tunable secondary electron yield. GaN and combinations of bialkali/alkali halide photocathodes show promise for broadband, higher quantum efficiency. Cross-strip anodes combined with compact ASIC readout electronics enable high spatial resolution over large formats and high dynamic range. Their technology readiness level are each being advanced through research grants for laboratory testing and rocket flights. Combining these capabilities would be ideal for a UV instrument onboard the Large UV/Optical/IR Surveyor (LUVOIR) or Habitable Exoplanet Imaging Mission (HabEx) concepts currently under study for NASA's Astrophysics Decadal Survey.

10397-38, Session 9

Microchannel plate life testing for UV spectroscopy instruments

Nathan Darling, Univ. of California, Berkeley (United States)

The Emirates Mars Mission (EMM) UV Spectrograph (EMUS) is a far ultraviolet (102-170 nm) imaging spectrograph for characterization of the Martian exosphere and thermosphere. Imaging is accomplished by a photon counting open-face microchannel plate (MCP) detector using a cross delay line (XDL) readout. A MCP gain stabilization (burn-in) followed by lifetime spectral line burn-in simulation has been completed at SSL. This has demonstrated gain and sensitivity stability of ≤ 5% for total dose of 2.3 x 10^12 photons cm-2 at ~6 kHz mm-2 counting rates after and initial burn in at low gain has been performed.

10397-39, Session 10

The LUVOIR Ultraviolet Multi-Object Spectrograph (LUMOS):instrument definition and design

Kevin C. France, Brian T. Fleming, Univ. of Colorado Boulder (United States); Garrett J. West, NASA Goddard Space Flight Ctr. (United States); Stephan R. McCandliss, Johns Hopkins Univ. (United States); John O'Meara, Saint Michael's College (United States); Jason Tumlinson, Space Telescope Science Institute (United States); David Schiminovich, Columbia Univ. (United States); Matthew R. Bolcar, NASA Goddard Space Flight Ctr. (United States); Walter M. Harris, The Univ. of Arizona (United States);

Leonidas A. Moustakas, Jet Propulsion Lab. (United States)

The LUVOIR Surveyor is being designed to pursue an ambitious program of exoplanetary discovery and characterization, cosmic origins astrophysics, and planetary science. The LUVOIR Ultraviolet Multi-Object Spectrograph, LUMOS, is being designed to support all of the UV science requirements of LUVOIR, from exoplanet host star characterization to tomography of circumgalactic halos to water plumes on outer solar system satellites. LUMOS offers point source and multi-object spectroscopy across the UV bandpass, with multiple resolution modes to support different science goals. The instrument will provide low (R = 5,000 – 15,000) and medium (R = 20,000 – 60,000) resolution modes across the far-ultraviolet (FUV: 100 – 200 nm) and near-ultraviolet (NUV: 200 – 400 nm) windows, and a very low resolution mode (R = 500) for spectroscopic investigations of extremely faint objects in the FUV. Imaging spectroscopy will be accomplished over a 2 ? 2 arcminute field-of-view by employing a holographically-ruled diffraction grating to control optical aberrations, microshutter arrays that build on the heritage of the JWST/NIRspec instrument, advanced optical coatings for high-throughput in the FUV, and next generation large-format photon-counting detectors. The spectroscopic capabilities of LUMOS are augmented by an FUV imaging channel (100 – 200nm, 30 milliarcsecond angular resolution, 2 x 2 arcminute field-of-view) that will employ a complement of narrow- and medium-band filters. We present an overview of LUMOS' observing modes and estimated performance curves for effective area, spectral resolution, and imaging performance. Example “LUMOS 100-hour Highlights” observing programs are presented to demonstrate the potential power of LUVOIR's ultraviolet spectroscopic capabilities.

10397-40, Session 10

The synergy instrument

Jonathan W. Arenberg, Northrop Grumman Aerospace Systems (United States); Carlton Wong, Xinetics Inc. (United States); Tom Mallen, Northrop Grumman Aerospace Systems (United States); Thomas Mooney, Materion Corp. (United States); John W. MacKenty, Jason Tumlinson, Space Telescope Science Institute (United States)

Synergy is an Explorer class mission concept to conduct a large area near-ultraviolet spectroscopic survey. This paper describes the optics and science instrument. The instrument has a wide field of view, 5 square degrees, and the capability of simultaneous imaging and low-resolution slitless spectroscopy in the 220-320 nm band and efficient rejection of out of band light. The wide FOV is achieved with an all reflective off-axis 4-mirror anastigmat, a dispersive element and an all-reflective reimaging system. The system level performance is sub-arcsecond level image quality and ?/d? from 200-600. The optical train mirrors are proven Silicon/Silicon Carbide technology. The high UV sensitivity is achieved through distributed out of-band rejection at each of the four telescope mirrors, achieving at least 104 and more typically105 rejection for out-of-band light, while maintaining more than 65% transmission in the near ultraviolet band onto six 4K x 4K CCDs with 15 micron pixels. A shutter and fused-silica dispersive element are located at the exit pupil of the telescope. The shutter can be positioned to enable the default imaging with spectra mode, a pure imaging mode and dark and flat field calibration modes. The operation of the instrument is also discussed.

10397-41, Session 10

The development and characterization of advanced broadband mirror coatings for the far-UV

Arika Egan, Brian T. Fleming, James H. Wiley, Univ. of Colorado Boulder (United States); Manuel A. Quijada, Javier G. Del Hoyo, NASA Goddard Space Flight Ctr. (United States); John Hennessy, Jet Propulsion Lab. (United States); Brian A. Hicks, Univ. of Maryland, College Park (United States) and NASA Goddard Space Flight Ctr. (United States); Kevin C. France, Nicholas Kruczek, Nicholas Erickson, Univ. of Colorado Boulder (United States)

We present a progress report on the development of new broadband mirror coatings that demonstrate > 80% reflectivities from 102 - 120 nm. We describe a multi-stage approach to the deposition and testing of these advanced coatings: First, the combination of high temperature physical vapor deposition developed at NASA Goddard Space Flight Center was used to coat the mirror with aluminum and a protective fluoride overcoat, and then an ultra-thin (10-30 angstroms) layer of a second fluoride was deposited via atomic layer deposition (ALD) at the Jet Propulsion Laboratory to increase durability. Second, a bench top system was fabricated at the University of Colorado to obtain the polarized reflectivities of the mirrors as a function of wavelength at optical and near-UV wavelengths. Polarized reflectivity into the far-UV was obtained in collaboration with the Synchrotron Ultraviolet Radiation Facility (SURF) at NIST. Third, we extrapolate on previous aging studies to assess the coating durability under exposure to controlled humidity. We find that our experimental coatings offer ~30% greater reflectivity than conventional Al+LiF, and that a protective ALD layer reduces the hygroscopic degradation of coatings such as LiF by as much as 35%, with further gains possible. We discuss the performance of these new coatings in the context of the requirements for the NASA concept missions LUVOIR and HabEx.

10397-42, Session 10

Optical measurements of the mirrors and of the interferential filter of the Metis coronagraph on Solar Orbiter

Paolo Sandri, Paolo Sarra, Paolo Radaelli, D. Morea, OHB Italia SpA (Italy); Radek Melich, Institute of Plasma Physics, TOPTEC department (Czech Republic); Arkadiusz Berlicki , Astronomical Institute, Academy of Sciences of the Czech Republic (Czech Republic); Ester Antonucci, INAF - Astrophysical Observatory of Torino (Italy); Marco M. Castronuovo, ASI - Agenzia Spaziale Italiana (Italy); Silvano Fineschi, INAF - Astrophysical Observatory of Torino (Italy); Giampiero Naletto, Dept. of Information Engineering - University of Padova (Italy) and CNR-IFN UOS Padova LUXOR (Italy); Gianalfredo Nicolini, INAF - Astrophysical Observatory of Torino (Italy); Marco Romoli, Dept. of Physics and Astronomy, University of Florence, (Italy)

The paper describes the wavefront error measurements of the concave ellipsoidal mirrors M1 and M2, of the concave spherical mirror M0 and of the flat interferential filter IF of the METIS coronagraph. METIS is an inverted occultation coronagraph on board of the ESA Solar Orbiter mission that will provide a broad-band imaging of the full corona in linearly polarized visible-light (580-640 nm) and a narrow-band imaging of the full corona in the ultraviolet Lyman ? (121.6 nm). METIS will observe the solar outer atmosphere from a close distance to the Sun as 0.28 A.U. and from up to 35deg out-of-ecliptic. The measurements of wavefront error of the mirrors and of the interferential filter of METIS have been performed in a ISO 5 clean room both at component level and at assembly level minimizing, during the integration, the stress introduced by the assembling of the optical items with the mechanical hardware. The wavefront error measurements have been performed with a digital interferometer for mirrors M0, M1 and M2 and with a Shack-Hartmann wavefront sensor for the interferential filter.

10397-43, Session 11

LRO-LAMP failsafe door-open performance: improving FUV measurements of dayside lunar hydration

Michael W. Davis, Thomas K. Greathouse, David E. Kaufmann, Kurt D. Retherford, Maarten H. Versteeg, Southwest Research Institute (United States)

The Lunar Reconnaissance Orbiter's (LRO) Lyman Alpha Mapping Project (LAMP) is a lightweight (6.1 kg), low-power (4.5 W), ultraviolet spectrograph based on the Alice instruments aboard the European Space Agency's Rosetta spacecraft and NASA's New Horizons spacecraft. Its primary job is to identify and localize exposed water frost in permanently shadowed regions (PSRs) near the Moon's poles, and to characterize landforms and albedos in PSRs. LRO launched on June 18, 2009 and reached lunar orbit four days later. LAMP operated with its failsafe door closed for its first seven years in flight. The failsafe door was opened in October 2016 to increase light throughput during dayside operations at the expense of no longer having the capacity to take further dark observations and slightly more operational complexity to avoid saturating the instrument. This one-time irreversible operation was approved after extensive review, and was conducted flawlessly. The improved throughput allows measurement of dayside hydration in one orbit, instead of averaging multiple orbits together to reach enough signal-to-noise. The new measurement mode allows greater time resolution of dayside water migration for improved investigations into the source and loss processes on the lunar surface. LAMP performance and optical characteristics after the failsafe door opening are described herein, including the new effective area, wavelength solution, and resolution.

10397-44, Session 11

Scattered light characterization of FORTIS

Stephan R. McCandliss, Anna Carter, Keith Redwine, Johns Hopkins Univ. (United States); Alexander S. Kutyrev, John G. Hagopian, Mary J. Li, Harvey H. Moseley, NASA Goddard Space Flight Ctr. (United States); Russell Pelton, Johns Hopkins Univ. (United States)

We describe our efforts to build a wide-field Lyman alpha geocoronal simulator (WFLaGs) for characterizing the end-to-end sensitivity of FORTIS (Far-UV Off Rowland-circle Telescope for Imaging and Spectroscopy) to scattered Lyman alpha emission from outside of the nominal (1/2 degree)^2 field-of-view (FOV). WFLaGs is a 50 mm diameter F/1 aluminum parabolic collimator fed by a hydrogen discharge lamp with a 80mm clear MgF2 window housed in a vacuum skin. It creates emission over a 10 degree FOV. WFLaGS will allow us to validate a recently developed scattered light model and verify our scatter light mitigation strategies, which will incorporate low scatter baffle materials, and possibly 3-d printed light traps, for covering exposed scatter centers. We present measurements of scattering intensity of Lyman alpha as a function of angle with respect to the specular reflectance direction for several candidate baffle materials. Initial testing of WFLaGs will be described. This work is supported by NASA grants to John Hopkins University, NNX11AG54G and NNX17AC26G.

10397-45, Session 11

Low-latitude ionospheric research using the CIRCE mission

Kenneth F. Dymond, Andrew C. Nicholas, Scott A. Budzien, Andrew W. Stephan, U.S. Naval Research Lab. (United States)

The Coordinated Ionospheric Reconstruction Cubesat Experiment (CIRCE) is a dual-satellite mission consisting of two 6U CubeSats actively maintaining a lead-follow configuration in the same orbit with a launch planned for the 2018-2019 time-frame. These nanosatellites will each feature two 1U ultraviolet photometers, observing the 135.6 nm emission of atomic oxygen at nighttime. The primary objective is to characterize the two-dimensional distribution of electrons in the Equatorial Ionization Anomaly (EIA). The methodology used to reconstruct the nighttime ionosphere employs continuous UV photometry from four distinct viewing angles in combination with an additional data source, such as in situ plasma density measurements or a wide-band beacon data, with advanced image space reconstruction algorithm tomography techniques. The COSMIC/FORMOSAT-3 (CF3) constellation featured six Tiny Ionospheric Photometers, a compact UV sensor design which served as the pathfinder for the CIRCE instruments. The TIP instruments on the CF3 satellites demonstrated detection of ionospheric bubbles before they had penetrated the peak of the F-region ionosphere. We present our mission concept, simulations illustrating the imaging capability of the sensor suite, and a range of science questions addressable using such a system.

10397-46, Session 11

The Colorado Ultraviolet Transit Experiment (CUTE): A dedicated cubesat mission for the study of exoplanetary mass loss and magnetic fields

Brian T. Fleming, Kevin C. France, Nicholas Nell, Richard A. Kohnert, Keri Hoadley, Jean-Michel Desert, Univ. of Colorado Boulder (United States); Pascal M. Petit, Univ. de Toulouse (France); Aline A. Vidotto, Univ. de Genève (Switzerland); Matthew Beasley, Planetary Resources, Inc. (United States); Luca Fossati, Austrian Academy of Sciences (Austria); Tommi T. Koskinen, The Univ. of Arizona (United States)

The Colorado Ultraviolet Transit Experiment (CUTE) is a near-UV (2500 – 3500 Angstrom) 6U cubesat mission designed to monitor transiting hot Jupiters for evidence of atmospheric mass loss and magnetic fields. CUTE maximizes the available cubesat space by means of an innovative optical system to achieve a projected effective area of ~22 cm^2, low instrumental background, and a spectral resolving power of R~2000 over the entire science bandpass. We present the CUTE optical and mechanical design, a summary of the science motivation and expected results, and an overview of the projected fabrication, calibration and launch timeline. CUTE will launch in 2020 and has a nominal baseline mission of 6 months.

Conference 10398: UV/Optical/IR Space Telescopes and Instruments: Innovative Technologies and Concepts VIII

SPIE. OPTICS+ PHOTONICS OPTICAL ENGINEERING+ APPLICATIONS

Sunday - Tuesday 6 –8 August 2017

Part of Proceedings of SPIE Vol. 10398 UV/Optical/IR Space Telescopes and Instruments: Innovative Technologies and Concepts VIII

10398-1, Session 1

The Habitable Exoplanet Imaging Mission (HabEx) *(Invited Paper)*

Bertrand P. Mennesson, Jet Propulsion Lab. (United States)

The Habitable-Exoplanet Imaging Mission (HabEx) is a candidate flagship mission being studied by NASA and the astrophysics community in preparation of the 2020 Decadal Survey. The HabEx mission concept is a large (~4 to 6.5m) diffraction-limited optical space telescope, providing unprecedented resolution and contrast in the optical, with likely extensions into the near UV and near infrared domains.

The primary goal of HabEx is to answer fundamental questions in exoplanet science, searching for and characterizing potentially habitable worlds, providing the first complete "family portraits" of planets around our nearest Sun-like neighbors and placing the solar system in the context of a diverse set of exoplanets.

At the same time, HabEx will enable a broad range of Galactic, extragalactic, and solar system astrophysics, from resolved stellar population studies that inform the stellar formation history of nearby galaxies, to characterizing the life cycle of baryons as they flow in and out of galaxies, to detailed studies of bodies in our own solar system.
